ABSTRACT

Benzyltetrahydroisoquinoline (BTHIQ) molecules are able to adopt widely differing conformations that depend on the presence or absence of N-substituents. To assess the possible role of BTHIQ conformation on the affinity of these compounds for α1-adrenergic receptors, of interest for the management of hypertension, the racemic N-unsubstituted BTHIQ norlaudanosine and a series of N-alkylated derivatives were assessed for binding to rat brain cortical sites labelled with the radioligand [3H]prazosin. The α1-adrenergic affinity in this series increased with the bulk of the substituent on the nitrogen atom, from the N-ethyl to the N-propyl analogue. Comparison of these results with published data for related BTHIQs and for the rigid mimics of the fully extended and semi-folded conformations of laudanosine, tetrahydropalmatine and glaucine, suggested that the α1-adrenergic receptor binding site is able to accommodate either conformation. The presence of a bulky substituent on the nitrogen atom seems to favor receptor binding independently of the favored conformation, and that the orientation in which BTHIQs are bound probably differs depending on the presence or absence of a hydroxyl group at a key position.

Keywords: α1-adrenergic receptor binding; norlaudanosine; laudanosine; N-alkynorlaudanosines; benzyltetrahydroisoquinolines; tetrahydropalmatine; glaucine

INTRODUCTION

Laudanosine (2) is a minor benzyltetrahydroisoquinoline (BTHIQ) alkaloidal constituent of opium, and a major metabolite of the clinically important skeletal muscle relaxant atracurium, as well as of its pure stereoisomer cisatracurium, both of which are used in combination with general anesthetics. One of the many pharmacological actions of laudanosine that may be of clinical concern in anesthesia is the relaxation of smooth muscle, mainly via blockade of α1-adrenergic receptors. On the other hand, subtype-selective α1-adrenergic antagonism is of interest as an approach to the management of hypertension, and a greater understanding of the structural features leading to subtype selectivity is a prerequisite for the development of useful drugs.

We have recently shown that α1-adrenergic antagonism also operates in the case of the related BTHIQ cochlaurine and some of its derivatives, although sometimes competing with Ca2+ entry blockade which also leads to a loss of vascular tone and thus to a reduction in arterial blood pressure. In the latter series, substitution on the nitrogen atom with a methyl or ethyl group resulted in small changes in α1-adrenergic receptor affinity without any general trend emerging, although in the cochlaurine and norarmepavine families, bearing a para hydroxyl group on the pendent benzyl moiety, N-substitution led to decreased affinities in the order H > CH3 > CH2CH3.

BTHIQs are flexible molecules that are able to adopt three main conformations: a completely extended one, a folded one, and one that we call “semi-folded”. The N-unsubstituted secondary amine BTHIQs show a clear preference for the extended conformation, and the N-alkylated analogues reside predominantly in the semi-folded conformation, as shown by NMR and molecular modeling studies. The extended and semi-folded conformations of BTHIQs approximate the molecular shapes of the berbine or tetrahydroberberine skeleton, and of aporphine alkaloids, respectively (Fig. 1). As a considerable number of these sterically constrained berbines and aporphines have also been shown to exhibit α1-adrenergic receptor blocking activity, we decided to compare the affinities of laudanosine (2), norlaudanosine (1) and its N-ethyl (3) and –propyl (4) derivatives with the published data for their extended and semi-folded rigid analogues, tetrahydropalmatine (5) and glaucine (6), and with our own results for the flexible cochlaurine and armepavine analogues.
**EXPERIMENTAL**

**General**

The following commercial drugs were used: prazosin and phentolamine were from Sigma (St. Louis, MO); [3H]prazosin (20.3 Ci mmol⁻¹) was from Amersham International (Buckinghamshire, UK). Other reagents and solvents were of analytical grade. Norlaudanosine (1) and its derivatives (2-4) assayed in this work were prepared in our laboratory, and their physical, spectroscopic, and analytical data and conformational studies have been previously reported by us.⁶

