Aim/Introduction: Radiohybrid PSMA (rhPSMA) ligands are a

new class of diagnostic/therapeutic PSMA-targeting agents which can be efficiently labeled with F-18 and radiometals and show only minimal renal excretion. Promising preliminary data have been reported for F-18-rhPSMA-7, which comprises four isomers. Based on preclinical findings, the single isomer, F-18-rhPSMA-7.3, was selected as the lead rhPSMA compound for clinical development. Here we report first efficacy data for primary N-staging in patients with intermediate and high-risk prostate cancer. Results were compared to morphological imaging and validated by histopathology. **Materials and Methods:** Fifty-six patients (median PSA 11.0 ng/mL, range: 2.4–296.0) with intermediate or high-risk prostate cancer (defined by D'Amico), who had undergone F-18-rhPSMA-7.3 PET imaging (median injected activity 349 MBq; range: 240–449 MBq, median uptake time 72 min; range: 58–102 min) at our center before radical prostatectomy and extended pelvic lymph node dissection, were included. PET and morphologic images were retrospectively rated by one experienced reader for the presence of lymph node metastases using a standard surgical template. Each anatomical field was rated on a five-point-scale independently for PET and for morphological imaging. Results were compared to histopathology findings on patient-, right vs. left-, and template-based analyses. **Results:** Lymph node metastases were present in 18/56 patients (32.1 %), located in 33/319 templates (10.3%). On the patient-based analysis the sensitivity, specificity and accuracy of F-18-rhPSMA-7.3-PET were 81.3%, 87.5% and 85.7%, and those of morphological imaging 33.3%, 89.5% and 71.4%, respectively. For the right vs. left analysis the sensitivity, specificity and accuracy of F-18-rhPSMA-7.3-PET were 70.8%, 96.6% and 91.1%, and for morphological imaging 25.0%, 95.5% and 80.4%, respectively. The template-based analysis showed the sensitivity, specificity and accuracy of F-18-rhPSMA-7.3-PET to be 63.6%, 97.9% and 94.4%, and those of morphological imaging to be 15.2%, 99.3% and 90.6%, respectively. On ROC analyses, F-18-rhPSMA-7.3-PET showed a significantly better performance than morphological imaging on patient-, right vs. left and template-based analyses, yielding AUC values of 0.842 vs. 0.697 ($p < 0.05$), 0.843 vs. 0.631 ($p < 0.001$) and 0.801 vs. 0.639 ($p < 0.001$), respectively. **Conclusion:** Our preliminary data from this small cohort indicate that F-18-rhPSMA-7.3 PET might be superior to morphological imaging for primary N-staging of intermediate and high-risk prostate cancer. Data analysis from a larger cohort is planned to confirm this significant difference. **References:** None

Choosing Wisely recommendations compliance in bone scan scintigraphies of newly diagnosed prostate cancer patients

I. Saura Lopez, Á. O. Rabines Juárez, N. A. Rudic Chipe, M. J. Ribelles Segura, M. I. Blanco Saiz, L. Paruta Araez, M. I. Morales Lozano, A. Camarero Salazar, E. Goñi Gironés; Navarra Hospital Complex, Pamplona, SPAIN.

Aim/Introduction: To examine the appropriate use of Choosing Wisely recommendations (ChW) for bone scintigraphy (BS) in newly diagnosed prostate cancer patients in the Navarra Hospital Complex. Most reports demonstrated the over-use of imaging explorations in staging for patients with newly diagnosed prostate cancer. This practice produces consequences in all stakeholders: patients, health providers, health system and society. These consequences include emotional stress, exposition of harm without net benefits or increased financial burden on the healthcare systems. For this reason, it is necessary to examine the appropriate use of existing recommendations in our services. **Materials and Methods:** This quantitative, observational and cross-sectional study included newly diagnosed prostate cancer patients undergoing bone scintigraphy within the Navarra Hospital Complex in 2019. A descriptive statistical analysis was performed to evaluate the characteristics of patients (age, PSA level, clinical manifestations suggestive of bone involvement, pre-existing bone lesion viewed in another imaging exploration); the frequency of results of bone scintigraphy (categorized as positive, negative or undefined for metastasis) and the frequency of compliance of ChW recommendations. An analysis using chi square test was used to determine whether there is a statistically significant difference between the frequencies of results of bone scintigraphy and compliance of ChW recommendations. **Results:** A total of 155 BS were included. The mean age was 70.46 \pm 8.30 y-o; 59.35% with PSA levels \geq 10 ng/ml. 5.81% had no previous biopsy. The Gleason score values were: 6 (12.90%), 7 (45.16%), 8 (17.42%), 9 (16.13%) and 10 (2.58%). Presence of symptoms of bone involvement and pre-existing bone lesions were viewed in 7.74% and 18.71% of patients, respectively. A 14.84% of overall patients were a positive BS, categorized as polyostotic (10.32%), monostotic (3.23%) and superscan (1.29%). The compliance of ChW recommendations was 72.26% of overall BS performed, with positive BS in 20.54% of those who met the criteria and none among those who did not meet that ($p < 0.001$). **Conclusion:** The compliance of ChW recommendations represents three quarters of newly diagnosed prostate cancer patients, this being a significant associated factor for the identification of bone metastases. **References:** None

EPS-122

Standardized Uptake Values are Adequate Measures of ¹⁸F-DCFPyL Uptake in Patients with Low- to Intermediate Tumour Burden: a Comparison to Tumour-to-Blood Ratio, a Validated Simplified Pharmacokinetic Analysis

D. Oprea, Y. J. L. Bodar, B. P. F. Koene, D. Meijer, B. H. E. Jansen, M. C. F. Cysouw, M. Yaqub, H. N. Hendrikse, A. N. Vis, R. Boellaard; Amsterdam UMC, Amsterdam, NETHERLANDS.

Aim/Introduction: Prostate cancer (PCa) is the second most prevalent cancer in men. To diagnose PCa in its primary and metastatic form, radiolabelled prostate-specific membrane antigen (PSMA) positron emission tomography/ computed

tomography (PET/CT) has been successfully introduced. This imaging technique relies on radiotracers, e.g. ^{18}F -DCFPyL, to bind to the overexpressed PSMA, class II transmembrane glycoproteins, on malignant prostate cells. To reliably assess PET-scans, radiotracer-uptake quantification is required. True quantification remains an intricate process, hence simplified semi-quantitative methods are preferable for daily practice. From pharmacokinetic analysis, it was demonstrated that the uptake of ^{18}F -DCFPyL can be reliably approximated by the Tumour-to-Blood ratio (TBR) [1], derived by normalizing mean tumor uptake (either Bq/cm³ or SUV) by the mean activity in the arterial blood pool (Bq/mL or SUV). However, TBR depends strongly on tracer uptake interval (i.e. time from injection to scan start), often difficult to adhere to in clinical practice. In this study we investigated whether the even more simple, and clinically preferred, standardized uptake value (SUV) could provide adequate quantification in selected patients. The aim was therefore to investigate whether SUV correlates to TBR for ^{18}F -DCFPyL PET/CT imaging, thereby providing a simplified measure that is less dependent on tracer uptake interval than TBR. **Materials and Methods:** A total of 116 PCa patients, in different stages of PCA (Primary staging, Biochemical Recurrence (BCR) or metastatic castration-resistant prostate cancer (mCRPC), that underwent ^{18}F -DCFPyL-PET/CT scans were analysed retrospectively. Reported suspicious lesions (suspect for intraprostatic tumours, lymph node, bone or visceral metastases) were delineated and assessed, using in-house developed software. SUV_{peak} was correlated to TBR and a sub-analysis was performed to assess the effect of total tumour volume (this included metastatic lesions), PSA and uptake time interval. **Results:** SUV highly correlated to TBR in PCa patients with a tumour volume <200cc ($R^2 = 0.931$). When the groups were plotted separately, this correlation remained high ($R^2 = 0.950$; 0.902 ; 0.956 , in respectively Primary PCa, BCR and mCRPC). Tracer uptake interval did not affect the correlation between SUV and TBR and R^2 , which measured in ascending order for tracer uptake interval was 0.907 , 0.925 and 0.955 (respectively <110min, 110-130min and >130min). **Conclusion:** SUV is suitable as a simplified quantitative method in PCa patients with a tumour volume of <200cc, with high correlation to TBR. **References:** 1. Jansen, B.H.E., et al., Simplified Methods for Quantification of (^{18}F)-DCFPyL Uptake in Patients with Prostate Cancer. *J Nucl Med*, 2019; 60(12):1730-35. PMID: 31000583.

EPS-123

Diagnostic accuracy of 68Ga-PSMA PET-CT at initial diagnosis in a population of prostate cancer patients submitted to radical prostatectomy as compared to pathology results

C. Varela Pinto, B. Martins, D. Calado, C. Loewenthal;
Hospital da Luz Lisboa, Lisbon, PORTUGAL.

Aim/Introduction: To evaluate the diagnostic accuracy of 68Ga-PSMA PET-CT results at initial staging before radical prostatectomy in prostate carcinoma patients. Prostate-specific membrane antigen (PSMA) is a transmembrane protein expressed in prostatic tissues, including neoplastic tissue, with highest expression in undifferentiated, metastatic and hormone-resistant tumors. 68Ga-PSMA PET-CT detects lesions avid for PSMA and is currently one of the most sensitive and specific tests in disease detection, even at low PSA values. 68Ga-PSMA PET-CT is well established in high risk patients with biochemical recurrence. Due to high diagnostic yield, 68Ga-PSMA PET-CT can be also be useful at initial staging, in order to improve localization of cancer sites before therapy decision-making, namely radical prostatectomy. **Materials and Methods:** Retrospective evaluation of clinical electronic records of 150 patients (mean age 66.2 years, range 39-88) who underwent 68Ga-PSMA PET-CT for initial staging of prostate carcinoma between February 2017 and April 2020. Biochemical, clinical, imaging and pathological findings were reviewed. We compared 68Ga-PSMA PET-CT results prior to surgery with pathology reports of radical prostatectomy specimens, and evaluated diagnostic accuracy of PET-CT results in prostate disease, in locoregional extraprostatic extension and in locoregional lymph nodes metastases. **Results:** One hundred and fifty patients underwent 68Ga-PSMA PET-CT for initial staging of prostate carcinoma. Thirty-seven patients underwent radical prostatectomy after PET-CT. Lymphadenectomy was performed in all but 6 patients. In these 37 patients, the mean PSA initial value was 12.7 ± 15.5 ng/ml. Gleason score was 6 in 2 patients, 7(3+4) in 8, 7(4+3) in 12, 8(4+4) in 9 and 9(4+5) in 6. On PET-CT, 32 patients had disease confined to the prostate, 3 had locally advanced disease and 2 presented with locoregional lymph nodes. Compared to pathology results, 68Ga-PSMA PET-CT detected prostatic lesions in 37/37 patients and lymph nodes in 2/2 patients. PET-CT did not detect focal microscopic unilateral lesions in seminal vesicles in 7/37 patients (19%). PET-CT referred false positives lesions in seminal vesicles in 2/37 patients (5%). **Conclusion:** PET-CT with 68Ga-PSMA is a sensitive imaging procedure for localization of prostate cancer lesions. Its high sensitivity brings added value to conventional imaging, improving localization of prostate cancer sites at initial staging. Its accuracy in seminal vesicle invasion warrants further study. **References:** None

Aim/Introduction: PSMA-ligand PET/CT is performed in patients with prostate cancer to stage the disease initially or to identify sites of recurrence after definitive therapy. ¹⁸F-PSMA-1007 is a promising PSMA-PET tracer based on clinical results but detailed histologic confirmation has been lacking. **Materials and Methods:** 96 patients with prostate cancer received a ¹⁸F-PSMA-PET/CT followed by either a radical prostatectomy with lymphadenectomy or a salvage lymphadenectomy. Patients undergoing radical prostatectomy without lymphadenectomy or biopsies were excluded. The histological findings of PSMA-PET-positive nodes were analysed retrospectively. A lesion and a patient-based analysis was performed comparing 1) all positive and 2) only lesions with a size larger than 3 mm in histopathology. **Results:** 90.6% of the patients received ¹⁸F-PSMA-PET/CT for staging before the primary treatment, while 9.4 % of the cohort underwent imaging for biochemical recurrence. In 34.4% of the cohort positive lymph nodes were present in imaging. A total of 1746 lymph nodes were dissected in 96 patients. PSMA-PET had a lesion-based sensitivity of 81.7% a specificity of 99.6%, a positive predictive value (PPV) of 92.4%, a negative predictive value (NPV) of 98.9% for detecting positive lymph nodes larger than 3 mm. In the analysis of all malignant nodes regardless the size the overall sensitivity, specificity, PPV, NPV on lesion-based

analysis was 71.2%, 99.5%, 91.3%, 97.9%. The patient-based analysis showed a sensitivity of 85.9% and a specificity of 99.5% for lymph nodes >3 mm. **Conclusion:** ¹⁸F-PSMA-1007-PET/CT reliably detects malignant lymph nodes and has an exceptional specificity of >99% for nodal metastases.

Pattern of prostate cancer recurrence in patients with biochemical failure following definitive therapy evaluated with [⁶⁸Ga]Ga-PSMA-11 PET/CT

I. Lawal^{1,2}, T. Lengana¹, K. Mokoala¹, T. Boshomane¹, J. Kleynhans^{1,2}, M. Vorster^{1,2}, N. Mokgoro¹, M. Sathekge^{1,2};
¹University of Pretoria, Pretoria, SOUTH AFRICA, ²Nuclear Medicine Research Infrastructure (NuMeRI), Pretoria, SOUTH AFRICA.

Aim/Introduction: [⁶⁸Ga]Ga-PSMA PET/CT has emerged as a whole-body imaging technique with excellent accuracy in the detection of prostate cancer (PCa) recurrence. Pelvic MRI is commonly used for this indication. Whole-body imaging affords the opportunity to determine extra-pelvic sites of recurrence. We aimed to determine the distribution of PCa recurrence in men who experience biochemical failure (BF) after definitive radiotherapy or radical prostatectomy (RP) using [⁶⁸Ga]Ga-PSMA-11 PET/CT. **Materials and Methods:** We retrospectively reviewed the images of all patients who had [⁶⁸Ga]Ga-PSMA-11 PET/CT at first confirmation of BF after definitive radiotherapy or RP. We determined the diagnostic sensitivity of [⁶⁸Ga]Ga-PSMA-11 PET/CT for the localization of the site of recurrence. We also determined the distribution of the sites of PCa recurrence. We further evaluated the impact of the type of primary therapy and PSA level on the distribution of recurrence. **Results:** A total of 184 men were included, the median age of 66 years (range:47-87). The median PSA and Gleason scores (range) were 2.98 (0.05-10.24) ng/mL and 8 (6 - 9), respectively. Definitive therapy was by RP in 112 patients and by radiotherapy in 74 patients. A total of 314 sites of recurrence were seen with a median lesion per patient of one (range: 1 - 12) lesion. At least one site of recurrence was seen in 152 patients (sensitivity of 82.61%). Fifty-seven patients had more than one lesion due to PCa recurrence. Local recurrence in the prostate gland/prostate bed or seminal vesicles was the commonest site of recurrence across all PSA levels (n=109) followed by recurrence in pelvic nodes (n=61). Loco-regional recurrence (local and regional pelvic nodes) was prevalent at PSA<2ng/mL with extra-pelvic lesions seen in only two patients in this PSA group. Skeletal recurrence was more prevalent at high PSA levels as 17 of 18 patients with skeletal sites of recurrence had a PSA>2ng/mL. In 8 patients, extra-pelvic sites of recurrence were seen without associated loco-regional pelvic recurrent disease. Patients treated by definitive radiotherapy were more likely to have a local recurrence in the prostate gland/ seminal vesicles

compared with patients treated by RP ($P < 0.001$). **Conclusion:** [^{68}Ga]Ga-PSMA-11 PET/CT has a high diagnostic sensitivity for the detection of PCa recurrence after definitive therapy. Loco-regional recurrence is commoner at lower PSA levels while skeletal recurrence is more prevalent at higher PSA levels. Whole-body imaging affords the opportunity to detect the extra-pelvic sites of recurrence. **References:** None

EPS-126

[^{68}Ga]Ga-PSMA-11 PET/CT in patients with recurrence of prostate cancer - usefulness of delayed phase in pelvic lesions detection

L. Krolicki, K. Pełka, S. Kujda, J. Kunikowska;
Medical University of Warsaw, Warsaw, POLAND.

Aim/Introduction: Prostate cancer is one of the most common cancers in men. The presence of prostate specific membrane antigen (PSMA) on the surface of prostate cancer cells and its metastases enables the use of this antigen in targeted diagnosis and therapy. **The aim** of this study was to evaluate the usefulness of delay phase image in the [^{68}Ga]Ga-PSMA-11 PET/CT. **Materials and Methods:** The study was performed in 64 patients aged 67.8 ± 7.0 years with diagnosed prostate cancer, after radical treatment, referred for [^{68}Ga]Ga-PSMA-11 PET/CT due to biochemical relapse. In the study group 48 patients underwent prostatectomy, 14 radical radiotherapy, 2 HIFU. In the histopathological examination Gleason score 5, 6, 7, 8, 9 was described in 4, 6, 33, 10 and 11 patients, respectively. In the study group, the average PSA concentration at the time of PET scan was 4.1 ± 6.7 ng/ml (range: 0.3–39.0). All patients underwent PET/CT imaging with [^{68}Ga]Ga-PSMA-11 (Siemens, Biograph 64), 60 minutes after injection of 135–205 MBq, and additionally 120–180 minutes delay phase targeted on the pelvis. For semi-quantitative evaluation maximal standard uptake value (SUV_{max}) was used. **Results:** [^{68}Ga]Ga-PSMA-11 PET/CT showed lesions in 50/64 (78%) patients. In pelvis 45 patients had 74 foci of increased tracer accumulation in the both phases with SUV_{max₆₀} 9.3 ± 10.5 and SUV_{max₁₂₀} 11.6 ± 12.8 . 7 foci of increased uptake were seen only in the study after 60 min with SUV_{max₆₀} 3.3 ± 1.2 , which was interpreted as physiological or inflammatory accumulation. 8 foci (in 7 patients) of increased tracer accumulation were visible only in delay image with SUV_{max₁₂₀} 5.7 ± 2.0 , on the CT part correspond - fine lymph nodes up to 4–5 mm and additional focus in the prostate gland. In the delayed phase additional lesions were seen in 11% of patients. The foci visible only in delayed phase: 3/8 with normal 60 minutes examination, 5/8 additional lesions. **Conclusion:** Delay phase of [^{68}Ga]Ga-PSMA-11 PET/CT doesn't significantly extend the duration of the examination, but it allows to visualize additional lesions in 11% of patients. The delayed phase should be considered in patients with biochemical relapse and negative examination after 60 min, and in patients

with before radiotherapy to accurate treatment planning.

Comparison of early imaging and imaging 60 minutes post injection after forced diuresis with furosemide in the assessment of local recurrence in prostate cancer patients with biochemical recurrence referred for [^{68}Ga]Ga-PSMA-11-PET/CT

S. Bayerschmidt, C. Uprimny, A. S. Kroiss, H. Sviridenka, G. di Santo, B. Nilica, S. Rauch, E. von Guggenberg, C. Decristoforo, I. Virgolini;
Medizinische Universität Innsbruck, Innsbruck, AUSTRIA.

Aim/Introduction: [^{68}Ga]Ga-PSMA-PET/CT is a promising method for the assessment of local recurrence in prostate cancer patients. The aim of this study was to evaluate the diagnostic performance of early [^{68}Ga]Ga-PSMA-11 PET imaging in comparison to [^{68}Ga]Ga-PSMA-11 PET imaging 60 minutes post injection (p.i.) in the detection of local recurrence in patients with biochemical recurrence of prostate carcinoma. **Materials and Methods:** 190 image sets of patients with biochemical recurrence in prostate cancer who underwent [^{68}Ga]Ga-PSMA-11-PET/CT were assessed retrospectively [median prostate specific antigen (PSA) value 0.69 ng/ml (range 0.1 - 105.6)]. Patients received an early static scan of the pelvic area [mean 248 s p.i. (range 56 - 923 s)] and whole-body scan 60 minutes post injection after forced diuresis with furosemide 20mg i.v.. We based the assessment on visual analysis and calculation of maximum standardized uptake value (SUV_{max}) of pathologic lesions present in the pelvic area found on early PET imaging and on 60 min-PET scans. **Results:** Image assessment resulted in 30 (15.8%) positive and 17 (9.0%) equivocal findings in early scans, and 28 (14.7%) positive and 25 (13.2%) equivocal findings of local recurrence. 20 (66.7%) findings were positive and 9 (30.0%) findings were equivocal in both scans. **Conclusion:** While there was no significant difference between the detection rates of positive findings, early scans yielded a lower number of equivocal findings. These findings suggest that early [^{68}Ga]Ga-PSMA-11-PET/CT scan is useful in the detection and characterization of local recurrence in prostate cancer. Combination of early scans and [^{68}Ga]Ga-PSMA-11-PET/CT scans 60 min p.i. might lead to a better assessment of local recurrence in the clinical routine. **References:** None

EPS-128

Ga68 PSMA PET/CT in the restaging of patients with prostate cancer. Correlation to PSA levels

V. Prassopoulos, T. Pipikos, D. Kechagias, M. Vogiatzis, V. Filippi, F. Vlachou, J. Andreou, K. Gogos, R. Efthymiadou;
PET/CT Department, Hygeia Hospital, Athens, GREECE.

Aim/Introduction: In the follow up of prostate cancer patients, a usual diagnostic problem is biochemical recurrence with elevated PSA and no discovered underlying pathology in the conventional imaging. Ga68 PSMA is a specific agent for the investigation of prostate cancer. Aim of this study is to evaluate the effectiveness of Ga68 PSMA PET/CT in prostate cancer patients with biochemical recurrence **Materials and Methods:** The data of 138 patients that underwent a Ga68 PSMA PET/CT study in our department in the last year because of elevated PSA were evaluated. **Results:** Mean time after surgery was 5,3 years(0,3 to 22 years) with a mean patients' age of 69 years. 98 of these patients showed abnormal uptake (98/138-71%). 18 had uptake only in the prostatic bed indicative of local recurrence, with a mean SUVmax value of 36,62 (7-94), while 80 patients had extra-prostatic abnormal findings with mean SUVmax value of 17,45. In the latter patient group the most common site of abnormal uptake was lymph nodes (60/80- 75%) with mean SUVmax 12,33 (2,9-70). 34 patients (34/80-42%) had abnormal bone uptake with mean SUVmax of 26,4 (3,9-94), 2 patients had peritoneal implantations, 4 patients were presented with uptake indicative of liver metastasis, while three had lung foci. When categorizing the patients based on PSA levels, in the group of patients with PSA levels up to 0,5 ng/dl (42 patients) PET/CT pathology was discovered in 16/42(38%), while in the group with PSA values 0,51-0,99 ng/dl(20 patients) in 12/20(60%). Overall in the group of patients with PSA values up to 0,99 ng/dl abnormal lesions were found in 28/62(45%) of the patients. In the group with PSA values of 1ng/dl or higher the rate of positive studies was 70/76(92%). **Conclusion:** Ga68 PSMA PET/CT study can be of great value in the restaging of patients with elevated PSA, especially in the group with PSA levels over 1 ng/dl. Although abnormal foci detection rate is lower in PSA levels <1 ng/dl, in the majority of the patients abnormal findings in the Ga68 PSMA PET/CT study are detected, with a great possible impact in the therapy planning especially in the early treatment. **References:** 1. EPS-129

Diagnostic value of Ga-68 PSMA PET/CT in biochemical progression in prostate cancer (PC) patients after radical prostatectomy in the low range values of prostate specific membrane antigen (PSA)

M. Dyankova^{1,2}, Z. Dancheva¹, T. Stoeva¹, S. Chausheva¹, T. Yordanova¹, B. Chaushev¹, A. Klisarova¹;

¹St. Marina University Hospital, Varna, BULGARIA, ²Medical University Varna Prof. Dr. Paraskev Stoyanov, Varna, BULGARIA.

Aim/Introduction: Currently Ga-68 PSMA PET/CT is making

a significant shift in the diagnosis, staging and restaging of PC patients. There were many questions raised concerning indications and sensitivity of the method. Most of them concerning the PSA value in biochemical progression, specifically in the low values, PSA up to 2.00 ng/ml. The aim of this study was to analyze the influence of PSA value in BP on PSMA sensitivity, detection rate and the relationship with regional or metastatic lesions incidence in patients after radical prostatectomy. **Materials and Methods:** We performed a retrospective analysis in 144 consecutive patients with radical prostatectomy. The mean age of the patients was 67.3 years. The patients were divided into six groups according to the PSA value: 1) 0.00- 0.040 ng/ml; 2) 0.041- 0.160 ng/ml; 3) 0.161- 0.500 ng/ml; 4) 0.501-1.0 ng/ml; 5) 1.001- 2.00 ng/ml; 6) >2.001 ng/ml. The relationship between PSA levels in the groups and PSMA sensitivity, detection rate and regional or metastatic lesions incidence were examined. **Results:** A total of 63 patients (42.6%) showed at least one positive lesion. PSMA PET/CT detection rate into the different groups were: 1) 6 (12.3%); 2) 3 (15.0%); 3) 11 (50%); 4) 7 (53.8%); 5) 4 (57.1%); 6) 31 (93.9%). There was a significant relationship between the PSA level and the ability of PSMA to reveal metastatic lesions ($p < 0.001$). Local recurrence was revealed in patients with higher PSA values, above 0.160 ng/ml. Distant metastases were seen most commonly in patients with low levels of PSA (up to 0.160 ng/ml) in 100.0% of patients, ($p < 0.001$). Bone metastases were most commonly found in patients with low PSA levels, including five patients with PSA level below 0.04 (83.33% of patients in the first group). A PSA-based analysis of overall sensitivity and specificity revealed values of 58% and 87% respectively. A sensitivity of 15% was found at lower PSA levels (0.041- 0.160 ng/ml). In the other groups was higher 3) 50.0%; 4) 53.0%; 5) 57.0%; 6) 93.0. **Conclusion:** This study confirms that PSMA PET/CT is an excellent tool for the detection of recurrent prostate cancer and metastatic spread with high sensitivity even at low PSA levels, which may influence further clinical management. Detection of local recurrence was positively associated with PSA level. Low level PSA BP after radical prostatectomy is more commonly related with distant metastases, specifically bone metastases in patients with lower levels of PSA, even below 0.04. **References:** None

EPS-130

High detection sensitivity in [¹⁸F]PSMA-1007 PET: initial experience focusing on biochemical recurrence in prostate cancer patients

T. Watabe¹, M. Uemura¹, F. Soeda¹, S. Naka², H. Sasaki², T. Kamiya², E. Shimosegawa¹, H. Kato¹, N. Nonomura¹, F. L. Giesel^{3,1};

¹Osaka University, Suita, JAPAN, ²Osaka University Hospital, Suita, JAPAN, ³University Hospital Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: ¹⁸F-labeled prostate-specific membrane

antigen (PSMA) ligand, [¹⁸F]PSMA-1007, is focusing attention for its higher synthetic yield and minimal excretion in the urine. High detection efficacy has been reported in biochemical recurrence (BCR) of prostate cancer after radical prostatectomy.¹⁾ In this study, we evaluated diagnostic performance of [¹⁸F]PSMA-1007 PET in prostate cancer patients, focusing on the BCR. **Materials and Methods:** We enrolled consecutive 45 patients (age: 48–87) with prostate cancer (BCR: 24, recurrence: 7, Castration Resistant Prostate Cancer (CRPC) without metastasis: 6, metastatic CRPC (mCRPC): 7, and initial staging: 1). [¹⁸F]PSMA-1007 solution was synthesized using MPS200 (Sumitomo Heavy Industries). PSMA-PET scanning was performed 60 min after intravenous injection of [¹⁸F]PSMA-1007 (242 ± 24 MBq). PSMA-PET images were evaluated for its lesion detection as well as its relation to PSA values and location in BCR patients. Detection rates were compared with the previous reports using [⁶⁸Ga]PSMA-11 PET.²⁾ **Results:** Abnormal uptakes, which suspected recurrent or metastatic lesion, was detected in 97.8% (44/45) of the whole patients. SUVmax were 14.8 ± 12.6 in local recurrence, 16.7 ± 21.1 in pelvic lymph nodes (LN), 28.6 ± 23.3 in extra-pelvic LN, and 27.3 ± 21.9 in bone metastasis. In BCR patients (n=24), detection rates were 75% in low PSA group (0.1–0.5 ng/mL), 86% in medium PSA group (0.5–1.0 ng/mL), and 100% in high PSA group (above 1.0 ng/mL). Among the PET-positive BCR patients (n=23), local recurrence was detected in 48% (11/23), pelvic LN in 39% (9/23), and bone metastasis in 39% (9/23). These detection rates were higher than reported values in [⁶⁸Ga]PSMA-11 PET. In 64% (7/11) of BCR patients who were suspected of local recurrence, focal uptakes were detected adjacent to the bladder on [¹⁸F]PSMA-1007 PET, suggesting its big advantage of low physiological urine excretion compared to [⁶⁸Ga]PSMA-11 PET. **Conclusion:** Although further follow-up is essential to confirm the true positive, [¹⁸F]PSMA-1007 PET detected recurrent and metastatic lesion with high sensitivity. In BCR patients, its higher detection lead to proper treatment strategy, such as salvage radiation therapy with confidence, or surgical removal of recurrent lymph nodes. It was suggested that [¹⁸F]PSMA-1007 PET will contribute to improve the prognosis in prostate cancer patients. **References:** 1. Giesel FL, et al. J Nucl Med. 2019. 2. Afshar-Oromieh A, et al. Assessment of early oxidative stress following the use of radiotheranostics agents ¹⁷⁷Lu-PSMA for prostate cancer and ¹⁷⁷Lu-DOTATATE for neuroendocrine tumors; radioprotective effect of vitamin C

M. Assadi¹, E. Jafari¹, H. Ahmadzadehfar², D. Bagheri³, A. Amini¹;
¹Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, ²Klinikum Westfalen, Knappschaft Hospital, Dortmund, GERMANY, ³Persian

Gulf University, Bushehr, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: In this study, we aimed first to evaluate the early oxidative stress changes following radionuclide therapy (RNT) with ¹⁷⁷Lu-PSMA and ¹⁷⁷Lu-DOTATATE and second to evaluate the protective effect of vitamin C on RNT-related oxidative stress. **Materials and Methods:** From December 2018 to October 2019, prostate cancer and neuroendocrine tumor (NET) patients referred to undergo radioligand therapy (RLT) with ¹⁷⁷Lu-PSMA and peptide receptor radionuclide therapy (PRRT) with ¹⁷⁷Lu-DOTATATE, respectively, were enrolled in this study. The patients were divided into two main groups; the control group underwent routine RNT without any intervention and the intervention group was asked to take effervescent tablets (500 mg) of vitamin C for two days prior to the RNT (three tablets per day). To measure oxidative stress, blood samples were taken immediately before treatment and 48 hours after treatment and the serums were separated and frozen. To evaluate oxidative stress, the serum levels of malondialdehyde (MDA) and glutathione (GSH) and the activity of glutathione reductase (GR) were measured before and two days after treatment. **Results:** 61 RNT cycles were evaluated in 34 patients with a mean age of 62.82 ± 16.54 years (range of 27–99); this total included 20 (59%) prostate cancer patients (35 cycles (57.4%)) and 14 patients (41%) with NET (26 cycles (42.6%)) who received ¹⁷⁷Lu-PSMA and ¹⁷⁷Lu-DOTATATE, respectively. The NET patients included five females (36%) and nine males (64%). Of the 61 evaluated cycles, 27 cycles were given in the control group and 34 cycles were given in the intervention group. The serum level of MDA was significantly increased after treatment compared to before treatment (p=0.02) in the control group, while no significant change in the serum level of MDA was observed in the intervention group (p=0.52). The serum level of GSH was insignificantly decreased after treatment compared to before treatment in the control group and slightly increased after treatment in the intervention group (p>0.05). The serum level of GR was insignificantly increased in all groups of patients after treatment (p>0.05). **Conclusion:** According to the results, radionuclide therapy with ¹⁷⁷Lu-PSMA and ¹⁷⁷Lu-DOTATATE induces oxidative stress which can be ameliorated with vitamin C. **References:** None

Prostate Primary Tumor Assessment by [⁶⁸Ga]Ga-PSMA PET/CT

P. Soeiro, R. Silva, R. Almeida, V. Sousa, G. Costa, J. Perdosso de Lima;
 Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: [⁶⁸Ga]Ga-PSMA PET/CT is widely considered to be the most accurate imaging technique for

the distant staging of prostate adenocarcinoma (PCa). In this study we aim to assess its ability to identify and characterize the primitive tumour, which currently is considered to be lacking. **Materials and Methods:** All PCa patients who underwent [⁶⁸Ga]Ga-PSMA PET/CT followed by radical prostatectomy (RP) were retrospectively selected. PET/CT data was reviewed for any apparent area of focal uptake and seminal vesicle invasion (SVI). Semi-automatic VOIs centered on the highest uptake area were then generated according to 5 different SUV thresholds (2; 2.5; 3; 3.5 and 4) to draw the tumour with as little operator intervention as possible. All [⁶⁸Ga]Ga-PSMA tumour uptake related variables, such as SUVmax, SUVmean and Prostate Tumour Volume (PTV-PSMA) were recorded. A new variable, named Total Lesion PSMA expression (TL-PSMA), was calculated by multiplying the SUVmean by the PTV-PSMA. Demographic, clinical and histological variables were recorded. **Results:** Twenty-nine patients fulfilled the inclusion criteria (65±6.4; 52–76 years). Four patients had an ISUP score of 1 (14%), 12 patients a score 2 (41%), and 13 patients a score 3 (45%). Average staging PSA was 17.3±16.24 ng/ml. The average elapsed time between PET/CT and surgery was 97±109 days. On visual analysis, the primary tumour was detected in 26 patients (90%). Among the 3 undetected tumours, 2 were of intermediate risk, despite the fact that high risk tumours represented the vast majority (90%). According to a rough estimate, tumour localization agreement between PET/CT and the pathological report was 76%. Accuracy, sensitivity, specificity, PPV and NPV for SVI detection was 90, 57, 100, 100, 88%, respectively. Statistical significant correlations between tumour mass and PTV-PSMA were found, the highest for a SUV threshold of 3 (spearman-r²:0.54, p:0.034). However, for the highest Gleason grade tumour mass (GTM) the strongest statistical significant correlation was found with TL-PSMA (spearman-r²:0.567, p:0.014) also for a SUV threshold of 3. Globally, stronger correlations with clinical variables, such as staging PSMA (spearman-r²:0.599, p:0.02), PSMA value at PET date (spearman-r²:0.448, p:0.028), and stage group (spearman-r²:0.432, p:0.035) were found for PTV-PSMA, than for TL-PSMA or SUVmax. **Conclusion:** [⁶⁸Ga]Ga-PSMA PET/CT was able to detect most PCa on visual analysis, especially high risk tumours, with only one being missed. Also, SVI was detected with extreme specificity and PPV, despite low sensitivity. Statistically significant correlations were found between PTV-PSMA and tumour mass and TL-PSMA and GTM. Correlations with clinical variables was globally stronger for PTV-PSMA, than for TL-PSMA or SUVmax. **References:** None

EPS-133

PSMA-positivity of the salivary glands in ⁶⁸Ga-PSMA-PET: Does fasting play a role?

