#### Abstract

We prove strong convergence and asymptotic normality for the record and the weak record rate of observations of the form $Y_{n}=X_{n}+T_{n}, n \geq 1$, where $\left(X_{n}\right)_{n \in \mathbb{Z}}$ is a stationary ergodic sequence of random variables and $\left(T_{n}\right)_{n \geq 1}$ is a stochastic trend process, with stationary ergodic increments. The strong convergence result follows from the Dubins-Freedman law of large numbers and Birkhoff's ergodic theorem. For the asymptotic normality we rely on the approach of [3], coupled with a moment bound for stationary sequences, which is used to deal with the random trend process. Examples of application are provided. In particular, we obtain strong convergence and asymptotic normality for the number of ladder epochs in a random walk with stationary ergodic increments.

Keywords: Record, stationary process, ergodic theorem, random trend, strong convergence, asymptotic normality.

## 1. Introduction

Records capture attention as they arise in diverse domains such as economics or meteorology and, of course, sports. The mathematical theory has been developed over decades and reached a fair level of maturity, which can be appreciated in [1, 21]; see also [14] for recent results on record counts from independent, identically distributed (iid) observations.

Papers on statistical analysis of record data reveal that records occur more often than predicted by the standard iid theory. This was early pointed out in [9], where a model with linear deterministic trend is considered. Later, a power model which partly retains the theoretical simplicity of the iid case, was introduced in [27].

The theory of records from observations with linear trend was initiated by Ballerini and Resnick in [2], who obtained strong convergence and asymptotic normality for the record rate from observations of the form $Y_{n}=X_{n}+c n$, where the $X_{n}$ are integrable, iid, with continuous common distribution, and $c$ is a positive constant. These results were later extended to stationary $X_{n}$ in [3], with applications to athletic data. Additional theoretical results for the model with deterministic trend, linear or not, are found in [5, 6]. Also, interesting distribution-free inference methods are developed in [8].

The study of record events has attracted the interest of scientists beyond the probabilitystatistics community in recent years. In particular, a fresh look at the problem of records from observations with linear trend can be found in articles from physics journals, such as $[10,19,20,24]$. See also $[25,26]$ for applications of the model with deterministic trend to the analysis of climate change.

The main results of this paper are the strong convergence (to a positive constant) and a central limit theorem for the record and the weak record rate in a model consisting of stationary ergodic observations, subject to a stochastic trend process, whose increments are stationary ergodic. These results generalize those of [3] for stationary observations with a deterministic linear trend.

The proof of the strong convergence of the record rate relies on a result of [7], about the almost sure (a.s.) convergence of the ratio of the sum of indicators to the sum of their conditional expectations, with respect to an increasing family of sigma algebras.

We show that the process of conditional expectations couples with a stationary process and then apply Birkhoff's pointwise ergodic theorem to obtain the strong convergence of the record rate, unlike in [3] where the proof is based on Kingman's subadditive ergodic theorem. For the central limit theorem we consider first a martingale approach, which leads to asymptotic normality with a random centering process. Then we follow the strategy in [3] to obtain a central limit theorem with deterministic centering where, as can be expected, extra moment and mixing conditions are needed, due to the presence of a stochastic trend process.

We provide various examples of applications of our results. In particular, we analyze the case of random walks with stationary increments. This problem has been studied in the literature when the increments are independent [19, 23]; our results are more general since they include the case of correlated increments.

## 2. Definitions and preliminaries

Let the base process $\left(W_{n}\right)_{n \in \mathbb{Z}}$, with $W_{n}=\left(X_{n}, \tau_{n+1}\right)$, be defined as a bivariate, (strictly) stationary and ergodic random sequence, such that $E\left[X_{0}^{+}\right]<\infty$ and $0<c:=$ $E\left[\tau_{0}\right]<\infty$, where $\mathbb{Z}$ denotes the set of integers, $x^{+}:=x \vee 0$ and $u \vee v:=\max \{u, v\}$. The base process is taken as double-ended stationary for convenience, since any stationary single-ended sequence can be extended to a double-ended one. Also, ergodicity is assumed for ease since, otherwise, the asymptotic record rate has to be expressed as expectation, conditional on the $\sigma$-algebra of invariant events of $\left(W_{n}\right)_{n \in \mathbb{Z}}$. We use the notation $W_{m}^{n}$ for $\left(W_{m}, \ldots, W_{n}\right)$, with $-\infty \leq m \leq n \leq \infty$.

Let $\left(Y_{n}\right)_{n \geq 1}$ be the sequence defined by

$$
\begin{equation*}
Y_{n}=X_{n}+T_{n}, \tag{2.1}
\end{equation*}
$$

where $T_{n}:=\sum_{k=1}^{n} \tau_{k}, n \geq 1$, denotes the random trend or drift process. The first observation $Y_{1}$ is conventionally taken as a record and, for $n \geq 2, Y_{n}$ is said to be a (upper) record if $Y_{n}>M_{n-1}$, where $M_{n-1}:=\max \left\{Y_{1}, \ldots, Y_{n-1}\right\}$ (also denoted by $\left.\bigvee_{i=1}^{n-1} Y_{i}\right)$. The record indicators are then given by $I_{1}=1$ and $I_{n}=\mathbf{1}_{\left\{Y_{n}>M_{n-1}\right\}}, n \geq 2$. Finally, the counting process of records is defined by the sums of indicators $N_{n}=$ $\sum_{k=1}^{n} I_{k}$ and the record rate by $N_{n} / n, n \geq 1$.

Remark 1. Note that the random drift $T_{n}$ can be described as positive and linear in expectation because $E\left[T_{n}\right]=n c>0$. Observe also that $Y_{n}$ can be decomposed as $Y_{n}=X_{n}^{\prime}+n c$, with $X_{n}^{\prime}:=X_{n}+T_{n}-n c$. Such representation apparently implies that the random drift can be reduced to a linear deterministic drift. However, this is not so because $X_{n}^{\prime}$ is not stationary in general and so, the type of sequence $Y_{n}$ studied in this paper generalizes those previously considered in the literature. On the other hand, we point out that both sequences $\left(X_{n}\right)$ and $\left(\tau_{n}\right)$ are allowed to be dependent (correlated), also possibly mutually dependent, but must yet have finite expectation.

Lemma 1. (i) $M_{n} \rightarrow \infty$ and $N_{n} \rightarrow \infty$ a.s.
(ii) The sequence $Z_{n}:=M_{n-1}-T_{n}, n \geq 2$, satisfies the recurrence relation

$$
\begin{equation*}
V_{n+1}=\left(V_{n} \vee X_{n}\right)-\tau_{n+1} . \tag{2.2}
\end{equation*}
$$

Proof. (i) As $M_{n}$ is increasing, it converges to a finite limit or diverges to $\infty$ a.s. On the other hand, $\forall a \in \mathbb{R}$ we have

$$
\begin{equation*}
P\left[M_{n}>a\right] \geq P\left[X_{n}>a-T_{n}\right] \geq P\left[X_{n}>a-n c / 2, T_{n} \geq n c / 2\right] \rightarrow 1 \tag{2.3}
\end{equation*}
$$

since $P\left[X_{n}>a-n c / 2\right]=P\left[X_{0}>a-n c / 2\right] \rightarrow 1$ and $P\left[T_{n} \geq n c / 2\right] \rightarrow 1$, by Birkhoff's theorem. Hence, $M_{n} \rightarrow \infty$, which clearly implies $N_{n} \rightarrow \infty$.
(ii) By direct substitution into (2.2).

We show next that (2.2) has a stationary solution, which couples with $Z_{n}$. Stochastic recursions appear in many areas of applied probability; see [11] for results related to the $(\max ,+)$ algebra.