**Binding studies**

Female Wistar rats, 180-200 g, were decapitated and the brain rapidly removed. The cerebral cortex was dissected and homogenized in 10 volumes (w/v) ice-cold buffer (Tris HCl 5 mM, sucrose 250 mM and EDTA 1 mM; pH 7.5 at 25 °C) using an Ultra-Turrax (3 × 15 s). The homogenate was centrifuged for 10 min at 1000 × g, the pellet was discarded and the supernatant was centrifuged at 26000 × g for 15 min at 4 °C. The final pellet was resuspended in assay buffer (Tris HCl 50 mM, pH 7.5 at 25 °C) and stored at -70 °C for later use. All membrane preparation procedures were conducted at 4 °C. Binding of [3H]prazosin to rat cerebral cortical membranes was saturable, reversible and showed high affinity, with a dissociation constant (Kᵢ) of 0.14 nM, and occurred at a single class of binding sites.⁴ The incubation volume was 1 ml (approx. 250 µg protein/tube). The assay tubes were incubated with [3H]prazosin (0.1-0.2 nM) in the absence or in the presence of drug at various concentrations. Incubations were carried out at 25 °C for 45 min and the binding reactions were then terminated by rapid vacuum filtration using a Brandel cell harvester (M24R) with fibre-glass filters (Schleicher and Schuell, Nº 30) presoaked in 0.3 % polyethyleneimine for 5 min. The filters were then washed with ice-cold 50 mM Tris-HCl buffer, pH 7.5 (4 × 4 ml) and the radioactivity bound to the filters was determined by liquid scintillation counting. Non-specific binding was determined in the presence of 10⁴ M phentolamine. Proteins were assayed according to the method of Bradford with γ-globulin as standard.⁷ All results were obtained in duplicate. Inhibition curves were analyzed by the weighted least-squares iterative Prism curve-fitting program (Graph Pad Software Inc., 2003), and inhibition constants (Kᵢ) were calculated by use of the Cheng and Prussoff formula.⁸ Results are presented as mean ± standard error of the mean (s.e.m.) of at least three experiments from at least two different batches of cerebral cortex. Where appropriate, one-way Anova test (available in Graph Pad Software Inc., 2003) for paired data was used, and values of P < 0.05 were regarded as significant.

**RESULTS AND DISCUSSION**

The affinities of racemic norlaudanosine (1) and its N-methyl (laudanosine, 2), N-ethyl (3) and N-propyl (4) derivatives for α₁-adrenergic receptors was assessed in binding studies in rat brain cortical homogenates using the subtype-nonselective radioligand [3H]prazosin. The specific binding of this α₁-adrenergic radioligand at a concentration of 0.2 nM represented approximately 90% of the total binding. All the compounds inhibited [3H]prazosin binding with the inhibition constants (Kᵢ) summarized in Table 1.

ALL binding experiments were carried out 3-5 times in duplicate. Differences are significant at the P < 0.001 level (one-way Anova).

These inhibition constants are high (signifying low potency) when compared with values recorded for α₁-adrenergic blockers such as prazosin (0.11 nM),⁹ but are quite comparable to those of related natural products (see below). To search for analogues with considerably higher affinities by introducing appropriate structural modifications on the easily accessible BTHIQ scaffold thus remains an attractive goal.

Norlaudanosine (1) and all its N-alkylated derivatives (2-4) bound to α₁-adrenergic receptors in a competitive manner and at a single site. Concentration-response curves are shown in Fig. 2. The rank order of affinities for norlaudanosine and its N-alkyl derivatives tested was N-propyl > N-ethyl > N-methyl = norlaudanosine. Although the differences are not great, they are statistically significant. It is particularly noteworthy that the affinity of N-propyl/norlaudanosine is more than double that of its N-ethyl analogue, and almost four times that of laudanosine or norlaudanosine.