K. Huang¹, A. D. J. Baur², H. Hupperts¹, J. M. M. Rogasch¹, J. Albers¹, W. Brenner¹, C. Furth¹, J. Müller³, H. Amthauer¹;

¹Charité - Universitätsmedizin Berlin, Department of Nuclear Medicine, Berlin, GERMANY, ²Charité - Universitätsmedizin Berlin, Department of Radiology, Berlin, GERMANY, ³Vivantes Klinikum Spandau, Clinic for Neurology, Berlin, GERMANY.

Aim/Introduction: Aim of the study was to evaluate the impact of fasting during the uptake-phase of a ⁶⁸Ga-PSMA-PET on PSMA-positivity of the parotid (PG), submandibular (SMG) and sublingual gland (SLG). **Materials and Methods:** From 145 consecutively examined patients with prostate cancer (median age: 72 [range 47–91] years; median activity 169 [132–203] MBq ⁶⁸Ga-PSMA; median uptake time: 99 [54–167] min), the PSMA-positivity of PG, SMG and SLG was retrospectively analyzed. The gastric filling was used as surrogate for fasting; additionally the patients were interviewed. SUVmax of PG, SMG and SLG were determined. A side-averaged ratio between SMG and PG (SMP-ratio) for each patient was calculated. 16 patients were excluded because of asymmetry of the salivary glands (>50% SUVmax of contralateral side). With Shapiro-Wilk-tests a normal distribution was excluded and Mann-Whitney-U-tests were performed. **Results:** Median SUVmax of PG was 21.8, of SMG 22.7 and of SLG 8.1. Median SMP-ratio was 1.11. SUVmax of PG for fasting patients (f) was lower than non-fasting patients (nf) (f: 20.6; nf: 22.9; p=0.004). SUVmax of SMG showed an converse behaviour (f: 24.4; nf: 19.8; p=0.001). SUVmax of SLG did not show significant differences (f: 8.5; nf: 7.5; p=0.117). Fasting had a high significant impact on SMP-ratio (f: 1.27; nf: 0.89; p<0.001). **Conclusion:** The results show for the first time, that the physiological secretion at rest (f: SMG>PG>>SLG) and under stimulation (nf: SMG=PG>>SLG) relevantly affect the PSMA-positivity of salivary glands in ⁶⁸PSMA-PET. A preventive reduction of salivary gland activity / secretion could be a promising approach to minimize damage of salivary glands due to radioligand therapies with PSMA-ligands. **References:** None

The Role of Interleukin-23 in Prostate Adenocarcinoma; Comparison to Ga-68 PSMA PET/CT Findings

N. Ergul¹, H. Serin², E. Beyhan¹, Ö. Erol¹, B. Yılmaz¹, C. Gündoğan¹, T. F. Çermik¹;

¹Istanbul Training and Research Hospital, Department of Nuclear Medicine, Istanbul, TURKEY, ²Istanbul Training and Research Hospital, Department of Biochemistry, Istanbul, TURKEY.

Aim/Introduction: The first treatment option in advanced stage prostate cancer is androgen deprivation therapy. However, the majority of patients develop progression due to the resistance to castration. Recent studies have reported that immune cells in the tumor microenvironment and various cytokines may play a role in the development of this resistance. In this prospective study, the role of interleukin-23 (IL-23), a cytokine expressed in many types

of cancer, in prognosis of prostate cancer was investigated. **Materials and Methods:** Twenty-three patients diagnosed with prostate cancer, who were referred for Ga-68 PSMA PET / CT were included in the study. While 13 of the patients were newly diagnosed and had no treatment, 10 patients were found to have increased PSA and / or progression in Ga-68 PSMA PET / CT under hormone therapy (HT). 5 ml of venous blood samples were derived from all patients on the day of Ga-68 PSMA PET / CT. Levels were measured by ELISA method using IL-23 receptor kit in serum separated from all samples. The relationship between the newly diagnosed patient group and the progressive patient group under HT, and the relationship between IL-23 levels, as well as Gleason scores, tPSA levels, bone and distant organ metastasis detection rates, prostate gland and pelvic lymph node SUVmax values and IL-23 levels were investigated. **Results:** In Gallium-68 PSMA PET / CT, 13 (56.5%) of all patients had bone metastasis, 10 (43.5%) had non-pelvic lymph nodes and organ metastases. While tPSA levels were stable in 2 of castration resistant patients, new developed metastases were detected in PET / CT. No significant difference was found between blood IL-23 levels of patients with newly diagnosed and no treatment was initiated and those who developed resistance to castration ($P = 0.689$). There was no significant difference in IL-23 levels between patients with and without bone and distant organ metastases. Also, there was no significant correlation between IL-23 levels and tPSA and primary tumor and pelvic lymph node SUVmax values. **Conclusion:** Since there was no significant relationship between serum IL-23 levels and development of castration resistance, metastatic disease and SUVmax values, it can be said that IL-23 has no place in the prognosis of prostate cancer. Ga-68 PSMA PET / CT has an important role in guiding the treatment by showing resistance to castration. **References:** 1. IL-23 secreted by myeloid cells drives castration-resistant prostate cancer. Detection of primary prostate cancer with ^{99m}Tc -PSMA-SPECT/CT

I. Farkas, Z. Besenyi, G. Sipka, S. Urbán, A. Maráz, Z. Bajory, L. Pávics;
University of Szeged, Szeged, HUNGARY.

Aim/Introduction: Although PSMA-PET tracers have been extensively studied in the last few years, its role in primary prostate cancer diagnosis is unclear. ^{99m}Tc -PSMA -SPECT/CT could be a promising cost effective alternative for prostate cancer imaging. The aim of this study was to quantify the difference between the physiological and pathological intraprostatic tracer uptake on PSMA-SPECT scans. **Materials and Methods:** We retrospectively analysed the SPECT/CT images of 25 patients with primary prostate

cancer (71 ± 7 yo ISUP Grade 1-5, serum PSA level $85,51 \pm 226,41$ ng/ml) and 5 healthy volunteers (70 ± 5 yo, serum PSA level 4 ± 3 ng/ml). All patients received androgen deprivation therapy during study. Whole-body PSMA-SPECT/CT imaging were performed with 660 ± 95 MBq of ^{99m}Tc -mas3-yna1-k(Sub-KuE). The images were evaluated visually and quantitatively. Normal and pathological tracer uptake was measured using maximum activity concentration within whole prostate gland. Tumour-to-background ratio (TBR) was calculated as maximum intraprostatic activity concentration physiological by mean mediastinal blood pool activity concentration. **Results:** ^{99m}Tc -PSMA -SPECT/CT sensitivity, specificity, positive predictive value, negative predictive value and accuracy for primary prostate adenocarcinoma were 80%, 100%, 100%, 50% and 83% respectively. In the case of 20 true positive lesions TBR was significantly higher ($7,67 \pm 12,12$) than the false negative cases ($1,28 \pm 0,27$); $p < 0,01$ but no significant difference was found in relative tracer uptake between the false negative and true negative cases (normal prostate to background ratio: $1,67 \pm 0,36$); $p < 0,05$. **Conclusion:** These preliminary data show that quantitative assessment of ^{99m}Tc -PSMA -SPECT/CT has the potential to be used to differentiate between the physiological and pathological intraprostatic tracer uptake. Further clinical investigations are warranted in larger patient groups and prospective trials. **References:** None

Kinetic Modelling of ¹⁸F-rhPSMA-7.3 Uptake in PET Imaging of Prostate Cancer

S. Malaspina¹, V. Oikonen¹, A. Kuisma², O. Ettala³, K. Mattila², P. J. Boström³, H. Minn², K. Kalliokoski¹, E. J. Postema⁴, M. P. Miller⁴, M. Scheinin⁵;

¹Turku PET Centre, University of Turku and Turku University Hospital, Turku, FINLAND, ²Department of Oncology, University of Turku and Turku University Hospital, Turku, FINLAND, ³Department of Urology, University of Turku and Turku University Hospital, Turku, FINLAND, ⁴Blue Earth Diagnostics Ltd, Oxford, UNITED KINGDOM, ⁵Clinical Research Services Turku - CRST Ltd, Turku, FINLAND.

Aim/Introduction: ¹⁸F-labeling of prostate-specific membrane antigen (PSMA) PET imaging agents is increasingly used instead of ⁶⁸Ga because of their longer half-life and improved logistics. Radiohybrid PSMA (rhPSMA) ligands can be labelled with both diagnostic (¹⁸F) and therapeutic (¹⁷⁷Lu) radionuclides. This phase 1 open-label study evaluated the uptake kinetics of a novel theranostic PET tracer, ¹⁸F-rhPSMA-7.3, to optimize its use for PET/CT imaging of prostate cancer (PCa). **Materials and**

Methods: Nine men, three with high-risk primary PCa, three with hormone-sensitive metastatic PCa and three with castration-resistant metastatic PCa, received a dynamic 45-min PET scan immediately after i.v. administration of 300 MBq ^{18}F -rhPSMA-7.3. Two whole-body PET/CT scans were then acquired 60 and 90 min post-injection. Venous blood samples were collected for pharmacokinetic analysis. Volumes of interest (VOIs) corresponding to PCa lesions and healthy reference tissues (bone marrow for bone lesions, blood pool for lymph node (LN) and prostate lesions) were recorded. SUV_{mean} and lesion-to-reference ratios were calculated from data collected at two time points: early (between 35 and 45 min) and late (between 60 and 118 min). Net influx rates (Ki) were calculated using Patlak plots. **Results:** Three patients had primary localized PCa, one had pelvic nodal metastases and five had distant metastatic disease, with lesions in LN only (n=2) or in bone and LN (n=3). All lesions analyzed (n=35) were clearly visualized by ^{18}F -rhPSMA-7.3 PET in the dynamic and whole-body scans, with optimal visual lesion detection starting 60 min post-injection. The ^{18}F signal from PCa lesions increased over time, while the signal from the reference tissues remained stable or decreased. The SUV_{mean} of all lesions increased by a mean \pm SD of $27\pm 18\%$ from early to late time points (mean \pm SD SUV_{mean} 8.6 ± 5.1 vs. 10.7 ± 6.2 g/mL). Lesion-to-reference ratio \pm SD of prostate, LN and bone metastases increased from 2.4 ± 0.9 , 4.1 ± 2.0 and 6.9 ± 3.6 at the early time point to 3.2 ± 1.9 , 6.1 ± 3.1 and 8.8 ± 4.5 at the late time point, respectively. Patlak plots derived from the lesion VOIs were linear, with minor downward curvature when data from the static scans were included, signifying almost irreversible uptake kinetics during the PET scan. The Patlak-derived Ki estimates, SUV_{mean} values, and lesion-to-reference ratios were in good agreement. **Conclusion:** ^{18}F -rhPSMA-7.3 showed high uptake in PCa lesions, with high lesion-to-background ratios. Optimal visual lesion detection started 60 min post-injection. Thus, ^{18}F -rhPSMA-7.3 emerges as a very promising radiotracer for diagnostic PET imaging of PCa, with possible further application in theranostics. **References:** None

OP-751

Pharmacokinetics of PSMA-617 - dynamics of radiopharmaceutical uptake in tumours

K. Bohn, M. Fürstner, M. Hentschel, I. Alberts, A. Rominger, A. Afshar-Oromieh;
Department of Nuclear Medicine, Inselspital/Bern University Hospital, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Following the introduction of PET-imaging with PSMA-ligands, a multitude of studies demonstrates that the majority of prostate cancer (PC) lesions present with an increasing tracer-uptake over time. For instance, scans at 3h p.i. show increased lesion contrast compared to those

at 1h p.i. However, neither for diagnostic nor therapeutic PSMA-ligands has the time point of maximum uptake been adequately investigated. The aim of this study was to assess the time of maximum uptake for PSMA-617 in PC lesions. **Materials and Methods:** In the context of dosimetry of PSMA-based endoradiotherapy with ^{177}Lu -PSMA-617, five patients were scanned with SPECT/CT at four different time points (4h, 1d, 2d and 3d p.i.). Amongst these patients, fifteen representative PC lesions were selected by random and analysed with regard to their SUV values at all mentioned time points. Thereafter, time-activity curves were drawn. **Results:** For the majority of lesions a clear maximum and then constant fall in tracer uptake was observed: 10 lesions in three patients maximum at 1 day and 5 lesions in two patients maximum at 4h p.i. **Conclusion:** Our preliminary data (more analyses in progress) show that, for the majority of lesions, the maximum uptake of PSMA-617 in PC lesions can be expected between few hours and 1d p.i. This observation may find further relevance once PSMA-ligands labelled with isotopes of longer half-lives become available for PET-imaging (e.g. ^{44}Sc , $T_{1/2}$ 4h). In challenging patients, e.g. very early biochemical recurrence of PC, the maximum performance of PSMA-PET/CT could be achieved with scans conducted at 4h p.i., with the option of additional later imaging at 24h p.i. thereby showing PC lesions with the maximum uptake. **References:** None

OP-752

Heterodimeric Radiotracer Targeting PSMA and GRPR for Imaging of Prostate Cancer: Optimisation of the Affinity towards PSMA by Linker Modification

F. Lundmark¹, A. Abouzayed¹, B. Mitran¹, S. S. Rinne¹, Z. Varasteh², M. Larhed³, V. Tolmachev⁴, U. Rosenström¹, A. Orlova¹;
¹Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, ²Nuclear Medicine, Klinikum rechts der Isar der TUM, Munich, GERMANY, ³Science for Life Laboratory, Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, ⁴Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) and gastrin-releasing peptide receptor (GRPR) are promising targets for molecular imaging of prostate cancer (PCa) lesions. Due to the heterogenic overexpression of PSMA and GRPR in PCa, a bispecific heterodimeric radiotracer with the ability to bind both targets could be beneficial. Recently, our group reported the novel heterodimer BQ7800 consisting of a urea-based PSMA inhibitor, the peptide-based GRPR antagonist RM26, and NOTA chelator. BQ7800 demonstrated high affinity towards GRPR but only modest affinity towards PSMA together with short tumour retention. This study aimed to improve the affinity towards PSMA of this heterodimer by changing the composition of the two linkers connecting the PSMA- and

GRPR-targeting parts. **Materials and Methods:** Three novel heterodimeric analogues were synthesised using SPPS by incorporation of phenylalanine in the functional linker of the PSMA-binding part and/or shortening the PEG-linker coupled to RM26. The heterodimers were labelled with indium-111 and their affinity towards PSMA and GRPR was evaluated in vitro. Binding specificity to both targets was studied for the heterodimer [¹¹¹In]In-BQ7812 in mice bearing PC3-pip tumours (PSMA and GRPR positive). In vivo biodistribution of [¹¹¹In]In-BQ7812 was studied over time and compared with the biodistribution of [¹¹¹In]In-BQ7800. NanoScan SPECT/CT images were performed in tumour bearing mice 1 and 3 h pi. **Results:** In the competitive binding assay, BQ7812, featuring phenylalanine and shorter PEG-linker, demonstrated a nine-fold improved affinity towards PSMA ($IC_{50} \sim 100$ nM) without losing affinity towards GRPR ($IC_{50} \sim 6$ nM). In the biodistribution study of [¹¹¹In]In-BQ7812, the activity uptake was two-fold higher in the tumour and three-fold higher in kidneys compared to [¹¹¹In]In-BQ7800, which corroborates with the higher affinity to PSMA for BQ7812. However, no enhanced tumour retention was observed. The highest tumour-to-organ ratios were observed 3 h pi: tumour-to-blood and tumour-to-muscle ~ 70 , tumour-to-bone ~ 30 , and tumour-to-intestine ~ 15 . The nanoScan SPECT/CT images confirmed ex vivo data. **Conclusion:** In this study, we demonstrated that the incorporation of hydrophobicity in the functional linker of a PSMA/GRPR targeting heterodimer was beneficial for the affinity towards PSMA. We also demonstrated that the length of the PEG-linker connected to the GRPR binding motif of the heterodimer affected the binding towards PSMA but not towards GRPR. **References:** None

OP-753

Correlation of PSMA-ligand uptake combining autoradiography, histopathology and immunohistochemistry in primary prostate cancer

H. Wang¹, M. Reiser², T. Horn³, K. Schwamborn², K. Steiger², H. Wester⁴, M. Schottelius⁴, W. Weber¹, M. Eiber¹;

¹Department of Nuclear Medicine, Klinikum rechts der Isar, Munich, GERMANY, ²Institute of Pathology, School of Medicine, Technical University Munich, Munich, GERMANY, ³Department of Urology, Klinikum rechts der Isar, Technical University Munich, Munich, GERMANY, ⁴Pharmaceutical Radiochemistry, Technical University Munich, Munich, GERMANY.

Aim/Introduction: Targeting PSMA has been highly successful in imaging and treatment of prostate cancer. However, heterogeneity in immunohistochemistry indicates limitations in the effect of imaging and radionuclide therapy of multifocal disease. The goal of this study was to investigate the heterogeneity of PSMA ligand uptake in prostate cancer in close correlation with histopathology and to investigate its potential for

prediction of tumor aggressiveness. **Materials and Methods:** To avoid the complexities and errors of co-registration of PSMA PET or SPECT images and histology we studied patients who underwent radioguided surgery (RGS) with ^{99m}Tc-PSMA-I&S for primary nodal positive prostate cancer and evaluated the distribution of ^{99m}Tc-PSMA-I&S within the resected specimens by autoradiography allowing a perfect spatial correlation to histopathology. ^{99m}Tc-PSMA-I&S was injected intravenously before surgery and autoradiography was performed with 5-7mm prostate specimen slices over 12-16 hours. The images were compared with H&E stained slides (Gleason Pattern [GP] and Gleason Score [GS]) and PSMA-immunohistochemistry. Radioactivity intensity was measured as CPM/mm² and after normalization as SUV, which was then matched with histology on a grid-base (3x3mm). The linear mixed model and the Kruskal-Wallis H test were used for statistics and "estimate" values indicating the power of the effect. **Results:** So far 9 patients (between 11/2018 and 05/2019) with a total of 1632 grids were included in the preliminary analysis. GP 4 (CPM/mm²: estimate: 4470, p<0.001) and GP 5 (CPM/mm²: estimate: 1675, p<0.001) correlated with higher uptake of ^{99m}Tc-PSMA-I&S compared with GP 3 and non-neoplastic tissue, and GP 4 showed stronger impact on PSMA uptake than GP 5. After standardization, we observed GP 4 strongly associated with higher uptake (SUV: estimate: 2.3, p<0.001), while GP 5 affected uptake in an intermediate level (SUV: estimate: 0.6, p<0.001) and GP3 weakly correlated to the higher uptake (SUV: estimate: 0.5, p<0.001). Regarding different GS groups, GS 6 was excluded because of the small sample size. Compared with normal tissue (12680±6810 CPM/mm², SUV: 7±3), GS 7a (24715±13054 CPM/mm², SUV: 15±5; p<0.001), 7b (23780±12969 CPM/mm², SUV: 16±7; p<0.001), 8 (28646±17351 CPM/mm², SUV: 15±8; p<0.001) and 9 (37667±14075 CPM/mm², SUV: 14±6; p<0.001) had significantly higher PSMA-ligand uptake. **Conclusion:** Prostate carcinoma with Gleason Pattern 4 showed significantly higher uptake compared with non-neoplastic prostate tissue. Therefore, our analyses indicate the potential of PSMA-ligands to identify high grade disease and imply its use as a noninvasive biomarker in prostate cancer. More samples are evaluated to confirm these results. **References:** None

Gallium-66 PET: Production and characterization of ⁶⁶Ga-NOTA-PEG₂-RM26 for PET-imaging of GRPR expression in prostate cancer

S. Rinne¹, A. Abouzayed¹, K. Gagnon², V. Tolmachev³, A. Orlova¹;

¹Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, ²GEMS PET Systems AB, Uppsala, SWEDEN, ³Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Gastrin releasing peptide receptor (GRPR) is an attractive molecular target in prostate cancer. RM26 is a GRPR-antagonist with promising characteristics for imaging and therapy of GRPR-expressing cancers. Earlier studies with RM26 have shown that next-day imaging could increase imaging sensitivity due to clearance of RM26 from healthy tissue. Gallium-66 is a positron-emitting radioisotope with an intermediate half-life (9.5 hours). We aimed to cyclotron-produce gallium-66 suitable for radiolabelling using a liquid target, and investigate the PET-imaging properties of ^{66}Ga for later-time-point-imaging of GRPR expression using the bombesin-like peptide NOTA-PEG₂-RM26 in a preclinical mouse model. **Materials and Methods:** ^{66}Ga was produced by proton irradiation (~25 μA ; ~70 min) of 1 M enriched $^{66}\text{Zn}[\text{Zn}(\text{NO}_3)_2]$ in 0.3 M HNO_3 in a ^{68}Ga PETtrace liquid target. To maximize specific activity, an additional intermediate strong anion exchange column (1x8) was included to published (1) method for ^{66}Ga GaCl_3 isolation on FASTlab. NOTA-PEG₂-RM26 was labelled with gallium-66 and stability of the radiolabel was tested. Binding specificity, binding kinetics, and cellular processing were studied in GRPR-expressing PC-3 cells. In vivo, binding specificity and biodistribution of ^{66}Ga Ga-NOTA-PEG₂-RM26 were studied using PC-3 xenografted Balb/c nu/nu mice 3 h and 22 h pi and compared with biodistribution of ^{68}Ga Ga-NOTA-PEG₂-RM26. microPET/MR imaging of ^{66}Ga Ga-NOTA-PEG₂-RM26 was performed 3 h and 22 h pi in tumour-bearing mice. **Results:** Total isolated ^{66}Ga GaCl_3 activity was ~320–340 MBq, with an activity concentration of 160–280 MBq/mL used for labelling. NOTA-PEG₂-RM26 was stably labeled with ^{66}Ga Ga with molar activity of 4–8 MBq/nmol. Binding was GRPR-specific with K_D of 188 ± 50 pM. Fraction of internalized activity was less than 17% of cell-associated activity after 24 h. In vivo, clearance of ^{66}Ga Ga-NOTA-PEG₂-RM26 was rapid and binding was GRPR-specific. Tumour uptake 3 h pi was 15 ± 1 %ID/g and decreased 2-fold at 22 h pi. Tumour activity uptake exceeded uptake in all other organs. ^{66}Ga -NOTA-PEG₂-RM26 cleared from GRPR-positive pancreas with time, but other normal tissue clearance was limited, resulting in no improvement of tumour-to-organ ratios with time. Still, GRPR-expressing xenografts were clearly visualized with ^{66}Ga -NOTA-PEG₂-RM26 at both time points using microPET/MR. No difference in uptake in GRPR-positive organs and xenografts was observed between ^{66}Ga - and ^{68}Ga -labeled NOTA-PEG₂-RM26, but uptake of ^{68}Ga -NOTA-PEG₂-RM26 in normal tissue was significantly lower. **Conclusion:** In conclusion, we successfully produced gallium-66 suitable for radiolabelling and demonstrated that ^{66}Ga Ga-PET-imaging can be used to visualize GRPR-expression using the GRPR-antagonist ^{66}Ga Ga-NOTA-PEG₂-RM26. **References:** (1) Nair et al. OP-755

Evaluation of ^{64}Cu -labelled GRPR-antagonist RM26 for PET-imaging of prostate cancer in a preclinical model

S. Rinne¹, B. Mitran¹, C. Baun², J. H. Dam³, B. B. Olsen², V. Tolmachev³, H. Thisgaard², A. Orlova¹;

¹Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, ²Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, ³Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Gastrin-releasing peptide receptor (GRPR) is a molecular target expressed in 65–100% of prostate cancers (PC) and a suitable target for diagnostic imaging of PC, especially in earlier stages. We have previously demonstrated that the bombesin-based GRPR-antagonist PEG₂-RM26 labeled with ^{55}Co ($T_{1/2}$ =17.5 h, β^+ -abundance: 76%) could visualize GRPR expression in preclinical models. PET-imaging at late time may allow clearance of radioactivity in normal tissues which could increase image contrast. ^{64}Cu ($T_{1/2}$ =12.7 h, β^+ -abundance: 17%) is an alternative nuclide for later time-point PET-imaging. Aim of this study was to investigate the potential of a ^{64}Cu Cu-label for PET-imaging of GRPR expression using GRPR-targeting ligands NOTA-PEG₂-RM26 and NODAGA-PEG₂-RM26, and compare them head-to-head with their earlier reported radiocobalt-labelled counterparts in a preclinical PC-model. **Materials and Methods:** ^{55}Co Co and ^{64}Cu Cu were cyclotron-produced in house. NOTA/NODAGA-PEG₂-RM26 were labelled with ^{64}Cu Cu and stability was tested. Novel ^{64}Cu Cu-ligands were evaluated in GRPR-expressing PC-3 cells for binding specificity, cellular processing and retention. IC50 was estimated for ^{nat}Cu -labelled ligands by a competitive binding assay. Biodistribution of ^{64}Cu Cu-NOTA/NODAGA-PEG₂-RM26 was studied in PC-3 xenografted mice (n=4/group, 45 pmol/mouse) and compared to radiocobalt-labelled NOTA/NODAGA-PEG₂-RM26 3 h and 24 h pi. Preclinical PET/CT (Siemens INVEON) was performed in tumour-bearing mice 3 h and 24 h after injection of 3.1–3.7 MBq (0.2 nmol [0.18–0.23]) ^{64}Cu Cu-NOTA/NODAGA-PEG₂-RM26 and 2.0–2.9 MBq (0.3 nmol [0.24–0.32]) of ^{55}Co Co-NOTA/NODAGA-PEG₂-RM26. **Results:** NOTA/NODAGA-PEG₂-RM26 were stably labelled with ^{64}Cu Cu with almost quantitative yields. Binding was GRPR-specific and cellular processing pattern of ^{64}Cu Cu-NOTA/NODAGA-PEG₂-RM26 was similar to earlier observed patterns (rapid binding and low internalized fraction) without differences between the conjugates. IC50 value of ^{64}Cu Cu-NOTA-PEG₂-RM26 (6.05 nM) was approximately 2-fold lower than for ^{64}Cu Cu-NODAGA-PEG₂-RM26. In vivo, ^{64}Cu Cu-NOTA/NODAGA-PEG₂-RM26 bound to GRPR-expressing tumours and displayed similar biodistribution profiles to ^{57}Co Co-NOTA/NODAGA-PEG₂-RM26 with fast clearance from blood and normal organs. The choice of

chelator and radiolabel did not influence the tumor uptake significantly. Tumour uptake exceeded normal tissue uptake 3 h pi for all radioligands. Tumour-to-organ ratios did not increase with time, because of significant clearance of tumor activity, despite the good binding affinity to GRPR. Radiocobalt-labelled ligands demonstrated more efficient clearance from blood and higher tumour-to-organ ratios at both time points. All radioligands could visualize the GRPR-expressing xenografts in preclinical PET/CT and images confirmed the findings from the biodistribution study. **Conclusion:** ^{64}Cu -labelled PEG₂-RM26 was able to visualize GRPR-expression using PET at early and later-timepoints. However, radiocobalt-labelled PEG₂-RM26 provided favorable PET-imaging contrast compared to its radiocopper-labelled counterparts. **References:** None

OP-756

Influence of the Versatile Bifunctional Chelator AAZTA⁵ on the Radiometal Labelling Properties and the in vitro Performance of a GRPr Antagonist

M. Hofstetter¹, E. Moon², F. D'Angelo¹, L. Geissbühler¹, F. Rösch², A. Rominger¹, E. Gourni¹;

¹Department of Nuclear Medicine, Inselspital, Bern University Hospital, Bern, SWITZERLAND, ²Department of Chemistry – TRIGA site, Johannes Gutenberg - University Mainz, Mainz, GERMANY.

Aim/Introduction: GRPr-based radioligands, mainly antagonists, have shown great promise for diagnostic imaging of GRPr-positive cancers, such as prostate and breast. Prostate Specific Membrane Antigen (PSMA)-based theranostics have also proven great success in the recent years in prostate cancer management. However, not all patients suffering from prostate cancer benefit from the advantages of PSMA targeting. Therefore, GRPr could play an essential complementary role for PSMA negative cancers, and for tumors characterized by a heterogeneity of receptors expressed on their cell surface. The present study aims at developing and evaluating a versatile GRPr-based probe for PET/SPECT imaging as well as intraoperative and therapeutic applications. Particular focus was given on the influence of the versatile chelator AAZTA⁵ on the radiometal labelling properties and the in vitro performance of the generated radiotracers. **Materials and Methods:** The potent GRPr-based antagonist D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH₂ was functionalized with the chelator 6-[Bis(carboxymethyl)amino]-1,4-bis(carboxymethyl)-6-methyl-1,4-diazepane (AAZTA⁵) via the spacer 4-amino-1-carboxymethyl-piperidine (Pip) to obtain AAZTA⁵-Pip-D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH₂ (LF1). LF1 was radiolabelled with ^{68}Ga (PET), ^{111}In (SPECT, intraoperative applications) and ^{177}Lu (therapy, SPECT). ^{68}Ga -, ^{111}In - and ^{177}Lu -LF1 were evaluated in vitro using the epithelial human prostate cancer cell line PC3. In vitro evaluation included stability studies, determination of lipophilicity, protein-

binding studies, determination of K_d and B_{max} as well as internalization studies. **Results:** LF1 was labelled with ^{68}Ga , ^{111}In and ^{177}Lu within 10 min at RT with a labelling yield >98 %. The specific activities were ranging between 70-80 MBq/nmol for ^{68}Ga -LF1, 10-20 MBq/nmol for ^{111}In -LF1 and ^{177}Lu -LF1. The three tested radiotracers were found to be stable for a period of 4 h post labeling exhibiting a hydrophilic profile with an average of a $\text{LogD}_{\text{octanol/PBS}}$ of -3, and with the bound activity to the human serum proteins being 10%. They revealed high affinity for PC3 cells, with K_d values between 5 and 13 nM while the required concentration of the radiotracers to saturate the receptors (B_{max}) was between 0.6 and 0.7 nM which correspond to approximately 4×10^5 receptors per cell. Low specific internalization rate was found in cell culture with a maximum of 10.0 % at 6 h, while at the same time point the total specific cell surface bound uptake was about 30.0 %. **Conclusion:** LF1 can efficiently be labeled with ^{68}Ga , ^{111}In and ^{177}Lu leading to radiotracers with high affinity towards GRPr. The promising acquired in vitro data prompt us to further continue on the evaluation of this precursor in tumor models. **References:** None

OP-757

Characterisation of a cyclohexanediamine-triazole-PSMA conjugate on spheroids of prostate cancer cells

W. Sühver¹, M. Saager¹, M. Walther¹, R. Wodtke¹, F. Reissig^{1,2}, C. Mamat^{1,2}, K. Kopka^{1,2}, J. Pietzsch^{1,2}, H. Pietzsch¹;

¹Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY, ²Technische Universität Dresden, Faculty of Chemistry and Food Chemistry, Dresden, GERMANY.

Aim/Introduction: A recently developed cyclohexanediamine-triazole-chelator enabling ^{18}F -labelling using the Al[^{18}F] F approach was conjugated via copper-catalysed azide-alkyne cycloaddition to the PSMA-binding motif glutamate-urea-lysine connected with 1-naphthyl-D-alanine [1] (ligand L). In the present study radiolabelled L will be characterized on PSMA-positive prostate cancer-spheroids. Three-dimensional cell models offer structure and functional properties closer to in vivo conditions than two-dimensional cell culture models. Spheroids show altered cell-cell and cell-extracellular matrix interactions and are useful for better understanding the nature of tumours concerning drug uptake, toxicity, hypoxia, tissue growth and therapeutic effects. The aim of this study was to investigate the radiopharmacological potential of ^{18}F - and ^{68}Ga -labelled L using LNCaP-spheroids regarding binding properties and internalisation behaviour. The results will be compared with data obtained from LNCaP-monolayer cell culture. **Materials and Methods:** Spheroids of LNCaP and PC3 (PSMA-negative) cells were created according to a protocol by the vendor. Freshly harvested cells were incubated with magnetic nanoparticles overnight. After loading, the cells were distributed in a 24-well-plate (10^4 cells/well), covered

with a lid equipped with 24 small magnet devices for 5 days and kept in an incubator so that the cells could form spheroids [2]. After incubation with radiolabelled ligand (RCY >95%) the spheroids were washed, exposed to a phosphor imaging plate and the data analysed. Internalisation experiments were carried out by the “acid wash” method. **Results:** The method of creating spheroids by magnetised prostate cancer cell lines and treating them with a magnet device was applied successfully and resulted in spheroids with a diameter size of about 500 μm . The evaluation of first saturation experiments with LNCaP spheroids provided preliminary affinity data with K_d values in the range of 30 to 40 nM. These results are comparable to that of monolayer cell homogenate. Internalisation experiments with LNCaP-spheroids are ongoing. **Conclusion:** The novel radiolabelled PSMA-ligand L can be radiopharmacologically characterised on prostate cancer cell homogenate but also spheroids. The establishing of three-dimensional cell aggregates by magnetised cells and, moreover, the investigation of new radiolabelled conjugates for potential PET/SPECT application or even therapeutic treatment of cancer entities using spheroids is a valuable and promising method. Next, it is planned to use the LNCaP-spheroids for evaluation of PSMA-radioligands in a proof-of-concept study applying the technology of Micro-Physiological Systems (multiorgan-chips) [3]. **References:** [1] Sihver, Eur. OP-758

Development and preclinical evaluation of ^{177}Lu -AMTG, a novel pharmacophore-modified GRPR-targeted antagonist with improved metabolic stability

T. Günther, R. Beck, V. Felber, S. Deiser, H. Wester;

Technical University of Munich, Garching, GERMANY.

Aim/Introduction: In order to further improve the metabolic stability and thus pharmacokinetics of Gastrin-releasing peptide receptor (GRPR)-targeted antagonists, we substituted the tryptophan moiety within the metabolically unstable pharmacophore of the potent antagonist RM2 (DOTA-Pip⁵-D-Phe⁶-Gln⁷-Trp⁸-Ala⁹-Val¹⁰-Gly¹¹-His¹²-Sta¹³-Leu¹⁴-NH₂) by the unnatural amino acid α -methyl tryptophan (α -Me-Trp⁸). Results of the preclinical evaluation of [α -Me-Trp⁸]RM2 (=AMTG) were compared with the current golden standards among GRPR-addressing compounds, RM2 and NeoBOMB1 (DOTA-pABzA-DIG-D-Phe-Gln-Trp-Ala-Val-Gly-His-NH-CH[CH₂-CH(CH₃)₂]). **Materials and Methods:** All compounds were synthesised via standard Fmoc-based solid-phase peptide synthesis (SPPS). ^{177}Lu -labelling was carried out at 95 °C within 10 min (1.0 M sodium acetate buffer, pH = 5.5, 0.1 M sodium ascorbate). GRPR affinity (IC_{50}) and internalisation (37 °C, 1 h) were evaluated on PC-3 cells.