Proposition 1. Let $Z_{n}^{*}=\bigvee_{k \geq 1}\left\{X_{n-k}-\sum_{j=n-k+1}^{n} \tau_{j}\right\}, n \in \mathbb{Z}$. Then
(i) $Z_{n}^{*}$ is a proper stationary solution of (2.2) and
(ii) $Z_{n}^{*}=Z_{n}$ a.s., for sufficiently large $n$.

Proof. For (i) note that $Z_{n}^{*}$ is a measurable function of $W_{-\infty}^{n-1}$, so $Z_{n}^{*}$ is stationary. Also, substitution into (2.2) shows that $Z_{n}^{*}$ solves the recurrence.

We verify that $Z_{n}^{*}$ is proper, that is, $P\left[Z_{n}^{*} \in \mathbb{R}\right]=1$. Due to stationarity it suffices to show that $P\left[X_{-k}>\sum_{j=-k+1}^{0} \tau_{j}\right.$, i.o. $]=0$ (i.o. stands for "infinitely often"). Birkhoff's
theorem implies that $P\left[\sum_{j=-k+1}^{0} \tau_{j} \leq k c / 2\right.$, i.o. $]=0$, hence

$$
\begin{equation*}
P\left[X_{-k}>\sum_{j=-k+1}^{0} \tau_{j}, \text { i.o. }\right] \leq P\left[X_{-k}>k c / 2, \text { i.o. }\right] \tag{2.4}
\end{equation*}
$$

Furthermore, by stationarity $P\left[X_{-k}>k c / 2\right]=P\left[X_{0}>k c / 2\right]$, for $k \geq 1$, and $\sum_{k=1}^{\infty} P\left[X_{0}>k c / 2\right]<\infty$ because $E\left[X_{0}^{+}\right]<\infty$. The conclusion then follows from the Borel-Cantelli lemma.

For (ii) we iterate (2.2) with starting value $Z_{2}$ to obtain

$$
Z_{n}=\bigvee_{k=1}^{n-2}\left(X_{n-k}-\sum_{j=n-k+1}^{n} \tau_{j}\right) \vee\left(Z_{2}-\sum_{j=3}^{n} \tau_{j}\right), n \geq 2
$$

We claim that, for $n$ large enough, $Z_{n}=\bigvee_{k=1}^{n-2}\left(X_{n-k}-\sum_{j=n-k+1}^{n} \tau_{j}\right)$ a.s. because $Z_{2}-\sum_{j=3}^{n} \tau_{j} \rightarrow-\infty$ a.s., by Birkhoff's theorem. To prove the claim let us assume on the contrary that $P\left[Z_{n}=Z_{2}-\sum_{j=3}^{n} \tau_{j}\right.$, i.o. $]>0$ which, from the definition of $Z_{n}$ in Lemma 1 (ii), is equivalent to $P\left[M_{n-1}=M_{1}\right.$, i.o. $]>0$. As this contradicts Lemma 1 (i), the claim is proven.

On the other hand, by iterating (2.2) with starting value $Z_{2}^{*}$ we obtain

$$
Z_{n}^{*}=\bigvee_{k=1}^{n-2}\left(X_{n-k}-\sum_{j=n-k+1}^{n} \tau_{j}\right) \vee\left(Z_{2}^{*}-\sum_{j=3}^{n} \tau_{j}\right), n \geq 2
$$

So, from the previous claim we have $Z_{n}^{*}=Z_{n} \vee\left(Z_{2}^{*}-\sum_{j=3}^{n} \tau_{j}\right)$ a.s., for $n$ large enough. Finally we obtain that $Z_{n}^{*}=Z_{n}$, for $n$ large enough, because

$$
P\left[Z_{2}^{*}-\sum_{j=3}^{n} \tau_{j}>Z_{n}, \text { i.o. }\right]=P\left[M_{n-1}<Z_{2}^{*}+T_{2}, \text { i.o. }\right]=0
$$

by Lemma 1 (i).
Definition 1. Let $\left(\mathcal{F}_{n}\right)_{n \in \mathbb{Z}}$ be the increasing family of $\sigma$-algebras given by

$$
\begin{equation*}
\mathcal{F}_{n}=\sigma\left\{X_{k}, \tau_{k+1}, k \leq n\right\}=\sigma\left\{W_{-\infty}^{n}\right\}, n \in \mathbb{Z} \tag{2.5}
\end{equation*}
$$

Also, let $G_{n-1}(x)=P\left[X_{n}>x \mid \mathcal{F}_{n-1}\right]$ and $G_{n-1}^{w}(x)=P\left[X_{n} \geq x \mid \mathcal{F}_{n-1}\right]$, for $x \in \mathbb{R}, n \in \mathbb{Z}$, be the (regular, conditional on $\mathcal{F}_{n-1}$ ) survival function and the weak survival function of $X_{n}$, respectively.

Proposition 2. Let $G_{n-1}(x)$ and $G_{n-1}^{w}(x)$ from Definition 1 and let $Z_{n}^{*}$ be as defined in Proposition 1. Then $G_{n-1}\left(Z_{n}^{*}\right), G_{n-1}^{w}\left(Z_{n}^{*}\right), n \in \mathbb{Z}$, are stationary and ergodic.

Proof. First note that $Z_{n}^{*}$ is $\mathcal{F}_{n-1}$ measurable, hence $G_{n-1}\left(Z_{n}^{*}\right)=P\left[X_{n}>Z_{n}^{*} \mid W_{-\infty}^{n-1}\right], n \in$ $\mathbb{Z}$. From the definition of conditional expectation, there exists a measurable function $f_{0}: \mathbb{R}^{\infty} \rightarrow \mathbb{R}$, such that $G_{0}\left(Z_{1}^{*}\right)=E\left[\mathbf{1}_{\left\{X_{1}>Z_{1}^{*}\right\}} \mid W_{-\infty}^{0}\right]=f_{0}\left(W_{-\infty}^{0}\right)$ and

$$
E\left[f_{0}\left(W_{-\infty}^{0}\right) g\left(W_{-\infty}^{0}\right)\right]=E\left[\mathbf{1}_{\left\{X_{1}>Z_{1}^{*}\right\}} g\left(W_{-\infty}^{0}\right)\right]
$$

for any bounded and measurable function $g: \mathbb{R}^{\infty} \rightarrow \mathbb{R}$. We claim that $f_{0}\left(W_{-\infty}^{n-1}\right)$ is a version of $E\left[\mathbb{1}_{\left\{X_{n}>Z_{n}^{*}\right\}} \mid W_{-\infty}^{n-1}\right]$ and therefore that $G_{n-1}\left(Z_{n}^{*}\right)$ is stationary and ergodic. The claim follows at once from the stationarity (and ergodicity) of $W_{n}$ since, for $n \in \mathbb{Z}$,

$$
E\left[f_{0}\left(W_{-\infty}^{n-1}\right) g\left(W_{-\infty}^{n-1}\right)\right]=E\left[f_{0}\left(W_{-\infty}^{0}\right) g\left(W_{-\infty}^{0}\right)\right]
$$

and

$$
E\left[\mathbf{1}_{\left\{X_{1}>Z_{1}^{*}\right\}} g\left(W_{-\infty}^{0}\right)\right]=E\left[\mathbf{1}_{\left\{X_{n}>Z_{n}^{*}\right\}} g\left(W_{-\infty}^{n-1}\right)\right] .
$$

The argument for $G_{n-1}^{w}\left(Z_{n}^{*}\right)$ is identical.

## 3. Main results

### 3.1. Strong convergence of the record and the weak-record rate

The strong convergence of the record rate, for stationary observations with random drift, is contained in the following theorem.