As the extended conformation of BTHIQs resembles the rigid shape of berbine alkaloids, while the semi-folded conformation approximates that of aporphines, a comparison of the affinities of the compounds studied here with those of closely related, tetramethoxylated berbines and aporphines seems warranted. The reported Kᵢ value for the berbine tetrahdroalpalmatine (5) at α₁-adrenergic receptors is 2.88 µM.⁵ On the other hand, the aporphine glaucine (6) also binds to these receptors with slightly greater affinity, and the inhibition

![Figure 2](image-url)
curves displayed shallow slopes which could be subdivided into high and low affinity components attributed to \( \alpha_{\text{a}} \) and \( \alpha_{\text{b}} \)-receptor binding (\( K_i = 0.07 \) and 1.20 \( \mu \text{M} \), respectively). The rather small differences in the affinities of tetrahydrodopalmatine and glaucine, on one hand, and of the \( N \)-unsubstituted and \( N \)-substituted BTHIQs, on the other, suggest that both the extended and the semifolded conformations can be accommodated by the ligand site of the \( \alpha_{\text{a}} \)-adrenergic receptor.

It should be pointed out that the published affinities for tetrahydrodopalmatine and glaucine correspond to the natural (S) isomers, while the compounds studied by us were racemic. Thus, if the (S) stereochemistry were preferred (which is not known at this time), the \( K_i \) values recorded here for the laudanosine congeners might be half as high. In the case of (S)- \( N \)-propylglaucine, its \( \alpha_{\text{a}} \)-adrenergic receptor affinity would be slightly better than that reported for (S)-tetrohydrdopalmatine. Thus, although the \( \alpha_{\text{a}} \)-adrenergic affinity of (S) glaucine and its \( N \)-alkylated derivatives increases for the mostly semi-folded \( N \)-ethyl- and -propyl compounds, the \( K_i \) values, particularly with regard to (S)-glaucine, do not clearly support the idea that these compounds mimic an aporphine-like conformation when bound to the receptor. It should be realized, however, that the biphilin portion of the aporphine skeleton is practically flat (with the two coaxial benzene ring planes forming angles of less than 30\(^\circ\)), while the median plane of the benzyl group of BTHIQs in their semi-folded conformation is nearly perpendicular to the plane of the tetrahydroisoquinoline benzene ring. This difference may well be sufficient to explain the weaker affinity of the BTHIQs. As the proportion of molecules in the semi-folded conformation, barring specific interactions with the receptor, is not expected to differ to any important degree for the \( N \)-methyl, -ethyl or -propyl derivatives, the fact that the affinities of norlaudanosine (1) and laudanosine (2) are rather similar and significantly lower than those of the compounds with larger substituents on the nitrogen atom demands another explanation. It seems reasonable to suggest that an ethyl or propyl group attached to the nitrogen atom may occupy a hydrophobic pocket in the binding site, rather like the \( N \)-propyl pocket described for \( D_{\text{a}} \)-dopaminergic receptors, which have considerable structural homology with adrenergic receptors. A similar trend was seen for 12- \( O \)-methylglucine and its \( N \)-methyl derivative, which exhibit \( K_i \) values of 12.02 and 5.12 \( \mu \text{M} \), respectively, although at the time no conclusion could be drawn from these results. In the coclaurine (7,12-dihydroxy-6-methoxyBTHIQ) series, however, \( \alpha_{\text{a}} \)-adrenergic affinities decrease about two-fold with each increasing carbon atom on going from the secondary amines to the \( N \)-methyl derivative. This suggests that BTHIQs bearing a hydroxyl group at the \textit{para} position of the benzyl ring, such as coclaurine and armepavine on one hand, and analogues lacking this hydrogen-bond donor on the other, may bind to the receptor in different orientations. In both cases the BTHIQs presumably compete with norepinephrine for its binding site, but considering the likelihood that the receptor is able to accept ligands in extended or semifolded conformations, and in different orientations, extreme caution should be exercised before proposing any hypothetical pharmacophore.