Hydrophilicity (expressed as n-octanol/PBS distribution coefficient; $\log D_{7.4}$) and metabolic stability in vitro in murine as well as human plasma (37 °C, 72 \pm 2 h) were investigated. Biodistribution studies at 24 h p.i. and $\mu\text{SPECT/CT}$ imaging at 1, 4, 8, 24 and 28 h p.i. were carried out on PC-3 tumour-bearing CB17-SCID mice. **Results:** Synthesis of the three derivatives via SPPS yielded 6–11% HPLC-purified labelling precursor. ^{177}Lu -labelling proceeded quantitatively. All peptides showed comparable GRPR affinity (IC_{50} [nM] of Lu-RM2: 3.45 \pm 0.18, Lu-NeoBOMB1: 4.22 \pm 0.14, Lu-AMTG: 3.04 \pm 0.08). Studies on the receptor mediated internalisation into PC-3 cells (37 °C, 1 h) displayed distinct differences for ^{177}Lu -RM2 (2.92 \pm 0.20%), ^{177}Lu -NeoBOMB1 (13.91 \pm 0.64%) and ^{177}Lu -AMTG (3.03 \pm 0.18%). Hydrophilicity ($\log D_{7.4}$) of the RM2-based compounds was higher than that of ^{177}Lu -NeoBOMB1 (^{177}Lu -RM2: -2.51 ± 0.02 and ^{177}Lu -AMTG: -2.28 ± 0.06 vs. ^{177}Lu -NeoBOMB1: -0.57 ± 0.03). Studies on the metabolic stability in vitro (37 °C, 72 \pm 2 h) revealed comparable amounts of intact tracer in murine plasma (^{177}Lu -RM2: 71.2 \pm 3.6%; ^{177}Lu -NeoBOMB1: 73.5 \pm 3.4%; ^{177}Lu -AMTG: 75.0 \pm 11.5%), but distinctly different intact tracer amounts in human plasma (^{177}Lu -RM2: 33.5 \pm 2.7%; ^{177}Lu -NeoBOMB1: 60.8 \pm 1.2%; ^{177}Lu -AMTG: 77.6 \pm 10.1%). In vivo, ^{177}Lu -AMTG exhibited the highest tumour-to-blood and tumour-to-muscle ratios at 24 h p.i. As demonstrated by $\mu\text{SPECT/CT}$ imaging, ^{177}Lu -RM2 showed a faster clearance from the tumour and the pancreas than ^{177}Lu -AMTG. Proof of concept studies in men have already been started. **Conclusion:** Based on its improved metabolic stability and very promising preclinical data, the novel GRPR-targeted antagonist AMTG might have the potential to compete with or even outperform the current golden standards among GRPR-targeted ligands (RM2, NeoBOMB1) for targeted radiotherapy in men. **References:** None

OP-759

A preclinical evaluation of ^{89}Zr -labeled PSMA ligands for pre-treatment dosimetry for ^{177}Lu -labeled PSMA therapy

B. Privé, Y. H. W. Derks, G. M. Franssen, S. M. B. Peters, M. W.

Konijnenberg, M. Gotthardt, M. J. R. Janssen, P. Laverman, J.

Nagarajah, S. Heskamp;

Radboudumc, Nijmegen, NETHERLANDS.

Aim/Introduction: [^{177}Lu]Lu-PSMA-I&T and [^{177}Lu]Lu-PSMA-617 are promising therapies for prostate cancer (PCa). To date, it is difficult to predict their efficacy upfront. While ^{177}Lu offers SPECT-based dosimetry, this is only possible after a therapeutic injection and because of the limited resolution, exclusively for larger tumours. Hence, PET based pre-treatment dosimetry may improve patient stratification. ^{89}Zr -labeled PSMA ligands could potentially be used for this, as ^{89}Zr has a longer $T_{1/2}$ compared to $^{68}\text{Ga}/^{18}\text{F}$ and may therefore be more suited to study uptake as well as retention of these ligands. Here, we describe

the radiolabelling of PSMA-I&T and PSMA-617 with ^{89}Zr . Furthermore, we compared their in vivo biodistribution and dosimetry with ^{177}Lu -labeled PSMA-I&T and PSMA-617 in tumour-bearing mice. **Materials and Methods:** ^{89}Zr ZrCl_4 was produced from $^{89}\text{Zr}(\text{ox})_2$ using a strong anion exchanger. (1) PSMA ligands were labelled with ^{89}Zr ZrCl_4 or ^{177}Lu LuCl_3 in 0.5M MES buffer pH 5.5 and purified using C18 SPE cartridges. Labelling efficiency and radiochemical purity were analysed by TLC and HPLC. In total, 96 BALB/c nude mice bearing PSMA⁺-LS174T and PSMA⁻-LS174T xenografts received either 0.50 nmol (0.6 - 1 MBq) ^{89}Zr -PSMA-I&T, ^{89}Zr -PSMA-617, ^{177}Lu -PSMA-I&T or ^{177}Lu -PSMA-617 intravenously. Ex vivo biodistribution was performed at 2, 24, 72 and 168 h post injection. **Results:** ^{89}Zr -PSMA-I&T and ^{89}Zr -PSMA-617 were labeled with a radiochemical yield of 30-60%, resulting in molar activities of 2.4 MBq/nmol and 1.3 MBq/nmol, respectively. All four radiotracers demonstrated high tumour accumulation in PSMA⁺ xenografts, with a mean uptake two hours p.i. of 8.8 ± 1.6 , 10.9 ± 1.9 , 11.6 ± 1.4 and 10.2 ± 1.0 %ID/g for ^{89}Zr -PSMA-I&T, ^{177}Lu -PSMA-I&T, ^{89}Zr -PSMA-617 and ^{177}Lu -PSMA-617, respectively. This resulted in a mean dose to the tumours of 143.1, 247.8, 381.5 and 309.0 mGy/MBq, respectively. Overall, ^{89}Zr -labeled PSMA ligands showed a comparable biodistribution to ^{177}Lu -labeled PSMA ligands (e.g. blood, salivary glands, liver). However, the mean doses in the skeleton and kidneys were 44.4, 5.0, 13.5 and 3.3 mGy/MBq, and 132.8, 357.9, 94.0 and 37.2 mGy/MBq for ^{89}Zr -PSMA-I&T, ^{177}Lu -PSMA-I&T, ^{89}Zr -PSMA-617 and ^{177}Lu -PSMA-617, respectively. **Conclusion:** PSMA-617 and PSMA-I&T were successfully labelled with ^{89}Zr and demonstrated high uptake in PSMA⁺ xenografts. The overall biodistribution of ^{89}Zr -PSMA-I&T and ^{89}Zr -PSMA-617 resembled the distribution of ^{177}Lu -PSMA-I&T and ^{177}Lu -PSMA-617, respectively. However, the concentration of ^{89}Zr in bone was higher compared to ^{177}Lu . Furthermore, ^{89}Zr -PSMA-617 overestimated the kidney and tumour uptake, while ^{89}Zr -PSMA-I&T underestimated these. Future studies are needed to clarify these differences and to optimize radiolabelling and purification. **References:** 1. Pandya et al., J Nucl Med 2019; 60:696-701

OP-760

Does the Injected Mass influence the Biodistribution of F-18-rhPSMA-7.3 on Positron Emission Tomography in Prostate Cancer Patients?

T. Langbein¹, A. Wurzer², A. Gafita^{1,3}, A. Robertson¹, H. Wang¹, A. Arçay^{1,4}, M. Herz¹, H. Wörther¹, C. Franz¹, W. Weber¹, H. Wester², M. Eiber¹;

¹Technical University of Munich, School of Medicine, Klinikum rechts der Isar, Department of Nuclear Medicine, Munich, GERMANY, ²Technical University of Munich, Chair for Pharmaceutical Radiopharmacy, Garching, GERMANY, ³Ahmanson Translational Theranostics Division,

Department of Molecular and Medical Pharmacology, University of California Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA, ⁴Department of Nuclear Medicine, Akdeniz University, Antalya, TURKEY.

Aim/Introduction: F-18-labeled PSMA ligands are increasingly used for prostate cancer imaging due to longer half-life and potential large batch productions in comparison with Ga-68-labeled counterparts allowing the use of a single batch for many patients over several hours. With defined activities for each patient the injected ligand mass substantially increases during the working day. Studies of F-18 labeled compounds in mice have shown a significant influence of the injected mass on the biodistribution of PSMA ligands. We investigated whether similar effects on organ uptake could be observed in patients using the novel PET radiotracer, F-18-rhPSMA-7.3. **Materials and Methods:** Patients with prostate cancer who underwent PET/CT with F-18-rhPSMA-7.3 at various timepoints after its production and therefore received different injected ligand masses were retrospectively grouped into two groups (low or high injected mass). Only patients with low tumour load were included to avoid variability due to "tumour sink" effects. The biodistribution of the PSMA ligand in the two groups was compared by drawing standardized isocontour-volumes of interest over normal organs and tumour lesions to detect SUVmean, and by obtaining full organ segmentation data using semiautomatic analysis with the software qPSMA. **Results:** Two groups, each with 42 patients, who either received a "low" or "high" mass of F-18-rhPSMA-7.3 ($1.7 \pm 0.2 \mu\text{g}$ vs. $18.4 \pm 3.6 \mu\text{g}$) were compiled from the database. Mean injected activities per body weight and uptake times did not vary significantly between the groups (3.95 ± 0.13 vs. 3.84 ± 0.37 MBq/kg; 72 ± 10.0 vs. 77 ± 12.5 min for low and high mass, respectively). SUVmean of the blood pool (2.1 ± 0.5 vs. 2.2 ± 0.4), liver (7.6 ± 2.3 vs. 7.5 ± 2.1), kidneys (35.4 ± 9.9 vs. 34.9 ± 9.4), bone (1.4 ± 0.4 vs. 1.5 ± 0.5) and muscle (0.8 ± 0.1 vs. 0.8 ± 0.2) showed no significant difference between the groups. There was also no significant difference in tumour uptake (10.0 ± 8.5 vs. 14.4 ± 14.8). A significantly decreased uptake by the parotid and submandibular glands was observed in patients with higher injected ligand mass compared with those with a lower injected mass (20.1 ± 5.3 vs. 17.4 ± 4.7 ; $p < 0.05$ and 22.4 ± 6.3 vs. 18.4 ± 5.3 ; $p < 0.01$, respectively). Similar results were found with spleen uptake (10.3 ± 4.0 vs. 8.1 ± 2.9 ; $p < 0.05$). **Conclusion:** The injected mass of rhPSMA-7.3 had only minimal effects on its biodistribution and no impact on clinical imaging interpretation. The stability of biodistribution over a 10-fold range of injected masses supports central production and distribution of F-18 labeled PSMA ligands. The uptake by salivary glands and the spleen appears saturable with increased mass of cold ligand, which warrants further investigation. **References:** None

OP-761**Competition ('steal' phenomenon) between ^{68}Ga -PSMA-11 uptake in prostate tumor and healthy tissue**

E. C. A. van der Sar, S. van den Doel, B. de Keizer, M. G. E. H. Lam, A. J. A. T. Braat;

UMC Utrecht, Utrecht, NETHERLANDS.

Aim/Introduction: Prostate specific membrane antigen (PSMA)-targeted radionuclide therapy for prostate cancer (PCa) has shown to be effective but with some side effects (fatigue, nausea, diarrhea, and xerostomia), potentially caused by irradiation of organs with physiological PSMA uptake. Because PCa cells have an overexpression of PSMA, the total tumor volume (TTV) might affect PSMA distribution. Filss et al., 2018 suggested that competition might induce a 'steal' phenomenon, resulting in diminished uptake in healthy tissue. In the current study, we aimed to investigate the influence of TTV on ^{68}Ga -PSMA-11 uptake in healthy tissue. If a 'steal' phenomenon exists, we might individualize PSMA-targeted radionuclide therapy based on TTV and potentially reduce/avoid unwanted side effects. **Materials and Methods:** Patients with PCa referred for a ^{68}Ga -PSMA-11 PET/CT were identified retrospectively from a single center from March 2016 to January 2019. Patients with recent prostate specific antigen (PSA) values (± 1 month) and ≥ 3 metastases on ^{68}Ga -PSMA-11 PET/CT were included, as difference in ligand binding is only expected in case of sufficient competition between tumor and healthy tissue. Patients were excluded if imaging followed previous treatment with ^{177}Lu -PSMA-617, ^{223}Ra -dichloride, or external beam radiation of the head/neck region. Quantitative image analysis was performed using the Syngo.via-software (Siemens version 05.01) on EARL reconstructions. Values were collected in line with the PERCIST parameters; Total Lesion Volume (TLV, derived from TLG; defined as Total Lesion PMSA-binding in $\text{SUV}_{\text{lbm}} \cdot \text{cm}^3$ ($\text{SUV}_{\text{lbm}} \cdot \text{cm}^3$)), and Metabolic Tissue Volume (MTV) of the lacrimal-, submandibular-, and parotid glands, kidneys and the TTV ($\text{SUV}_{\text{lbm}} \cdot \text{cm}^3$, derived from total TLG) of the PCa. Relevant volumes of interest were (semi-)automatically segmented based on blood pool activity (i.e. in line with PERCIST). **Results:** 488 patients were screened, 92 patients met the inclusion criteria. Median TTV was $703.37 \text{ SUV}_{\text{lbm}} \cdot \text{cm}^3$ (IQR 5.76-34043.37), median TLV of the lacrimal-, submandibular-, and parotid glands, kidneys was respectively $14.06 \text{ SUV}_{\text{lbm}} \cdot \text{cm}^3$ (IQR 1.25-59.28), $194.75 \text{ SUV}_{\text{lbm}} \cdot \text{cm}^3$ (IQR 22.99-576.83), $552.54 \text{ SUV}_{\text{lbm}} \cdot \text{cm}^3$ (IQR 119.98-1544.73), and $8092.75 \text{ SUV}_{\text{lbm}} \cdot \text{cm}^3$ (IQR 3209.20-15855.18). A significant (p -value < 0.01) but weak correlation was found between the TTV and TLV of the parotid-, and submandibular glands and kidneys (correlation coefficient of respectively -0.447, -0.345, and -0.394). No correlation was found between TTV and TLV of the lacrimal glands. **Conclusion:** The weak correlation between the TTV and TLV

of healthy tissue (salivary glands and kidneys) suggests that healthy tissue uptake of ^{68}Ga -PSMA-11 is not solely influenced on TTV. Thus, modification of therapeutic ^{177}Lu -PSMA activity should not be adjusted based on TTV alone. **References:** doi:10.3413/Nukmed-0937-17-10

OP-762**Estimation of tumor burden from ^{68}Ga -Dotatate-PET/CT and day-7 planar ^{177}Lu images, for patients treated with ^{177}Lu -Dotatate**

K. Sjögren Gleisner¹, J. Gustafsson¹, A. Stenvall¹, D. Roth¹, C. Hindorf², L. Jönsson¹, E. Larsson², T. Olsson², A. Sundlöf^{3,1};

¹Medical Radiation Physics, Clinical Sciences, Lund, SWEDEN,

²Department of Radiation Physics, Skane University Hospital, Lund, SWEDEN, ³Oncology and Pathology, Clinical Sciences Lund, Skane University Hospital, Lund, SWEDEN.

Aim/Introduction: The total tumor burden (TuB) has been identified as a factor that may affect the rate of peptide accumulation and thereby the absorbed dose to organs and tumors for NET patients treated with ^{177}Lu -Dotatate. TuB refers to the total tumor volume and can be estimated from 3D images such as ^{68}Ga -PET/CT. In the clinical trial Illuminet (EUDRACT 2011-000240-16), post-therapeutic ^{177}Lu gamma-camera images were acquired for dosimetry. A hybrid planar-SPECT/CT protocol was used, where the last whole-body scan was made 7 days after administration, when mainly tumors retain activity. The aim was to develop a semi-automatic method for segmentation of the TuB, applicable in both 2D and 3D images, and to compare the TuB estimated from ^{68}Ga -PET/CT to surrogate metrics from ^{177}Lu day7-planar images. **Materials and Methods:** ^{68}Ga -PET/CT and ^{177}Lu planar whole-body images for 18 patients acquired within 20 weeks (14 pts within 10 weeks) were included. The planar images were processed for activity quantification, including pixel-wise attenuation correction using a CT-scout, and a deconvolution filter for scatter correction. The segmentation method was constructed as a difference of Gaussians (DOG) filter, implemented as a scale pyramid in which Gaussian filters (2D or 3D) with gradually increasing width were applied to the image. A sequence of high-pass filtered images were obtained by subtraction of the image from a lower level of filtering from the next level. A region-growing algorithm was applied to each of these high-pass filtered images, where seeds were automatically generated from the image coordinates whose value exceeded a predefined threshold in any of the high-pass

filtered images. The binary masks obtained from region-growing of each level were combined to form the final tumor-burden mask. The DOG filtering was implemented in a graphical user interface in which the number of levels and the gradient thresholds could be adjusted, and false positive regions removed. **Results:** Pearson's correlation coefficient was determined for the TuB determined from the 68Ga-PET/CT images versus different metrics determined for the day7-planar image (total activity in tumors, projected tumor area, total-body activity). The highest correlation coefficient (approximately 0.8) was obtained for the total activity in tumors, followed by the total-body activity. **Conclusion:** The DOG filtering enables fast assessment of the TuB in planar or tomographic images. The correlations obtained support the use of day7-planar ^{177}Lu images for assessment of the TuB. **References:** None

Comparison of The Effect of 1L Vs 2L Lysine/Arginine Solution (25g/L Each) on Kidney Absorbed Doses and Acute Side Effects in Patients Undergoing Lutathera Treatment

D. Gillett¹, S. Ballout¹, E. Varzakis¹, I. Harper¹, D. Pitfield², A. Powell¹, R. T. Casey^{3,2}, S. Heard¹, L. Aloj^{4,1};

¹Department of Nuclear Medicine, Addenbrooke's Hospital CUHFT, Cambridge, UNITED KINGDOM, ²Department of Endocrinology, Addenbrooke's Hospital CUHFT, Cambridge, UNITED KINGDOM, ³Department of Genetics, University of Cambridge, Cambridge, UNITED KINGDOM, ⁴Department of Radiology, University of Cambridge, Cambridge, UNITED KINGDOM.

Aim/Introduction: Lu-177 DOTATATE (Lutathera®) is an approved treatment for patients with metastatic GEP-NET tumours. As with most small negatively-charged peptides there is significant kidney retention following infusion. Coadministration of high concentrations of Lysine and Arginine have been shown to reduce kidney retention and absorbed doses in patients undergoing treatment. Our institution traditionally used 2L of solution (25g Arginine/25g Lysine in 1L saline) injected at 333 mL/hour starting approximately 1h prior to Lutathera (7.4 GBq). Administering high doses of amino acids is known to cause acute side effects such as nausea and vomiting, which can persist for several days, as well as transient acute kidney toxicity, so we recently adopted a reduced regimen of 1L of the solution over 5h (200mL/hr) as recommended by the manufacturer. We aim to identify whether this change in regimen significantly impacts kidney absorbed doses and side effects. **Materials and Methods:** Patients undergoing Lutathera treatment were routinely imaged at three time points up to one week after radiopharmaceutical administration for each cycle. SPECT studies of the abdomen (one of which had a co-registered CT) were obtained at each time point. Absolute radioactivity concentrations were estimated using GE

Xeleris Volumetrix AC OSEM reconstruction and a camera-specific sensitivity factor. Kidney volumes were determined from the CT component. Effective half-lives and absorbed dose estimates were obtained using 3D Slicer and RADAR dose factors. The incidence and severity of acute side effects and other laboratory findings of acute metabolic effects (where available) were also reviewed. **Results:** 23 treatment infusions were analysed for 6 patients whose treatment straddled the regime change in the period May 2019 to March 2020. The mean kidney effective half-lives and doses were calculated for each patient for both kidney blocking regimes. The mean patient-specific effective half-lives were found to be 4.31 and 4.58 days for regime A (2L of solution) and B (1L) respectively. Mean patient-specific kidney doses were found to be 2.13 and 2.58 Gy for regime A and B respectively. These results indicate increases of 6.3% and 21.1% for effective half-lives and absorbed doses respectively. **Conclusion:** Our initial experience with the manufacturer-recommended reduced regimen indicates a small increase to kidney half-lives, contributing to increased kidney absorbed doses. No significant acute side effects have been observed since modifying the amino acid infusion scheme. Data on whether these changes have any impact on long term kidney toxicity are not yet available. **References:** None

OP-764

Absorbed doses to kidneys based two SPECT measurements versus seven SPECT measurements patients with neuroendocrine tumours receiving ^{177}Lu -DOTATATE therapy

M. Sandstrom¹, A. Sundin², M. Lubberink¹;

¹Medical Physics, Uppsala, SWEDEN, ²Nuclear medicine and PET, Uppsala, SWEDEN.

Aim/Introduction: As in all therapies using ionizing radiation, a patient-specific optimization of the delivered radiation should be performed in therapy with ^{177}Lu -DOTATATE. At our centre, the number of treatments is based on the absorbed dose (AD) to the kidneys. For logistical reasons, estimation of absorbed doses should be performed with as few measurements as possible. The aim of the present work was to study how well kidney AD estimations using a method with two measurement points agree with a method that is based on seven imaging points. **Materials and Methods:** Six patients (three female and three male) with neuroendocrine tumors with high somatostatin receptor expression were included. They were injected with 500MBq ^{177}Lu -DOTATATE and no kidney protection was used. SPECT/CT over the abdomen were acquired at 0.5, 1, 1.5, 2.5, 4, 24 and 96h after injection of ^{177}Lu -DOTATATE. AD were calculated using single exponential fits to data from 2 measurements (24-96) or trapezoidal integration up to 24h and then exponential fit after 24h. Bias of AD values relative

to those based on the seven-point measurement were calculated for both right and left kidney. To test statistical significance a Wilcoxon matched-pairs signed rank test with a P-value of 0.05 for significance was used. Median, Min and Max of the deviations were also calculated for the AD. For the early measurement points, estimations from the (24-96) for the time of measurement were compared with the measured values. **Results:** Bias versus AD(seven) was -0.4%(-1.1-3.8) (Median(Min-Max)) for the right kidney and -0.2%(-1.1-5.4) for the left kidney when the AD(24-96) method was used. The P-values were 0.69 for the right kidneys and 0.84 for the left kidneys and this show no significant difference between the two methods. With errors as small as these and using a fixed limit of the absorbed dose to the kidneys, this would mean that really few patients would be given unoptimized number of treatments. The difference of the estimated activity concentrations for every point was in general small (less than 5%) but could vary up to about 30% for single values. A larger study including more patients and preferably also a later timepoint (maybe 7 days) is highly warranted. **Conclusion:** With a difference of less than about 5% for all the measurements the results from this study indicate that the influence of early measurements (earlier than 24 h) is fairly small and can be ignored. **References:** None

³Sapienza University of Rome, Ph.D. Program in Morphogenesis & Tissue Engineering, Rome, ITALY, ⁴Department of Physics and Earth Sciences, Ferrara University, Ferrara, ITALY, ⁵Section of Diagnostic Imaging, Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, ITALY.

Aim/Introduction: Peptide-receptor radionuclide-therapy (PRRT) has become a standard treatment modality for patients affected by neuroendocrine tumors. A phase II study FENET2016 (University Hospital Sant'Anna, Ferrara, Italy) is presented. Treatment protocol relies on either five PRRT cycles with ^{177}Lu -DOTATOC or a sequence of ^{177}Lu followed by ^{90}Y -DOTATOC spaced two months apart. We report about tumors and organ-at-risk (OAR) dosimetry and evaluation of the dose-response relationship for liver metastases. **Materials and Methods:** 80 patients underwent PRRT therapy with systemic administration of cumulative activities between 11 and 28 GBq. A validated method based on three-time-point (at 1, 24, 48 hours after administration)

SPECT/CT was developed to calculate the absorbed doses (AD) to tumors and OARs. Tumors and kidneys AD were calculated according to MIRD scheme, while L2-L4 lumbar vertebrae imaging method was used to calculate AD to BM. Dosimetric results between first and fifth cycle were compared as well as those obtained with ^{177}Lu and $^{177}\text{Lu}/^{90}\text{Y}$ modalities. Tumor response was evaluated applying the Response Evaluation Criteria In Solid Tumors (RECIST 1.1) to hepatic lesions. The CTs were performed no earlier than 4 weeks before the treatment and no later than 12 weeks after it. By comparing the lesions in the CT with the areas of high uptake in SPECT/CT, only the superimposable lesions were selected, resulting in 29 lesions in 15 patients. The variations of lesion diameter recorded by CECT and the corresponding absorbed doses were correlated. **Results:** The cumulative doses ranged from 13 to 310 Gy for tumors, from 3.5 to 40 Gy for kidneys and from 0.03 to 1.2 Gy for BM. High variability in tumor AD per unit activity was observed with values ranging from 2.5 to 45 mGy/MBq and from 1 to 107 mGy/MBq for ^{177}Lu and $^{177}\text{Lu}/^{90}\text{Y}$. The percentage reduction of lesion diameters treated with $^{177}\text{Lu}/^{90}\text{Y}$ resulted higher than those obtained with ^{177}Lu (mean=29.3%, SD=17.6 for $^{177}\text{Lu}/^{90}\text{Y}$; mean=3.4%, SD=19.41 for ^{177}Lu). The dose-response correlation ($r=0.92$) turned out to be highly significant with a level of sampling significance superior than 99% when considering lesions above 3 cm in diameter treated with $^{177}\text{Lu}/^{90}\text{Y}$. No correlation was found below 80 Gy. **Conclusion:** The dosimetric protocol routinely established provides reproducible, standardized and patient-tailored dose estimates. The highly significant correlation between the lesion response and the absorbed dose we found for large metastases treated with $^{177}\text{Lu}/^{90}\text{Y}$ is highly promising for the clinical benefit derived from the implementation of dosimetry in PRRT. **References:** None

OP-766

Lesion-wise dosimetry for multiple bone metastases in mCRPC patients undergoing Lu-177-PSMA therapy: comparison of five dosimetric methods

J. Brosch¹, C. Uribe², A. Gosewisch¹, L. Kaiser¹, P. Bartenstein¹, A. Todica¹, H. Ilhan¹, A. Rahmim³, A. Celler³, S. Ziegler¹, G. Böning¹;
¹Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, ²PET Functional Imaging, BC Cancer, Vancouver, BC, CANADA, ³Department of Radiology, University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: Although metastatic, castration-resistant prostate cancer (mCRPC) patients undergoing Lu-177-PSMA-therapy show a large number of bone metastases, tumor dosimetry is typically performed only for a limited number of lesions per patient. To differentiate between responding/non-responding bone lesions, dosimetric calculation for all bone lesions is required. We aimed to investigate the accuracy of 4 computationally-efficient

dosimetric methods against Monte-Carlo (MC) based dosimetry as gold-standard. **Materials and Methods:** 10 mCRPC patients, receiving their 1st cycle of Lu-177-PSMA-I&T-therapy (7.4-9GBq), were enrolled. Each patient underwent quantitative Lu-177-SPECT/CT at 24h, 48h and 72h p.i. with 3 bed positions (shoulders-knees). All lesions with volumes >1ml were segmented on the 24h SPECT (kmeans segmentation, PMOD v4.005) and the resulting volumes of interest (VOIs) were copied to the subsequent co-registered SPECTs. For each lesion, the effective half-life was obtained by mono-exponential fitting of activities in these VOIs. To preserve the 3D distribution information within the lesions, the time-integrated activity image was estimated based on the 24h SPECT. Dose estimates per lesion from MC (GATE v8.2) were compared with those from: A) OLINDA v2.0 using unit-density sphere model, B) OLINDA weighted with CT-based average lesion density, C) ICRP soft tissue Lu-177 voxel-S-values (GATE), and D) voxel-S-values with CT-based voxel density weighting. **Results:** In total, 125 lesions (volumes 1.5-420.6ml) were analyzed. On average, method A overestimated doses for all lesions (mean: +10%, range: -12% to +47%), while method B underestimated them (mean: -14%, range: -28% to -2%). Similarly, method C overestimated the lesion doses (mean: +20%, range: -8% to 57%), whereas results from method D were closest to the MC dose estimates showing the smallest range of deviations (mean: -4%, range: -9% to -3%). **Conclusion:** Full MC dosimetry is complex and time-consuming, while commonly employed OLINDA is simple and fast. The advantage of MC and voxel-S-value methods is the generation of 3D dose distributions, contrary to OLINDA which assumes spherical tumors and provides only mean doses. Our results show that doses estimated by methods A and C (assuming unit density) reveal a large range of deviations from MC, which is reduced when CT-based density weighting (methods B and D) is applied. To conclude, dosimetric calculation using voxel-S-values with CT-based density weighting represents a simple, yet accurate dosimetric method compared to the gold-standard MC dose estimates. This practical approach would enable determination of dose estimates for all bone lesions in mCRPC patients and visualization of 3D dose maps.

Individualization of ¹⁷⁷Lu-PSMA Therapy based on important physiologic parameters using global sensitivity analysis and a physiologically-based pharmacokinetic model

G. Glattig^{1,2}, P. Kletting^{1,2}, N. J. Begum¹, M. Eiber³, A. J. Beer², S. A. Pawiro⁴, D. Hardiansyah⁴;

¹Medizinische Strahlenphysik, Nuklearmedizin, Universität Ulm, Ulm, GERMANY, ²Klinik für Nuklearmedizin, Universität Ulm, Ulm, GERMANY, ³Nuklearmedizin, Klinikum rechts der Isar, Technische

Universität München, München, GERMANY, ⁴Medical Physics and Biophysics, Physics Department, Faculty of Mathematics and Natural Sciences, Universitas Indonesia, Depok, INDONESIA.

Aim/Introduction: Individualized treatment planning is expected to improve outcome of radionuclide therapy. In this study, we identify the most important physiologic parameters for the determination of the individual kidneys and tumor absorbed doses (ADs) in ¹⁷⁷Lu-PSMA therapy. Therefore, a global sensitivity analysis (GSA) and a physiologically-based pharmacokinetic (PBPK) model are used. **Materials and Methods:** A whole-body PBPK model that has been developed for treatment planning in ¹⁷⁷Lu-PSMA therapy was used. As the fixed model parameters have a relatively small effect on the estimation of time-integrated activity coefficients (TIACs) and thus the ADs, the model parameters of interest for the GSA analysis in this study were the parameters that have been estimated from the biokinetic data such as the organ receptor densities R_{dens} , organ flows f and organ release rates. GSA with the extended Fourier Amplitude Sensitivity Test (eFAST) algorithm was chosen based on its high accuracy for non-linear models and the low number of model evaluations needed. An in-house GSA with eFAST program based on MATLAB software (version R2019b) was developed. The frequency-based sampling method with a log-normal distribution was used to avoid negative values of the sampled parameters. The main effects S_i and total effects S_{Ti} were calculated and analyzed using the GSA program and the PBPK model to identify the importance of each model parameter i for the individualization of the ADs in ¹⁷⁷Lu-PSMA therapy. To warrant the convergence of the calculated S_i and S_{Ti} , various numbers of model simulations were performed, i.e. 129, 257, 513, 1025, 2049, 4097 and 8193. **Results:** The inter-individual variability of tumor ADs (coefficients of variation CV around 60%) was higher than that in the kidneys (CV around 30%). Based on the GSA with the eFAST algorithm results, the individual calculated tumor ADs were mostly depending on the receptor density R_{densTU} (S_i and S_{Ti} values up to 0.72) for the tumor lesions. For the kidneys, receptor density in kidneys R_{densK} ($S_i=0.25$, $S_{Ti}=0.30$) and flows f_K ($S_i=0.36$, $S_{Ti}=0.43$) were identified as the most important parameters determining the individual kidneys ADs. **Conclusion:** We have shown the first implementation of the GSA with the eFAST algorithm to identify the most important parameters that affect the individualization of the calculated ADs in ¹⁷⁷Lu-PSMA therapy. These results suggest an accurate measurement of these parameters, i.e. receptor density and blood flow, before ¹⁷⁷Lu-PSMA therapy to decrease the inter-individual variability of the ADs in kidneys and tumor.

OP-768**[⁹⁰Y]Y-PSMA-617 -Post-therapeutic kidney, bone marrow and tumor dosimetry for individualized treatment of metastatic castration-resistant prostate cancer**

J. Kurth, B. J. Krause, O. W. Hakenberg, S. M. Schwarzenböck, M. Heuschkel;
Rostock University Medical Center, Rostock, GERMANY.

Aim/Introduction: PSMA ligands have been established as a treatment option for patients suffering from mCRPC. To date, Y-90 hasn't been extensively used for PSMA-targeted therapies, although it is hypothetically assumed that larger lesions could benefit from enhanced crossfire effects. As mCRPC-patients are heavily pretreated all reasonable efforts should be made to protect the organs at risk (OAR). Therefore, dosimetry accompanying therapy is indispensable. As intra-therapeutic quantitative Y-90-imaging is challenging, dosimetry of a previous study was only estimated based on previously performed [¹⁷⁷Lu] Y-PSMA-617 therapies [1], Therefore, aim of this study was to establish an imaging protocol and a workflow allowing post-therapeutic dosimetry for kidneys and bone marrow in [⁹⁰Y]Y-PSMA-617 therapy. **Materials and Methods:** 17 patients (mean age: 72y (range: 59-84ys)) presenting insufficient response to [¹⁷⁷Lu]Lu-PSMA-617 treatment were selected for [⁹⁰Y]Y-PSMA-617 therapy. For dosimetry, each patient underwent SPECT/CT imaging of the upper abdomen at approximately 2, 24, 48 and 72h p.i., (Siemens Symbia T6; HEGP-collimators; energy-window: 125keV±20%; matrix: 128x128; 64 projections, 35 sec each). Quantitative SPECT/CT reconstruction was performed (3D-OSEM; 5i15s) with corrections for attenuation, scatter and detector blurring using a fully Monte Carlo based collimator modeling (Hermes Hybrid Recon v.3.0) [2]. A special calibration factor adapted to the general kidney geometry was determined. The required phantom inserts were manufactured using a rapid prototyping technology [3] and inserted into a torso phantom. Absorbed doses (AD) of kidneys and tumor lesions were calculated based on a voxel level dosimetry scheme (Hermes Voxel Dosimetry, v.1.0.1). VOIs based on CT were applied to calculated dose map to extract AD for kidneys and tumor lesions. Red bone marrow dosimetry was performed based on blood sampling according to EANM guideline. **Results:** The therapy was well tolerated by all patients. Mean administered activity was 4.23±0.54 GBq. Mean AD in the kidneys was 2.1±1.0Gy/GBq and 0.19±0.18Gy/GBq for the red bone marrow. For tumor lesions (19 osseous and 15 soft tissue lesions) the mean AD was 16.4±7.8Gy/GBq. Compared to [¹⁷⁷Lu]Lu-PSMA-617, AD of the kidney and bone marrow are approximately 2.8 and 5 times higher, respectively. **Conclusion:** [⁹⁰Y]Y-PSMA-617 offers an alternative treatment option for patients without sufficient response to Lu-177-PSMA therapy. AD of tumor lesions are higher, but also OAR are more affected. However, quantification of the

Y-90-SPECT/CT still needs further validation and critical discussion. **References:** [1] Rathke H et al. JNM Nov 2, 2018 [2] Porter et al. EJNMMI Research (2018) 8:7 [3] Kurth J et al. JNM. 2013;54(suppl 2):2174

OP-769**Targeted Alpha PSMA-based Therapy of mCRPC patients: previsual dosimetry and radiobiological evaluation**

A. Sarnelli¹, M. Belli¹, E. Mezzenga¹, F. Cesarini¹, P. Caroli¹, V. Di Iorio¹, M. Cremonesi², L. Strigari³, A. Romeo¹, S. Nicolini¹, F. Matteucci¹, S. Severi¹, G. Paganelli¹;
¹Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, ITALY, ²European Institute of Oncology, IRCCS 20141 Milano, Milan, ITALY, ³Policlinico S. Orsola-Malpighi, 40138 Bologna, Bologna, ITALY.