## Theorem 1.

$$
\begin{equation*}
\frac{N_{n}}{n} \rightarrow p:=E\left[G_{0}\left(Z_{1}^{*}\right)\right]=P\left[X_{1}>\bigvee_{k \geq 1}\left\{X_{1-k}-\sum_{j=2-k}^{1} \tau_{j}\right\}\right] \quad \text { a.s. } \tag{3.1}
\end{equation*}
$$

Proof. Let $G_{n-1}(x)$ and $Z_{n}$ be as described in Definition 1 and Lemma 1 (ii). We invoke Proposition 6, with $U_{n}=I_{n}$ and $\mathcal{G}_{n}=\mathcal{F}_{n}$, recalling that, from Lemma 1 (i), $N_{n} \rightarrow \infty$ a.s. Hence, $\sum_{n \geq 1} U_{n}=\infty$ a.s. and (5.2) holds. Further, the conditional expectation of $I_{n}$ is easily calculated as

$$
\begin{equation*}
E\left[I_{n} \mid \mathcal{F}_{n-1}\right]=P\left[Y_{n}>M_{n-1} \mid \mathcal{F}_{n-1}\right]=P\left[X_{n}>M_{n-1}-T_{n} \mid \mathcal{F}_{n-1}\right]=G_{n-1}\left(Z_{n}\right), \tag{3.2}
\end{equation*}
$$

$n \geq 2$, and so, from (3.2) and (5.2) we obtain

$$
\begin{equation*}
\frac{N_{n}}{\sum_{k=2}^{n} G_{k-1}\left(Z_{k}\right)} \rightarrow 1 \quad \text { a.s. } \tag{3.3}
\end{equation*}
$$

On the other hand, by Proposition 2, $G_{n-1}\left(Z_{n}^{*}\right)$ is stationary ergodic and so Birkhoff's theorem yields

$$
\begin{equation*}
\frac{1}{n} \sum_{k=1}^{n} G_{k-1}\left(Z_{k}^{*}\right) \rightarrow E\left[G_{0}\left(Z_{1}^{*}\right)\right] \quad \text { a.s. } \tag{3.4}
\end{equation*}
$$

Further, from Proposition 1 (ii) we know that $Z_{n}$ and $Z_{n}^{*}$ couple, hence (3.4) also holds with $Z_{n}$ replacing $Z_{n}^{*}$, that is,

$$
\frac{1}{n} \sum_{k=1}^{n} G_{k-1}\left(Z_{k}\right) \rightarrow E\left[G_{0}\left(Z_{1}^{*}\right)\right] \quad \text { a.s. }
$$

and the conclusion follows from (3.3).
A weak record is an observation which is greater than or equal to the current maximum. We define the indicators of weak records by $I_{1}^{w}=1$ and $I_{k}^{w}=\mathbf{1}_{\left\{Y_{k} \geq M_{k-1}\right\}}, k \geq 2$; the counting process and the rate by $N_{n}^{w}=\sum_{k=1}^{n} I_{k}^{w}$ and $N_{n}^{w} / n$, respectively. Of course, records and weak records coincide unless the distribution of the observations has discontinuities; see $[12,13]$ for results in the iid case. Observe that $N_{n}^{w} \geq N_{n} \rightarrow \infty$, by Lemma 1 (i). We now state the analog of Theorem 1 for weak records.

## Theorem 2.

$$
\begin{equation*}
\frac{N_{n}^{w}}{n} \rightarrow p^{w}:=E\left[G_{0}^{w}\left(Z_{1}^{*}\right)\right]=P\left[X_{1} \geq \bigvee_{k \geq 1}\left\{X_{1-k}-\sum_{j=2-k}^{1} \tau_{j}\right\}\right] \quad \text { a.s. } \tag{3.5}
\end{equation*}
$$

Proof. As that of Theorem 1, mutatis mutandis.
About the positivity of the limits in Theorems 1 and 2, we have the following result. Observe that the integrability hypothesis of $X_{0}$ is crucial.

Proposition 3. Let $p, p^{w}$ be as defined in Theorems 1 and 2. Then $p^{w} \geq p>0$.
Proof. Clearly, since records are also weak records, we have $p^{w} \geq p$ and so, it suffices to prove that $p>0$. Observe that $p=E\left[G_{0}\left(Z_{1}^{*}\right)\right]=0$ implies $G_{0}\left(Z_{1}^{*}\right)=0$ a.s. and so, by stationarity, $G_{n-1}\left(Z_{n}^{*}\right)=0, \forall n \in \mathbb{Z}$, a.s. Now, since $Z_{n}^{*}$ and $Z_{n}$ couple, the series $\sum_{n \geq 1} G_{n-1}\left(Z_{n}\right)$ converges. Therefore, by (5.1), $\sum_{n \geq 1} I_{n}<\infty$, thus contradicting Lemma 1 .

Remark 2. It is easy to find an example with $p=1$ (see after Proposition 4). In this case, all observations are records, except for a finite number. Indeed, we consider the indicators of not being a record, that is, $1-I_{n}$. Then, by (5.2), the total number of
no-records $\sum_{n \geq 1}\left(1-I_{n}\right)$ is finite if and only if $\sum_{n \geq 1}\left(1-G_{n-1}\left(Z_{n}\right)\right)$ is finite. The last sum converges because $p=1$ implies $G_{0}\left(Z_{1}^{*}\right)=1$ a.s.

### 3.2. Asymptotic normality

The asymptotic normality of $N_{n}$ was first investigated in [2], in the context of a base process $W_{n}$ where the $X_{n}$ are iid, with continuous distribution $F$, and the drift process is deterministic, i.e., $\tau_{n}=c$. The result was later extended in [3] to stationary, strongly mixing and square-integrable $X_{n}$, always under deterministic drift. Their method of proof relies on the approximation of the indicators $I_{n}$ by stationary ones.

We consider first a different approach based on the conditional centering of $N_{n}$. It is clear that $N_{n}-\sum_{k=1}^{n} E\left[I_{k} \mid \mathcal{F}_{k-1}\right], n \geq 1$, is a martingale with bounded increments. So the martingale central limit theorem can be applied; see, for example, Corollary 3.1 in [17]. To that end observe that the Lindeberg-type condition is satisfied and, letting $\xi_{k}=I_{k}-E\left[I_{k} \mid \mathcal{F}_{k-1}\right]$, we have $E\left[\xi_{k}^{2} \mid \mathcal{F}_{k-1}\right]=G_{k-1}\left(Z_{k}\right)\left(1-G_{k-1}\left(Z_{k}\right)\right)$. Hence, by Proposition 1 (ii), Proposition 2 and Birkhoff's theorem,

$$
\begin{equation*}
\frac{1}{n} \sum_{k=1}^{n} E\left[\xi_{k}^{2} \mid \mathcal{F}_{k-1}\right] \rightarrow E\left[G_{0}\left(Z_{1}^{*}\right)\left(1-G_{0}\left(Z_{1}^{*}\right)\right)\right] \quad \text { a.s. } \tag{3.6}
\end{equation*}
$$

We have thus proven:
Proposition 4. If $\sigma_{M}^{2}:=E\left[G_{0}\left(Z_{1}^{*}\right)\left(1-G_{0}\left(Z_{1}^{*}\right)\right)\right]>0$, then the following convergence holds in distribution:

$$
\begin{equation*}
\frac{1}{\sqrt{n}}\left(N_{n}-\sum_{k=1}^{n} G_{k-1}\left(Z_{k}\right)\right) \rightarrow N\left(0, \sigma_{M}^{2}\right) \tag{3.7}
\end{equation*}
$$

Examples with $\sigma_{M}=0$ are easy to construct: take $\left(X_{n}\right)_{n \in \mathbb{Z}}$ iid uniform in [0,1] and $\tau_{n}=3$ then $Y_{n} \in[3 n, 3 n+1]$ and $G_{n-1}\left(Z_{n}\right)=1$, for $n \geq 1$. So, all observations are records and there is no asymptotic normality for $N_{n}$.

