Enteric duplication cysts are uncommon congenital anomalies of the gastrointestinal tract that may arise anywhere along the digestive tract. They most frequently occur in the small intestine (terminal ileum) on its mesenteric border and rarely communicate with the digestive tract. Enteric duplication cysts are usually asymptomatic and diagnosed during childhood (first 2 years of life). We report a case of unusual presentation in an asymptomatic 21-year-old patient, who was diagnosed by contrast-enhanced multislice computed tomography. Keywords: Computed tomography, Enteric duplication cyst.