Aim/Introduction: For tumors refractory to beta-radiation therapy, the use of alpha emitters in radiometabolic treatment is a promising option. Target-alpha therapy (TAT) combines high-LET ²²⁵Ac alpha-emitter with PSMA (prostate-specific-membrane-antigen) carrier highly affine to tumor cells in metastatic prostate-cancer patients (mCRPC). Nevertheless, the therapeutic window is limited by high rate of xerostomia. A prospective trial is ongoing in our institute to test the efficacy of salivary gland protectors administered in combination with ¹⁷⁷Lu-PSMA therapy. In this study we explore a possible advantage of salivary gland protectors in TAT-PSMA by extrapolating provisional dosimetry for ²²⁵Ac-PSMA from ¹⁷⁷Lu-PSMA absorbed doses (AD). **Materials and Methods:** Sequential planar images and blood samples were acquired for 13 ¹⁷⁷Lu-PSMA patients at 1, 16-24, 36-48, and 120h post-injection. The same biokinetics was assumed for both radionuclides and ¹⁷⁷Lu time-activity curves were corrected for ²²⁵Ac physical decay. 100 MBq/kg injection activity was assumed for ²²⁵Ac-PSMA, indicated as safe dosage with no salivary gland protectors [1]. Assuming all daughters in equilibrium, each contribution was summed for AD calculation. OLINDA/EXM adult male phantom was used for kidneys, red marrow (RM) and whole body (WB) AD estimation; spherical model was used for parotid and submandibular glands (PGs, SGs). Biologically effective dose (BED) was calculated for salivary glands and compared to the BED values of external-beam radiotherapy (EBRT) schedules. RBE values equal to 5 and 1 were used for alpha and beta/gamma radiation, respectively. Considered the data reported in [1] as reference for TAT without salivary gland protectors, we scaled our data accordingly to the ratio between the mean AD value of our data and this reference. The probability of xerostomia for ²²⁵Ac-PSMA with and without salivary glands protector was estimated based on NTCP model derived from EBRT. **Results:** Median (range) AD/MBq were 0.67 Bd_{RBE=5}/MBq (0.15-1.81), 0.86 Bd_{RBE=5}/MBq (0.49-2.43), 1.05 Bd_{RBE=5}/MBq (0.42-1.98), 0.07 Bd_{RBE=5}/MBq (0.03-0.14), 0.04 Bd_{RBE=5}/MBq (0.02-0.11) for kidneys, PGs,

SGs, RM and WB, respectively. A reduction of 53% for salivary gland mean AD was observed as compared to previously published data (2.33 $Bd_{RBE=5}/MBq[1]$). Median (range) BED values were 2.1Gy(1.2–9.7) for PGs and 2.7Gy(0.9–8.1) for SGs vs. 33.5Gy of EBRT dose constraint on PGs. The predicted probability of acute G2+ xerostomia based on NTCP model were 49%(95%CI:18%–71%) vs 98%(82%–100%) with or without salivary gland protector administration. **Conclusion:** Our results suggest a possible efficacy of salivary gland protectors in TAT-PSMA. However, for toxicity evaluation, prospective clinical trials are required in order to confirm the promising extrapolation showed by our data. **References:** [1] Kratochwill(2017)JNM

Aim/Introduction: Radiohybrid prostate-specific membrane antigen (rhPSMA)-ligands are a new class of theranostic radiopharmaceuticals currently under evaluation in patients with prostate cancer. Based on in vitro data the single isomer rhPSMA-7.3 is a promising candidate. We aimed to investigate ^{177}Lu -rhPSMA-7.3 in comparison with established agent, ^{177}Lu -PSMA-I&T, for potential endoradiotherapy in metastatic castration resistant prostate cancer (mCRPC) using pre-therapeutic comparative dosimetry. **Materials and Methods:** Three patients with mCRPC underwent both ^{177}Lu -rhPSMA-7.3 and ^{177}Lu -PSMA-I&T pre-therapeutic dosimetry after injection of 1 GBq of each ligand (mean for ^{177}Lu -PSMA-I&T: 1102.3±99.6 MBq and for ^{177}Lu -rhPSMA7.3: 1004±68.0 MBq). Whole-body scintigraphy was performed at 1h, 4h, 24h, 48h and 7d after administration. Regions of interest covering the whole body, organs of interest, and a total of 3 lymph node and 7 bone lesions were drawn. Organ and tumour masses were derived from pretherapeutic ^{18}F -rhPSMA-7.3 PET/CT. Absorbed doses for individual patients and pretherapeutic cycles were calculated using OLINDA/EXM. The “therapeutic index” defined as the activity in lesions divided by the activity in kidneys was used to compare the two agents in each patient. Subsequent

radioligand therapy was performed with the superior ligand. **Results:** Mean effective doses of ^{177}Lu -rhPSMA-7.3 vs. ^{177}Lu -PSMA-I&T for the whole-body, liver and kidneys were 0.133±0.025 vs. 0.057±0.013 Sv/GBq, 0.134±0.013 vs. 0.053±0.006 Gy/GBq, and 1.680±0.235 Gy/GBq vs. 0.644±0.126 Gy/GBq, respectively. Tumour lesions absorbed a mean of 8.088±8.644 Gy/GBq (range 1.527–29.250 Gy/GBq) using ^{177}Lu -rhPSMA7.3 and a mean of 2.873±2.937 Gy/GBq (range 0.520–9.800 Gy/GBq) using ^{177}Lu -PSMA-I&T. The “therapeutic indices” for ^{177}Lu -rhPSMA-7.3 vs. ^{177}Lu -PSMA-I&T were 1.27 vs. 1.60 for patient 1, 4.74 vs 3.71 for patient 2 and 7.83 vs 7.97 for patient 3, respectively. **Conclusion:** Pre-therapeutic organ- and tumour-absorbed activities for ^{177}Lu -rhPSMA-7.3 are higher than those for ^{177}Lu -PSMA-I&T with a similar increase for tumour lesions and kidneys as the most relevant organ at risk. These clinical dosimetric results hold promise that binding and kinetic characteristics of ^{177}Lu -rhPSMA-7.3 could lead to a similar therapeutic effect without increased side effects at substantial lower activity levels compared with ^{177}Lu -PSMA-I&T. Therefore, future ^{177}Lu -rhPSMA-7.3 radioligand therapy might be performed with lower costs and with potential advantages as a result of lower nuclide demand in case of upcoming shortages. **References:** None

OP-771

Quantitative SPECT imaging for Ac-225-based radionuclide therapy: a phantom feasibility study and first patient trial

A. Gosewisch, **M. Schleske**, **F. J. Gildehaus**, **A. Todica**, **J. Brosch**, **L. Kaiser**, **P. Bartenstein**, **H. Ilhan**, **G. Böning**;
 Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: Ac-225-PSMA therapy is a promising option for patients suffering from metastasized prostate cancer. Although Ac-225 shows a noticeable gamma emission (e. g. 26 % for 440 keV), image-based dosimetry via quantitative SPECT is challenging due to the low therapeutic activities. Further, imaging of the 440 keV photopeak shows a complex detector point-spread-function (PSF), consisting of geometrical response, collimator scatter, and septal penetration. In this study, the feasibility of quantitative Ac-225 SPECT imaging with consideration of a distance-dependent 2D PSF model was investigated via a phantom experiment. Respective results from the simulation study were applied to a first patient case. **Materials and Methods:** A self-made cylindrical phantom (3.5 l) containing three inserts (20, 45, 200 ml), a total activity of 2.8 MBq, and a foreground-to-background ratio of approx. 10:1 was imaged on a Siemens Symbia Intevo T16 system equipped with a HEGP collimator (32 projections p. head, 128x128 pixel, 60 s p. projection, 440 keV +/- 10 %, lower adjacent scatter window (width 10 %)). Quantitative SPECT reconstruction

was carried out via an in-house MAP (15i4s), including CT-based attenuation and DEW scatter correction. Modelling of the collimator-detector-response was achieved via a distance-dependent 2D PSF model (2D-MAP), simulated for distances of up to 70 cm via SIMIND. For a prostate cancer patient, Ac-225 imaging of the abdomen was performed 24 h p. i. of 8.1 MBq Ac-225-PSMA-I&T (16 projections p. head, 128x128 pixel, 210 s p. projection). SPECT reconstruction was performed via the proposed 2D-MAP. The measured kidney uptake was combined with the patient-specific kidney effective half-life of a former Lu-177-PSMA-I&T cycle to derive a respective kidney absorbed dose estimate. **Results:** The phantom experiment resulted in recoveries of 72, 53, and 42 % and signal-to-noise ratios of 33, 24, and 18 for 200, 45, and 20 ml. Regarding the patient case, an absorbed dose of $1.6 \text{ Sv}_{\text{RBE=5}}$ and $1.4 \text{ Sv}_{\text{RBE=5}}$ was estimated for the left and right kidney, respectively (volume: 214 and 180 ml). A small lesion could be identified in the right hip, which was also noticeable in the pre-therapeutic F-18-PSMA-I&T PET/CT. **Conclusion:** Image-based kidney dosimetry for Ac-225 radionuclide therapy is feasible. Further effort has to be spent to improve Ac-225 imaging with regard to dosimetry for salivary glands or lesions, respectively to provide improved lesion detection. Further, a trade-off between image quality and patient examination time is required. **References:** None

OP-772

Patient-specific kidney absorbed doses in mCRPC patients treated with ^{177}Lu -PSMA-617: a post-hoc analysis of a prospective phase 2 study

C. Meyer¹, D. Mirando², T. Adams², D. Ranganathan³, R. Esfandiari⁴, E. Delpassand⁴, J. Czernin¹, J. Calais¹, M. Dahlbom¹;
¹Ahmanson Translational Theranostics Division, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, ²MIM Software Inc, Cleveland, OH, UNITED STATES OF AMERICA, ³Radiomedix, Houston, TX, UNITED STATES OF AMERICA, ⁴Department of Clinical Nuclear Medicine, Excel Diagnostics Imaging Clinic, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: To move towards more personalized PSMA-targeted molecular radiotherapy, dosimetry can be used to devise safe therapeutic activities to deliver maximal tumor doses while delivering as low as achievable doses to non-target volumes. More investigation is needed on the performance of different imaging-based dosimetry methods. The aim of this study was to estimate the absorbed doses in the kidneys, salivary glands, and lesions in metastatic castrate-resistant prostate cancer (mCRPC) patients treated with ^{177}Lu -PSMA-617 using a hybrid approach: one single SPECT/CT and four planar imaging scans. **Materials and Methods:** This is a post-hoc retrospective dosimetry analysis in a cohort of patients treated with ^{177}Lu PSMA-617 who were included in a bi-centric single-arm prospective phase

II trial (NCT03042312). Lutetium-177 gamma imaging was acquired after the administration of the first cycle of ^{177}Lu PSMA (5.9–8.1 GBq): whole body planar imaging at 4h, 24h, 48h, 72h, optional 9 days, and quantitative SPECT/CT at 24h. Image analysis was performed using commercial dosimetry software compatible with the hybrid SPECT and planar data. Kidneys were segmented on SPECT/CT images and the ROIs propagated to the serial planar images for background and activity overlap corrections. Time-activity curves were generated from the biokinetics in the planar images and scaled by the quantitative SPECT counts, followed by multiexponential decay function curve-fitting. Organ-level doses were calculated using a ^{177}Lu dose kernel derived from Monte Carlo simulations. **Results:** 11/51 mCRPC patients (age range 59–76) were included in this preliminary report. Retrospective dosimetry calculations estimated radiation absorbed doses of $2.60 \pm 1.31 \text{ Gy}$ (mean \pm SD) to each kidney, or $0.39 \pm 0.20 \text{ Gy/GBq}$ (range 0.12–0.79 Gy/GBq). This estimate is similar to other reports for ^{177}Lu -PSMA-617 using 3D multi-time point SPECT approaches up to 4 days following treatment (1). **Conclusion:** In mCRPC patients treated with ^{177}Lu -PSMA-617, dosimetry calculations based on a hybrid approach using one single quantitative SPECT/CT (+24h) and serial planar imaging (4h, 24h, 48h, 72h +/- 9 days) estimated kidney absorbed doses of approximately 0.39 Gy/GBq with significant inter-patient variability in absorbed doses. **References:** ¹Violet J, Jackson P, Ferdinandus J, et al. Aim/Introduction: Sorafenib, an anti-angiogenetic drug, is the standard of care in patients with advanced hepatocellular carcinoma (HCC). Due to its poor tolerability, narrow therapeutic effects and high costs, the early identification of patients who can benefit from Sorafenib is important. Aim: to investigate the potential role of PET with ^{13}N -ammonia (perfusion tracer) for evaluating response to Sorafenib (acting on angiogenesis) in patients with advanced HCC (highly vascularized cancer). **Materials and Methods:** Six male patients (mean age: 69.2 ± 6.1 years) with advanced HCC, prospectively enrolled, underwent contrast-enhanced CT and dynamic ^{13}N -ammonia PET (370MBq; 20min) before (baseline) and 8-10 weeks after (post-therapy) the beginning of Sorafenib treatment. Quantitative analysis: VOIs drawn on descending aorta (input function), on up to six HCC lesions and on two normal liver areas using baseline and post-therapy contrast-enhanced CT, and transferred on baseline and post-therapy PET, respectively. For each VOI, K_1 (ml/min/gr) and k_2 (min^{-1}) values were estimated using 1-tissue compartment model. For each patient, ΔK_1 and Δk_2 (percentage changes between baseline and post-therapy PET) in HCC lesions were compared with standard

response, based on clinical evaluation and mRECIST criteria. **Results:** median K_1 and k_2 values were higher in HCC lesions ($n=25$) than in normal liver both at baseline (0.76 vs 0.38, $p=0.0016$ and 0.15 vs 0.05, $p=0.0001$, respectively) and at post-therapy PET (0.62 vs 0.29, $p=0.0002$ and 0.12 vs 0.03, $p<0.0001$, respectively). At standard response assessment, 4/6 patients were classified as “disease control” (3 with stable disease and 1 with partial response) and 2/6 patients as “no disease control” (progression). At post-therapy PET, a reduction in K_1 was observed in all patients; reduction was greater in patients with disease control compared to those with no disease control (mean $\Delta K_1 = -31.7\%$ vs -11.8%). A reduction in k_2 was observed in 5 patients (4 disease control, 1 progression), whereas one patient (progression) showed an increase of k_2 . Overall, a greater change in k_2 was found in patients with disease control than other group (mean $\Delta k_2 = -30.0\%$ vs -9.2%). **Conclusion:** Dynamic ^{13}N -ammonia PET seems a promising tool for evaluating response to anti-angiogenetic drugs used in highly vascularized cancer as HCC. Changes in quantitative parameters observed after treatment are in line with standard response assessment. The evaluation of the role of ^{13}N -ammonia perfusion changes for predicting tumour response is ongoing. This should assume an important clinical relevance in the selection of patients with “no control disease” candidates to Sorafenib discontinuation. **References:** None

OP-779

The Combination of Pretreatment Total Metabolic Tumor Volume on PET/CT and MYC/Bcl-2 Protein Dual Expression Further Improves Prognostic Stratification of Patients with Primary Gastrointestinal Diffuse Large B-cell Lymphoma

C. Jiang¹, C. Ding², Y. Teng³, J. Xu⁴, J. Chen⁵, Z. Zhou¹;
¹Department of Nuclear Medicine, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing Unive, Nanjing, CHINA, ²Department of Nuclear Medicine, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, CHINA, ³Department of Nuclear Medicine, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, CHINA, ⁴Department of Hematology, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, CHINA, ⁵Department of Pathology, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, CHINA.

Aim/Introduction: The aim of the study was to explore whether a combination of pretreatment total metabolic tumor volume (TMTV) and MYC/BCL-2 protein dual expression (DE) would improve the prognostic stratification of primary gastrointestinal diffuse large B-cell lymphoma (PGI-DLBCL) patients. **Materials and Methods:** Eighty-three patients between March 2011 and July 2019, diagnosed with PGI DLBCL without any treatment, were enrolled in this

retrospective study. TMTV on pretreatment PET/CT scans were calculated using the boundaries of voxels presenting a $SUV_{max} \geq 2.5$. Expression patterns of MYC and BCL-2 were detected at protein levels via immunohistochemistry. The distributions of Progression-free survival (PFS) and overall survival (OS) rates were estimated using the Kaplan-Meier method and differences were compared using a log-rank test followed by multivariate analysis using the Cox proportional hazards model. **Results:** During the follow-up period of range between 3–96 months (32.1 ± 19.7 months), high TMTV and DE were significantly associated with a worse PFS ($\chi^2=26.054, P<0.001$; $\chi^2=10.120, P=0.001$) and OS ($\chi^2=1.462, P<0.001$; $\chi^2=3.930, P=0.047$). Both TMTV and DE were each independent predictors of PFS ($P<0.001, P=0.021$), whereas TMTV was the only independent predictor of OS ($P<0.001$). A combination of TMTV and DE allowed for a significantly better division of PGI-DLBCL patients into three groups as follow: low-risk group, intermediate-risk group and high-risk group. **Conclusion:** High TMTV and DE identified a subset of PGI-DLBCL patients with dismal survival outcomes. Furthermore, a combination of TMTV and DE status may further improve the ability of clinicians to stratify PGI-DLBCL patients with differential prognosis. **References:** None

OP-780

Baseline Total Lesion Glycolysis on FDG PET/CT Improves the Prognostic Value of NCCN-IPI in Primary Gastric Diffuse Large B-cell Lymphoma Patients Treated with the R-CHOP Regimen

C. Jiang¹, C. Ding², Y. Teng³, J. Xu⁴, Z. Wang⁵, Z. Zhou¹;

¹Department of Nuclear Medicine, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing Unive, Nanjing, CHINA, ²Department of Nuclear Medicine, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, CHINA, ³Department of Nuclear Medicine, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, CHINA, ⁴Department of Hematology, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, CHINA, ⁵Department of Pathology, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, CHINA.

Aim/Introduction: The aim was to explore whether baseline total lesion glycolysis (TLG) can improve the prognostic value of the National Comprehensive Cancer Network-International Prognostic Index (NCCN-IPI) in patients diagnosed with primary gastric diffuse large B-cell lymphoma (PG-DLBCL) treated with the R-CHOP like regimen. **Materials and Methods:** Ninety-four PG-DLBCL patients who underwent baseline PET/CT between July 2010 and May 2019 were enrolled in this retrospective study. The FDG-avid lesions in each patient were segmented to calculate the maximum standardized uptake value

(SUV_{max}), total metabolic tumor volume (TMTV), and TLG. Progression-free survival (PFS) and overall survival (OS) were used as end points to evaluate patient prognosis. **Results:** During the follow-up period of 5–108 months (35.3 ± 23.5 months), high TLG and high NCCN-IPI were significantly associated with worse PFS and OS. TLG and NCCN-IPI were independent predictors of PFS and OS. The patients were stratified into three groups according to the combination of TLG and NCCN-IPI for PFS ($P < 0.001$) and OS ($P < 0.001$): high-risk group with $TLG > 1159.1$ and an NCCN-IPI score of 4–8 (PFS and OS were 57.7% and 61.5%, respectively, $n = 42$), intermediate-risk group with $TLG > 1159.1$ or an NCCN-IPI score of 4–8 (PFS and OS were both 76.9%, $n = 26$), and low-risk group with $TLG \leq 1159.1$ and an NCCN-IPI score of 0–3 (PFS and OS were 97.6% and 100.0%, respectively, $n = 26$). For patients at stage I/II, the combination of TLG and NCCN-IPI can also be used to stratify the patients. **Conclusion:** Both TLG and NCCN-IPI are independent predictors of the PG-DLBCL patient survival outcome. Moreover, the combination of TLG and NCCN-IPI improved patient risk stratification and might contribute to the ability to personalize therapeutic regimens. **References:** None

OP-781

Dynamic PET Perfusion Imaging in Esophageal Cancer Patients Receiving Radiation Therapy

K. Binzel, E. D. Miller, C. L. Wright, Y. Hsieh, A. Wollett, E. Ives, M. V. Knopp;

The Ohio State University Wexner Medical Center, Columbus, OH, UNITED STATES OF AMERICA.

Aim/Introduction: To assess the utility of dynamic perfusion PET imaging for the evaluation of esophageal tumors over the course of radiation therapy. **Materials and Methods:** Ten patients with esophageal tumors were imaged over one bed position at the site of the primary tumor for 15 minutes immediately following injection of 185 MBq ¹⁸F-FDG. Imaging was performed on a digital photon counting system (Philips Vereos). Patients spent the remaining uptake period in the injection suite followed by whole body imaging at 75 minutes post-injection as standard imaging. Listmode data from the dynamic acquisition were reconstructed with 1 minute per frame. Regions of interest were placed over the primary tumor, aorta, and a portion of healthy liver. Imaging was performed prior to radiation therapy, at a 3 month interim timepoint, and post-therapy, about 6 months after baseline imaging. **Results:** Excellent image quality and quantifiably robust data were produced for all acquisitions. Physiologic motion could readily be corrected for, however very little motion was observed. Differences in perfusion and dynamic uptake patterns in the individual tumors were identifiable. Most patients had tumors with small initial perfusion peaks followed by relatively stable uptake levels over the 15-minute dynamic acquisition. Three such

patients showed marked decreases in tumor uptake curves at both the interim and follow-up, averaging 35% decreases from baseline at both later timepoints. Four patients had similar baseline and interim curves, averaging 18% different at interim compared to baseline. However, these patients then had greater decreases in dynamic uptake at the follow-up timepoint, averaging a 47% decrease. Two patients had increased perfusion and dynamic uptake at the interim, 48% and 12% increases compared to baseline, respectively. At follow-up one of these patients had a continued increase compared to baseline while the other now presented with a 33% reduction as compared to baseline. One patient did have a strong initial perfusion peak and also had similar dynamic curves on all three acquisitions, only 0.6% and 8.5% changed from baseline values. Correlation with pathology results and clinical outcomes is ongoing. **Conclusion:** We have demonstrated that dynamic perfusion FDG PET/CT is robustly achievable. Quantification of tumor features is robust as well as changes in perfusion and uptake during therapy. This PET-based methodology can be applied to assess changes in rates of tumor perfusion and radiotracer uptake over the course of therapy, adding additional insight beyond delayed, static measures of SUV. **References:** None

Utility of ¹⁸F-FDG PET/CT in Management of Pancreatic and Periapillary Masses : Experience of a Tertiary Care Center in South India

C. Singareddy¹, R. Manthri², T. Kalawat², V. Venkatarami Reddy², H. Narendra², B. Vijaya Lakshmi Devi², A. Chowhan²;
¹SVIMS, Tirupati, INDIA, ²Sri Venkateswara Institute Of Medical Sciences, Tirupati, INDIA.

Aim/Introduction: Characterizing a mass lesion in pancreas as benign or malignant on conventional imaging is difficult due to overlapping morphological features. ¹⁸F-FDG PET/CT is a molecular imaging technique that is reported to have higher sensitivity and specificity in the differentiation of benign and malignant pancreatic and periapillary masses. Aim of this study is to study the utility of ¹⁸F-FDG PET/CT in the diagnosis and treatment of pancreatic and periapillary masses. **Materials and Methods:** In this prospective study, we evaluated the utility of ¹⁸F-FDG PET/CT in patients with recently diagnosed pancreatic and periapillary masses. Based on FDG uptake pattern, diffuse or absent uptake was considered as benign and focal increased uptake as malignant. **Results:** Among the 32 patients included in the study, pathological examination confirmed 25 as positive for malignancy and remaining 7 as benign etiology. Based on FDG uptake pattern, sensitivity, specificity, PPV, NPV and accuracy of the study were 92%, 42.8%, 85.2%, 60%, and 81.3% respectively. ¹⁸F-FDG PET/CT had a statistically significant higher detection rate in evaluation of regional lymph nodes and distant organ metastases compared to

radiological imaging. In 7/25 malignant cases, ¹⁸F-FDG PET/CT detected additional distant metastases which were not detected by conventional imaging and thus resulting in their change in management from curative resection to palliative therapy. **Conclusion:** ¹⁸F-FDG PET/CT uptake pattern can characterize pancreatic and periapillary masses as benign or malignant with good accuracy. But it has very limited role in the evaluation of pancreatic solid pseudopapillary neoplasm. Using ¹⁸F-FDG PET/CT for initial staging in pancreatic and periapillary cancer helps in accurate staging and optimal selection of treatment modality compared to conventional imaging techniques. **References:** 1. Can FDG PET/CECT Accurately Restage Hilar Cholangiocarcinoma?

J. Paudel;

Chitwan Medical College, Bharatpur, NEPAL.

Aim/Introduction: To evaluate the diagnostic performance of contrast enhanced F-18 FDG PET/CT in restaging hilar cholangiocarcinoma. **Materials and Methods:** A retrospective analysis of histopathological proven patients with hilar cholangiocarcinoma (age range 33-79 years; mean age 53.52 years; Male/ female 23/11) was performed in 34 patients. All patients had been treated previously with either surgery, radiotherapy or chemotherapy alone or in combination and referred for F-18 FDG PET/CT to rule out residual or recurrent disease. On FDG PET any abnormal tracer uptake with corresponding lesion on CECT was taken as positive. Histopathological examination and clinical or imaging follow up were taken as gold standard. **Results:** Out of the 34 patients, 21 patients were true positive for primary disease. FDG PET/CT detected abnormal FDG uptake in 27 patients. Uptake at the primary site was detected in 15 (44.1%) patients and only metastatic lesions in 11 (32.3%) patients. Out of 15 patients with primary lesions, 12 had adjacent liver involvement, 2 had adjacent pancreas involvement, 6 had regional lymph nodes, 7 had distant lymph nodes involvement, 6 had both regional and distant lymph nodes involvement, 10 had both regional and distant lesions and 6 had only primary lesion. On lesion based analyses in 21 patients with distant metastases, lymph nodes, abdominal wall/muscle metastases, peritoneal deposits, liver, lung,

adrenal, pancreas, omental and mesenteric deposits were noted in 17, 5, 15, 15, 4, 1, 2, 1, 4 patients respectively. Additionally we also detected metachronous primary in the thyroid in 1 patient and confirmed it on histopathology. We found FDG PET/CT sensitivity, specificity, PPV, NPV and accuracy 94%, 56%, 86%, 71% and 93% respectively for residual/recurrence detection ($P < 0.05$). On ROC curve analysis, SUVmax > 2.7 had sensitivity and specificity of 63.8% and 81.4% respectively for detection of residual/recurrent disease on F-18 FDG PET/CT (Area under the ROC curve is 0.729 at 95% confidence Interval (P value 0.0004)). We also observed that there was no correlation between SUVmax and patient survival (Spearman's coefficient rank correlation). **Conclusion:** We concluded that 18F-FDG PET/CT had high diagnostic accuracy for suspected residual/recurrent disease in hilar cholangiocarcinoma patients and also useful in detection of additional metachronous second primary. **References:** None

OP-784

4FMFES and FDG-PET imaging in uterine cancer patients: preliminary assessment

M. Paquette¹, E. Espinosa-Bentancourt¹, É. Lavallée¹, S. Phoenix¹, K. Lapointe-Milot², P. Bessette², B. Guérin¹, É. E. Turcotte¹;

¹Université de Sherbrooke, Sherbrooke, QC, CANADA,

²CIUSSS de l'Estrie-CHUS, Sherbrooke, QC, CANADA.

Aim/Introduction: In order to improve imaging of uterine cancers, other groups explored the use of the estrogen-like [18F]-16 α -fluoroestradiol (FES) PET tracer in the clinical setting. FES tumor uptake was shown to correlate well with the biopsy-determined Estrogen receptor (ER) status in endometrial cancers. However, FES-PET has some shortcomings, including slow blood clearance and rapid metabolism, both factors increasing non-specific signal and hence reducing tumor detectability. In this phase II clinical trial, the metabolism-resistant, ER-targeting molecule, 4-fluoro-11 β -methoxy-16 α -[18F]fluoroestradiol (4FMFES), will be investigated in combination with FDG-PET for the diagnosis of uterine cancer patients. **Materials and Methods:** Uterine cancer patients ($n = 20$) were recruited in the imaging protocol in collaboration with our local gynaeco-oncology department before surgery. All patients harbored ER+ diseases. Among them, 7 patients had endometrial carcinoma, 11 had endometrioid adenocarcinoma, 1 were diagnosed with endometrial intraepithelial neoplasia and 1 had a benign lesion. Patients were scheduled to undertake FDG- and 4FMFES-PET with less than 10 days apart, with injected doses of 3 MBq/kg for each tracer. Tumor uptake for each tracer was reported as SUVMax values, and background proximal to each lesion reported as SUVMean. Shortly before injection of 4FMFES, 15 patients received medication aiming to slow down progression of the radioactive intestinal bolus

toward the lower abdomen resulting from the biliary excretion of the tracer. **Results:** 4FMFES primary tumor uptake ranged between 3.0 and 14.4 (9.7 ± 3.2), whereas FDG uptake spread between 0 and 22.0 (7.2 ± 5.4). One endometrioid adenocarcinoma patient was FDG-negative (4FMFES SUVMax = 9.6). Tumor-to-background ratio were significantly higher ($p < 0.001$) for 4FMFES (17.8 ± 6.4) than for FDG (7.6 ± 5.0). Two of the endometrial carcinoma cases had sentinel node involvement according to pathology assessment that were FDG and 4FMFES-negative, but those nodal lesions were less than 5 mm in size. Tumor uptake for 4FMFES peaks at grade 2, whereas FDG uptake have a trend to increase according to grade. Apparent tumor volume is higher using 4FMFES than FDG in most cases, the latter being more representative of the true tumor size. **Conclusion:** 4FMFES-PET enables high-contrast detection of ER+ uterine tumors, regardless of grade and subtype. Size assessment is better defined using CT and FDG than 4FMFES. 4FMFES-PET is a good companion tracer for FDG-PET and improves diagnostic confidence. **References:** None

Preliminary application of ⁶⁸Ga-PSMA PET/CT in detection of ovarian cancer

M. Xin, L. Xu, Q. Xia, W. Lou, J. Liu;

Renji hospital, School of medicine, Shanghai

Jiao Tong university, Shanghai, CHINA.

Aim/Introduction: The extensive clinical adaptation of prostate-specific membrane antigen (PSMA)-targeted PET imaging has played crucial role in the evaluation of patients with prostate cancer. Meanwhile, PSMA overexpression in neovascular endothelium of some non-prostatic malignancies has motivated novel theranostic applications of anti-tumor strategies. The goal of the study was to explore the value of ⁶⁸Ga-PSMA PET/CT imaging in detection of female ovarian cancer, as PSMA-targeted therapy has showed a promise in treatment of advanced carcinomas. **Materials and Methods:** We prospectively investigated 9 female patients with suspected pelvic occupying diseases (carbohydrate antigen-125 > 35 U/mL) who underwent ⁶⁸Ga-PSMA PET/CT before surgery. The PET/CT scan was performed approximately 1 h after an intravenous injection of 2 MBq/Kg of ⁶⁸Ga-PSMA. Two nuclear medicine physicians independently recorded the sites of PSMA-PET/CT positivity. **Results:** The mean age of patients was 58.3 ± 12.9 years (range: 36-79 years); mean carbohydrate antigen-125 was 1546.2 ± 1825.0 U/mL (range: 63.5-5857.0 U/mL). 5/9 (55.5%) patients displayed bilateral foci, 1 patient presented unilateral lesion, and 3/9 (33.3%) patients had ambiguous pelvic mass. In CT imaging of pelvic primary lesions, 3/9 (33.3%) sites appeared as soft tissue density, and 6/9 (66.7%) presented a solid-cystic type. Determined by postoperative pathology, 6/9 (66.7%) were malignant lesions

including high grade serous carcinoma, endometrioid adenocarcinoma and neuroendocrine carcinoma, 1 case was borderline serous cystadenoma, and 2/9 (22.2%) were benign diseases. ^{68}Ga -PSMA PET/CT showed 100% positive in detecting ovarian malignant and borderline tumors, with an average uptake SUVmax of 7.5 ± 1.6 (range: 6.1–10.1) in the primary lesions, and 7.1 ± 1.4 (range: 5.6–8.7) in the peritoneal metastatic lesions. Less sensitivity of PSMA PET/CT detection was found in lymph node (2 cases) and distant organ metastasis (1 case). **Conclusion:** Our pilot study shows that ^{68}Ga -PSMA PET/CT could effectively detect primary ovarian cancer and peritoneal metastases, rendering it a potential molecular imaging modality in the monitoring and evaluation of advanced ovarian cancer therapies. **Acknowledgements:** This work was supported by grants from National Natural Science Foundation of China (No. 81701725), and Shanghai “Rising Stars of Medical Talent” Youth Development Program (SHDC2012105). **References:** 1. Assessment of radiomic PET analysis in the evaluation of cervical cancer treatment

F. Scalorbi, A. Alessi, G. Centonze, M. Signorelli, G. Calareso, M. Kirienko, A. Lorenzoni, G. Bogani, F. Martinelli, G. Argiroffi, F. Raspagliesi, E. Seregni;
Istituto Nazionale Tumori Milano, Milan, ITALY.