Proposition 5. If $\sigma_{M}=0$ the martingale $N_{n}-\sum_{k=1}^{n} G_{k-1}\left(Z_{k}\right)$ converges a.s.
Proof. The argument is like in Proposition 3: $\sigma_{M}=0$ implies $G_{k-1}\left(Z_{k}^{*}\right)(1-$ $\left.G_{k-1}\left(Z_{k}^{*}\right)\right)=0, k \in \mathbb{Z}$, and because of the coupling of $Z_{k}$ and $Z_{k}^{*}$, the series $\sum_{k \geq 1} E\left[\xi_{k}^{2} \mid \mathcal{F}_{k-1}\right]=$ $\sum_{k \geq 1} G_{k-1}\left(Z_{k}\right)\left(1-G_{k-1}\left(Z_{k}\right)\right)$ converges and so does the martingale.

Remark 3. Observe in the proof above that the random variables $G_{k-1}\left(Z_{k}^{*}\right)$ take values in $\{0,1\}$ and the same is true for $G_{k-1}\left(Z_{k}\right)$, for $k$ large enough. So, since
$\sum_{k=1}^{\infty}\left(I_{k}-G_{k-1}\left(Z_{k}\right)\right)<\infty$, we have $I_{k}=G_{k-1}\left(Z_{k}\right)$, for $k$ large enough. Suppose, for example, $X_{n}$ iid with distribution $F$ and $\tau_{n}=c$, then $G_{0}\left(Z_{1}^{*}\right)=P\left[X_{1}>Z_{1}^{*} \mid \mathcal{F}_{0}\right] \geq$ $P\left[X_{1}>X_{0}-c \mid X_{0}\right]=1-F\left(X_{0}-c\right)>0$. So $P\left[G_{0}\left(Z_{1}^{*}\right)=0\right]=0$, which implies $G_{k-1}\left(Z_{k}^{*}\right)=1 \forall k$ and $G_{k-1}\left(Z_{k}\right)=1$, for $k$ large enough. In other words, in this model $\sigma_{M}=0$ entails $p=1$ and all observations are records save a finite number. This is not true in the general case of stationary observations.

The result of Proposition 4 does not depend on any mixing condition on the base process but it is not satisfactory because the centering sequence is random and there seems to be no simple way of replacing it by a deterministic one. We present below a second central limit theorem for $N_{n}$, with deterministic centering, requiring the strong mixing of the base process $W_{n}$ plus some moment conditions on $X_{n}$ and $\tau_{n}$. The proof follows closely that of Theorem 2 in [3], but needs extra conditions for handling the tail probabilities in the presence of random trend. In fact we rely on a bound for moments of stationary mixing sequences from [28]; see Lemma 2. We recall the definition of the $\alpha$-mixing coefficients. Let $\mathcal{F}_{-\infty}^{0}=\sigma\left\{W_{-\infty}^{0}\right\}, \mathcal{F}_{n}^{\infty}=\sigma\left\{W_{n}^{\infty}\right\}$ and

$$
\alpha(n):=\sup _{A \in \mathcal{F}_{-\infty}^{0}, B \in \mathcal{F}_{n}^{\infty}}|P[A B]-P[A] P[B]|
$$

Let also $\mathcal{F}_{-\infty}^{0, \tau}=\sigma\left\{\ldots, \tau_{-1}, \tau_{0}\right\}, \mathcal{F}_{n}^{\infty, \tau}=\sigma\left\{\tau_{n}, \tau_{n+1}, \ldots\right\}$ and

$$
\begin{equation*}
\alpha^{\tau}(n):=\sup _{A \in \mathcal{F}_{-\infty}^{0, \tau}, B \in \mathcal{F}_{n}^{\infty, \tau}}|P[A B]-P[A] P[B]| \tag{3.8}
\end{equation*}
$$

Theorem 3. Suppose that $\sum_{n \geq 1} \alpha(n)<\infty, E\left[X_{0}^{2}\right]<\infty, E\left[\left|\tau_{0}\right|^{r+a}\right]<\infty$ and that, for some $r>4, a>0, \sum_{n \geq 1} n^{r / 2+1}\left[\alpha^{\tau}(n)\right]^{a /(r+a)}<\infty$. Then the following convergence holds in distribution

$$
\begin{equation*}
\frac{N_{n}-n p}{\sqrt{n}} \rightarrow N\left(0, \sigma^{2}\right) \tag{3.9}
\end{equation*}
$$

if $\sigma>0$, where $p=E\left[I_{0}^{*}\right]=P\left[X_{0}>Z_{0}^{*}\right]$ and $\sigma^{2}=p(1-p)+2 \sum_{n \geq 1} \gamma(n)$, with $\gamma(n)=\operatorname{Cov}\left(I_{0}^{*}, I_{n}^{*}\right)$ and $I_{n}^{*}=\mathbf{1}_{\left\{X_{n}>Z_{n}^{*}\right\}}$, for $n \in \mathbb{Z}$.

Proof. We follow the strategy of [3], which consists in proving a central limit theorem for a sequence of strongly mixing indicators and then transferring the result to $N_{n}$. Let $Z_{n}^{k}=\bigvee_{i=1}^{k}\left\{X_{n-i}-\sum_{j=n-i+1}^{n} \tau_{j}\right\}$, for $k \geq 1, n \in \mathbb{Z}$, and recall that $Z_{n}^{*}=\bigvee_{i \geq 1}\left\{X_{n-i}-\right.$ $\left.\sum_{j=n-i+1}^{n} \tau_{j}\right\}$. Let also $I_{n}^{k}=\mathbf{1}_{\left\{X_{n}>Z_{n}^{k}\right\}}$, for $n \in \mathbb{Z}$, and $N_{n}^{k}=\sum_{i=1}^{n} I_{i}^{k}, N_{n}^{*}=\sum_{i=1}^{n} I_{i}^{*}$, for $n \geq 1$.

As in the above cited work (page 807), we note that $I_{n}^{k}, n \in \mathbb{Z}$, is stationary, with mixing coefficients $\alpha_{k}(n)$ such that $\alpha_{k}(n) \leq 1$, for $n \leq k$, and $\alpha_{k}(n) \leq \alpha(n-k)$, for $n>k$. Since, by hypothesis, the mixing coefficients are summable, Theorem 18.5.4 in [18] can be applied to yield the following: let $p_{k}=E\left[I_{0}^{k}\right]$ and $\sigma_{k}^{2}=\gamma_{k}(0)+2 \sum_{n \geq 1} \gamma_{k}(n)$, with $\gamma_{k}(n)=\operatorname{Cov}\left(I_{0}^{k}, I_{n}^{k}\right)$. Then $\sigma_{k}^{2}<\infty$ and, if $\sigma_{k}>0$, the following convergence holds in distribution:

$$
\begin{equation*}
\frac{N_{n}^{k}-n p_{k}}{\sqrt{n}} \rightarrow N\left(0, \sigma_{k}^{2}\right) \tag{3.10}
\end{equation*}
$$

The next step is to apply Theorem 4.2 of [4] to obtain the asymptotic normality of $N_{n}^{*}$ by letting $k \rightarrow \infty$ in (3.10). To that end we first show (in Lemmas 3 and 4) that $p_{k} \rightarrow p$ and $\sigma_{k} \rightarrow \sigma$, as $k \rightarrow \infty$. Finally, in Lemma 5 we verify that

$$
\lim _{k \rightarrow \infty} \limsup _{n \rightarrow \infty} P\left[\left|\left(N_{n}^{k}-n p_{k}\right)-\left(N_{n}^{*}-n p\right)\right|>\epsilon \sqrt{n}\right] \rightarrow 0, \forall \epsilon>0
$$

The conclusion (3.9) follows because the coupling of $Z_{n}$ and $Z_{n}^{*}$ implies $\left(N_{n}-N_{n}^{*}\right) / \sqrt{n} \rightarrow$ 0 a.s.

