# **Nonlinear Event Detection in the Chilean Stock Market**

## **Abstract**

This paper search for economic and political events that might explain the episodic nonlinearities detected in the returns series of the Chilean stock market index. This methodology is a reverse form of event study. After applying the Hinich portmanteau bicorrelation test to detect episodes of nonlinear behavior of the index, we investigate what might be the explanation of this behavior. Our findings might help to explain the difficulty to forecast asset returns. We also shed some light into the major political and economic events that contributes to the numerous short burst of nonlinear dependence in the Chilean stock market.

JEL Classification: C12, G19

Key words: Chilean stock market, episodic nonlinearity, Hinich portmanteau bicorrelation test, event detection

We would like to thank the helpful comments of Claudia Blanco, Enrique Caviedes, and Carlos Maquieira. We would like to thank Joaquin Santibañez for his work as research assistant.

## **I. Introduction**

Since the pioneering work of Hinich and Patterson (1985), there has been growing evidence that stock market returns presents sporadic nonlinear behavior. We find studies of nonlinearity across developed and developing capital markets. There are examples of studies in developed capital markets like the US (Hinich and Patterson, 1985; Scheinkman and LeBaron, 1989; Hsieh 1991); the UK (Abhyankar et al, 1995; Opong et al, 1999) and Germany (Kosfeld and Robé, 2001), while examples for developing capital markets are Taiwan (Ammerman and Patterson, 2003); Turkey (Antoniou et al, 1997); several Asian stock markets (Lim and Hinich, 2005a); and several Latin American stock markets (Bonilla et al, 2006).

In spite of the existence of worldwide evidence of nonlinear behavior of stock market returns, there is little knowledge about the factors behind this behavior. Hence, the aim of this paper is to shed further light into this widely observed episodic feature of financial time series. In order to do that, we use a reverse form of event study in the same spirit of Brooks et al (2000) and Lim and Hinich (2005b). This methodology has two steps. First, we apply the Hinich portmanteau bivariate test to detect episodes of nonlinear behavior of the Chilean index. Second, we investigate what might be the major economic and political event that explains that behavior. We expect that our findings will help to explain why it is so difficult to forecast asset returns.

The Chilean economy is a small and open economy. Working with a small economy facilitates the identification of important economic and political events. Another characteristic of the Chilean capital markets is its openness, which makes this market highly integrated to the international

capital market. We observe that many of the Chilean blue chip companies have issued ADR in the US and that there are few restrictions to capital movement in this small country.

On statistical grounds, this paper uses the windowed testing procedure to apply the Hinich portmanteau bicorrelation non-parametric test (Hinich and Patterson, 1995 and Hinich, 1996) in the Chilean stock markets. This procedure divides the data in frames to test for nonlinearity. Examples of applications using similar methodologies are Brooks (1996), Brooks and Hinich (1998), Lim and Hinich (2005), and Bonilla et al (2006). Brooks (1996) finds evidence of nonlinearities in a set of ten daily sterling exchange rates covering the entire post Bretton-Woods era. Brooks and Hinich (1998) examine the episodic nature of ten European exchange rates and conclude that the nonlinear structure that is present in the data invalidate the GARCH specification usually assumed in the study of exchange rates. Lim and Hinich (2005), apply the windowed testing procedure to fourteen Asian stock market indices and find several nonlinear episodes. Bonilla et al (2006) encounters similar results for the seven most important Latin American stock market indices.

Nonlinear episodes detected in the Chilean stock return index would be the result of market adjustment to unexpected local and international shocks. When new information arrives to the market, it would generate a pattern of nonlinear price movements relative to previous movements since the traders are unsure of how to react, and hence they respond slowly. Moreover, we would expect that regulatory changes that affect the private pension funds (AFP) industry might cause nonlinear behavior.

After identifying some windows of nonlinearity, we search for economic and political events that might explain this behavior. There are some interesting results in related papers. Ammermann and Patterson (2003) find that the episodic dependence in the Taiwan stock return index would be directly attributable to changes in the price limits implemented during the year 1987 and 1988. Brooks et al (2000) find that the nonlinear dependency structures in ten daily Sterling exchange rates are highly localized in time, and that they would be attributed to widespread upsets in the currency markets and a changes in U.S. accounting procedures that affected U.S. firms with business abroad. Finally, Lim and Hinich (2005b) identify a number of key events that explain seven nonlinear episodes in the Malaysian stock return index, such as the Baring debacle, local political en economic changes, and international political and financial relevant news.

## **II. The Hinich Portmanteau Bicorrelation Test**

In this section we briefly describe the windowed test procedure and the Hinich portmanteau bicorrelation test statistic (denoted as  $H$  statistic). Let the sequence  $\{y(t)\}$  denote the sampled data process, where the time unit  $t$  is an integer. The test procedure employs non-overlapped data window, thus if  $n$  is the window length, then the  $k$ -th window is  $\{y(t_k), y(t_k+1), \dots, y(t_k+n-1)\}$ . The next non-overlapped window is  $\{y(t_{k+1}), y(t_{k+1}+1), \dots, y(t_{k+1}+n-1)\}$ , where  $t_{k+1} = t_k+n$ . The null hypothesis for each window is that  $y\{t\}$  are realizations of a stationary pure noise process that has zero bicorrelation. The alternative hypothesis is that the process generated within the window is random with some non-zero bicorrelations  $C_{yyy}(r, s) = E[y(t)y(t+r)y(t+s)]$  in the set  $0 < r < s < L$ , where  $L$  is the number of lags that define the window.