Aim/Introduction: To investigate the possible value of radiomic ^{18}F -FDG-PET/CT analysis in the assessment of neoadjuvant chemotherapy response and post-surgery decision-making in locally advanced cervical cancer of uterus (LACC). **Materials and Methods:** We retrospectively enrolled patients with LACC diagnosis treated with cisplatin-based neoadjuvant chemotherapy (NACT) at our Institute, between 2014–2018. The patients were classified as Ib3-IIb in accordance with clinical FIGO classification. MRI was performed to evaluate the response to treatment and plan the radical surgery. A dedicated radiologist evaluated all the MRI and applied RECIST1.1 criteria defining good-responders (CR, PR > 50%) vs poor-responders (PR < 50%, SD, PD). All the patients performed a PET after NACT on the same tomograph. Primary tumor volume was delineated by a nuclear physician, applying an estimated SUVmax threshold and a semiautomatic algorithm (PET_Tumor_Segmentation_Effect) implemented on 3DSlicer. On the volume of interest, 136 first-second order features were

extracted per patient by Pyradiomics. After hysterectomy, patients were treated with adjuvant therapies or followed-up, according to Sedlis criteria. Wilcoxon's test was performed to compare every feature with NACT response (Outcome1) and post-surgery decision-making (Outcome2). Fisher's test was applied to evaluate possible interaction between FIGO, patient age and outcome1/outcome2 results. Principal component analysis (PCA) was carried out for reducing the dimension of radiomic features and investigate relationships between them. Group differences in the principal components were assessed using Hotelling's T-squared test. **Results:** We enrolled 27 women (mean age 46; range 24–77), 13/27 were classified as Ib3 FIGO, 14/27 as Ila-IIb. According to RECIST1.1, 21 (77.8%) patients were classified as good responders and 6 (22.3%) as poor responders. According to Sedlis criteria, 18 (66.7%) patients were followed-up and 9 (33.3%) were treated with adjuvant therapies. Considering radiomic PET analysis, 26 features resulted significant in distinguishing between responders and non-responders to NACT, 12 features in distinguishing follow-up from neoadjuvant therapy decision (Wilcoxon's test $p < 0.05$). Considering PCA, the first (PC1) and the second (PC2) principal component explained 61.5% and 15.3% of the overall variability, respectively. PC1 had multiple significant positive correlations with 25 features and had negative correlation with 6 features. Evaluating Outcome1, the two principal components were statistically significant in predicting good- from poor-responders ($p = 0.04$). PC2 was significantly correlated to Dependence Non Uniformity Normalized. No statistical differences were found considering Outcome 2. Fisher's test was not significant. **Conclusion:** Radiomic analysis of ^{18}F -FDG-PET/CT performed after NACT can have a role in the assessment of therapy response and post-surgery decision-making. **References:** None

OP-787

18F-FDG PET/CT incidental gynecological uptake: a 8-year retrospective analysis

P. Bellini¹, D. Albano¹, S. Lucchini², F. Motta², A. Peli², M. Bertoli², G. Bosio², E. Cerudelli², M. Gazzilli², F. Dondi¹, A. Mazzeletti¹, A. Calabrò¹, M. Gregorelli¹, M. Bonacina³, F. Bertagna¹, R. Giubbini¹;
¹Nuclear Medicine, University of Brescia, Spedali Civili Brescia, Brescia, ITALY, ²Nuclear Medicine, Spedali Civili Brescia, Brescia, ITALY, ³Nuclear Medicine, Fondazione Poliambulanza, Brescia, ITALY.

Aim/Introduction: Incidentalomas are defined as asymptomatic and unexpected lesions, found during the course of examination and imaging for other reasons and related to a different organ. These lesions can be incidentally detected by several imaging techniques, like PET/CT. The description of an unexpected finding can trigger additional investigations including unnecessary

tests, other diagnostic examinations and sometimes treatments. For this reason, it is crucial to understand when proceeding with further investigations. The aim of this study was to establish the prevalence and the pathological nature of gynecological incidental uptake among patients studied with 18F-FDG-PET/CT between 2008 and 2015. **Materials and Methods:** We have retrospectively evaluated 11000 women who underwent 18F-FDG PET/CT from January 2008 to December 2015. The PET images were analyzed visually and semi-quantitatively by measuring the maximum standardized uptake value (SUVmax) of the gynecological incidentaloma; every focal tracer uptake deviating from physiological distribution and background was considered as suggestive of incidentaloma. Final diagnosis of gynecological incidentaloma was obtained by cytological/histological examination or other imaging examinations. **Results:** Unexpected FDG-uptake in female reproductive organs was found in 158 (1.4%) 18F-FDG PET scan performed in 158 different women (109 in reproductive age, 33 in menopause, 16 with unknown status). 103 focal uptake was reported in uterus, 41 in ovaries and 14 in both sites. In 82 patients gynecological uptake was judged as physiological, in 54 as indeterminate and in 22 as malignant at PET/CT. After subsequent follow-up, 13 incidentalomas were classified as malignant (5 ovarian cancer, 3 endometrial cancer, 2 cervical cancer, 1 non-Hodgkin lymphoma, 2 with unknown origin), 19 as benign (11 fibromas, 2 myomas, 1 leiomyoma, 5 ovarian cysts) and 92 as physiological. In the remaining 34 patients, gynecological incidentaloma was not investigated subsequently. Average SUVmax in malignant lesions was significantly higher than non-malignant (19.64 vs 6.91; $p < 0.001$). No patients with uptake judged as physiological found malignancy after follow-up exams. **Conclusion:** 18F-FDG PET/CT focal incidental gynecological uptake may be a relevant diagnostic reality which requires further investigations. 18F-FDG uptake in female reproductive organs can have many different meanings: PET images related with anamnesis could be effective and specific in characterization of physiological uptake¹. SUVmax was significantly higher in malignant lesion. **References:** ¹ Zhu ZH, Cheng WY, Cheng X et al; Characteristics of physiological uptake of uterus and ovaries on 18F-fluorodeoxyglucose positron emission tomography; *Acta Academiae Medicinae Sinica*, 2007, 29(1): 124-129.

Transthyretin gene mutation carriers: can bone scintigraphy identify disease markers early?

F. Mattana¹, R. Bonfiglioli¹, L. Muraglia¹, A. Paccagnella¹, R. Mei¹, G. Caponetti², G. Saturi², P. Massa², M. Sguazzotti², A. Ponziani², C. Gagliardi², S. Longhi², N. Galiè², S. Fanti¹;

¹Department of Nuclear Medicine, S.Orsola-Malpighi University Hospital, Bologna, ITALY, ²Department of Cardiology, S.Orsola-Malpighi University Hospital, Bologna, ITALY.

Aim/Introduction: Cardiac amyloidosis (CA) caused by amyloid-transthyretin (ATTR) deposition is a progressive and often fatal disease that may be easily underdiagnosed. Carriers are defined as patients with pathogenic transthyretin gene mutation (TTRm), asymptomatic and with no evidence of disease. Technetium-99m-DPD-scintigraphy (99mTc-DPD-S) is an important diagnostic and prognostic tool in amyloidosis patients, but in carriers its role is still unclear, considering that a cardiac uptake (CU) has been described in a few cases. There is no consensus on carriers management due to its wide range of clinic presentation, penetrance and clinical progression, but an early diagnosis is important above all considering that new specific therapies are now available. The present study was designed to evaluate the role of 99mTc-DPD-S in TTRm carriers management. **Materials and Methods:** We enrolled 50 consecutive patients with TTRm from 2004 to 2019. All patients underwent 99mTc-DPD-S using a dual-head camera (ECAM, Siemens Medical Systems; Discovery NM/CT 670, GE Healthcare), according to EANM guidelines. Visual image analysis was performed in consensus by two experienced nuclear medicine physicians blinded to all other patient data. Visual scoring of CU was scored on planar images using a scoring system (Perugini score). All patients were analysed at cardio lab using echocardiography, electrocardiography and, when diagnosis was unclear, with cardiac magnetic resonance. **Results:** In this group of TTRm carriers, 40 patients (23 female/27 male; group A) did not show myocardial tracer uptake (MTU), whereas 10 patients

(4 female/6 male; group B) showed MTU (Perugini score: mild in 3 case, moderate in 5, strong in 2 for operator one; mild in 4 case, moderate in 3, strong in 3 for operator two). In group B, cardio lab tests were normal at the time of the first positive scintigraphy; in all these patients a diagnosis of CA was settled within 3,5 years. When CU was not present, the patients showed no signs of cardiac amyloidosis after a median follow-up of 3,6 years. **Conclusion:** Our study, with the highest number of TTRm carriers, showed that ^{99m}Tc -DPD-S could play an important diagnostic role also in TTRm carriers with a high prognostic value and impact on the clinical management. In non Val30Met patients, the CU seems to be not correlated with a specific gene mutation, though some mutations seem to be correlated with a worst scintigraphic/clinical progression within 1 or 2 years. **References:** None

Evaluation Of The Regional Distribution Of ^{99m}Tc -DPD In The Left Ventricle In Patients With Transthyretin Cardiac Amyloidosis

N. Martínez Amador¹, I. Martínez-Rodríguez¹, A. Sánchez-Salmón¹, R. Quirce¹, J. Jiménez-Bonilla¹, M. de Arcocha-Torres¹, S. Ruiz-Llama¹, G. Molina-Mendoza¹, O. Cuenca-Vera¹, J. Andrés-Pacheco¹, A. Gutiérrez-González¹, M. J. Zarauza-Navarro², I. Banzo¹;

¹Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN, ²Cardiology Service. Marqués de Valdecilla University Hospital, Santander, SPAIN.

Aim/Introduction: To know the regional distribution of ^{99m}Tc 3,3-diphosphono-1,2-propanodicarboxylic acid (^{99m}Tc -DPD) in the left ventricle of patients diagnosed with transthyretin cardiac amyloidosis (TTR-CA). **Materials and Methods:** This retrospective study included 60 patients (12 women, mean age 79.5 ± 10.6 years) diagnosed with TTR-CA, in whom a bone scintigraphy (whole-body scan in anterior and posterior projections and chest SPECT) were carried out 2-3 hours after the i.v injection of 740 MBq ^{99m}Tc -DPD. Images of cardiac uptake were first assessed visually by two nuclear medicine specialists according to Perugini score system (grade 0: absent cardiac uptake and normal bone uptake, grade 1: mild cardiac uptake inferior to bone uptake, grade 2: moderate cardiac uptake associated with attenuated bone uptake, and grade 3: strong cardiac uptake with mild or absent bone uptake). Grades 2 and 3 were considered as positive for TTR-CA. Then, a semiquantitative analysis was performed using standardized 20-segment polar maps of the left ventricle to assess the amyloid burden in the left ventricle. **Results:** On visual analysis, 51/60 (85%) patients had grade 3 cardiac uptake and 9/60 (15%) patients had grade 2 cardiac uptake. According to polar maps, 50/51 (98%) patients included in

the grade 3 group showed greater uptake in the septum wall: inferoseptal-mid (23/51), inferoseptal-apical (19/51), anteroseptal-mid (6/51) and anteroseptal-apical (2/51) segments. In 1/51 (2%) patient, the highest uptake was observed in the inferior-apical segment. On the other hand, 7/9 (77.8%) patients included in grade 2 group showed greater uptake as well in the septum wall: inferoseptal-mid (4/7) and inferoseptal-apical (3/7) segments. In 2/9 (22.2%) patients, the highest uptake was also found in the inferior-apical segment. Globally, the semiquantitative analysis revealed that the septal segments had the highest uptake, with a mean value 82.5 ± 10.2 for grade 3 group and 74.5 ± 3.5 for grade 2 group. These mean values had statistically significant differences with the remaining left ventricular segments ($p = 0.02$ for grade 3 and $p = 0.03$ for grade 2). **Conclusion:** Patients with TTR-CA and Perugini score grade 2 and 3 showed a higher percentage of ^{99m}Tc -DPD uptake in septum wall segments than in the remaining segments of the left ventricle, suggesting a relationship with the amount of amyloid fiber deposit, the ventricular wall involvement, and, finally, the cardiac dysfunction. **References:** None

OP-791

Quantifying Right Ventricle Uptake Of ^{99m}Tc -DPD In Cardiac Transthyretin Amyloidosis Through SPECT/CT. Preliminary Results In A Single Center

J. Rodríguez Gomez¹, F. Ferrando-Castagnetto², C. Wakfie Corieh¹, M. Pedrera Canal¹, M. Ollarves Carrero¹, M. Meneses Navas¹, J. Diz³, E. Silvera⁴, A. Zamarrón¹, Y. Santero¹, M. Pérez Castejón¹, J. Carreras Delgado¹;

¹Servicio de Medicina Nuclear, Hospital Clínico San Carlos, Madrid, SPAIN, ²Departamento de Cardiología-CCVU, Hospital de Clínicas, Facultad de Medicina, Universidad de la República., Montevideo, URUGUAY, ³Instituto Cardiovascular, Hospital Clínico San Carlos, Madrid, SPAIN, ⁴Departamento de Medicina Nuclear, Hospital de Clínicas, Facultad de Medicina, Universidad de la República, Montevideo, URUGUAY.

Aim/Introduction: To characterized the right ventricle (RV) involvement in consecutive ATTR-CA patients referred to ^{99m}Tc -DPD scintigraphy with the aid of SPECT/CT quantified parameters. Myocardial uptake of phosphate bone-seeking radiotracers like ^{99m}Tc -DPD are remarkably sensitive for detecting transthyretin cardiac amyloidosis (ATTR-CA). However, the diagnosis of cardiac amyloid deposit has mainly relied on the tracer affinity for left ventricular (LV) mass. **Materials and Methods:** Images were acquired in a sample of consecutive patients with ATTR-CA through a dual head hybrid SPECT/CT camera. Heart/Contralateral Lung ratio activity (H/CL) and Perugini graded score were obtained in each case. Cardiac SPECT/CT images were processed to quantify RV involvement. A dedicated processing protocol was systematically applied to compare inter and intraventricular activities using grounded ROIs of

12–16 pixels as maximal counts in RV/maximal counts in LV septum (RV/LVsept) in attenuation corrected (AC, applying iterative and filtered back projection methods) and non-corrected (NC) images. The site of maximal activity in RV was also documented. The relation between RV scores and H/CL ratio was estimated for NC and AC images through linear regression analysis. **Results:** Eleven consecutive patients with diagnosed ATTR-CA based on expert consensus criteria were included; 91% males, 70–92 years, 9/11 with isolated ATTR-CA and 2/11 with combined TTR and light chain CA. The H/CL score was 2.9 ± 0.5 , grade 3 = 91% and LVEF was $49.0 \pm 14.8\%$. The percentage of LV mass showing a tracer activity of at least 40% was $24.3 \pm 17.5\%$. Although ECHO and cardiac nuclear resonance found RV hypertrophy and/or dysfunction in 40% of patients, myocardial uptake of ^{99m}Tc -DPD in RV was detected in all patients through SPECT/CT, mainly distributed on its anterior free wall. The RV/LVsept activity ratio tended to be associated inversely with H/CL ratio, especially when considering AC images. The best fit line was obtained after processing AC images by filtered back projection method (p -value = 0.07). **Conclusion:** RV involvement is a constant finding in patients with ATTR-CA, as previously reported in cardiac nuclear resonance case series. A trend toward more pronounced amyloid deposit in patients with greater activity in septal LV supports the hypothesis of a late RV involvement during slow natural course of ATTR-CA. The potential prognostic value of different patterns of biventricular myeloid deposit applying several image processing protocols deserves further evaluation. **References:** None

OP-792

Incidental Disphosphonate cardiac Uptake In Bone Scintigraphy As A Recommendation For Cardiological Monitoring

J. Bonilla, M. Gomez Martinez, L. Rincon, O. Ajuria, P. Azpeitia, I. Lopez Villar, P. Jane, M. Rioja, M. Orduña Diez; Hospital Ramón y Cajal, Madrid, SPAIN.

Aim/Introduction: Imaging techniques have taken center stage in diagnostic algorithms for cardiac transthyretin amyloidosis (ATTR), eliminating the need for invasive tests. Scintigraphy with diphosphonates has become the diagnostic technique of choice. Our purpose is to analyze the frequency of incidental appearance of cardiac radiopharmaceutical uptake in patients undergoing bone scintigraphy for neoplastic or traumatic pathology and its relationship with concurrent cardiovascular pathology. **Materials and Methods:** ^{99m}Tc HDP bone scintigraphy performed from 2001 to 2018 with significant myocardial deposits (Perugini grade 2–3) were retrospectively analyzed. The mean time elapsed since the examination was 5.5 ± 3.3 years. The follow-up of patients was performed by reviewing the medical history. The incidental finding of significant

cardiac uptake appeared in 74 patients (85% male; mean 83 ± 5 years). Most of them had attended the prostate cancer extension study (75.7%). **Results:** During follow-up, 76% of patients with significant deposits presented cardiovascular pathology: congestive heart failure with different degrees of myocardial hypertrophy on echocardiogram (53%), conduction disorders (12%), ischemic heart disease (4%) or mixed (7%). In the rest of the patients, the existence of cardiovascular pathology was not found. None were diagnosed with cardiac amyloidosis nor received specific treatment. Mortality was 52% (71% cardiovascular) during this period. **Conclusion:** Patients with significant myocardial radiopharmaceutical deposits in ^{99m}Tc HDP bone scintigraphy, even as an incidental finding, present a high frequency of concurrent cardiovascular disease. Given the possibility of ATTR once this deposit has been detected, we should recommend starting assessment and follow-up by Cardiology given the current possibility of using new treatments that may change the natural history of this pathology. **References:** None

OP-793

Optimising myocardial suppression and diagnostic confidence in cardiac ^{18}F -FDG PET/CT by adding a high-fat, low-carbohydrate dietary preparation

M. Naik, K. L. Wallitt, S. R. Khan, L. Alves, C. Bowen, W. E. Svensson, N. D. R. Soneji; Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Cardiac ^{18}F -FDG PET/CT (cPET/CT) is used in the assessment of active myocardial inflammation in cardiac sarcoidosis (CS). Several preparation techniques to suppress physiologic myocardial activity are described, including the implementation of a high-fat, low-carbohydrate (HFLC) diet before an extended fast. This study assesses whether the addition of a HFLC diet decreases physiologic myocardial activity, thereby increasing diagnostic confidence of the cPET/CT studies.

Materials and Methods: A preliminary retrospective review of cPET/CT for CS was performed before and after the addition of a HFLC diet. Patients with diabetes, taking steroids or administered with heparin were excluded. Group 1 patients had an 18-hour fast pre-cPET/CT. Group 2 patients followed an additional 12-hour HFLC diet prior to the 18-hour fast. Ten consecutive cPET/CT studies in each group were independently reviewed by 3 nuclear medicine consultants. Myocardial suppression was graded as excellent, moderate or poor as per 2017 SNMMI-ASNC guidelines. Background myocardial uptake was visually compared with left ventricular blood pool activity (below, similar to, above or significantly above blood pool). Overall interpretation of the findings (positive, negative or indeterminate for active myocarditis) was recorded.

Confidence of interpretation was graded using a five-point scale (very low-very high). **Results:** There were 30 reads in each Group. In Group 1, background myocardial suppression was excellent in 9/30 (30%), moderate 5/30 (17%) and poor 16/30 (53%) with a significant improvement in Group 2 ($p < 0.04$ for each reviewer independently); excellent 25/30 (83%) and moderate 5/30 (17%) with no cases interpreted as poor. Background myocardial uptake was below blood pool activity in only 5/30 (17%) in Group 1 compared to 23/30 (77%) in Group 2 ($p < 0.02$ for each reviewer). There were more cases interpreted as 'indeterminate' in Group 1 (15/30; 50%) compared to Group 2 (2/30; 6%), statistically significant for 2/3 reviewers. Reviewers also scored improved diagnostic confidence in interpretation in Group 2 with confidence scored as high or very high in 25/30 (83%) compared to 11/30 (37%) in Group 1, again significant for 2/3 reviewers. **Conclusion:** These preliminary results suggest significantly improved myocardial suppression, fewer indeterminate studies and increased confidence in the interpretation of cPET/CT studies for CS following addition of a HFLC diet before an extended fast. A further 100 cPET/CT studies will be reviewed with presentation of full results and statistical analysis. **References:** Joint SNMMI-ASNC Expert Consensus Document on the Role of 18F-FDG PET/CT in Cardiac Sarcoid Detection and Therapy Monitoring. J Nucl Med. 2017.

OP-794

Dietary compliance and interpretability of ^{18}F -FDG PET-CT scans in diabetic population evaluated for cardiac sarcoidosis

K. Wechalekar, S. Clark, S. Hatipoglu, S. R. Underwood, G. Keramida, A. Maenhout, R. Sharma, V. Kouranos;
Royal Brompton and Harefield NHS Foundation
Trust, London, UNITED KINGDOM.

Aim/Introduction: ^{18}F -FDG PET-CT has important role in cardiac sarcoidosis (CS) with special dietary and fasting preparation to suppress normal myocardial uptake. If the preparation protocol is adhered to, only inflamed myocardium shows FDG uptake. Achieving appropriate preparation can be difficult in diabetes mellitus (DM) and there is less clarity on how it impacts on interpretation of images. We retrospectively analysed DM patients over last 7 years from electronic records. These were compared to age matched non-DM patients. We assessed the ability of reporters to confidently identify cardiac inflammation in these populations. **Materials and Methods:** Our preparation protocol for CS involves no carbohydrate diet- 1 day before the scan followed by 18 hours of fast. For DM patients the instructions include taking OHA or Insulin with food and avoid the doses during fasting period. Dietary preparation was extended for 48 hours in 2 Type II DM patients since the blood glucose levels were higher than 12mM/l. If

preparation was not followed, scan was rescheduled. We identified 100 PET-CT scans in patients with a history of DM (Type I, II) referred for diagnosis or disease monitoring of CS between 2012-2019 at our institution. Average age 59 (38-80, median 58) years. 100 age matched non-DM scans, average age 57 (range 30-81, median 57) years on non-DM patients suspected for CS were analysed for comparison. **Results:** Out of 100, 97 scans with Type II DM, 3 scans were with Type I DM. 4 Patients were on diet control, 60 oral hypoglycaemic agents (OHA) and 33 on insulin. Out of 100 studies, 54 studies had no uptake in heart (negative for CS), 36 studies showed abnormal uptake in heart (positive) and 9 patients showed non-specific uptake (low-grade uptake in basal lateral wall) and 1 patient had protocol failure (intense homogeneous uptake in LV myocardium only) making 10% non-compliant. 7 patients had blood glucose level higher than 10mM/lit but scans were interpretable in 6 with 5 negative, 1 positive but 1 non-specific uptake due to suspected inadequate suppression. In the non-DM group, 50 negative, 32 positive, 14 with nonspecific uptake and 4 clear dietary non-compliance (18%) **Conclusion:** Compared to the DM population, non-DM patients had more failures with dietary compliance for CS assessment with FDG PET-CT scans. This is possible since diabetics are more aware of dietary composition, specially carbohydrates and are more likely to understand the preparation than nondiabetic patients. **References:** None

OP-795

Preliminary Results of ^{18}F -FSPG PET/CT in Patients Referred for Exclusion of Active Cardiac Sarcoidosis after Non-Contributory ^{18}F -FDG PET/CT

A. Iagaru, H. Duan, L. Baratto, S. S. Gambhir, R. Witteles;
Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: ^{18}F -FDG PET is recommended for the assessment of active cardiac sarcoidosis; however, up to 1/3 of patients fail to follow the required complex dietary restrictions, resulting in non-diagnostic scans. ^{18}F -labeled FSPG, an L-glutamate derivative, is a promising radiotracer for PET imaging of the amino acid antiporter system xC- that is involved in detoxification processes and balancing oxidative stress, including in sarcoidosis. No dietary restrictions are required prior to ^{18}F -FSPG PET. Here we evaluated the utility of ^{18}F -FSPG PET for assessment of cardiac sarcoidosis, in comparison to negative, equivocal or non-diagnostic ^{18}F -FDG PET. **Materials and Methods:** Patients referred to Nuclear Medicine to rule out active cardiac sarcoidosis were prospectively enrolled after the ^{18}F -FDG PET/CT results were negative, equivocal or non-diagnostic. ^{18}F -FSPG whole-body imaging started 46-83 minutes (mean \pm SD: 56.3 \pm 8.8), while dedicated cardiac imaging started 55-99 minutes (mean \pm SD: 70.29.9) after injection of 7.1-8.9 mCi (mean \pm SD: 8.1 \pm 0.4). The mean

delay time between F18-FDG PET and F18-FSPG PET was 23.3 days. A state-of-the-art SiPM-based PET/CT scanner (GE Discovery MI) was used for all scans. **Results:** Data from 6 women and 13 men, 32–79 year-old (mean±SD: 58.5±12.3) were collected. Eleven of the 19 participants had no F18-FDG uptake compatible with cardiac sarcoidosis; 2 of the 11 had F18-FDG uptake in lung nodules and mediastinal lymph nodes, while 4 of the 11 had F18-FDG uptake in mediastinal lymph nodes compatible with sarcoidosis. F18-FSPG uptake was seen in the lung nodules and mediastinal lymph nodes in the same 6 participants with F18-FDG uptake, while no F18-FSPG uptake was identified in the myocardium. Seven patients had non-diagnostic cardiac F18-FDG PET due to non-compliance with dietary instructions and 1 patient had equivocal findings; F18-FDG uptake in lung nodules and mediastinal lymph nodes was seen in 1 of these 8 patients. These lung nodules and mediastinal lymph nodes also had F18-FSPG uptake. No F18-FSPG myocardial uptake was identified in the 8 patients with non-diagnostic or equivocal cardiac F18-FDG PET. **Conclusion:** F18-FSPG shows promising results in ruling out cardiac sarcoid involvement in a cohort with negative, equivocal or non-diagnostic F18-FDG PET. The F18-FSPG protocol does not require patient preparation. Further evaluation in larger cohorts is needed to confirm our data. In addition, future studies should evaluate F18-FSPG usage in patients with confirmed active cardiac sarcoidosis. **References:** None

OP-796

Effect of oral corticosteroids on cardiac 68Ga-DOTANOC uptake in inflammatory cardiomyopathy : a proof of concept study

P. Kaushik, C. Patel, S. Seth, P. Gupta;

All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Somatostatin receptor imaging using 68Ga-DOTANOC PET/CT is an emerging technique to assess inflammatory activity in cardiac sarcoidosis and acute myocarditis. We hypothesized that if 68Ga-DOTANOC binds to receptors on inflammatory cells in the myocardium, oral corticosteroids should reduce its uptake by virtue of their immunosuppressant effect. This is a proof of concept study to test the same. **Materials and Methods:** Patients with cardiac sarcoidosis and acute myocarditis were included in the study. Diagnosis of cardiac sarcoidosis was based on revised Japanese Circulation Society criteria and acute myocarditis was diagnosed based on clinical features, endomyocardial biopsy, serum enzyme levels and imaging features. 68Ga-DOTANOC cardiac PET/CT scans done at diagnosis and after oral corticosteroids were analyzed visually and semi quantitatively. SUV_{max} of myocardial region with maximum uptake on visual analysis was calculated at baseline and after corticosteroid treatment. In addition, lesion to blood pool (L/BP) and lesion to remote myocardial (L/M) SUV_{max}

ratios were calculated at both timepoints. The pre- and post-treatment values were compared using paired t test. **Results:** Eight patients (6 male and 2 female) were included in the study (6 with cardiac sarcoidosis and 2 with acute myocarditis). The median duration of steroid intake was 34 weeks. On visual analysis there was reduction in 68Ga-DOTANOC uptake in 7 out of 8 patients. The mean SUV_{max} L/BP and L/M at baseline were 2.2, 2.6 and 2.3 respectively. Post treatment values of the parameters were 1.4, 1.4 and 1.3 respectively. There was significant reduction in values of all three parameters after treatment as calculated by paired t test (p value < 0.005). **Conclusion:** Oral corticosteroids cause a significant reduction in myocardial 68Ga-DOTANOC uptake in cardiac sarcoidosis and acute myocarditis as assessed by visual and semiquantitative analysis. This indirectly indicates that cardiac imaging with 68Ga-DOTANOC indeed measures myocardial inflammation and can potentially be used for monitoring effect of oral corticosteroid treatment. **References:** None

Prognostic role of serial cardiac 18F-FDG PET-MR imaging in Anderson-Fabry disease: preliminary results

C. Nappi¹, A. Ponsiglione¹, A. Pisani², E. Riccio², E. Nicolai³, W. Acampa¹, M. Imbriaco¹, A. Cuocolo¹;

¹Department of Advanced Biomedical Sciences, Federico II University, Naples, ITALY, ²Department of Public Health, Nephrology Unit, Federico II University, Naples, ITALY, ³IRCCS SDN, Naples, ITALY.

Aim/Introduction: Anderson-Fabry disease (AFD) is a rare genetic disorder. Early enzyme replacement therapy (ERT) before irreversible organ injury might lead to better outcome. Cardiac 18F-FDG PET-MR imaging allows different disease patterns identification. The FASTEX score has been proposed for systemic disease progression estimation. We explored the prognostic role of cardiac 18F-FDG PET-MR and its potential relationship with FASTEX score in AFD patients. **Materials and Methods:** We enrolled 16 consecutive AFD patients (8 males, mean age 44±14 years). The FASTEX score was calculated considering the weighted variation of neurological, renal and cardiac parameters across two different temporal points, at baseline and at follow-up (FU). Cardiac 18F-FDG PET-MR imaging was performed at baseline and FU (58±13 months). Left ventricular (LV) volumes, hypertrophy and late-gadolinium enhancement (LGE) patterns were analysed. Focally increased cardiac 18F-FDG uptake indicated active cardiac inflammation. **Results:** From the initial population of 16 patients, 3 patients did not perform FU 18F-FDG PET-MR imaging due to ICD implantation. Therefore, 13 patients underwent both baseline and FU cardiac PET-MR. At baseline, 6/16 patients were already on ERT and among them 5 showed LGE at MR. Of the 9 (69%) patients without LGE at baseline MR that were not under

ERT, 6 demonstrated homogeneous ^{18}F -FDG uptake and 3 focally increased ^{18}F -FDG uptake localised in the infero-lateral region of the LV. At FU scan, while 7/9 patients were on ERT, negative PET-MR imaging findings were observed in all 9 patients, including those 3 demonstrating a focally increased ^{18}F -FDG uptake at baseline. Among the remaining 7 patients showing advanced disease at baseline, PET-MR imaging findings were confirmed at FU in the 4 patients who performed the scan. In the remaining 3 patients who did not undergo the FU scan, ICD implantation indicated disease worsening. With regard to FASTEX score, 2 patients not needing ERT yet, reported a FASTEX score of 0, indicating globally stable disease. Although all the remaining 14 patients showed systemic disease worsening, the FASTEX score was significantly lower in patients without LGE at baseline compared to the 7 patients with evidence of cardiac damage at baseline (41 ± 14 vs. 80 ± 26 ; $P=0.004$). **Conclusion:** ^{18}F -FDG PET/MR is effective in detecting cardiac involvement in AFD at early stage, to timely start ERT, thus improving patient outcome. FASTEX score, indicating systemic disease worsening, is lower in patients without evidence of cardiac fibrosis at baseline scan, highlighting greater benefits of early ERT before irreversible damage occurs. **References:** None

OP-798

Immune checkpoint inhibitor therapy affects inflammatory activity in large arteries - a retrospective analysis using 18[F]-FDG PET/CT imaging

R. Calabretta, C. Hoeller, V. Pichler, M. Mitterhauser, G. Karanikas, A. Haug, X. Li, M. Hacker;
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Besides typical cardiovascular risk factors, cardio-toxicity induced by antineoplastic drugs remains a critical issue. Cancer immunotherapy with immune checkpoint inhibitors (ICIs), such as monoclonal antibodies targeting PD-1 (Nivolumab, Pembrolizumab), PD-L1 (Atezolizumab), or CTLA-4 (Ipilimumab), stimulates previously inactivated cytotoxic T-cells to recognize and target cancer cells. Interference with the CTLA-4 and PD-1 axes can cause immune-related adverse events, which in some cases leads to serious and potentially fatal cardiovascular toxicity. PD-1/PD-L1 and CTLA-4 chemokine axes play important roles in limiting T-cell mediated autoimmune inflammation. The effect of T-cells produces large amounts of pro-atherogenic cytokines that may contribute to both the growth and destabilization of atherosclerotic plaques, suggesting cancer patients receiving ICIs therapy may be at an increased risk for atherosclerotic cardiovascular or cerebrovascular events. Previous studies suggested that PET/CT with ^{18}F -Fluorodeoxyglucose (FDG) is a valid tool to assess and to reliably quantify atherosclerotic inflammatory activity by evaluating the glucose

metabolism of corresponding immune cells and predicted severe cardio- and cerebrovascular events in oncological patients. **Materials and Methods:** 20 patients with melanoma treated with ICIs and available FDG PET/CT scans before and during/after treatment have been retrospectively analyzed. FDG maximum focal uptake in the arterial walls was evaluated visually and maximum standardized uptake values (SUV_{max}) were derived by placing 1 cm³ volumes of interest (VOIs) along six artery segments (ascending aorta, aortic arch, descending and abdominal aorta, iliac arteries). For bloodpool correction of FDG, three cubic VOIs (1 cm³) were placed within the lumen of the superior vena cava and the mean SUV was calculated as SUV_{bloodpool}. Target-to-background ratios (TBRs) were calculated by correcting SUV_{max} and SUV_{mean} values for SUV_{bloodpool}. As surrogate markers of systemic immune cell activation, FDG uptake was also measured in bone marrow and in spleen before and after ICIs therapy. **Results:** Cancer immunotherapy with ICIs resulted in a significant increase of inflammatory activity in 318 measured lesions of both the aorta and the iliac arteries (mean TBR_{max_pre} = 2.18 ± 0.84 vs. mean TBR_{max_post} = 3.46 ± 0.4 ; $p < 0.05$). FDG uptake measured before and after ICIs therapy in bone marrow and in spleen did not show statistical differences (SUV_{max_bonemarrow_pre} = 2.38 ± 0.53 vs. SUV_{max_bonemarrow_post} = 2.55 ± 0.83 , $p = 0.15$; SUV_{max_spleen_pre} = 3.76 ± 1.14 vs. SUV_{max_spleen_post} = 3.67 ± 1.14 , $p = 0.42$). **Conclusion:** Significantly increasing FDG-uptake in the large arteries is pointing towards an induction of inflammatory activity after cancer immunotherapy with ICIs and might cause increased cardio-/cerebrovascular complications. **References:** None

OP-799

SPECT-CT Optimimization of Lung Perfusion Quantification

S. Menendez Sanchez, E. Carrillo Villamizar, A. Cardozo Saavedra, R. Bellviure Meiro, S. Aguade, J. Castell;
Hospital Universitario Vall d'Hebron, Barcelona, SPAIN.