Remark 4. If the increments $\tau_{n}$ of the trend process are bounded, then the condition on $\alpha^{\tau}(n)$ in Theorem 3 can be relaxed to $\sum_{n \geq 1}(n+1)^{r / 2+1} \alpha^{\tau}(n)<\infty$; see Theorem 2 in [28].

Remark 5. Theorem 3 and the corresponding lemmas can be easily adapted to weak records, yielding

$$
\frac{N_{n}^{w}-n p^{w}}{\sqrt{n}} \rightarrow N\left(0, \sigma_{w}^{2}\right)
$$

where $\sigma_{w}^{2}=p^{w}\left(1-p^{w}\right)+2 \sum_{n \geq 1} \operatorname{Cov}\left(I_{0}^{w *}, I_{n}^{w *}\right)$, with $I_{n}^{w *}=\mathbb{1}_{\left\{X_{n} \geq Z_{n}^{*}\right\}}$, for $n \in \mathbb{Z}$.

## 4. Examples

Example 1. Let $\left(X_{n}\right)_{n \in \mathbb{Z}}$ be iid, with common distribution function $F$ (not necessarily continuous).
(a) Let $\tau_{n}=c>0, n \in \mathbb{Z}$. Then, from Theorems 1 and 2,

$$
\frac{N_{n}}{n} \rightarrow p=\int \prod_{k \geq 1} \tilde{F}(x+k c) F(d x), \quad \frac{N_{n}^{w}}{n} \rightarrow p^{w}=\int \prod_{k \geq 1} F(x+k c) F(d x)
$$

where $\tilde{F}(x)=P\left[X_{1}<x\right]$. Also, Theorem 3 can be applied to obtain the asymptotic normality of $N_{n}$ and $N_{n}^{w}$.

For the Gumbel distribution $F(x)=e^{-e^{-x}}$, the explicit result $p=1-e^{-c}$ is easily obtained; see [2]. This particular case is interesting in its own right because the sequence $Y_{n}$ can be seen as an $F^{\alpha}$-scheme, that is, the $Y_{n}$ are independent with respective distribution functions $F_{n}(x)=F(x)^{\alpha_{n}}$, where $\alpha_{n}=e^{n c}$. Therefore, the record indicators $I_{n}$ are independent and so, strong convergence and asymptotic normality follow; see [21] for information on the $F^{\alpha}$-scheme. Also, the variance in Theorem 3, whose exact evaluation is in general out reach, is given by $\sigma^{2}=p(1-p)$.
(b) Let $\left(\tau_{n}\right)_{n \in \mathbb{Z}}$ be iid, independent of $\left(X_{n}\right)_{n \in \mathbb{Z}}$. Then, from Theorem 1,

$$
\frac{N_{n}}{n} \rightarrow p=\int E\left[\prod_{k \geq 1} \tilde{F}\left(x+T_{k}\right)\right] F(d x)
$$

For $F(x)=e^{-e^{-x}}$ we have

$$
p=E\left[\int_{0}^{1} u^{\sum_{k=1}^{\infty} e^{-T_{k}}} d u\right]=E\left[\left(1+\sum_{k=1}^{\infty} e^{-T_{k}}\right)^{-1}\right]
$$

Example 2. [Ladder variables] Let $\left(\eta_{n}\right)_{n \geq 1}$ be a stationary ergodic sequence, with $E\left[\eta_{1}\right]>0$, and let $S_{n}=\sum_{j=1}^{n} \eta_{j}, n \geq 1, S_{0}=0$. We are interested in the asymptotic record rate, denoted by $\lambda$, of the random walk (with positive drift) $S_{n}$. In this context, record times and record values are referred to as (ascending) ladder epochs and heights respectively. To that end we define a base process $\left(W_{n}\right)_{n \in \mathbb{Z}}$, with $X_{n}=0, \forall n$, and $\left(\tau_{n}\right)_{n \in \mathbb{Z}}$ the stationary ergodic double-ended extension of $\left(\eta_{n}\right)_{n \geq 1}$, with $\tau_{n}=\eta_{n}$, for $n \geq 1$. Given that the number of ladder epochs of $S_{n}$ is equal to $N_{n}$, from Theorem 1 we obtain

$$
\lambda=P\left[\bigwedge_{k \geq 1}\left\{\sum_{j=1-k}^{0} \tau_{j}\right\}>0\right]
$$

where $\Lambda$ denotes the min operator. Observe that $\lambda$ depends on the auxiliary random variables $\tau_{n}, n \leq 0$, instead of depending only on the original increments $\eta_{n}$. However, due to stationarity, we have

$$
\lambda=\lim _{n \rightarrow \infty} P\left[\eta_{n}>0, \eta_{n}+\eta_{n-1}>0, \ldots, \eta_{n}+\cdots+\eta_{1}>0\right]
$$

Observe also that $\lambda=\lim _{n \rightarrow \infty} P\left[V_{n}>0\right]$, where $V_{n}:=\min \left\{\eta_{n}, \eta_{n}+\eta_{n-1}, \ldots, \eta_{n}+\right.$ $\left.\cdots+\eta_{1}\right\}$ satisfies $V_{n+1}=\left(V_{n}+\eta_{n+1}\right) \wedge \eta_{n+1}, n \geq 1$, with $V_{1}=\eta_{1}$. This representation can be useful when $\left(\eta_{n}\right)_{n \geq 1}$ is a Markov chain since then $\left(V_{n}, \eta_{n}\right)_{n \geq 1}$ is also a Markov chain and $\lambda$ can be obtained in terms of its stationary distribution.

On the other hand, if the increments are reversible, in the sense of $\left(\eta_{1}, \ldots, \eta_{n}\right)$ and $\left(\eta_{n}, \ldots, \eta_{1}\right)$ being equally distributed, for all $n \geq 1$, then $\lambda$ is simply $P\left[\bigwedge_{k \geq 1} S_{k}>0\right]$, the probability that the random walk stays strictly positive. Reversibility occurs, for instance, when $\eta_{n}$ is a time-reversible Markov chain.

In the case of iid increments $\eta_{n}$, the limit above is well known, since $N_{n}$ can be seen as the counting function of a renewal process and therefore $N_{n} / n \rightarrow 1 / E\left[L_{1}\right]$, where $L_{1}$ is the first ladder epoch. The reader further interested in ladder variables can consult Chapters 2, 3 of [16]. Up to the authors' knowledge, the result in the general stationary case appears to be new.

We also consider weak records in the random walk $S_{n}, n \geq 0$, corresponding to weak ladder variables. From Theorem 2, the asymptotic rate of weak ladder epochs is given by

$$
\lambda^{w}=P\left[\bigwedge_{k \geq 1}\left\{\sum_{j=1-k}^{0} \tau_{j}\right\} \geq 0\right]
$$

In this case $\lambda^{w}=\lim _{n \rightarrow \infty} P\left[V_{n}^{\prime} \geq 0\right]$, where $V_{n}^{\prime}:=V_{n} \wedge 0, n \geq 1$, satisfies $V_{n+1}^{\prime}=$ $\left(V_{n}^{\prime}+\eta_{n+1}\right) \wedge 0, n \geq 0$, with $V_{0}^{\prime}=0$; that is, $V_{n}^{\prime}$ is a random walk taking values in $(-\infty, 0]$, with increments $\left(\eta_{n}\right)_{n \geq 1}$ and reflecting barrier at 0 .

