© 2018 S. Karger AG, Basel. Introduction: The laparoscopic approach for the treatment of gastric cancer has many advantages. However, outside Asia there are few large case series. Aim: To evaluate postoperative morbidity, long-term survival, changes in indication, and the results of laparoscopic gastrectomy. Methods: We included all patients treated with a laparoscopic gastrectomy from 2005 to 2014. We compared results across 2 time periods: 2005-2011 and 2012-2014. Median follow-up was 39 months. Results: Two hundred and eleven patients underwent a laparoscopic gastrectomy (median age 64 years, 55% male patients). In 135 (64%) patients, a total gastrectomy was performed. Postoperative morbidity occurred in 29%. A significant increase in the indication of laparoscopic surgery for stages II-III (32 vs. 45%; $p = 0.04$) and higher lymph node count (27 vs. 33; $p = 0.002$) were observed between the 2 periods. The 5-year overall survival was 72%. According to the stage, the 5-year overall survi