Aim/Introduction: The aim was to compare the presurgical lung perfusion quantification using planar geometric means of the upper and lower lung halves with that of SPECT-CT 3D anatomical lung lobes segmentation. **Materials and Methods:** 58 patients (mean age 64.5 years /17 women) from the thoracic surgery department were selected for pre-surgical quantification and subsequent surgery planning. Planar and SPECT-CT lung perfusion images were acquired with $^{99\text{m}}\text{Tc}$ -MAA on a GE Discovery

670 gamma camera. Geometric means of the upper and lower half of each lung (Lung Analysis, Xeleris GE) were used to quantify planar images (anterior and posterior acquisition) and (Q-Lung, Xeleris GE) was used to delineate each lung lobe on the CT and obtaining the lobar activity in perfusion images. Planar and SPECT-CT quantifications were compared by Student's T for paired data, considering p value < 0.05 as statistically significant. **Results:** Global planar quantification found an average uptake of the right lung (RL) of $52\% \pm 11.3$, compared to the left lung (LL) of $48\% \pm 11.3$. Global SPECT-CT quantifications results were: RL $52.3\% \pm 11.9$ and LL $47.6\% \pm 11.9$ (p ns). The planar halves subdivision results were: upper right $24.5\% \pm 7.4$, lower right $27.5\% \pm 7.5$, upper left $24.3\% \pm 5.9$ and lower left 23.8 ± 7.7 . Anatomical lobe based quantification was: right upper lobe (RUL) $17.4\% \pm 7.5$, Right middle lobe (RML) $9.9\% \pm 5.1$, right lower lobe (RLL) $25\% \pm 9\%$, left upper lobe (LUL) $47.6\% \pm 11.9$ and left lower lobe (LLL) $24\% \pm 7.8$. Significant difference ($p < 0.001$) was obtained in RL delimitation: the upper half against RUL and the lower half against the sum of RML and RLL. No significant differences were found on LL. Planar method did not identify the functional contribution of each lobe. **Conclusion:** SPECT-CT anatomical lung lobes delineation allows more accurate quantification of the functional contribution of each lung lobe to predict the effect of surgical resection. **References:** None

Pulmonary Ventilation / Perfusion Scintigraphy In Patients With Chronic Thromboembolic Disease With And Without Confirmed Pulmonary Hypertension. A Clinical-Radiological Prediction

J. Cañadas Salazar¹, F. Gómez-Caminero López¹, P. García-Talavera San Miguel¹, P. Álvarez-Vega², J. G. Villanueva Curto¹, A. C. Peñaherrera Cepeda¹, C. Riola Parada¹, M. P. Tamayo Alonso¹, S. Cadenas Menéndez¹;

¹Sacyl, Salamanca, SPAIN, ²SESPA, Gijón, SPAIN.

Aim/Introduction: To compare the findings of the ventilation / perfusion scintigraphy (V / Q) in patients diagnosed with chronic pulmonary thromboembolism (CTEP) with confirmed pulmonary hypertension (PH) and patients with CTEP without PH and its possible associations with the main pulmonary artery diameter (mPA) and functional classification (FC) of the patient according to NYHA score. **Materials and Methods:** We reviewed 387 lung perfusion and ventilation scans of patients with suspected chronic PE performed from July 2015 to October 2019. Visual analysis of each of the studies was performed by an experienced nuclear medicine physician, we observed 43 of the patients with suggestive scintigraphic criteria of CTEP, of which 15 were clinically and radiologically diagnosed with PH. The total number of visualized defects (nTD) was gathered in each of these, the mPA measurement was performed on

a CT with contrast (Iohexol) in the axial plane, and later the functional clinical data of the patients was required to clinical medicine. **Results:** After conducting normality tests and showing an asymmetric distribution in the variable nTD and symmetric in mPA and FC, the results are described based on the interpretation of the total defects in the scintigraphy, in which no statistically significant association was found using Spearman's coefficient of correlation between nTD and mPA ($p: 0.82$) or CF ($p: 0.85$). **Conclusion:** Our study shows that greater scintigraphic involvement in patients with CTEP is associated with a trend of higher risk of developing HP and, apparently, a worse functional class. Although without statistical correlation, probably due to the sample size, the V / Q scan is a key test in the evaluation of chronic thromboembolic disease. **References:** None

OP-801

⁷⁵Se-SeHCAT test in bile acids malabsorption.

Methodological contributions

A. Bronte, J. Bastidas, J. Rosales, F. Grisanti, J. Zuaznabar, M. Herraiz, J. Richter;
University Clinic of Navarra, Pamplona, SPAIN.

Aim/Introduction: To evaluate the kinetics of ⁷⁵Selenium-homocholeic acid taurine (⁷⁵Se-SeHCAT) during the first 3 hours after oral administration and predict its association with the abdominal retention of ⁷⁵Se-SeHCAT measured after 7 days (AR₇). Moreover, to describe the results obtained in our center in the diagnosis of bile acids malabsorption (BAM). **Materials and Methods:** A total of 38 patients with chronic diarrhea were evaluated. Imaging protocol included abdominal static projections performed at 1, 2 and 3 hours and the 7th day after oral administration. 1 to 3 hours images determined 6 uptake patterns of ⁷⁵Se-SeHCAT enterohepatic recirculation: gallbladder at 3 hours, gallbladder-abdominal at 3 hours, gallbladder at 2 and 3 hours, lower abdominal at 3 hours, abdominal at 3 hours, upper left abdominal. The association of these patterns with the AR₇ (Fisher, STATA) were investigated. Patients were classified as non-MAB (AR₇>15%), mild-BAM (AR₇<15-10%), moderate-BAM (AR₇<10-5%), severe-BAM (AR₇<5%). The clinical characteristics of each patient such as digestive surgery (DS), intestinal biopsy, digestive pathologies and treatments (Trt) were collected. **Results:** In total 38 patients were included, 23 women and 15 men, age 18-81 years. Half patients (19/38) had an AR₇ diagnostic of BAM (7 mild-BAM, 5 moderate-BAM, 7 severe-BAM), and the other half had a non-BAM AR₇. In the BAM group, intestinal biopsy was performed in 7 patients in which 2 had an organic cause; 6 had a DS; 1 had pancreatic insufficiency and 1 received Trt with lenalidomide. 16/19 received standard Trt with cholestyramine (symptoms improved in 13 of them and clinical follow up is pending in 3 of them). In the non-BAM group 11 patients had another diagnosis confirmed.

Patients with MAB had a statistically significant association with “gallbladder-abdominal at 3 hours” uptake pattern ($p=0.008$), while patients with non-BAM had a statistically significant association with “gallbladder at 2 and 3 hours” uptake pattern ($p=0.02$). **Conclusion:** ^{75}Se -SeHCAT diagnosed MAB in 50% of patients, of which 47.37% had digestive pathologies. Gallbladder and abdominal uptake pattern at 3 hours was associated with the posterior diagnosis of MAB. Symptoms improved in 81.25% of the patients treated with cholestyramine. **References:** None

OP-802

Prevalence of Bile Acid Malabsorption Diagnosed by ^{75}Se HCAT Retention Test in the Last Decade at the Bellvitge University Hospital

M. Pudis, P. C. Notta, A. Sabaté-Llobera, J. Suils, M. T. Bajen, A. Rodriguez-Gasen, J. Guardiola, M. Cortés; Bellvitge University Hospital, Barcelona, SPAIN.

Aim/Introduction: Bile acid malabsorption (BAM) is a cause of several gut-related problems, the main one being chronic diarrhoea (CD). The purpose of this study was to evaluate the prevalence of BAM in patients with long lasting CD by performing a 75-selenium homotaurocholic acid retention test (^{75}Se HCAT). **Materials and Methods:** A retrospective assessment (from 2010 to 2018) of 2184 patients with long lasting (> 1 year) CD in whom a primary programme for diagnostic evaluation had not revealed a cause. The ^{75}Se -SeHCAT abdominal retention was measured in these patients, after 7 days of ^{75}Se HCAT capsule ingestion (370 kBq). A retention value (RV) of $\leq 10\%$ was considered diagnostic of BAM. A severity classification into mild ($\leq 10\%$), moderate ($\leq 8\%$) and severe ($\leq 4\%$), based on retention values on the seventh day, was applied. **Results:** MAB was the most common diagnosis in these patients. Out of 2184 patients studied, 946 (43.3%) had a RV of $\leq 10\%$. When classified by severity, 554 patients (58.5%) had mild, 323 (34.2%) moderate and 69 (7.3%) severe MAB. The second most prevalent diagnosis was irritable bowel syndrome (IBS), diagnosed in 359 patients (16.4%). **Conclusion:** This study reveals that the ^{75}Se HCAT retention test should be performed in all the patients with long lasting CD with an unknown cause because MAB is the most common diagnosis in this group of patients. IBS represents the second most common cause. **References:** None

OP-803

^{75}Se HCAT scan in chronic diarrhea for bile acid malabsorption: update of an Italian single center experience

N. Fraccascia¹, E. Tabacchi¹, L. Zanoni¹, G. Barbara², V. Stanghellini², M. Bortolotti², L. Rotondo², M. Levorato¹, R. Bonfiglioli¹, S. Fanti¹;

¹Nuclear Medicine-DIMES University of Bologna, S.

Orsola-Malpighi Hospital, Bologna, ITALY; ²Department of Digestive Diseases, University Hospital S. Orsola; DIMEC, University of Bologna, Bologna, ITALY.

Aim/Introduction: Bile acid malabsorption (BAM) is a common and likely under-diagnosed and under-treated cause of chronic diarrhea. Diagnosis of BAM can be confirmed using 75 Selenium homotaurocholic acid test (^{75}Se HCAT), a tool which is not consistently part of the diagnostic flow-chart, although regularly licensed in Italy, and remains unavailable in most centers and underutilized. The aim of our study was to update our experience with the use of ^{75}Se HCAT test.

Materials and Methods: A retrospective analysis on patients (pts) who routinely underwent ^{75}Se HCAT in our Nuclear Medicine Unit was conducted. ^{75}Se HCAT procedure was performed following the current standard prescribing information. According to 7-day retention, BAM status was reported as: normal >15% (borderline 15-20%), mild 10-15%, moderate 5-10%, severe <5%. Records detailing i.e. clinical history, results, treatment and clinical follow-up were collected. **Results:** Overall 64 pts underwent ^{75}Se HCAT test in our Center (November 2017-January 2020): 32 F and 32 M; mean age 44 years (median 42, range 17-80); pts were referred by local gastroenterologists with clinical suspicion of BAM for chronic diarrhea without a recognizable cause by traditional diagnostic test (42/64, 65%) or IBS-D not responder to standard medications (17/64, 26%) (5/64: not available-na). Time of significant gastrointestinal symptoms varied: <12 months (5), 1-3 years (15), 3-5 years (7), >5 years (23), from birth (1), unknown (13). Concomitant anti-diarrheal medications, potentially influencing ^{75}Se HCAT absorption, were assumed by most pts (61/64, 95%) but they were interrupted at least 1 week before, until the end of the test in all cases. Overall, the mean retention score was 22% (median 18%; range 1-88). BAM was confirmed in 30/64 (47%) pts (10 mild; 12 moderate; 8 severe; mean and median retention 8%, range 1-14); excluded in 25/64 (39%) pts (mean retention 40%, median 36% range 21-88), and resulted borderline in 9/64 (14%) cases (mean retention 18%, median 19%, range 16-20). Follow-up data was available in 51/64 (79%) pts. The diagnostic performance of ^{75}Se HCAT led to a change in patient management in 35/50 (64%) cases, in particular 32/35 pts were addressed to bile acid sequestrant (BAS) therapy, with clinical benefit in 21/32 (65%). **Conclusion:** ^{75}Se HCAT scan is a simple test able to reliably diagnose BAM and to select patients who might benefit treatment with BASs. Further analyses on larger population are warranted to establish a diagnostic algorithm of chronic diarrhea and to determine whether ^{75}Se HCAT represents a cost-effective option in the differential diagnosis. **References:** None

OP-804**Usage of hepatobiliary scintigraphy imaging in stratification of patients with chronic viral hepatitis**D. Jocius¹, D. Vajauskas², A. E. Tamosiunas¹;¹Vilnius University Faculty of Medicine, Vilnius, LITHUANIA, ²Lithuanian University of Health Science Kauno klinikos, Kaunas, LITHUANIA.

Aim/Introduction: Viral hepatitis B and C is the one of leading causes of chronic liver damage resulting liver fibrosis and cirrhosis. Routine work up for viral hepatitis patients includes laboratory testing, medical imaging and liver biopsy in selected cases. Liver biopsy used as the “gold standard”, is widely questionable. Therefore quantitative medical imaging including magnetic resonance and ultrasound elastography are incorporated in clinical practice. Nuclear medicine imaging is not used as an option determining the degree of liver fibrosis and only scarce literature can be found on this topic. Nonetheless dynamic hepatobiliary scintigraphy with ^{99m}Tc labeled mebrofenin may have potential role assessing liver fibrosis. This is prospective study investigating the potential value of dynamic hepatobiliary scintigraphy with ^{99m}Tc labeled mebrofenin in staging chronic liver disease. **Materials and Methods:** We prospectively enrolled patients with chronic viral hepatitis B and C referred for liver biopsy prior to treatment. All patients underwent liver shear wave elastography followed by dynamic hepatobiliary scintigraphy with ^{99m}Tc-mebrofenin. Liver stiffness was measured in right liver lobe taking 10 measurements and results were expressed in kilopascals. Dynamic hepatobiliary scintigraphy was performed immediately after intravenous tracer injection for 30 minutes scanning time. Multiple quantitative scintigraphy parameters were assessed: whole liver lobe and focal area time to peak (ttp), 30 minutes to peak ratio (30/peak), whole lobe and focal area slope index in 350s (slope_350), remaining whole lobe and focal area uptake after 30 min. (BLUR). Liver biopsy took place shortly after imaging. **Results:** Total of 72 HCV (68) and HBV (4) patients were included in the study. All imaging parameters were compared to histological examination. Shear wave elastography correctly discriminated between each fibrosis stage (p value <0,0001) and also differentiated non-advanced and advanced fibrosis (p value <0,0001). Quantitative hepatobiliary scintigraphic parameters were found to be statistically significant differentiating significant and nonsignificant fibrosis (30/peak_dex - p 0,03; focal 30/peak_dex - p 0,016), also separating both advanced fibrosis (e.g. ttp_dex - p 0,007; focal ttp_dex - p 0,025; slope_dex - p 0,0001 etc) and cirrhosis (e.g. ttp_dex - p 0,024; 30/peak_dex - p 0,000006; slope_dex - p 0,00001 etc). **Conclusion:** Dynamic hepatobiliary scintigraphy with ^{99m}Tc labeled mebrofenin is good quantitative imaging tool evaluating patients with diffuse liver disease. Moreover, whole liver imaging may give additional information about fibrosis

heterogeneity imaging whole liver. This feature could allow to compare different liver areas as a post processing feature.

OP-805**The effect of protein binding on calculated glomerular filtration rates using [^{99m}Tc] Tc-DTPA: identifying, quantifying and resolving the issue**

S. Townrow, M. Burniston, N. Sizer;

Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: An audit of glomerular filtration rate (GFR) studies for patients who required a blood sample 24 hours post-injection (n=58), either with suspected ascitic volume or poor renal functions, indicated that the inclusion of the 24 hour sample universally reduced the GFR (average 27%, minimum 13%, maximum 38%) independent of the extent of ascites or observed renal function. This suggested that the GFR tracer [^{99m}Tc]Tc-DTPA may be binding to proteins resulting in a complex that is unable to be filtered through the kidneys, delaying clearance of the tracer from the body and reducing the apparent GFR. **Materials and Methods:** Blood samples taken between 2 and 24 hours after the tracer was administered were processed and counted normally to establish a baseline before undergoing ultrafiltration at 2300g, with a molecular weight cut-off of 10kDa, to extract any protein-bound [^{99m}Tc]Tc-DTPA. The reduction in counts (after decay correction) has been used to estimate the fraction of each sample that was protein bound, and in conjunction with the intercept of the clearance curve (plasma count rate at the injection time) indicates how much of the tracer is protein bound. These results were compared with the radiopharmacy QC values to determine whether binding could be identified before the tracer was administered to patients. **Results:** The protein bound fraction of plasma samples at 2 hours ranged from negligible to 27% (n=36, average=11.5%) while at 24 hours it ranged from 7% to 93% (n=31, average=72%) indicating that this was strongly influencing the measured counts in the 24 hour samples. Replacing the original plasma count rate for the 24 hour sample with the value obtained after ultrafiltration increased the GFR in all 31 patients, by 2% to 52% (average=29%). **Conclusion:** The potential for protein binding for [^{99m}Tc]Tc-DTPA is hard to quantify before it is administered and can significantly reduce the GFR for patients requiring a 24 hour sample, but protein binding is also observed in blood samples taken at 2 hours and will affect the GFR for routine patients. Protein binding measurements will be required for all patients unless the manufacturing process can be validated as free from protein binding or a QC check can be developed prior to administration. The production process has been revised locally and provisional results are encouraging, but further validation is required. **References:** None

OP-806**Correlation of CT KUB based renal parenchymal abnormalities with 99m - Technitium Dimercaptosuccinic Acid SPECT Renal Scintigraphy: A Specialized Centre Experience**

M. Siddique¹, A. Iqbal², M. K. Nawaz¹;

¹Pakistan Kidney and Liver Institute & Research Centre, Lahore, PAKISTAN, ²LINCS Diagnostic & IR Services, Lahore, PAKISTAN.

Aim/Introduction: To assess the degree of correlation of renal parenchymal abnormalities on unenhanced multidetector CT KUB with 99m-Technetium Dimercaptosuccinic acid (99m-Tc DMSA) planar scintigraphy (PS) and the incremental diagnostic value of single photon emission tomography (SPECT). Secondly, our objective was to evaluate whether conventional radiological imaging results are equivalent or sufficient when compared to DMSA scintigraphy in the assessment of hydronephrosis/atrophy. **Materials and Methods:** Retrospectively 114 cases with renal abnormalities (obstructive hydronephrosis and/or atrophy, vesico-ureteric reflux or pyelonephritis) who underwent CT KUB and DMSA scans were evaluated. Detection rates and number for cortical defects in both kidneys were compared between PS and SPECT. Differential cortical uptake function was calculated by geometric mean method. Correlation between renal scintigraphy and CT KUB findings was done using Cohen's Kappa coefficient. **Results:** Of total 114 patients [male:female, 70:44; mean age 42±17.5, range: 2-70 years], 56(49%) had hydronephrosis, 27(24%) had unilateral atrophic kidney, 25(22%) patients had hydronephrosis with secondary parenchymal thinning and 6(5%) cases with pyelonephritis. On the basis of radiological imaging, 26% cases had congenital renal outflow obstruction and 74% had acquired obstructive nephropathy due to nephrolithiasis. Of cases with unilateral atrophic kidneys (maximum CT parenchymal thickness <5mm), DMSA revealed nonfunctioning kidneys (uptake<10%) in 93% cases and those with low to moderate degree hydronephrosis, bilateral scarring was seen on DMSA with variable CT KUB parenchymal thickness (mean: 16±1.2 mm). Negative findings on PI in 45 cases with low grade hydronephrosis (32%) were modified to positive findings by adding SPECT. The detection rate of SPECT was significantly higher than that of PI (92% vs. 56%, p<0.01) for small cortical defects as compared to the larger ones. DMSA imaging had significantly higher (p<0.001) diagnostic utility for interpreting renal abnormalities in pyelonephritis as compared to CT KUB with preserved parenchymal thickness (>15 mm). Overall mild agreement (K-value:0.19) was seen between CT KUB and Renal DMSA scintigraphy for interpreting scarring in cases with obstructive hydronephrosis. **Conclusion:** DMSA scintigraphy shows higher sensitivity for assessment of renal scarring in cases with high grade hydronephrosis and/or atrophy,

and is particularly useful for evaluating functional status preoperatively. The study results emphasize that, compared with planar imaging, Tc-99m DMSA SPECT can detect small cortical defects with greater sensitivity. **References:** None

OP-807**Can Dynamic Renal Scintigraphy Predict Renal Outcome in Acute Kidney Injury?**

M. Nicod Lalonde, M. Altarelli, M. Jreige, G. Allenbach, N.

Schaefer, J. O. Prior, A. Schneider;

University hospital of Lausanne, Lausanne, SWITZERLAND.

Aim/Introduction: Acute kidney injury (AKI) is characterized by rapid loss of renal function (<48hrs). Dynamic Tc-99m-MAG3 or I-123-Hippuran renal scintigraphy (RS) is regularly requested by clinicians from our institution to evaluate renal function in patients with AKI. The aim of our study is to evaluate the ability of dynamic RS to predict renal recovery after AKI. **Materials and Methods:** We retrospectively included 115 patients (84M/31F) with a mean age of 63±15y, who underwent RS during AKI. During RS, the accumulation index (AI) defined as the percentage of injected activity extracted by the kidney during one minute was calculated and the slope of the accumulation curve (SAC) of the most functional kidney was measured. Renal function was assessed 3 months after RS, and patients were divided into two groups: patients with renal recovery and patients with no significant recovery, defined as recovery of less than 33% of the loss of function during AKI. **Results:** When RS was performed during AKI, the sum of the AI of both kidneys was significantly higher in patients with renal function recovery three months after AKI than in patients with no significant renal recovery (8.8 [5.9-10.9] versus 5.9 [4.8-7.0]; p<0.01). The SAC of the most functional kidney was also significantly higher in patients with renal function recovery (0.26 [0.16-0.47] than without 0.19 [0.10-0.27] (p=0.04). **Conclusion:** AI and SAC measured during RS seem to be useful indices to help predict renal function recovery after AKI. **References:** None

OP-808**Is there a relevance of Hystero-Salpingo-Scintigraphy in SPECT/CT era?**

Aim/Introduction: The incidence of infertility is steadily increasing according to published WHO data. 8 to 12 % of couples with intentions of having a family are infertile. At the background of infertility might be anatomical, genetic, immunological, hormonal or psychic abnormality or alterations. 40 % of female infertility can be traced back to ovarian problems, 30 % to the uterine tubes, and only 5-10 % are caused by genetic abnormalities. The permeability of the uterine tube can be examined by several methods, among these the hystero-contrast-sonography (HyCoSy), hysterosalpingography (HSG) and hysterosalpingoscintigraphy (HSSG) are routinely used. Nevertheless the invasive laparoscopic chromopertubation are used as the gold standart in assessment of uterine tube status. The aim of our study was to investigate the effectiveness of HSSG with SPECT/CT on assessment of the permeability of the Fallopian tubes. **Materials and Methods:** 70 infertile female patients (average age: 31 years) were studied between 01.03.2017 and 01.12.2019 in our Institution. The examinations were timing on the 7th-14th days of their menstrual cycle. The patient were lying in a supine position under the SPECT camera. With the assistance of a gynecologist 37 MBq of ^{99m}Tc nanoalbumon were delivered through a cannula placed into the uterine cavity. Firstly we started 40x30 sec. dynamic images (simple dynamic). Then the flow of delivered radiopharmaceutical was forced with direct administration of 5 ml of physiological saline liquid and another dynamic acquisition was performed with 10x30 sec. images (forced dynamic). Finally additional SPECT/CT (128x128 matrix size, 10sec/frame, 120kV and 10 mAs) was done to localise activity in the pelvic area.(forced SPECT) **Results:** Different acquisition methods were evaluated in according their diagnostic performance. We found that forced SPECT showed the best diagnostic performance in contrast with simple and forced dynamic acquisition (sensitivity 100%, 87%, 87%, specificity 89%, 72% and 89%). All these methods have excellent negative predictive value (100% in forced SPECT and 97% in dynamic methods). CT did not provide significant additional information. **Conclusion:** The HSSG with good NPV is an excellent simple diagnostic method to evaluate permeability of Fallopian tubes. Using only forced SPECT we can improve the diagnostic accuracy without dynamic acquisition. It is time-consuming and more comfortable for the patient. No need additional CT. **References:** Kissler S et al. Uterine contractility and directed sperm transport assessed by hysterosalpingoscintigraphy (HSSG) and intrauterine pressure (IUP) measurement. OP-809

Rest/Stress Intradermal Lymphoscintigraphy in Women with Lipedema

G. Tartaglione, F. P. Ieria;

Cristo Re Hospital, Rome, ITALY.

Aim/Introduction: Lipedema is a painful progressive disease due to an abnormal and disproportionate deposition of subcutaneous fat. It is characterized by a symmetrical and bilateral swelling of the lower limbs, but feet are not involved. Lipedema is believed to affect nearly 1 out of 9 of adult women worldwide. Despite this relatively common disease the lipedema is often confused with primary lymphedema or simple obesity. We proposed Rest/Stress Intradermal Lymphoscintigraphy to evaluate lymphatic drainage in women with a clinical diagnosis of lipedema. **Materials and Methods:** We studied 54 consecutive women, age 47.1 y +/-19.3 (range 17-86), with a clinical diagnosis of lower limbs lipedema. The mean Body Mass Index was 32.3 (range: 21.7- 58.5, normal value = 18.5 - 25). Two doses 50 MBq, 0.3-0.4 mL, of ^{99m}Tc-nanocolloid, were intradermally injected bilaterally in two sites: at the first intermetatarsal space and at the external malleolar area. Two planar static scans in anterior and posterior views were acquired at rest, immediately following the injection. Subsequently, all patients were asked to make an isotonic muscular exercise (stepping) for 2 minutes. Then, post exercise scans were performed to monitor the tracer pathway. After that, the patient performed a prolonged exercise limited by symptoms (walking), for 30-40 minutes. Delayed scans, including abdomen, were acquired 1 hour after tracer injection. **Results:** We imaged a total of 108 lower limbs. Rest scan showed a normal visualization of lymphatic vessel along the great saphenous vein and inguinal lymph nodes in 36 limbs (33.3%). Stress and Delayed scans showed collaterals and/or deep vessels in 53 limbs (49.1%) (Popliteal lymph node uptake appeared in 39 limbs); Tracer stagnation area in 16 limbs (14.8%); Dermal backflow in 3 limbs (2.8%). A tortuous course of lymph pathway was observed in about 75% of legs. The Tracer Appearance Time (TAT) in the inguinal lymph node was <10 mins in 100 Limbs (92.5%). The mean value of Trasport Index was 9 (range 3-16). **Conclusion:** A normal TAT with a tortuous course of lymphatic vessels and minor findings of lymphatic disorder are frequent in early clinical stage of Lipedema. Over time the lymph adapts its course to increasing deposit of fat in subcutaneous tissue. If the fat continues to build up, it might block the lymphatic vessels causing a secondary lymphedema (Lipo-Lymphedema). Major findings of lymphatic damage may appear in advanced clinical stages. **References:** Boursier V et al J Mal Vasc. 2004;29(5):257-61.

OP-810**Role of 18F-FDG PET/CT in the evaluation of pyrexia of unknown origin**

D. Khan, S. Sagar, A. Raj ST, S. Kumar, M. Tripathi, M. Sharma, R. Kumar;

All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: To evaluate role of F-18 Fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) in the evaluation of pyrexia of unknown origin (PUO). **Materials and Methods:** Four seventy eight patients who underwent 18-F-FDG PET/CT for the evaluation of PUO (by standard definition¹) from 2016 to 2020 were evaluated retrospectively. Images were acquired on Biograph-mCT scanner (Siemens Inc.) 45-60 minutes after intravenous administration of 6-10mCi of 18-F-FDG. Scans were evaluated qualitatively by two experienced Nuclear medicine physicians. Each scan was read by two nuclear medicine physicians and based on the imaging findings, each scan was given three differential diagnosis by consensus. Histopathological reports of patients who underwent guided biopsy using FDG PET were analysed for final diagnosis and correlated with the first diagnosis by consensus. **Results:** Four seventy eight patients having mean age of 39.5 ± 1.0 years (range 2-90 years), male : female = 1.4:1, with PUO underwent PET/CT. The diagnostic yield of 18-F-FDG PET/CT in PUO cases was found out to be 52%. Among one fifty three patients (153/478) underwent guided biopsy, conclusive histopathology report was available in 109 patients, remaining patients (44/153) had inconclusive reports. Most common reports were inflammatory/vasculitis, lymphoma, other malignancies and tuberculosis (35,20,22,17 respectively). Considering histopathological evidence as gold standard, guided biopsy had an accuracy of 54% and sensitivity of 84.6%. Out of the 14 patients (14/109) of whom we reported as negative, 4 patients were discharged with improved clinical outcome and negative biopsy report while 10 patients came out positive on biopsy. **Conclusion:** 18-F-FDG PET/CT is a valuable non-invasive tool in the evaluation of PUO and can guide biopsy site and direct treatment by identifying underlying pathophysiology of lesions and is most contributory to the diagnosis of lymphoma, malignancy and vasculitis. **References:** 1. Bharucha T, Rutherford A, Skeoch S, Alavi A, Brown M, Galloway J; FDG-PET/CT in fever of unknown origin working group. Diagnostic yield of FDG-PET/CT in fever of unknown origin: a systematic review, meta-analysis, and Delphi exercise. Clin Radiol. 2017 Sep;72(9):764-771.

EPS-136**Digital PET/CT 4D: A Study Phantom On The Effect Of Respiratory Gating In Volumes And SUV Recoveries**

A. Belly-Poinsignon¹, P. Finitzer¹, M. M. Alabdoaburas¹, C. Provost², L. Champion³, L. Ammour¹, R. Belshi¹;

¹Institut Curie-Saint Cloud, Medical Physics Department, Paris, FRANCE, ²Institut Curie-Saint Cloud, Radiopharmacology Department, Paris, FRANCE, ³Institut Curie-Saint Cloud, Medical Imaging Department, Paris, FRANCE.

Aim/Introduction: PET is established as one of the major biomedical imaging modality for diagnostic, staging and follow-up. In radiotherapy, PET images are used to determine irradiation volumes. However, artefacts due to respiration motion persist to be an important factor in degrading PET image quality and quantification. The aim of this study is to evaluate achievable accuracy of tumors volumes and Standard Uptakes Values (SUV) with 4D digital PET/CT acquisitions (Vereos, Philips Healthcare). **Materials and Methods:** Dynamic thorax phantom, (CIRS, Model 008A-15) with a hollow plastic sphere placed in the left lung region was used. To avoid partial volume effects, the 8ml sphere (diameter 24.8 mm) was chosen in this first study. ¹⁸F-FDG activity concentration of 40 kBq/ml was prepared to fill the sphere to simulate a hot tumor in lung. Four different breathing motions (2 translations, hysteresis and pulmonary) were imposed on the sphere along the superior and inferior direction with an external motor. They are detected and recorded using a pressure sensor placed in a belt (Medspira Breath Hold ES). According to patients' protocols, the first two phantom acquisitions were non-gated 3D PET/CT, without, then with breathing motions. The third acquisition was a prospective gated 4D PET/CT. Delineation methodology was validated with a static NEMA phantom study in order to confirm the 40% threshold as the best value for volumes determination. Two commercial softwares, Mirada XD or IntelliSpace Portal, are used to calculate tumor spread, volumes, SUVmax. **Results:** Calculated volumes are largely degraded without respiratory correction and clearly improved with 4D PET/CT acquisitions. Deviations from nominal volume are respectively -5.7%/0.8% for hysteresis, -10.8%/0.8% for 1 cm translation, 111.6%/0.0% for 2 cm translation, -17.0%/3.2% for pulmonary motion. Results depend on sphere movement amplitude for SUVmax metric. In case of large range motion as 2 cm translation, SUVmax is 0.55 with 3D PET/CT and 0.95 with 4D PET/CT, whereas for

small pulmonary movement SUVmax is 1.20 versus 1.03 respectively. There is no significant improvement with 4D PET/CT for intermediate amplitude movements (hysteresis: 0.95/0.96 and 1 cm translation 1.04/0.97). **Conclusion:** Obtained results confirm the ability of the system to correct breathing movement by improving the recovering of volumes and SUVmax, particularly in case of large movement. Test for irregular pulmonary motions significant of patients showed the same trend. This study has to be completed for the smaller spheres in order to assess the contribution of digital technology. **References:** None

EPS-137

Negative oral contrast agents Utilization in PETCT studies

N. Bashank¹, W. Diab¹, S. Hassanein², M. Abdel Tawab², M. S. Keshk¹;

¹Assuit university, AUH, clinical oncology and nuclear medicine department, Assuit, EGYPT, ²Assuit university, AUH, Diagnostic Radiology department, Assuit, EGYPT.

Aim/Introduction: To compare the performance of different negative oral contrast agents in bowel distension in patient referred for PET/CT studies for various causes aiming for identification of ideal negative oral contrast agent (NOCA). **Materials and Methods:** 80 patients were included in this study divided into four groups of 20 patients each. Group I: No intervention (control). Group II: patients received 1500 ml water. Group III: patients received 1500 ml milk with 5% fat. Group IV: patients received lactulose 40 gm dissolved in 1500 ml water. Patients received 1000 ml of the NOCA immediately after F18 FDG injection at a rate of 150 ml every 5-10 min for 45-60 min. another 500ml received 5-10 min before imaging. Assessments of bowel distention at various levels with mural visibility of bowel were studied and graded as follows: (0) No distension, (1) poor = 1 cm distension, (2) reasonable = 1-2 cm distension, (3) excellent = >2 cm distension. For the study analysis, % of patients with criteria 2 and 3 were considered as good visualization. The effect of oral contrast on F18 FDG uptake on the gut was classified into (1) Minimal FDG uptake, (FDG activity less than the liver), (2) Moderate (FDG activity same as the liver), (3) Intense (FDG uptake more than the liver). Also gaseous distension was graded as (1) Mild amount of gas in the abdomen (2) Moderate gaseous distention (3) severe. Chi-square test was used as test of significance for qualitative data. ANOVA was the test of significance for quantitative data. Value <0.05 was considered as significant. **Results:** Bowel distention & mural visualization were significantly improved in group II, III, IV compared to group I ($p < 0.001$). No statistically significant differences were seen between group III and IV regarding the degree of bowel distention and mural visualization with significant difference between group III & II and group IV & II. Milk in group III was better tolerated and acceptable than water and lactulose in

group II and IV with almost no abdominal side effects like abdominal discomfort, nausea, vomiting and diarrhea. Milk was the least agent to produce gaseous distension and intense FDG uptake by the gut. **Conclusion:** Distension and visualization of the bowel was significantly improved with NOCA utilization. Milk was comparable to lactulose regarding bowel distention and bowel wall visualization with a lower cost, better patient tolerability, & fewer side effects. **References:** None

EPS-138

TOF Resolution Assessment based on Time Alignment Procedure

V. Panin, D. Bharkhada, H. Rothfuss; Siemens Medical Solutions USA, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: TOF resolution estimation is an important assessment of TOF PET scanner performance. Its NEMA standard methodology has evolved over years and current methodology is designed specifically for a line source in scattered media. A time alignment (TA), also referred to as timing calibration, procedure is performed on a regular basis and TOF resolution assessments results strongly depend on TA performance. With the introduction of SiPM scanners TA standards were tightened due to significant improvements in TOF resolution. The Siemens Biograph Vision scanner TA method is designed for arbitrary objects based on non-TOF data reconstruction. Practically, Vision TA is performed on a uniform cylindrical phantom, placed arbitrarily in the scanner. Nevertheless, the same TA can be executed on the line source, arbitrarily placed in the scanner. In addition, the mathematics behind the TA method, which differs from the NEMA method, can be used to estimate TOF resolution from a line phantom. The goal behind this study was to compare performances of NEMA and TA methods in estimation of TOF resolution from a line source after on either cylindrical or line phantom TA. **Materials and Methods:** A standard, 28 cm long Ge-68 uniform cylindrical phantom, TA procedure was performed on a Siemens Biograph Vision PET/CT scanner. The outcome of this procedure is the crystal time offsets (TO) array, which is downloaded by firmware for TOF bin index correction in the subsequent list mode data acquisitions. The Ge-68 line source was placed at the center of the scanner to evaluate time resolution according to the NEMA and TA method. Additional TA (self-TA) was performed for this phantom. Residual TOs were applied during list mode data re-writing by changing the TOF bin indexing. **Results:** The TOF resolution from the line source was 207ps with standard TA. After additional self-TA, time resolution was marginally improved by 4ps. NEMA and TA methods coincided in TOF resolution assessment within 0.3 ps. **Conclusion:** The TA procedure, performed on a wider cylindrical phantom and a line source, results in nearly the same line TOF resolution. Line source self-TA however is

optimized for a smaller amount of coincidence data. The TA is a necessary scanner procedure, designed for an arbitrary object. The proposed TA based TOF resolution assessment method, mostly performed in projection space, can be a suitable replacement of the current NEMA method, mostly performed in image space and designed for line sources only. **References:** None

EPS-139

Development of an automatic calculation method for the specific binding ratio in [I-123]ioflupne SPECT

H. Okazawa¹, M. M. Islam^{1,2}, M. G. M. Rahman¹, T. Tsujikawa¹;

¹University of Fukui, Fukui, JAPAN, ²Khulna University of Engineering & Technology, Khulna, BANGLADESH.

