Treatment of Chagas disease

© 2017 Elsevier Inc. All rights reserved. Although Chagas disease has existed for at least 9000 years, its treatment is recent: the internationally accepted drugs nifurtimox and benznidazole date from the 1970s. Both drugs are effective in acute cases, in congenital cases, in reactivation of chronic cases, and in new chronic cases. Its usefulness in chronic cases has not been shown, except in young women of childbearing age where it has prevented congenital infection and in some cases prevented the development of heart disease. In chronic chagasic cardiopathy benznidazole doesn’t improve the clinical course of the disease. Both drugs cause at least 30% of secondary effects. Other drugs, such as inhibitors of ergoesterol, itraconazol, posaconazol, and ravuconazol, although decreasing parasitemia don’t cure the disease. In the treatment of Chagas disease it is very important pre- and posttherapy to control clinical and parasitological parameters and record of the side effects of the drugs.