Example 3. [Range of a Bernoulli random walk] Let $\left(\eta_{n}\right)_{n \geq 1}$ be a stationary ergodic sequence, with $\eta_{n} \in\{-1,1\}, P\left[\eta_{1}=1\right]=\rho>1 / 2$, and let $S_{n}=\sum_{j=1}^{n} \eta_{j}, n \geq 1$, $S_{0}=0$. We consider $R_{n}$, the range of the walk up to time $n$, defined as the number of distinct values in $\left(S_{1}, S_{2}, \ldots, S_{n}\right)$. As in Example 2, we define a base process $\left(W_{n}\right)_{n \in \mathbb{Z}}$, with $X_{n}=0, n \in \mathbb{Z}$, and $\left(\tau_{n}\right)_{n \in \mathbb{Z}}$ the stationary ergodic double-ended extension of $\left(\eta_{n}\right)_{n \geq 1}$, with $\tau_{n}=\eta_{n}$, for $n \geq 1$. Note that, due to the nature of $\eta_{n}, R_{n}$ and $N_{n}$ are asymptotically equivalent in the sense that $R_{n}-N_{n}$ converges a.s. as $n \rightarrow \infty$. Hence, from Theorem $1, R_{n} / n \rightarrow \lambda$, where $\lambda$ is defined in Example 2. This result is a particular instance of the Kesten-Spitzer-Whitman theorem; see [22], page 38.

Also, from Theorem $3,\left(R_{n}-\lambda n\right) / \sqrt{n} \rightarrow N\left(0, \sigma^{2}\right)$ in distribution. For illustration we explicitly calculate below $\lambda$ and $\sigma$, in the case of iid increments $\eta_{n}$.

From the gambler's ruin problem we have $\lambda=2 \rho-1$. Now $\operatorname{Cov}\left(I_{0}^{*}, I_{n}^{*}\right)=E\left[I_{0}^{*} I_{n}^{*}\right]-$
$\lambda^{2}$ and, because of the independence of the $\tau_{n}$, we obtain

$$
\begin{aligned}
E\left[I_{0}^{*} I_{n}^{*}\right] & =P\left[\sum_{j=-k+1}^{0} \tau_{j}>0, \sum_{j=n-k+1}^{n} \tau_{j}>0, \forall k \geq 1\right] \\
& =P\left[\sum_{j=0}^{k-1} \tau_{j}>0, \sum_{j=n}^{n+k-1} \tau_{j}>0, \forall k \geq 1\right] \\
& =P\left[\sum_{j=0}^{k-1} \tau_{j}>0,1 \leq k \leq n\right] P\left[\sum_{j=n}^{n+k-1} \tau_{j}>0, \forall k \geq 1\right] \\
& =P\left[\sum_{j=0}^{k-1} \tau_{j}>0,1 \leq k \leq n\right] \lambda .
\end{aligned}
$$

So $\operatorname{Cov}\left(I_{0}^{*}, I_{n}^{*}\right)=\lambda P\left[T_{k}>0,1 \leq k \leq n\right]-\lambda^{2}$. Note also that

$$
P\left[T_{k}>0,1 \leq k \leq n\right]-\lambda=P\left[n+1 \leq H_{0}<\infty\right]
$$

where $H_{0}=\min \left\{k \geq 1: T_{k} \leq 0\right\}$ (hitting time of $\{\ldots,-1,0\}$ ). Therefore

$$
\sum_{n \geq 1} \operatorname{Cov}\left(I_{0}^{*}, I_{n}^{*}\right)=\lambda \sum_{n \geq 1} P\left[n+1 \leq H_{0}<\infty\right]=\lambda E\left[\left(H_{0}-1\right) \mathbf{1}_{\left\{H_{0}<\infty\right\}}\right]
$$

We have $P\left[H_{0}=1\right]=1-\rho$ and, from the hitting time theorem (see [15], page 79),

$$
P\left[H_{0}=n\right]=\frac{\rho}{n-1} P\left[T_{n-1}=-1\right], \quad n \geq 2
$$

Hence
$E\left[\left(H_{0}-1\right) \mathbf{1}_{\left\{H_{0}<\infty\right\}}\right]=\rho \sum_{n \geq 1} P\left[T_{n-1}=-1\right]=\rho \sum_{m \geq 0}\binom{2 m+1}{m} \rho^{m}(1-\rho)^{m+1}=\frac{1-\rho}{2 \rho-1}$
and thus $\sigma^{2}=4 \rho(1-\rho)$.
Remark 6. Records in random walks, as considered in Examples 2 and 3, have received much attention in the physics literature in recent years. The unbiased case (zero drift) was analyzed in [20] using a theorem of Sparre Andersen; for this model, assuming the independence of the increments, $E\left[N_{n}\right] \sim 2 \sqrt{n / \pi}$ regardless of the (symmetric and continuous) distribution of the increments.

The biased case, assuming iid increments, with density symmetric around $c>0$, is studied in [19]. In that paper, no restriction on the moments of the increments is imposed. In particular, it is shown that $E\left[N_{n}\right]$ grows as a power of $n$ when the
distribution of the increments has no expectation. Also, when the increments have no variance, the distribution of $N_{n}$ approaches a non-Gaussian limit. Our results do not cover those situations since we need finite expectation of the increments to obtain the linear record rate (Theorem 1) and another moment condition implying the existence of variance, required for the Gaussian limit law of $N_{n}$ (Theorem 3). A differential feature of our results is that we do not impose the independence of the increments, neither the continuity or symmetry of their distribution. In that sense, our results in Theorems 1 and 3 reveal a kind of universality principle for random walks, with correlated increments and positive drift: under some moment restrictions, the number of records grows linearly and fluctuations are Gaussian, when $n$ is large.

## 5. Appendix

To make the paper self contained we present in this appendix a key result used in our proofs. We also collect technical lemmas related to the proof of Theorem 3.

Proposition 6. (Dubins-Freedman strong law.) Let $\left(U_{n}\right)_{n \geq 1}$ be a sequence of nonnegative and bounded random variables, adapted to the increasing family of $\sigma$-algebras $\left(\mathcal{G}_{n}\right)_{n \geq 0}$. Then

$$
\begin{equation*}
\left\{\sum_{n \geq 1} U_{n}=\infty\right\}=\left\{\sum_{n \geq 1} E\left[U_{n} \mid \mathcal{G}_{n-1}\right]=\infty\right\} \text { a.s. } \tag{5.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{\sum_{k=1}^{n} U_{k}}{\sum_{k=1}^{n} E\left[U_{k} \mid \mathcal{G}_{k-1}\right]} \rightarrow 1 \quad \text { on } \quad\left\{\sum_{n \geq 1} E\left[U_{n} \mid \mathcal{G}_{n-1}\right]=\infty\right\} \text { a.s. } \tag{5.2}
\end{equation*}
$$

Proof. See [7] or [17].

Lemma 2. Let $\left(\tau_{n}\right)_{n \in \mathbb{Z}}$ be the stationary process of Section 2, with $E\left[\tau_{0}\right]=c \neq 0$. Suppose that $E\left[\left|\tau_{0}\right|^{r+a}\right]<\infty$ and $\sum_{n \geq 1} n^{r / 2+1}\left[\alpha^{\tau}(n)\right]^{a /(r+a)}<\infty$, for some $r>$ $2, a>0$, where $\alpha^{\tau}(n)$ is defined in (3.8). Then

$$
P\left[\frac{1}{n c} \sum_{j=1}^{n} \tau_{j} \leq 1 / 2\right] \leq K n^{-r / 2}
$$

Proof. Let $S_{n}=\sum_{j=1}^{n}\left(\tau_{j}-c\right)$ and $c>0$. Then, from Markov's inequality and

Theorem 1 in [28],

$$
P\left[\sum_{j=1}^{n} \tau_{j} \leq n c / 2\right]=P\left[S_{n} \leq-n c / 2\right] \leq P\left[\left|S_{n}\right|^{r}>(n c / 2)^{r}\right] \leq E\left[\left|S_{n}\right|^{r}\right] /(n c / 2)^{r} \leq K n^{-r / 2}
$$

where $K>0$ is a constant. The argument for $c<0$ is identical.