Aim/Introduction: A fully-automatic method for specific binding ratio (SBR) calculation in [¹²³I]ioflupane (FP-CIT) SPECT studies was proposed by creating volumes of interest of the striatum (VOI_{st}) and reference region (VOI_{ref}) without manual-handling steps to avoid operator-induced variability with rapid quantitative calculation. **Materials and Methods:** The present study involved 105 patients (72±10 years) suspected of parkinsonian syndrome (PS) who underwent FP-CIT SPECT. All patients were classified into PS and non-PS groups according to the results of clinical follow-up and SPECT images. The data from 200 patients in our previous study were used for evaluation and validation of the new program. The SPECT images were reconstructed with two methods; CT-attenuation correction with scatter (ACSC) and without scatter correction (CTAC). Consecutive slices containing striatal intensive counts were selected and a trapezoidal volume of interest (VOI_t) was created automatically. VOI_{st} was then created using our previous method [1]. SBR values were calculated from the mean values of VOI_{st} and VOI_{ref} determined by the whole brain region outside of VOI_t. To exclude low count voxels in the VOI_{ref} several thresholds were applied for choosing an appropriate cut-off level. The SBR values from the new method were compared with those from our previous semi-automatic method and the Tossic-Bolt (TB) method [2]. **Results:** The fully-automatic method with the VOI_{ref} threshold of 75% maximum reference count, determined from the previous data (200 patients), showed a good linear correlation between the SBRs from the semi- and fully-automatic methods in both patient data sets ($r > 0.98$). The areas under the curves (AUCs) of receiver operating characteristics (ROC) analysis showed no significant difference between the semi- and the fully-automatic methods for both our previous (AUC > 0.99) and new (AUC > 0.95) data. Diagnostic accuracy of the two methods with ACSC and CTAC reconstruction showed similar results (> 92%), and both were better than the TB method. The mean running time of the fully-automatic method was 9±1 sec for each patient. **Conclusion:** The proposed method

successfully created the automatic VOIs and calculated SBR rapidly without any manual operation, avoiding the operator-induced variability and providing objective SBR results. **References:** 1) Rahman MGM, et al. Count-based method for specific binding ratio calculation in [I-123]FP-CIT SPECT analysis. *Ann Nucl Med.* 2019; 33: 14-21. 2) Tossic-Bolt, et al. Quantification of [¹²³I]FP-CIT SPECT brain images: an accurate technique for measurement of the specific binding ratio. *Eur J Nucl Med Mol Imaging.* 2006; 33: 1491-9.

EPS-140

A new automated method for analysis of cerebrovascular reserve capacity deficiency by rCBF SPECT with acetazolamide test: Preliminary results

S. Urbán¹, G. Sipka¹, A. Balogh², Z. Besenyi¹, J. Csirik², L. Pávics¹;

¹Department of Nuclear Medicine, University of Szeged, Szeged, HUNGARY, ²Institute of Informatics, University of Szeged, Szeged, HUNGARY.

Aim/Introduction: The rCBF SPECT with acetazolamide test is a well-known, reliable method for the evaluation of cerebrovascular reserve capacity. The investigation could predict the increased risk for stroke in patient population with significant hemodynamic ischemia. Most nuclear medicine clinicians use visual assessment for the interpretation of rCBF SPECT. Quantitative assessment of the presence and degree of cerebrovascular reserve capacity could lead to more precise, patient-based treatment strategies. The aims of this study was to develop a new, automated method for quantification the difference between rCBF SPECTs before and after acetazolamide test and to validate with visual assessment. **Materials and Methods:** The automated method consists of five main steps: 1) SPECT brain images were translated into the MNI space (to ICBM Average Brain - ICBM152) using rigid and affine image registration methods; 2) Brain images were normalized by the average voxel value of the cerebellum (cerebellum atlas [1]); 3) the difference image obtained by subtracting the two aligned normalized SPECT images; 4) abnormal regions were detected using automated IQR analysis based on cortical and subcortical regions (Harvard-Oxford atlas); 5) for each detected subregion the size, median difference and anatomical region are extracted. The validation process contained two steps. Firstly, the founded subregions were evaluated based on the visual probability of decreased vascular reserve capacity using three main groups (proved, probable or not proved). Secondly, a region based comparison was performed between the visual assessment and the automated method. 15 patients' (7 men, 8 women, mean age: 66 years) rCBF SPECT images were evaluated. **Results:** All pathological cortical and subcortical regions were recognized by the automated method. In total 129 subregions with decreased vascular reserve were identified by the method. Forty two (32,56%)

visually proved or probable subregions were confirmed. The volume determined by our automated method in proved and probable subregions differed significantly from the not proved subregions (Kruskal-Wallis, $P < 0,0001$). The proved subregions do not differ from probable subregions (Kruskal-Wallis, $P > 0,05$). **Conclusion:** A new, automated method for analysis of brain perfusion reserve was developed. Based on the evaluation the method detected all of the affected regions. Despite the detected subregions large number based on our study in the future the clinically relevant subregions can be separated from the clinically irrelevant areas. **References:** [1] Diedrichsen, J. et al., A probabilistic MR atlas of the human cerebellum, *Neuroimage*, 2009 May 15;46(1):39–46

Quantification of 18F-Florbetapir amyloid brain PET scans using commercial software: a comparison with an experienced and independently reviewed clinical report

L. Perry¹, N. H. Patel¹, J. Lilja^{2,3}, S. R. Khan¹, S. Curry⁴, F. Loreto⁵, M. Golemme¹, H. McMeekin⁶, L. Alves¹, K. S. Nijran¹, P. Malhotra^{1,5}, R. J. Perry^{1,5}, Z. Win¹;

¹Imperial College Healthcare NHS Trust, London, UNITED KINGDOM, ²Uppsala University, Uppsala, SWEDEN, ³Hermes Medical Solutions, Stockholm, SWEDEN, ⁴King's College London, London, UNITED KINGDOM, ⁵Imperial College London, London, UNITED KINGDOM, ⁶Hermes Medical Solutions, London, UNITED KINGDOM.

Aim/Introduction: BRASS software can be used to quantify 18F-Florbetapir amyloid PET/CT scans performed for suspected Alzheimer's disease. BRASSv4.0 applies an automated PET-only registration method utilising an adaptive template based on principal component analysis. Work by our group has shown accurate registration of amyloid PET images to a template is possible without need of an MR(T1) driven template registration ($R^2=0.996$). Previous versions of BRASS used a standard rather than adaptive PET template. The aim of this work was to assess the potential of the BRASSv4.0 software to aid interpretation of 18F-Florbetapir scans. **Materials and Methods:** The clinical report for 226 18F-Florbetapir scans was agreed by two experienced readers following independent review. The scans were classified as type A (typical features) or non-type A (atypical features including image noise and atrophy) for both positive and negative scans. Quantitative analysis was performed using BRASSv4.0 and the regional values were normalised using the Pons region to give regional amyloid uptake ratios (SUV_R). The mean SUV_R across the regions was recorded (mean SUV_R) together with a coefficient identified in the linear model that correlated with amyloid load ($A\beta$ -index). The quantitative values were compared with the clinical report. ROC curves were used to evaluate regions and threshold values which minimised disagreement to

the clinical report (false positive and false negative scans). These results were compared to those obtained using the software with standard template. **Results:** 183(81%) scans were classified as type A (87 positive,96 negative). 43(19%) scans were classified as non-type-A (23 positive,20 negative). In BRASSv4.0 the optimum threshold for $A\beta$ -index and mean SUV_R was found to be -0.05(AUC 0.96) and 0.74 (AUC 0.96, 94% sensitivity and 93% specificity) respectively. The left and right (i)lateral temporal cortex ($SUV_R=0.75,AUC=0.97$; $SUV_R=0.76,AUC=0.96$), (ii)Precuneus ($SUV_R=0.73,AUC=0.95$; $SUV_R=0.76,AUC=0.95$) and (iii) frontal cortex ($SUV_R=0.75,AUC=0.95$; $SUV_R=0.77,AUC=0.95$) brain regions showed best separation between positive and negative cohorts. For atypical studies an increase in specificity (79% versus 37%) with preserved sensitivity (79%) was found when comparing results from BRASSv4.0 with the previous version. A small improvement in agreement with the report was seen for typical scans (97% compared to 89% agreement previously, 99% sensitivity, 91% specificity). **Conclusion:** The updated BRASSv4.0 software utilising an adaptive template registration shows improved agreement with clinical report for 18F-Florbetapir PET/CT scans compared to a standard template registration. This study has shown very good agreement of atypical scans which are often difficult to interpret and require high degree of experience. **References:** None

EPS-142

Evaluation of myocardial perfusion images in patients with left ventricular dilatation using software program provided Artificial Neural Network (ANN)

K. Koyama¹, M. Kanou¹, T. Ogura¹, S. Naito¹, T. Higuchi², T. Toyama³;

¹Gunma prefectural cardiovascular center, Maebashi, JAPAN, ²Gunma Faculty of medicine Graduate School, Maebashi, JAPAN, ³Toyama cardiovascular Clinic, Maebashi, JAPAN.

Aim/Introduction: Left ventricular (LV) dilatation has several causes such as ischemic heart disease (IHD) or cardiomyopathy. Patients with LV dilatation and severely impaired LV function will be under heart failure condition. Heart failure is expected poor prognosis and is the leading cause of hospital admission in over 65s. Myocardial perfusion images (MPI) analyzed by ANN provides various indices. To investigate these indices, it will be possible to define the characteristic of myocardium and to approach proper treatment. We compared these indices of patients with LV dilatation caused by IHD and non-IHD. **Materials and Methods:** Thirty patients with LV dilatation were enrolled in this study. They were divided into two groups, IHD group (group A) and non-IHD group (group B). All of them underwent MPI. In visual assessment, two expert physicians in nuclear medicine detected myocardial abnormality. Indices from MPI analyzed by ANN were compared. **Results:** The age of

the patients range was from 47 to 74 years old. Average of LV ejection fraction (LVEF), end-diastolic volume (EDV) and summed rest score (SRS) of patients in group A were 47%, 214 mL and 24 and those in group B were 47%, 253 mL and 25, respectively. In LV diastolic function analysis, peak filling rate and 1/3 mean filling rate of patients in group A were 1.87/sec. and 0.93/sec. and those in group B were 2.32/sec. and 1.27/sec., respectively. In phase dyssynchrony analysis, Bandwidth, Phase standard deviation (SD) and Entropy in group A were smaller than those in group B. In regional wall motion analysis, SD of time to end systolic of patients in group A was 9.68% and that in group B was 17.39% (p:0.07). **Conclusion:** MPI analyzed by ANN provides various indices. In LV diastolic function analysis, phase dyssynchrony analysis and regional wall motion analysis, indices showed the difference between IHD group and non-IHD group. They will offer valuable information and lead us to proper treatment. **References:** None

EPS-144

Deep learning image enhancement for short-duration whole-body FDG PET scans

A. Mehranian¹, K. Su², M. D. Walker³, M. Chetan³, D. R. McGowan^{3,4}, F. Gleeson⁵, A. Brown⁶, R. Johnsen², S. D. Wollenweber²;

¹GE Healthcare, Oxford, UNITED KINGDOM, ²GE Healthcare, Waukesha, WI, UNITED STATES OF AMERICA, ³Oxford University Hospitals NHS FT, Oxford, UNITED KINGDOM, ⁴University of Oxford, Oxford, UNITED KINGDOM, ⁵National Consortium of Intelligent Medical Imaging (NCIMI), University of Oxford, Big Data Institute, Oxford, UNITED KINGDOM, ⁶Oregon Health & Science University, Portland, OR, UNITED STATES OF AMERICA.

Aim/Introduction: Reducing scan time in PET without compromising the diagnostic value of images is of importance for increasing patient throughput and follow-up exams. In this work, we aimed to leverage a deep learning image enhancement (DLE) model to reduce scan time in oncology whole-body FDG PET scans by up to half and reconstruction time by up to two-third. **Materials and Methods:** 137 ¹⁸F-FDG PET scans were collected from two PET centers using different GE PET/CT scanners. List-mode data were retrospectively thinned into short-duration scans by factors of 3/4, 1/2 and, if feasible, 1/4. Full-duration datasets were reconstructed using the advanced Q-Clear (beta: 350-400) algorithm, whereas short-duration ones using the faster OSEM algorithm. The datasets were split into train (298), validation (30) and test (36) sets. A DLE model was trained to map short-duration images into their target full-duration ones. The best model was selected based on quantification analyses of lesions, liver and lungs in validation set. Test datasets included only 3-quarter and half-duration scans to avoid false findings caused by lack of signal or physiology mismatches. Beside quantitative

evaluations, four experienced readers ranked the quality of images (85 series including Q-Clear) on a 4-point scale (1: very low, 2: acceptable, 3: good and 4: very good) **Results:** For 64 identified lesions, the 3/4 - and 1/2 -duration OSEM images and their corresponding DLEs showed respectively SUV_{max} errors of -19±15, -18±16, -5±15, -6±17% with respect to their target full-duration Q-Clear images (all p-values <0.001). The SUV_{mean} errors for lungs and liver were below 4% for all four images. Standard deviation of SUVs in liver was on average 0.17, 0.25, 0.30, 0.16 and 0.18 for Q-Clear, 3/4-OSEM, 1/2-OSEM, 3/4-OSEM+DLE and 1/2-OSEM+DLE images, respectively. The scores rated by readers based on overall quality of the images were on average 3.3±0.4, 2.0±0.5, 1.5±0.4, 3.1±0.5, 3.0±0.5 for the above-mentioned methods, respectively. The readings showed that short-duration images depict an “acceptable” image quality, while DLE makes their quality as “good” as the target Q-Clear images **Conclusion:** The qualitative and quantitative results of this study show that the developed DLE model allows to reduce the scan time of whole-body FDG scans from 21±6 min to 10±3 min and the reconstruction time from 2.4 to 0.8 min/bed without substantially compromising the quantitative accuracy and diagnostic value of PET images. This work will be continued by including 2000 datasets provided by National Consortium of Intelligent Medical Imaging **References:** None

EPS-145

Deep-learning based urinary bladder segmentation using 18FDCFPyL (PyL-PSMA) PET/CT images

J. Brynolfsson¹, K. Johnsson¹, H. Sahlstedt¹, J. Richter¹, K. Sjöstrand¹, L. Edenbrandt^{1,2}, A. Anand¹;
¹Exini Diagnostics AB, Lund, SWEDEN, ²University of Gothenburg, Gothenburg, SWEDEN.

Aim/Introduction: Organ segmentation of medical images is an important step in clinical workflows, both when diagnosing and treating patients. Multiple different deep learning methods for automatic organ segmentation have been implemented to that end, usually based on CT or MRI images. When considering segmentation of the urinary bladder in prostate cancer patients, there may be multiple factors that make the delineation difficult. If the patient has a catheter, or has had a prostatectomy, this could change the anatomy and position of the urinary bladder, or the patient may have metallic implants creating image artifacts. When acquiring PET/CT images the PET tracer accumulates in the urinary bladder, making it clearly visible. One approach could be to segment the urinary bladder is segmented using the PET image instead of the CT. However, there may be lesions in the prostate gland or in nearby lymph nodes with high tracer uptake which might then erroneously be segmented as urinary bladder. In this study we evaluate a deep learning based method that takes

both PET and CT images as input to segment the urinary bladder. **Materials and Methods:** A data set consisting of 39 PYL-PSMA PET/CT images with manually crafted urinary bladder segmentations was used to train and evaluate the deep-learning segmentation. The network was trained on 31 images and evaluated on 8 images. Cross-validation was performed such that the evaluation set was rotated, and the network re-trained until evaluation had been performed on all 39 images. The Sørensen-Dice score was used to evaluate the performance of the segmentation. Two sets of U-net neural network structures were trained (Ronneberger et al, 2015), one which only received the CT image, and one which took both the CT and the PET image as input. **Results:** Evaluated on all images, the network using only low-dose CT as input achieved a mean Dice score of 0.73 with a standard deviation of 0.20. The network receiving the PET/CT image pair as input achieved a Dice score of 0.76 with a standard deviation of 0.14. **Conclusion:** By utilizing the PET image in addition to CT image as input to a deep-learning based semantic segmentation, bladder segmentation improves. We will continue to evaluate possible benefits of utilizing both PET and CT images for semantic segmentation, both on a larger data set as well as for additional organs. **References:** None

Impact of [¹⁸F]FDG uptake time on non-small cell lung cancer PET radiomics and their repeatability

G. D. Kolinger¹, D. Vázquez García¹, A. S. Dirand², G. M. Kramer³, V. Frings³, O. S. Hoekstra³, E. F. Smit^{4,5}, A. J. de Langen^{4,5}, R. A. J. O. Dierckx¹, I. Buvat², R. Boellaard^{1,3};

¹Medical Imaging Center, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS, ²Laboratoire d'Imagerie Translationnelle en Oncologie, INSERM, Institut Curie, Université Paris-Saclay, Orsay, FRANCE, ³Department of Radiology and Nuclear Medicine, Amsterdam University Medical Centers, location VU Medical Center, Amsterdam, NETHERLANDS, ⁴Department of Pulmonology, Amsterdam University Medical Centers, location VU Medical Center, Amsterdam, NETHERLANDS, ⁵Department of Thoracic Oncology, Amsterdam University Medical Centers, location VU Medical Center, Amsterdam, NETHERLANDS.

Aim/Introduction: In recent years, PET radiomics have gained increased interest. The impact of image reconstruction settings and lesion segmentation on radiomics features (RF) has been extensively studied, however, the influence of tracer uptake interval on RFs has not been explored yet. In this study, we explored the impact of tracer uptake time in combination with reconstruction settings and lesion delineation methods on PET RFs as well as the impact on RF repeatability. **Materials and Methods:** Ten NSCLC patients underwent two baseline [¹⁸F]FDG-PET scans on two consecutive days (test-retest study) prior to systemic

treatment. At each day, scans were obtained at both 60min and 90min post-injection and reconstructed following EARL1 and with point-spread-function resolution modelling (PSF-EARL2). Lesions were delineated using thresholds at $SUV=4.0$, 40% of SUV_{max} , and with a contrast-based isocontour (at $0.5 * (SUV_{peak} + SUV_{background})$). Then, RFs were calculated with LIFEX software and divided into classes: conventional, shape, histogram, grey-level co-occurrence matrix (GLCM), grey-level run-length matrix (GLRLM), grey-level zone-length matrix (GLZLM), and neighbourhood grey-level different matrix (NGLDM). Wilcoxon signed-rank tests were performed for statistical comparison and a significance level at 0.05 was considered. **Results:** Most shape features were not significantly impacted by tracer uptake time (median average difference and interquartile range of 2%[1%-3%]). On the other hand, conventional and grey-level-based features were significantly impacted by uptake interval, with median average differences of 12%[10%-13%] for conventional, 6%[3%-12%] for GLCM, 10%[1%-19%] for GLRLM, 14%[7%-23%] for GLZLM, and 14%[7%-17%] for NGLDM features. Features were not significantly different between test-retest (<10% changes) studies. Histogram (2%[1%-7%]), GLZLM (4%[2%-8%]), and NGLDM (4%[2%-7%]) had worse repeatability than other classes (median average differences of <2%). PSF-EARL2 images (3%[1%-6%]) had slightly worse repeatability than EARL1-images (2%[1%-4%]), and fixed SUV threshold delineation provided overall more repeatable RFs (1%[0.3%-4%]) than the use of other segmentation methods (3%[1%-5%]). Repeatability of RFs was improved with longer uptake time, with test-retest differences at 60min and 90min being, respectively, 2%[1%-5%] and 2%[1%-3%] for GLCM, 2%[0.5%-4%] and 1%[0.4%-3%] for GLRLM, 5%[3%-8%] and 3%[2%-7%] for GLZLM, and 6%[2%-9%] and 3%[2%-5%] for NGLDM. **Conclusion:** Radiomic features other than shape features were significantly impacted by tracer uptake time, emphasizing the need of timely procedures. A longer tracer uptake time improved the repeatability of radiomic features (90min vs 60min post-injection). (This project is funded by EC H2020 #764458.) **References:** None

EPS-147

Optimal ⁶⁸Ga-PSMA-11 and ¹⁸F-PSMA-1007 PET window levelling for gross tumour volume delineation in primary prostate cancer

K. Goffin¹, C. Draulans², R. De Roover², U. A. van der Heide³, L. Kerckmeijer⁴, R. J. Smeenk⁴, F. Pos³, W. V. Vogel³, J. Nagarajah⁵, M. Janssen⁵, S. Isebaert², F. Maes⁶, C. Mai⁷, R. Oyen⁷, S. Joniau⁸, M. Kunze-Busch⁴, K. Haustermans²;

¹Nuclear Medicine, University Hospitals Leuven, Leuven, BELGIUM, ²Radiation Oncology, University Hospitals Leuven, Leuven, BELGIUM, ³Radiation Oncology, The Netherlands Cancer Institute, Amsterdam, NETHERLANDS, ⁴Radiation Oncology, Radboud University Medical Centre, Nijmegen, NETHERLANDS, ⁵Radiology &

Nuclear Medicine, Radboud University Medical Centre, Nijmegen, NETHERLANDS, ⁶Electrical Engineering, ESAT/PSI, KU Leuven, Leuven, BELGIUM, ⁷Radiology, University Hospitals Leuven, Leuven, BELGIUM, ⁸Urology, University Hospitals Leuven, Leuven, BELGIUM.

Aim/Introduction: Using uniform window levels for PSMA PET-based gross tumour volume (GTV) contouring in primary prostate cancer focal boost strategies reduces interobserver variability. The aim of this study was to determine optimal threshold-based window levels for both ⁶⁸Ga-PSMA-11 and ¹⁸F-PSMA-1007 PET-based GTV contouring. **Materials and Methods:** Nine ⁶⁸Ga-PSMA-11 and ten ¹⁸F-PSMA-1007 PET scans including GTV-delineations of four expert teams (GTV_{manual}) and a majority-voted GTV (>50% of individual segmentations) (GTV_{majority}) were assessed with respect to a registered histopathological GTV (GTV_{histo}) as gold standard reference. The standard uptake values (SUVs) per voxel were converted to a percentage (SUV%) relative to the SUV_{max} measured in the corresponding prostate and seminal vesicles. The optimal threshold was defined as the threshold that maximizes accuracy for semi-automatic contouring. A leave-one-out cross validation receiver operating characteristic (ROC) curve analysis was performed to identify this statistically optimal SUV% thresholding (SOST) threshold for both tracers. The SOST-analysis was performed twice: once with the GTV_{histo} contour as training structure (GTV_{SOST-H}) and once with the GTV_{majority} contour as training structure (GTV_{SOST-MA}) to correct for any limited misregistration. The accuracy of both SOST-based semi-automatic contours was calculated relative to the histological reference structure in the 'leave-one-out' patient of each fold and compared with those obtained by the manual contours. **Results:** A median voxel-wise accuracy for GTV_{manual} ranging between 85.7%–92.3% and between 72.1%–93.2% per team for ⁶⁸Ga-PSMA-11 and ¹⁸F-PSMA-1007 PET-based contours, respectively, was found. ROC-curve analysis revealed a median GTV_{SOST-H} threshold of 24 SUV% (range, 22–27 SUV%) and 40 SUV% (range, 39–44 SUV%) (p<0.001) for ⁶⁸Ga-PSMA-11 and ¹⁸F-PSMA-1007 PET, respectively. Median GTV_{SOST-MA} thresholds of 41 SUV% (range, 40–43 SUV%) for ⁶⁸Ga-PSMA-11 PET and 45 SUV% (range, 43–46 SUV%) for ¹⁸F-PSMA-1007 PET were calculated (p<0.001). A statistically significant pairwise difference in accuracy was found when comparing the accuracy of GTV_{SOST-H} contours with GTV_{SOST-MA} contours for the 'leave-one-out'-patient of each fold (median, -5.7%; IQR, -16.6 - -0.2%; p=0.001). No significant pairwise difference was found when comparing the accuracy of GTV_{SOST-MA} contours with the median accuracy of GTV_{manual} contours (median, -0.5%; IQR, -4.9 - 0.5%; p=0.184), whereas for the GTV_{SOST-H} contours a significant pairwise difference was observed (median, -6.5%; IQR, -27.8 - 0.3%; p=0.011). **Conclusion:** Semi-automatic GTV_{majority}-trained SOST-based contours achieve accuracy comparable to manual contours to

delineate GTV_{histo}. The obtained optimal SUV% thresholds could serve as a base for optimal ⁶⁸Ga- and ¹⁸F-PSMA PET window levelling to reduce interobserver and inter-tracer delineation variability. **References:** None

EPS-148

Methodological Quality of Guidelines for Positron Emission Tomography is Suboptimal

Q. Li^{1,2}, W. Hou¹, L. Li², M. Su¹, Y. Ren², W. Wang², K. Zou², R. Tian¹, X. Sun²;

¹Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA, ²Chinese Evidence-based Medicine Center, West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: Facilitated by clinical application of novel tracers and imaging modalities, guidelines for positron emission tomography (PET) are released increasingly to assist patient care. The potential benefits of guidelines depend on the quality of themselves. However, the methodological quality of PET guidelines have never been examined. We hereby examined the methods used for evidence synthesis and recommendation formation in peer-reviewed guidelines for PET. **Materials and Methods:** We systematically searched PubMed from inception to 2 December 2019 for the latest version of PET guidelines published in English. Evaluation criteria were adapted from an internationally developed and validated guideline assessment instrument, the AGREE (Appraisal of Guidelines for Research and Evaluation) II instrument. We also examined the use of evidence in procedure guidelines released in recent five years. **Results:** We included 47 guidelines, published between 2004 and 2020, among which, 19 (40.4%) focused on the appropriate use of PET in diverse clinical indications, 27 (57.4%) were procedure guidelines providing step-by-step instructions, and one guideline (2.1%) equally discussed both. Guidelines for PET indications were mainly (17, 89.4%) based on literature review. 12 guidelines (63.1%) reported the level of evidence, 4 (21.0%) reported the strength of recommendations, 8 (42.1%) involved methodologist(s), and 3 (15.7%) described external review. The 2018 EANM/EAN series of guidelines for neurodegenerative conditions reported the most rigorous development methodology. Guidelines for procedures were mainly (24, 88.9%) consensus without literature review. Only one guideline (3.7%) reported the level of evidence, one (3.7%) reported the strength of recommendations, 7 (25.9%) involved methodologist(s), and 3 (11.1%) described external review. Recent procedure guidelines poorly referenced evidence and varied in contents. Evidence-based recommendations were available in merely 7 guidelines (33.3%) on radiation safety, 8 (38.0%) on radiopharmaceutical dosage, 11 (52.3%) on patient preparation, and 12 (57.1%) on equipment quality control. No recommendation was provided for radiation safety in 10 guidelines (47.6%) and for personnel

qualification in 9 guidelines (42.9%). Two procedure guidelines presented evidence-based recommendations for all necessary contents: the 2019 joint EANM/EANO/RANO/SNMMI guideline for gliomas and the 2015 EANM guideline for tumour imaging. **Conclusion:** This is the first study on the methodological quality of guidelines for PET. Our results advised guideline users that the rigor of evidence synthesis and recommendation formation is suboptimal in PET guidelines, and suggested guideline developers that efforts are needed to improve the methodological quality. Critical appraisals are warranted to thoroughly examine the development and reporting of PET guidelines. **References:** None

Reporting Standards for Bland-Altman Agreement Analysis: a Systematic Review of Methodological Reviews

O. Gerke^{1,2};

¹Dept. of Nuclear Medicine, Odense University Hospital, Odense C, DENMARK, ²Dept. of Clinical Research, University of Southern Denmark, Odense C, DENMARK.

Aim/Introduction: Bland-Altman Limits of Agreement (BA LoA) are a popular and widespread means of analyzing the agreement of two methods, instruments, or raters in quantitative outcomes. Agreement analysis could be reported as stand-alone research articles but are more often than not conducted as a minor quality assurance project in a subgroup of patients in a larger diagnostic accuracy study, clinical trial, or epidemiological survey, leading to brief descriptions and few details in the main report [1]. To this end, reporting items for Bland-Altman analysis have been proposed in different medical areas. The aim of this study was to identify such reporting standards proposals for BA agreement analysis, find the most comprehensive one, and exemplify it with interrater data of a Bland-Altman analysis from our institution. **Materials and Methods:** MEDLINE/PubMed was searched including publications until March 3, 2020. All papers that proposed a list of items for standardizing BA plots were included, irrespective of article type (systematic reviews, narrative reviews, original articles, commentaries, editorials, letters, and case studies). **Results:** The literature search resulted in 5,600 hits. Seven proposals were identified, three of which were derived from reviewing anesthesia journals. Four studies leaned on publications within 2-year time frames, and the number of included publications varied from 0 to 394 (median: 50). Across included studies, 16 reporting items were proposed. Broad consensus was seen for the a priori establishment of acceptability benchmarks, the estimation of repeatability of measurements, description of the data structure, visual assessment of the normality and homogeneity assumption, and plotting and numerically reporting of both bias and BA LoA including 95% confidence intervals. Abu-Arafah

et al. proposed the most comprehensive and prudent list, identifying 13 key items for reporting [2]. **Conclusion:** The unbowed popularity of BA plots, the limited extent as to which BA plots are reported and interpreted in the literature, and the associated need for standardization as evidently expressed by the included proposals obligate researchers to more diligence and warrant journal editors to consider the work of Abu-Arafah et al. [2] as an essential supplement to GRRAS [1] with respect to statistical analysis of agreement with BA plots. **References:** (1) Kottner J, et al. Guidelines for Reporting Reliability and Agreement Studies (GRRAS) were proposed. *J Clin Epidemiol.*2011;64(1):96-106. <https://doi.org/10.1016/j.jclinepi.2010.03.002>. (2) Abu-Arafah A, et al. Bone metastasis classification in bone scintigraphy using densely-connected convolutional neural networks

N. Papandrianos¹, E. I. Papageorgiou², A. Anagnostis^{3,4}, A. Feleki⁵, K. Papageorgiou⁶, D. J. Apostolopoulos⁷;

¹University of Thessaly, Lamia, GREECE, ²Department of Energy Systems, Faculty of Technology, University of Thessaly, Geopolis Campus, Larissa, GREECE, ³University of Thessaly, Computer Science and Telecommunications Department, Lamia, GREECE, ⁴Institute for Bio-economy and Agri-technology, Center for Research and Technology Hellas, Volos, GREECE, ⁵Faculty of Technology, University of Thessaly, Geopolis Campus, 41500, Larissa, GREECE, ⁶University of Thessaly, Computer Science & Telecommunications Department, Lamia, GREECE, ⁷University of Patras, Medical School, Department of Nuclear Medicine, PC 26504, Rio, Achaia, GREECE.

Aim/Introduction: Bone metastasis is one of the most frequent cancer complications and mainly emerges in patients suffering from certain types of primary tumors. The development of automated image analysis tools for bone scans is a challenge to accurately classify patterns of bone lesions. This paper addresses the image recognition problem of bone metastasis diagnosis, using whole-body scans, by investigating the promising capabilities of densely connected convolutional neural networks (CNN). **Materials and Methods:** This study employs the dense convolutional network (DenseNET), as an efficient type of deep network with transfer learning capabilities, to recognize medical images by extracting their insightful features and using them for their precise classification. The retrospective study included 808 sequential male patients suffering from prostate cancer, who underwent whole-body bone scans. A nuclear medicine physician classified all the cases into 3 categories: normal, malignant, and degenerative, which was used as gold standard. The provided dataset

of images was shuffled and split into a 85% training and validation set and a 15% testing set. The network's weights were pre-trained using the ImageNet database with natural images, allowing the network to learn general image features. The network was then fine-tuned using the whole-body scans. The experiments were performed in a collaborative environment, with free GPU acceleration, called Google Colab. A meticulous CNN exploration process was accomplished, in which different sets of configurations, regarding various drop rates, epochs, number of dense nodes, pixel sizes and batch sizes, were explored. **Results:** After CNN exploration analysis, the best DenseNET-based model parameters include: batch-size=32, dropout=0.2, pixel=350x350x3, flatten, dense nodes=1024-1024, epochs=200. The network's accuracy (ACC), sensitivity (SEN), specificity (SPEC), and AUC were evaluated on an independent 15% testing dataset. The results revealed that the method is sufficiently precise when it comes to differentiate the metastatic bone from degenerative changes as well as from normal tissue (overall ACC = 91.26%±2.95%, loss 0.25±0.12, SEN 0.894, SPEC 0.946, and AUC 0.93). The accuracy of prostate cancer identification regarding normal, malignant or degenerative changes was up to 95.8±1.1%, 94.3±2.2% and 90.8±2.1%, respectively. To strengthen the outcomes of the study, authors further compared the proposed classifier with the popular VGG16 (ACC 89.47±4.53%, loss 0.33±0.16, SEN 0.882, SPEC 0.933, and AUC 0.906). **Conclusion:** The proposed approach is proven as an efficient and robust decision support tool that can help nuclear medicine physicians to make immediate and accurate diagnosis of bone metastasis in prostate cancer patients, using bone scans. **References:** colab.research.google.com

EPS-151

Segmentation Protocols in ^{99m}Tc-MAA SPECT/CT for ⁹⁰Y Radioembolization Treatment Planning

G. Mok, Z. Lu;

University of Macau, Taipa, MACAO.