The Hinich portmanteau  $H$  statistics and its corresponding distribution are:<sup>1</sup>

$$H = \sum_{s=2}^L \sum_{r=1}^{s-1} G^2(r, s) \sim \chi^2_{(L-1)(L/2)} \quad (1)$$

where  $G(r, s) = (n-s)^{-\frac{1}{2}} C_{ZZZ}(r, s)$ , and  $C_{ZZZ}(r, s) = (n-s)^{-1} \sum_{t=1}^{n-s} Z(t)Z(t+r)Z(t+s)$  for  $0 \leq r \leq s$ .

The  $Z(t)$  are the standardized observations, obtained by subtracting the sample mean of the window and dividing by its standard deviation. The number of lags  $L$  is specified as  $L = n^b$  with  $0 < b < 0.5$ , where  $b$  is a parameter under the choice of the analyst. Based on results from Monte Carlo simulations (see Hinich and Patterson, 1995), the recommended use of  $b$  is  $b=0.4$  in order to maximize the power of the test while ensuring a valid approximation to the asymptotic theory. In this test procedure, a window is significant if the  $H$  statistic rejects the null of pure noise at the specified threshold level.

### III. The Data

The analysis presented here is based on daily data for the IGPA, the Chilean stock market index. The data was obtained from ECONOMATICA. The sample period for the index is January 1990 to September 2002. The data were transformed in the following way:  $r_t = \ln(p_t/p_{t-1})$ , where  $p_t$  is the closing price of the market stock index in day  $t$ . This standard transformation may be interpreted as a continuously compounded daily return (see Brock et al, 1991).

---

<sup>1</sup> For a mathematical derivation of this statistics and its small sample properties see Hinich and Patterson (1995) and Hinich (1996)

Information about the major economic and political events that may trigger episodic nonlinearities was obtained from different sources: First, we used monthly reports obtained from the Chilean Security Commission. Then, we study the Official Newspaper (a newspaper that publishes any legal change and important information for the Chilean business community). Finally, we search international newspapers, available in the national public library, to get information about international events.

#### **IV. Empirical Results**

Before checking for episodes of nonlinearity, we removed linear dependencies by fitting an AR(p) to the return series. Then, we may apply the Hinich bicorrelation test to the residuals of the AR(p) model. We do that to demonstrate that the nonstationarity is a consequence on nonlinearity, which is episodically present in the data, rather than a form of linear dependence.

In order to apply the test, we divided the data into a set of non-overlapped window of 25 days. The window length should be sufficiently long to validly apply the test and yet short enough for the data generating process to have remained roughly constant (Brooks and Hinich, 1998). The portmanteau bicorrelation test is then applied to the residuals of the fitted AR(0) model. Table 1 presents the results for the bicorrelation test using the windowed test procedure for the IGPA returns series. We see in the third column that the Chilean index has fifteen windows where significant nonlinearity is present, rejecting the random walk hypothesis of the rate of returns for the specific threshold level<sup>2</sup>.

<<Insert Table 1 here>>

Interestingly, the percentage of significant windows (11.81%) of the Chilean index is much larger than the respective proportion found in other European, Latin American or Asian indices, as has been reported in previous studies (see Brroks and Hinich, 2000, Bonilla at al, 2006 and Lim and Hinich, 2005). This peculiarity of the Chilean market requires further research, and this paper attempt to give some preliminary answers.

It has been proposed that the regulation of the highly important Chilean private pension funds (AFP) industry may play a role in the episodic nonlinearities that we found. Our findings give support to this hypothesis since for several windows of nonlinearities there were events associated with changes in the AFP regulations.

However, there are also important international events that may affect the behaviour of the Chilean stock market (see the last column of Table 1). For example, given the dependence of the Chilean economy to commodity prices, we find that the shocks in oil and copper markets may help to explain some episodes of nonlinearity (40% of the Chilean exportations come only from cupper). Moreover, the Chilean stock market index seems to be highly affected by international crisis, such

---

<sup>2</sup> In this study the threshold level was set at 0.01. The level of significance is the bootstrapped thresholds that correspond to 0.01.

as the Gulf War, the Baring debacle, the War of Kosovo and the attack to the Twin Towers. This high sensitivity to international events may be due to the high integration of the Chilean capital market to the rest of the world (Parisi, 1996).

## **V. Conclusions**

Using the Hinich portmanteau bicornelation test, we investigate the economic and political events that may provoke the episodic nonlinearities detected on the return series of the Chilean stock market index. We use a reverse form of event study in the same spirit of Brooks et al (2002) and Lim and Hinich (2005b).

We found that the percentage of significant nonlinear windows (11.81%) of the Chilean index is larger than what has been found in previous studies that apply the same methodology to European, Latin American and Asian countries. This paper attempts to give some preliminary answer to this peculiarity of the Chilean market, we find that for several windows of nonlinearity there were events associated with changes in the AFP regulations.

Moreover, there are also important international events that affect the behaviour of the Chilean stock market, among them the evolution of commodities prices and international crisis.

The study of the Chilean stock market is interesting not only because the small size of this market facilitate the identification of important economic and political events, but also because this market is highly integrated with the international capital market.

Our findings help explain why there are difficulties in forecasting asset returns. We also shed some light on the major political and economic events that contributes to the short burst of nonlinear dependence in the Chilean stock market. Future research should definitely take a close look to the individual stocks that cause these nonlinear episodes.