Lemma 3. Under the hypotheses and with the notation of Theorem 3.
(i) There exists a random variable $K_{n}$ such that $Z_{n}^{*}=Z_{n}^{K_{n}}$, for all $n \in \mathbb{Z}$, and
(ii) $p_{k} \rightarrow p$ and $\gamma_{k}(n) \rightarrow \gamma(n)$, as $k \rightarrow \infty$.

Proof. (i) By stationarity we take $n=0$. Clearly $Z_{0}^{k} \uparrow Z_{0}^{*}$ a.s. and the result follows if we show that only finitely many terms $X_{-i}-\sum_{j=-i+1}^{0} \tau_{j}, i \geq 1$, are greater than the first, a.s. That is, if $P\left[X_{-i}-\sum_{j=-i+1}^{0} \tau_{j}>X_{-1}-\tau_{0}, i \geq 1\right.$, i.o. $]=0$. Using the same argument of Proposition 1, this probability is bounded above by $P\left[X_{-i-1}-X_{-1}>\right.$ $i c / 2, i \geq 1$, i.o.]. Observe that

$$
P\left[X_{-i-1}-X_{-1}>i c / 2\right] \leq P\left[\left|X_{-i-1}\right|+\left|X_{-1}\right|>i c / 2\right] \leq 2 P\left[\left|X_{0}\right|>i c / 4\right]
$$

so $\sum_{i \geq 1} P\left[\left|X_{0}\right|>i c / 4\right]<\infty$, because $E\left|X_{0}\right|<\infty$, and the conclusion follows.
(ii) From (i) we have $I_{0}^{*}=I_{0}^{K_{0}}$ a.s. and so, $I_{0}^{k} \rightarrow I_{0}^{*}$ as $k \rightarrow \infty$, which yields $p_{k} \rightarrow p$ and $\gamma_{k}(n) \rightarrow \gamma(n)$, by the dominated convergence theorem.

Lemma 4. Under the hypotheses and with the notation of Theorem 3.
(i) There exists a summable sequence $\bar{\gamma}(n)$ such that $\left|\gamma_{k}(n)\right| \leq \bar{\gamma}(n)$ and
(ii) $\sigma_{k}^{2} \rightarrow \sigma^{2}$, as $k \rightarrow \infty$.

Proof. (i) As in [3], page 808, if $k \leq a_{n}:=\lfloor n / 2\rfloor$ we have $\left|\gamma_{k}(n)\right| \leq \alpha\left(a_{n}\right)$. When $k>a_{n}$ we bound $\left|\gamma_{k}(n)\right|$ but $c i$ is replaced by the corresponding random trend. Observe that if $l \leq k$ then $I_{n}^{l} \geq I_{n}^{k}$ and $I_{n}^{k}=I_{n}^{k} I_{n}^{l}$. So $I_{0}^{k} I_{n}^{k}=I_{0}^{k} I_{n}^{a_{n}}-I_{0}^{k} I_{n}^{a_{n}}\left(1-I_{n}^{k}\right)$ and hence

$$
\begin{equation*}
\left|\gamma_{k}(n)\right|=\left|E\left[I_{0}^{k} I_{n}^{k}\right]-p_{k}^{2}\right| \leq\left|E\left[I_{0}^{k} I_{n}^{a_{n}}\right]-p_{k}^{2}\right|+E\left[I_{0}^{k} I_{n}^{a_{n}}\left(1-I_{n}^{k}\right)\right] . \tag{5.3}
\end{equation*}
$$

Let $A_{n k}^{\prime}$ and $B_{n k}^{\prime}$ be the first and second summand in rhs of (5.3) respectively, then

$$
\begin{align*}
B_{n k}^{\prime} & \leq P\left[Z_{n}^{a_{n}}<X_{n} \leq \bigvee_{i=a_{n}+1}^{k}\left\{X_{n-i}-\sum_{j=n-i+1}^{n} \tau_{j}\right\}, X_{0}>Z_{0}^{k}\right] \\
& \leq P\left[\bigcup_{i=a_{n}+1}^{k}\left\{X_{n-i}-X_{n} \geq \sum_{j=n-i+1}^{n} \tau_{j}\right\}\right] \\
& \leq \sum_{i>a_{n}} P\left[X_{n-i}-X_{n} \geq \sum_{j=n-i+1}^{n} \tau_{j}\right]  \tag{5.4}\\
& \leq \sum_{i>a_{n}} P\left[\left|X_{n-i}\right|+\left|X_{n}\right| \geq \sum_{j=n-i+1}^{n} \tau_{j}\right] \\
& \leq \sum_{i>a_{n}} P\left[\left|X_{0}\right| \geq \frac{1}{2} \sum_{j=1}^{i} \tau_{j}\right]+\sum_{i>a_{n}} P\left[\left|X_{0}\right| \geq \frac{1}{2} \sum_{j=-i+1}^{0} \tau_{j}\right]
\end{align*}
$$

Observe that both probabilities above can be bounded by $P\left[\left|X_{0}\right| \geq c i / 4\right]+P\left[\sum_{j=1}^{i} \tau_{j} \leq\right.$ $c i / 2]$ and that $\sum_{i>a_{n}} P\left[\left|X_{0}\right| \geq c i / 4\right]$ is well defined and summable (with respect to $n$ ), because $X_{0}$ is square-integrable. Also, by Lemma $2, P\left[\sum_{j=1}^{i} \tau_{j} \leq c i / 2\right] \leq K i^{-r / 2}$, for some constant $K$. So, $B_{n k}^{\prime}$ is summable because, from the inequalities above,

$$
B_{n k}^{\prime} \leq B_{n}^{\prime}:=2 \sum_{i>a_{n}}\left(P\left[\left|X_{0}\right| \geq c i / 4\right]+K i^{-r / 2}\right)
$$

On the other hand,

$$
\begin{align*}
A_{n k}^{\prime} & \leq\left|E\left[I_{0}^{k} I_{n}^{a_{n}}\right]-p_{a_{n}} p_{k}\right|+p_{k}\left(p_{a_{n}}-p_{k}\right) \\
& \leq \alpha\left(a_{n}\right)+p_{a_{n}}-p_{k}  \tag{5.5}\\
& \leq \alpha\left(a_{n}\right)+P\left[Z_{n}^{a_{n}}<X_{n} \leq \bigvee_{i=a_{n}+1}^{k}\left\{X_{n-i}-\sum_{j=n-i+1}^{n} \tau_{j}\right\}\right]
\end{align*}
$$

and we see that the probability on the last line of $(5.5)$ is bounded as in $(5.4)$, hence $A_{n k}^{\prime} \leq A_{n}^{\prime}:=\alpha\left(a_{n}\right)+B_{n}^{\prime}$.
(ii) By Lemma 3 (ii), $\gamma_{k}(n) \rightarrow \gamma(n)$ and, by (i) of this lemma, $\gamma_{k}(n)$ is dominated by $\bar{\gamma}(n):=A_{n}^{\prime}+B_{n}^{\prime}$, which is summable, and consequently, the result follows from the dominated convergence theorem applied to $\sum_{n \geq 1} \gamma_{k}(n)$.

Lemma 5. Under the hypotheses and with the notation of Theorem 3

$$
\begin{equation*}
\limsup _{n \rightarrow \infty} P\left[\left|\left(N_{n}^{k}-n p_{k}\right)-\left(N_{n}^{*}-n p\right)\right|>\epsilon \sqrt{n}\right] \rightarrow 0, \forall \epsilon>0 \tag{5.6}
\end{equation*}
$$

as $k \rightarrow \infty$.

Proof. We estimate the variance

$$
\begin{equation*}
\operatorname{Var}\left(\frac{N_{n}^{k}-N_{n}^{*}}{\sqrt{n}}\right)=\frac{1}{n} \operatorname{Var}\left(\sum_{l=1}^{n}\left(J_{l}^{k}-q_{k}\right)\right)=\operatorname{Var}\left(J_{0}^{k}\right)+\frac{2}{n} \sum_{l=1}^{n-1}(n-l) \operatorname{Cov}\left(J_{0}^{k}, J_{l}^{k}\right) \tag{5.7}
\end{equation*}
$$

where $J_{l}^{k}=I_{l}^{k}-I_{l}^{*}=\mathbf{1}_{\left\{Z_{l}^{k}<X_{l} \leq Z_{l}^{*}\right\}}=\mathbf{1}_{\left\{Z_{l}^{k}<X_{l} \leq \bigvee_{i=k+1}^{\infty}\left\{X_{l-i}-\sum_{j=l-i+1}^{l} \tau_{j}\right\}\right\}}$ and $q_{k}=$ $p_{k}-p=P\left[Z_{0}^{k}<X_{0} \leq \bigvee_{i>k}\left\{X_{-i}-\sum_{j=-i+1}^{0} \tau_{j}\right\}\right]$. For the variance term we have, by Lemma 3 (ii),

$$
\begin{equation*}
\operatorname{Var}\left(J_{0}^{k}\right)=q_{k}\left(1-q_{k}\right) \leq q_{k} \rightarrow 0 \tag{5.8}
\end{equation*}
$$

For the covariances assume that $n>2 k$, then, as $k \rightarrow \infty$,

$$
\begin{align*}
& \frac{2}{n} \sum_{l=1}^{2 k}(n-l) \operatorname{Cov}\left(J_{0}^{k}, J_{l}^{k}\right) \leq \frac{2}{n} \sum_{l=1}^{2 k}(n-l) \operatorname{Var}\left(J_{0}^{k}\right) \leq 4 k q_{k} \\
& \leq 4 k P\left[\bigcup_{i>k}\left\{X_{-i}-X_{0} \geq \sum_{j=-i+1}^{0} \tau_{j}\right\}\right] \\
& \leq 4 k \sum_{i>k}\left(P\left[\left|X_{-i}\right| \geq \frac{1}{2} \sum_{j=-i+1}^{0} \tau_{j}\right]+P\left[\left|X_{0}\right| \geq \frac{1}{2} \sum_{j=-i+1}^{0} \tau_{j}\right]\right)  \tag{5.9}\\
& \leq 8 k \sum_{i>k}\left(P\left[\left|X_{0}\right| \geq c i / 4\right]+P\left[\sum_{j=1}^{i} \tau_{j} \leq c i / 2\right]\right) \rightarrow 0
\end{align*}
$$

We bound $\operatorname{Cov}\left(J_{0}^{k}, J_{l}^{k}\right)$, for $l>2 k$. Let $L_{l}^{k}=\mathbf{1}_{\left\{X_{l}>\bigvee_{i=k+1}^{\lfloor L / 2\rfloor}\left\{X_{l-i}-\sum_{j=l-i+1}^{l} \tau_{j}\right\}\right\}}$ then

$$
\begin{equation*}
\operatorname{Cov}\left(J_{0}^{k}, J_{l}^{k}\right)=\operatorname{Cov}\left(J_{0}^{k}, J_{l}^{k}\left(1-L_{l}^{k}\right)\right)+\operatorname{Cov}\left(J_{0}^{k}, J_{l}^{k} L_{l}^{k}\right) \tag{5.10}
\end{equation*}
$$

and

$$
\begin{aligned}
\left|\operatorname{Cov}\left(J_{0}^{k}, J_{l}^{k} L_{l}^{k}\right)\right| & \leq E\left[J_{l}^{k} L_{l}^{k}\right] \\
& \leq P\left[Z_{l}^{k}<X_{l} \leq \bigvee_{i>\lfloor l / 2\rfloor}\left\{X_{l-i}-\sum_{j=l-i+1}^{l} \tau_{j}\right\}\right] \\
& \leq P\left[X_{l} \leq \bigvee_{i>\lfloor l / 2\rfloor}\left\{X_{l-i}-\sum_{j=l-i+1}^{l} \tau_{j}\right\}\right] \\
& \leq \sum_{i>\lfloor l / 2\rfloor} P\left[X_{l-i}-X_{l} \geq \sum_{j=l-i+1}^{l} \tau_{j}\right] \\
& \leq 2 \sum_{i>\lfloor l / 2\rfloor}\left(P\left[\left|X_{0}\right| \geq c i / 4\right]+P\left[\sum_{j=1}^{i} \tau_{j} \leq c i / 2\right]\right)
\end{aligned}
$$

Hence

$$
\begin{equation*}
\left|\frac{2}{n} \sum_{l=2 k+1}^{n-1}(n-l) \operatorname{Cov}\left(J_{0}^{k}, J_{l}^{k} L_{l}^{k}\right)\right| \leq 4 \sum_{l>2 k} \sum_{i>\lfloor l / 2\rfloor}\left(P\left[\left|X_{0}\right| \geq c i / 4\right]+P\left[\sum_{j=1}^{i} \tau_{j} \leq c i / 2\right]\right) \rightarrow 0 \tag{5.11}
\end{equation*}
$$

as $k \rightarrow \infty$. For the first term in the rhs of (5.10) it suffices to see that its absolute value is bounded above by $\alpha(\lfloor l / 2\rfloor)$. Indeed, $J_{l}^{k}\left(1-L_{l}^{k}\right)$ is the indicator of

$$
\begin{aligned}
&\left\{Z_{l}^{k}<X_{l} \leq Z_{l}^{*}, X_{l} \leq \bigvee_{i=k+1}^{\lfloor l / 2\rfloor}\left\{X_{l-i}-\sum_{j=l-i+1}^{l} \tau_{j}\right\}\right\} \\
&=\left\{Z_{l}^{k}<X_{l} \leq \bigvee_{i=k+1}^{\lfloor l / 2\rfloor}\left\{X_{l-i}-\sum_{j=l-i+1}^{l} \tau_{j}\right\}\right\} \in \mathcal{F}_{l-\lfloor l / 2\rfloor}^{\infty}
\end{aligned}
$$

Therefore,

$$
\begin{equation*}
\left|\frac{2}{n} \sum_{l=2 k+1}^{n-1}(n-l) \operatorname{Cov}\left(J_{0}^{k}, J_{l}^{k}\left(1-L_{l}^{k}\right)\right)\right| \leq 2 \sum_{l>2 k} \alpha(\lfloor l / 2\rfloor) \rightarrow 0, \tag{5.12}
\end{equation*}
$$

as $k \rightarrow \infty$. The conclusion follows from (5.8), (5.9), (5.11), (5.12) and Tchebychev's inequality applied to (5.6).

## Acknowledgements

The authors are grateful to the editor and an anonymous referee for their useful comments. Support from project PFB-03-CMM, Fondecyt grant 1120408 and project MTM2010-15972 of MINECO is gratefully acknowledged. The authors are members of the research group Modelos Estocásticos (DGA and FSE-ESF).