Aim/Introduction: Segmentation of lungs, tumor and normal liver is a major source of errors for ^{99m}Tc-MAA SPECT/CT-based dosimetry for ⁹⁰Y radioembolization. The goal of this study is to assess different segmentation protocols for lung shunt fraction (LSF) and tumor-to-normal liver ratio (TNR) for ^{99m}Tc-MAA SPECT/CT. **Materials and Methods:** The XCAT phantom was used to simulate 10 patient anatomies with ^{99m}Tc-MAA distribution, with 5%-20% LSF, axial respiratory motion of 2 cm, different TNR and tumor size. An analytical projector for low energy high resolution parallel-hole collimator was used to simulate 128 realistic noisy projections. The OS-EM method was used for reconstruction with 4 iterations and 16 subsets with attenuation correction using averaged attenuation map, effective source scatter estimation and

geometric collimator-detector-response modelling. For LSF, lungs were segmented based on different CT images, i.e., helical CT at end-inspiration (HCT-IN), helical CT at mid-respiration (HCT-MID), helical CT at end-expiration (HCT-EX) and cine averaged CT (CACT). For measuring the lung counts, 2.21 cm lung basal region was excluded to calculate the lung mean count density and then multiply with the original lung volume [1] from different CTs. Liver was segmented based on SPECT images with 2.5% lower threshold or contouring on respective CT images. For TNR, tumors and normal liver were segmented from intensity thresholding on SPECT, contouring on various contrast HCTs or by combining the information from both of them [2]. The mean errors of LSF and TNR for different phantoms were computed for different protocols. **Results:** For liver segmentation in various LSFs, the LSF errors are generally higher for CT-based segmentation as compared to those of SPECT-based segmentation, which can reach 15% when using HCT-EX to segment the lungs. The mean LSF error is lowest for the use of CACT to segment the lungs, i.e., <1%. The TNR errors can be over 30% when using contrast HCT-EX as the segmentation method. The mean TNR error is lowest for SPECT-based segmentation with 50% and 2.5% lower threshold for tumor and liver respectively. **Conclusion:** It is recommended to use SPECT thresholding based method to segment the liver and to use CACT to segment the lungs for LSF calculation. The TNR can be measured based on SPECT data with good quantitation accuracy without the use of contrast CT for ⁹⁰Y radioembolization treatment planning. **References:** [1] Yu N, et al. EPS-152

A new mathematical concept omitting fitting procedures to describe radio tracer processes in kidneys using linear response theory

B. Geist¹, M. Hacker¹, H. Neufeld²;

¹Medical University Vienna, Vienna, AUSTRIA,

²University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Compartmental kinetic models (KM) are commonly used to mathematically describe a measured tracer time activity curve (TAC) of an organ, acquired from dynamically performed imaging scans. They ideally cover the main biochemical processes, which are quantified after applying fitting procedures to measured TACs. In case of the kidneys, the application of a KM is hampered due to the complexity of renal processes and intra-renal delays, leading to a high number of fit parameters or vague descriptions. We thus developed mathematical tools to describe renal TACs without the need for fitting procedures. **Materials and Methods:** The description follows the approach to track the tracer particles along their journey according to

the continuity equation. Employing the methods of linear response theory, a probability density function (PDF) is calculated, reflecting tracer processes at certain time points. The approach was applied on kidney TACs from an accomplished and a running study performed at the Division of Nuclear Medicine (Medical University of Vienna, ethical approval numbers 1068/2015 and 1734/2017): adult subjects were scanned twice, with a renal scintigraphy using $[^{99m}\text{Tc}]$ -mercaptoacetyltriglycine (MAG3) and with a dynamic positron emission tomography (PET) scan using 2-deoxy-2- $[^{18}\text{F}]$ fluoro-D-glucose (FDG). While MAG3 is not filtered in the glomeruli and mainly excreted from the kidneys, FDG is filtered, partially re-absorbed and excreted. The obtained probabilities from the PDFs were compared to the clinical parameters renal blood flow (RBF), glomerular filtration rate (GFR), transit time (TT) and outflow efficiency (OE). **Results:** So far, the MAG3 and FDG TACs from 14 subjects were investigated. For MAG3, the PDF revealed a high initial venous outflow, correlating with the RBF by $r = 0.94$ ($P < 0.001$), no re-absorption from the renal system, and finally a high outflow at averaged 4.3 minutes, correlating with the OE by $r = 0.85$ ($P < 0.001$) and with the TT by $r = 0.90$ ($P < 0.001$), respectively. For FDG, the PDF revealed a continuous venous outflow matching with re-absorption of averaged 20 % within the first two minutes. The filtrated proportion correlated with the GFR by $r = 0.82$ ($P < 0.001$). FDG was excreted after averaged 3.8 minutes, correlating with the OE by $r = 0.62$ ($P < 0.001$). **Conclusion:** To describe the various renal processes and intra-renal delays, a new approach was developed omitting the usage of fits. A first evaluation showed promising results, which will be presented together with further analyzed data. **References:** None

OP-824**Therapy and Beyond***J. Nonnekens; Erasmus MC, Molecular Genetics and Radiology & Nuclear Medicine, Rotterdam, NETHERLANDS.***OP-825****Disturbing redox balance enhances the biological effect of PRRT but not EBRT in a panel of cancer cell lines***W. Delbart, G. E. Ghanem, P. Flamen, Z. Wimana; Institut Jules Bordet, Brussels, BELGIUM.*

Aim/Introduction: Radiobiology of radionuclide therapy has often been extrapolated from external beam radiation therapy (EBRT), where DNA damage has been attributed a central role in ionizing radiation-induced cell death, via direct and indirect effects. In case of low LET radiation, such as with ^{177}Lu , biological effects are mostly relying on indirect effects, via reactive oxygen species (ROS) production. Hence oxidative damage to DNA and other macromolecules occur if ROS can exceed the cell antioxidant defenses. Our in vitro study aims at comparing the radiosensitizing potential of decreasing antioxidant defenses in combination with ^{177}Lu -DOTATATE versus EBRT. **Materials and Methods:** Human cancer cell lines expressing somatostatin receptors were selected for their different intrinsic radiosensitivities to radiation therapy: HBL and MM162 (melanoma-radioresistant), COLO-677 and EJM (multiple myeloma-radioresistant),

MIA-PACA-2 and HT-29 (pancreatic and colon carcinoma-intermediate radioresistance). Cells were irradiated at 2Gy of EBRT or exposed to 5MBq ^{177}Lu -DOTATATE during 4 hours. In the combination experiments, the glutathione (GSH) synthesis inhibitor, BSO (10^{-7} M), was already added 24h prior irradiation and was maintained during the entire experiment of 10 days. Cell survival was assessed using crystal violet. **Results:** Cell lines displayed various sensitivities to radiation therapy. Except in the radioresistant HT-29, cell survival was significantly decreased by ^{177}Lu -DOTATATE and EBRT in all cell lines. Supplementation with BSO could further significantly decrease cell survival of HBL (-40%), MM162 (-11%), EJM (-23%), and MIA-PACA-2 (-28%) compared to ^{177}Lu -DOTATATE alone (all p values < 0.05). When increasing BSO concentration to 10^{-6} M, its radiosensitizing effect was also observed in COLO-677 (-55%) and even in the radioresistant HT-29 (-20%). In contrast, BSO had no added value when added in combination with EBRT. **Conclusion:** Our results showed that disturbing the cell redox balance using a GSH synthesis inhibitor had a radiosensitizing effect in all cell lines when used in combination with ^{177}Lu -DOTATATE, while it had no additional benefit in combination with EBRT. This highlights differences in radiobiological mechanisms between these 2 radiation-based treatment modalities. Additionally, these encouraging results pave the way to new combination strategies not yet explored in the context of radionuclide therapy. **References:** None

OP-826 **^{225}Ac -labeled anti-EphA2/EGFR bispecific radioimmunoconjugate prolongs survival of mice bearing triple negative breast cancer xenograft***B. Khan¹, R. Solomon¹, E. Alizadeh¹, N. Thiele², P. Causey³, R. Perron³, D. Gendron³, J. Wilson², T. Behzad¹, F. Vizeacoumar¹, A. Freywald¹, H. Fonge¹;*¹University Of Saskatchewan, Saskatoon, SK, CANADA,²Cornell University, Ithaca, NY, UNITED STATES OF AMERICA,³Canadian Nuclear Laboratories, Chalk River, ON, CANADA.

Aim/Introduction: Triple negative breast cancer (TNBC) is a deadly form of breast cancer (BC). Epidermal growth factor receptor I (EGFR) is overexpressed in over 85% of TNBC, anti-EGFR targeted therapies have been evaluated albeit with very limited success. In addition, about 70% of TNBC tumors overexpress the subtype A2 of the erythropoietin-producing hepatocellular (EphA2) tyrosine kinase. For the first time we have developed a bispecific antibody (bsAb) against EGFR and EphA2. Our hypothesis is simultaneous targeting of EGFR/EphA2 using alpha particle (^{225}Ac) labeled radioimmunoconjugates will prolong survival of mice bearing EGFR+/EphA2+ TNBC tumors. To accomplish this, we have developed ^{89}Zr -bsAb for microPET/CT imaging and ^{225}Ac -bsAb for alpha particle therapy in EGFR/EphA2 TNBC mouse models. **Materials and Methods:** Anti-EphA2/

EGFR bsAb was radiolabeled with ^{89}Zr for microPET imaging and biodistribution. Tumor uptake of ^{89}Zr -bsAb ,control ^{89}Zr -human IgG was studied in CD-1 nude mice inoculated with EphA2+/EGFR+ MDA-MB-231 TNBC cells. BsAb was radiolabeled with ^{225}Ac for alpha particle therapy. The (radio)immunoconjugates and controls were characterized by flow cytometry, HPLC and internalization rate (live-cell imaging). In vitro cytotoxicity was studied in EphA2+/EGFR+ MDA-MB-231. In vivo radioimmunotherapy using ^{225}Ac -bcAb was studied in EphA2+/EGFR+ MDA-MB-231 model following treatment with three doses of 350 nCi/dose administered 10 days apart. A panel of EphA2-/EGFR+, EphA2+/EGFR- and EphA2-/EGFR- cells are developed to further characterize the imaging properties of ^{89}Zr -bsAb and study in vitro cytotoxicity and in vivo efficacy of ^{225}Ac -bsAb. **Results:** Flow cytometry showed > 90% binding to the cells. The microPET imaging data showed persistently high tumor uptake of ^{89}Zr -bsAb in EphA2+/EGFR+ MDA-MB231 xenograft. The uptake of ^{89}Zr -bsAb was clearly visible as early as 24 h p.i. ($6.1 \pm 0.9\%$ IA/g) and peaked at around 48 h p.i. ($6.6 \pm 1.3\%$ IA/g). In vitro studies showed enhanced cytotoxicity (IC_{50}) of ^{225}Ac -bsAb (1.8 ± 0.6 nM; 0.5 nCi/mL) compared with control ^{225}Ac -IgG (5.8 ± 1.9 nM; 1.5 nCi/mL) and non-labeled antibodies: bsAb (113.5 ± 0.4 nM); human IgG (374.1 ± 1 nM), respectively. ^{225}Ac -bsAb prolonged the survival of mice bearing EphA2+/EGFR+ MDA-MB231 TNBC xenograft compared with control ^{225}Ac -human IgG or non-treated mice. 1/5 mice treated injected with ^{225}Ac -bsAb had complete remission. Median survival after > 90 days since start of treatment are: ^{225}Ac -bsAb (not yet reached); unlabeled bsAb (37 days), control ^{225}Ac -human IgG (24 days), non-treated (20 days). **Conclusion:** ^{225}Ac -labeled anti-EGFR/EphA2 bispecific radioimmunotherapeutic shows great promise in TNBC. Validation of this radioimmunoconjugate in other TNBC xenografts is ongoing. **References:** None

OP-828

Comparison of intravenous and intraperitoneal dosing of the Targeted Alpha Therapy Thorium-227-*anetumab corixetan* in a model of peritoneal carcinomatosis of mesothelioma

U. Hagemann¹, M. I. Suominen², I. Moen³, M. Brand¹, C. Ellingsen³, A. S. Cuthbertson³, D. Mumberg¹;
¹Bayer Ag, Berlin, GERMANY, ²Pharmatest Services, Turku, FINLAND, ³Bayer AS, Oslo, NORWAY.

Aim/Introduction: Peritoneal carcinomatosis is common in abdominal cancers of mesothelium and ovary appendix. The treatment may include cytoreductive surgery followed by hyperthermic intraperitoneal chemotherapy. Mesothelin-targeted thorium-227 conjugate (MSLN-TTC, ^{227}Th -*anetumab corixetan*) is a new targeted alpha therapy (TAT; 1, 2) currently being tested in phase 1 in patients suffering from mesothelioma and serous ovarian cancer (NCT03507452)

and dose administration is pursued intravenously. An alternative treatment option could be administration of MSLN-TTC into the intraperitoneal cavity. We present the differences in biodistribution, efficacy and tolerability of the two administration routes, studied in a mouse model of peritoneal carcinomatosis of mesothelioma. **Materials and Methods:** Nude mice with established intraperitoneal (i.p.) luciferase-tagged mesothelioma NCI-H226 tumors were allocated to 7 groups (n=10 each) after stratification using bioluminescence imaging signals (BLI). Animals were treated either intravenously (i.v.) or intraperitoneally (i.p.) with MSLN-TTC (2 x 250 kBq/kg, 8 weeks apart, or 1 x 500 kBq/kg). Tumor burden was followed by weekly bioluminescence imaging (BLI). Mice were sacrificed when a critical BLI signal intensity was reached. Tolerability was followed by hematology measurements. In a biodistribution study, MSLN-TTC accumulation was compared to a murine cross-reactive MSLN-surrogate-TTC, both administered either i.v. or i.p. at a dose of 500 kBq/kg. Organs and tumors were harvested two weeks after administration to determine accumulated thorium-227. **Results:** In the biodistribution study, a statistically significant higher tumor accumulation was observed for MSLN-TTC after i.p. administration when compared to i.v. Accumulation in all organs, including isolated peritoneum, was not statistically significantly different. Similarly, there was no difference in organ and tumor accumulation between MSLN-TTC and the murine cross-reactive MSLN-surrogate-TTC. In the efficacy study, animals were euthanized upon reaching a critical BLI signal. Vehicle treated animals showed a medium survival time (MST) of 25 days and the MST for radiolabeled isotype control treated animals was 55 days after i.v. or i.p. administration. However, animals treated with MSLN-TTC showed MST of 80 to 98 days after i.v. or i.p. dose administration. However, based on tumor weight data upon sacrifice, i.p. administration of MSLN-TTC appeared to be more effective than i.v. administration. Intravenous administration of MSLN-TTC resulted in longer lasting leukopenia. **Conclusion:** Intraperitoneal administration of MSLN-TTC in an intraperitoneal model of mesothelioma resulted in increased efficacy and decreased myelosuppression. **References:** 1. Aim/Introduction: Multiple myeloma (MM) is a B-cell malignancy of terminally differentiated plasma cells developing in the bone marrow. Despite a considerable improvement over the past 30 years, cure is almost never achieved. We have already demonstrated the usefulness of Targeted Alpha-Therapy (TAT) to eradicate residual cells in a MM preclinical syngeneic model by administering a single high dose of monoclonal antibody anti-CD138 radiolabeled with astatine-211 as alpha particle-emitting radionuclide. The aim of this study was to evaluate the benefit of dose fractionation or repeated doses of an astatine-211-labelled anti-mouse CD138 antibody (²¹¹At-9E7.4) in term of survival or side effects in the same syngeneic mouse MM model compared to one injection therapy. **Materials and Methods:** C57BL/KaLwRij mice were grafted with 10⁶ 5T33 MM cells by intravenous injection and received a first injection of ²¹¹At-9E7.4 ten days after. A group of mice was used to evaluate the fractionated doses protocol in which a 660 kBq efficient activity was administered in one injection, in 2 fractions of 330 kBq or in 3 fractions of 220 kBq with 1 or 2 weeks interval. A second group was used to evaluate the repeated doses protocol: a 660 kBq activity was administered once or twice with 1 or 2 weeks interval. Hematologic parameters were monitored as well as survival. Data were compared to our previously data obtained with single-dose. **Results:** As a reminder, a single-dose of 740 kBq of ²¹¹At-9E7.4 was able to cure 65% of mice until 150 days after engraftment while 1100 kBq provoked radiotoxic lethality 14 days after treatment injection. Without any treatment, mice died around 42 days after engraftment presenting paraplegia in most of the cases. In this study, a single-dose of 660 kBq cured 40% of mice at D100. The fractionation in 2 doses treated only 20% of mice regardless of the time interval between the 2 doses. By fractionating the dose of 660 kBq in 3 parts of 220 kBq, even less survival benefit was observed. Concerning the repeated dose protocol, an interval of one week between 2 injections of 660 kBq appeared lethal while an interval of 2 weeks appeared possible in term of early radiotoxicity but gave no benefit in term of survival. **Conclusion:** In the particular context of MM disseminated microlesions treatment, it appears that neither the split-dose protocol nor the repeat-dose protocol provided better results than the single-dose treatment. **References:** None

Increased SST₂ Expression on Pulmonary Neuroendocrine Tumor Cells by Epigenetic Drug Treatment with Histone Deacetylase Inhibitors

I. Klomp, S. U. Dalm, P. M. van Koetsveld, F. Dogan-Oruç, M. de Jong, L. J. Hofland;
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Our aim is to increase the expression of somatostatin type-2 receptors (SST₂) on the pulmonary neuroendocrine tumor (NET) cell line NCI-H727 by using epigenetic drugs. We tested the effect of six histone deacetylase inhibitors (HDACis), aiming to promote the euchromatin state supporting SST₂ gene transcription. This approach may possibly open up opportunities for NET patients with insufficient tumoral SST₂, thereby increasing the number of patients eligible for SST₂-targeted therapies such as peptide receptor radionuclide therapy (PRRT). We also compared our results with similar studies performed in the pancreatic NET cell line BON-1. **Materials and Methods:** EC₅₀ values on cell growth were determined in NCI-H727 after 7-day HDACi treatment. Valproic acid (VPA), tacedinaline (TAC), entinostat (ENT), LMK-235, mocetinostat (MOC) and panobinostat (PAN) were evaluated. After a 7-day treatment, (1) samples were collected for RT-qPCR to determine SST₂ mRNA expression levels and (2) internalization studies were performed by incubating NCI-H727 with 1mL of 1nM [¹¹¹In]In-DOTA-TATE (50MBq/nmol), +/- 1µM unlabeled DOTA-TATE. To study the reversibility of the observed effects, samples were collected for RT-qPCR 1 and 3 days after HDACi-withdrawal. **Results:** For all HDACis, except MOC, the uptake of [¹¹¹In]In-DOTA-TATE was significantly increased, reaching a maximum upregulation of 4.2-fold for VPA. In line with this, SST₂ mRNA levels were upregulated as well, although statistical significance was not reached for LMK-235 and PAN. For MOC, both SST₂ mRNA levels and uptake of [¹¹¹In]In-DOTA-TATE were significantly downregulated. Already 1 day after HDACi-withdrawal, SST₂ mRNA levels were significantly lowered for 5 of the 6 HDACis. Only VPA-treated cells reached control levels at this time. Three days after drug withdrawal, SST₂ mRNA levels reached control levels for all treatments. In comparison, control levels were not reached yet in BON-1 7 days after HDACi-withdrawal for 4 of the 6 HDACis. Moreover, the percentage increased uptake of [¹¹¹In]In-DOTA-TATE was higher in BON-1. **Conclusion:** In conclusion, SST₂ expression is evidently upregulated by HDACi treatment in NCI-H727, characterized by intermediate basal SST₂ expression levels. Effects were more prominent in BON-1, probably due to lower basal expression levels of this cell line. Our results support the possibility for a combined treatment approach of HDACi and SST₂-targeted therapies. Furthermore, our in vitro results predict the importance of precise timing as SST₂ upregulation is reversible. Future studies focus

on confirming (1) upregulation of SST₂ protein levels and (2) the epigenetic mechanism-of-action, and (3) in vitro therapy studies by colony forming assays. **References:** None

Aim/Introduction: Many cancer types exhibit increased translocator protein (TSPO) expression, which has been related to an aggressive phenotype and poor prognosis. Therefore, imaging of TSPO in cancer could be a useful tool for treatment planning and/or the development of new TSPO targeting drugs. In cancer, TSPO-PET imaging has been, with a few exceptions, focused to brain gliomas. Our aim of this study was to evaluate the usability of the TSPO-PET tracer [¹⁸F]F-DPA in head and neck cancer (HNC). **Materials and Methods:** [¹⁸F]F-DPA uptake was measured in vivo in FaDu control and RT-treated (locally to tumour, 2 x 5 Gy) xenografts and compared to the uptake of [¹⁸F]FDG. Following imaging, ex vivo biodistribution, tumour autoradiography (ARG) and radioactive metabolite measurements were performed. The uptake of [¹⁸F]F-DPA was also measured in non-irradiated and irradiated parental and TSPO-silenced FaDu cells. TSPO and xCT (a cystine-glutamate transporter) protein expression levels were determined from the xenografts. In addition, TSPO and xCT mRNA expression was also determined from FaDu cells. Blocking studies were done with the TSPO ligand PK11195. **Results:** Significantly higher [¹⁸F]F-DPA uptake was measured in irradiated xenografts ($p < 0.001$) and cells ($p < 0.001$) compared to controls, whereas the [¹⁸F]FDG uptake remained either unchanged or decreased depending on the time after RT. Pre-treatment with PK11195 reduced [¹⁸F]F-DPA uptake by 70% and 85% in xenografts and cells, respectively. A moderate, yet not significant, increase in TSPO protein and mRNA levels was detected after RT. The effect of RT on xCT expression was significant, but changed during the time after RT. No effect of RT on [¹⁸F]F-DPA uptake was detected in TSPO-silenced cells, in which TSPO mRNA and protein levels were significantly ($p < 0.0001$ and $p <$

0.01, respectively) reduced. Ex vivo tissue measurements revealed significantly increased [¹⁸F]F-DPA uptake in adrenal glands ($p < 0.05$) and kidneys ($p < 0.05$) after local RT to tumours. The amount of radioactive metabolites was only approximately 5% in both control and RT treated tumours, whereas approximately 35% of [¹⁸F]F-DPA was metabolized in blood. **Conclusion:** Our results show that [¹⁸F]F-DPA can be used for TSPO imaging in HNC. Furthermore, [¹⁸F]F-DPA uptake did reveal RT-induced and TSPO-dependent changes in FaDu xenografts and cells, indicating that TSPO-PET imaging might be utilized in predicting and monitoring RT outcomes. Further studies are needed to determine whether the RT-induced [¹⁸F]F-DPA uptake reflects inflammation, reactive oxygen production, or changes in energy demand. **References:** None

Ultrasound enhanced brain delivery of ⁸⁹Zr-Cetuximab, an anti-EGFR based immunotherapy followed by immunoPET

A. Schweitzer-Chaput¹, A. Novelli¹, N. Tournier¹, V. Tran¹, B. Jegou¹, B. Larrat², C. Truillet¹;

¹Université Paris-Saclay, cea, cnrs, inserm, BioMaps, Orsay, 91401, FRANCE, ²Université Paris-Saclay, cea, cnrs, NeuroSpin/baobab, Gif sur Yvette, 91191, FRANCE.

Aim/Introduction: Glioblastoma (GBM) is the most common and aggressive malignant brain tumour in adults, with a survival rate of approximately 5% at five years. The main source of resistance is the blood brain barrier (BBB), regulating the access of molecules to the brain. Several methods of BBB opening have been developed, among which the use of focus ultrasound (FUS) with gas microbubbles, causing a transient and targeted opening. In this project, we studied the delivery and diffusion of an anti-EGFR monoclonal antibody, the cetuximab (CTX), after BBB opening by FUS of a large part of the brain of healthy mice and then of an orthotopic GBM mouse model monitored by positron emission tomography (PET). **Materials and Methods:** First, the affinity constant (K_d) of CTX for human and murine EGFR were determined. The CTX was then labelled with zirconium-89 (⁸⁹Zr). In vivo experiments involved four groups of nude mice (n=8) with intact BBB: sham group (without FUS), Sham group with a pharmacologic dose of CTX, FUS group and FUS group with pharmacologic dose. BBB opening was achieved using a focused transducer on a large square region (6x6 mm). After FUS, all group received similar dose of ⁸⁹Zr-DFO-CTX (0.24 ± 0.07 MBq/g) under the PET scanner. 60min dynamic PET acquisition were performed immediately after injection, then 30min static PET acquisition until 7 days after injection. **Results:** K_d of CTX for human EGFR was 950pM and 65nM for mouse EGFR, showing low affinity of CTX for murine EGFR. After FUS, ⁸⁹Zr-DFO-CTX brain uptake was almost two

time higher in FUS groups compared to sham groups. The difference between FUS and sham remained significant even 168h after injection. The uptake of ^{89}Zr -DFO-CTX to the brain was not impacted by the addition of pharmacologic dose of CTX, showing that the ^{89}Zr -DFO-CTX diffusion was not due to specific binding. The elimination half-life from brain was $5.01 \pm 0.7\text{h}$ in sham and $21.4 \pm 1.7\text{h}$ in FUS group. **Conclusion:** In this study we have shown that with FUS we could increase significantly the uptake of ^{89}Zr -DFO-CTX across the BBB. Furthermore, after BBB opening, we observe a slight diffusion back to the blood compartment and a slow diffusion within brain parenchyma. Following these results, we are conducting a study of effectiveness of ^{89}Zr -DFO-CTX + FUS for treatment of orthotopic mice model of GBM. **References:** None

Pharmacological inhibition of mTORC1 increases CCKBR-specific tumor uptake of radiolabeled minigastrin analogue [^{177}Lu]Lu-PP-F11N

M. Grzmil¹, Y. Qin¹, C. Schleuniger¹, S. Frank², S. Imobersteg¹, A. Blanc¹, R. Schibli^{1,3}, M. Behe¹;

¹Paul Scherrer Institute, Villigen PSI, SWITZERLAND, ²Institute of Pathology, University of Basel, SWITZERLAND, ³Department of Chemistry and Applied Biosciences, ETH Zurich, SWITZERLAND.

Aim/Introduction: High expression of G-protein coupled receptors (GPCRs) that selectively bind their peptide ligands allowed the development of peptide receptor radionuclide therapy (PRRT) for human cancers. The molecular strategies, which increase uptake of radiolabeled peptides selectively in cancer tissue while sparing healthy organs from cytotoxic side effects, have huge potential to improve PRRT efficacy. In the present study, we searched for the novel opportunities to increase tumor-specific uptake of lutetium-177 labeled minigastrin analogue [^{177}Lu]Lu-PP-F11N that targets overexpressed cholecystokinin B receptor (CCKBR) in human cancers. **Materials and Methods:** Drug library screens followed by the proliferation and internalization assays were employed to identify compounds which can increase uptake of [^{177}Lu]Lu-PP-F11N in human epidermoid carcinoma A431 cells which overexpress CCKBR and in rat pancreatic acinar AR42J cells. Western blot (WB) analysis verified inhibition of signaling pathways and CCKBR level. Biodistribution and SPECT imaging of A431/CCKBR xenograft mouse model as well as histological analysis of dissected tumors were used for in vivo validation. **Results:** Our kinase inhibitor library screen identified the mammalian target of rapamycin in complex 1 (mTORC1) pathway, which inactivation increased cell uptake of [^{177}Lu]Lu-PP-F11N. Pharmacological mTORC1 inhibition by RAD001 or metformin increased internalization of [^{177}Lu]Lu-PP-F11N in A431/CCKBR and in AR42J cells. Analysis of the protein lysates from RAD001-treated cells revealed increased level

of CCKBR and lack of mTORC1-regulated phosphorylation of ribosomal protein S6 at Ser235/236. In A431/CCKBR-tumor bearing nude mice, RAD001 pretreatment significantly enhanced tumor-specific uptake of [^{177}Lu]Lu-PP-F11N, whereas metformin treatment did not show a significant difference. Quantification of SPECT/CT images confirmed higher uptake of [^{177}Lu]Lu-PP-F11N in RAD001-treated tumors. The hematoxylin and eosin staining as well as immunohistochemistry of RAD001-treated tumors showed significant increase in the necrosis and a reduction in the number of proliferative and mitotically active cells. No significant difference in the tumor vascularization was observed after a five-day RAD001 or metformin treatment. Currently, our recent screens with FDA-approved drug library identified several other compounds, which can enhance uptake of radiolabeled minigastrin analogue [^{177}Lu]Lu-PP-F11N. **Conclusion:** Our data demonstrate that increasing CCKBR protein level by RAD001 pretreatment has the potential to improve tumor uptake of [^{177}Lu]Lu-PP-F11N and provide proof-of-concept for the development of molecular strategies aimed at enhancing level of the targeted receptor to increase efficacy of PRRT and nuclear imaging. The most recent results and their potential in the theranostics application will be presented and discussed. **References:** None

OP-834

The prevalence and severity of image degradation from motion in rest-stress rubidium-82 PET on a SiPM PET-CT system

I. Armstrong¹, M. Memmott¹, C. Hayden², P. Arumugam¹;

¹Manchester University NHS Foundation Trust, Manchester, UNITED KINGDOM, ²Siemens Medical Imaging Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: We have previously demonstrated the benefit of a high temporal resolution data-driven motion correction (DDMC) algorithm for rubidium-82 relative perfusion PET images [1]. To date, there is limited data on the prevalence of motion degradation during perfusion PET studies. This work compares visual differences between non-corrected (NC) images and their corresponding DDMC images in a large number of cases to demonstrate the prevalence of motion degradation. **Materials and Methods:** Rest and stress relative perfusion images from 300 consecutive patients (181 male; stress agent: 266 adenosine, 34 regadenoson) were reconstructed with and

without DDMC. Patients were administered 740 MBq of Rb-82 for each acquisition with images acquired on a Siemens Biograph Vision and reconstructed with OSEM+PSF+TOF. The 600 image pairs (NC and DDMC) were blinded and shown to two observers who gave a visual difference score (VDS) of 0, 1 or 2 as such: 0 - no difference perceivable; 1 - subtle difference perceivable and 2 - a clear difference perceivable. The NC images from the pairs with a VDS of 2 were graded according to image quality as good, adequate or non-diagnostic. The number of non-diagnostic NC studies were further categorised where either rest or stress, or both images within the study were graded as non-diagnostic as a direct result of motion blurring. **Results:** The distribution of VDS 0, 1 and 2 were 200, 92 and 8 for rest images and 127, 145 and 28 for stress images respectively. Complete results are shown in the Table. For the 36 cases with a VDS of 2, the NC image quality was adequate in 29 images and non-diagnostic for 7 images (5 stress and 2 rest). None of these 36 images were graded as good quality. In one case, the non-diagnostic quality images were rest and stress from the same study while the 5 remaining non-diagnostic images were part of separate studies meaning that 6 of the 300 studies were non-diagnostic as a consequence of motion affecting one or both images within a study. **Conclusion:** The visual impact of motion was seen in 33% of rest and 58% of stress relative perfusion images from rubidium-82 studies. As a result of motion degradation, 2% of studies were considered to be non-diagnostic. This highlights the need for motion correction on modern high-resolution PET systems. **References:** [1] Armstrong IS, Hayden C, Arumugam P. Eur J Nucl Med Mol Imaging 2019; 46:S18-S19

Comparison of respiratory motion estimation methods in cardiac PET/MR

A. Villagran Asieres¹, C. Munoz², T. Kuestner³, T. Vitadello³, C. Rischpler⁴, T. Ibrahim³, R. Botnar³, C. Prieto³, S. Nekolla³;
¹Klinikum rechts der Isar, München, GERMANY, ²King's College London, London, UNITED KINGDOM, ³Klinik und Poliklinik für Innere Medizin I, Klinikum rechts der Isar, School of Medicine, Technical University of Munich, Munich, GERMANY, ⁴Department of Nuclear Medicine, University Hospital Essen, University of Duisburg-Essen, Essen, GERMANY.

Aim/Introduction: During the cardiac images acquisition, heart motion due to physiological processes degrades the image quality that might lead to misinterpretation of non-viable myocardial areas and miscalculation of cardiac morphology and function [1]. Particularly in cardiac PET studies, respiratory and cardiac cycles generate heart displacements greater than 1cm, and with that the blurring of myocardial structures and bias / underestimation in PET tracer uptake. Previous studies have tried to mitigate these effects using external devices (belt), PET data-driven (PDD)

methods, or dedicated MR sequences (INAV) that track the position of the diaphragm. A novel PET/MR approach (INAV + CMRA) that uses INAV to directly localize the myocardium showed promising results[1]. In this ongoing study, we quantitatively compared different approaches for respiratory motion correction in cardiac PET images based on INAV, belt and PDDs techniques. **Materials and Methods:** PET/MR viability assessment exams were performed on 11 patients with chronic coronary diseases. INAV + CMRA sequences, acquired in the last 10 minutes of the protocol, were used to correct for respiratory motion the simultaneous FDG PET images. Respiratory cycles were tracked with an external belt. PDD tracking was obtained by computing the center of mass of the PET sinograms constructed every 250 ms and 1s (PDD1s and PDD250ms). On the other hand, PET reconstructions were carried out with motion corrected and uncorrected attenuation correction maps (MoCo and Static umap). To compare nongated-uncorrected PET images (reference) with gated PET images and motion corrected PET images, profile analysis was performed to compute the thickness and FDG uptake of the myocardial wall (Gaussian FWHM and height values) for all the PET images. **Results:** A preliminary analysis in the first patient showed that motion estimation based on INAV reduced FWHM up to 40% for gated PET images and up to 20% for motion corrected PET images, outperformed belt (dFWHM: -20% / -5%) and PDDs methods (dFWHM: -30% / -5% for 250ms, and -12% / +2% for 1s). **Conclusion:** In general, all the methods reduced the image blurring but the quantitative analysis showed that the INAV method outperformed belt and PDD corrections. As was expected, PDD motion estimation improved when increasing the time resolution. Similar results for motion corrected and uncorrected umaps. **References:** [1] Munoz, (2018). Clinical impact of trigger attenuation correction combined with MR-gating in the correction of respiratory artifacts in thoracic-upper abdominal PET/MR

H. Li¹, X. Meng¹, X. Guan¹, H. Liu², Y. Zhang¹, B. Yu¹, H. Zhu¹, N. Li¹, Z. Yang¹;

¹Peking University Cancer Hospital & Institute, Beijing, CHINA, ²United Imaging Healthcare, Shanghai, CHINA.

Aim/Introduction: Respiratory motion often leads to blurry the PET images in thoracic-upper abdomen region. For the simultaneous PET/MR acquisition, the MR part can provide different sequences for motion correct, such as trigger, which reduce the lesion's uptake quantification error and align the PET and MRI images well. In this study, we

evaluated the clinical value of MR gated PET reconstruction combining with triggered attenuation correction (AC) in the thoracic-upper abdominal regions. **Materials and Methods:** In total, 20 oncologic patients with thoracic-upper abdominal hypermetabolic foci in FDG PET/CT were enrolled in this study, all patients were scanned in an integrated PET/MR system. 28 lesions (17 in liver, 3 in spleen, 3 in pancreas, 2 in peritoneum and 3 in lung) were selected as target lesions. The PET images were reconstructed into 4 groups with different combination of gating and AC (with MR triggered AC vs. breath-hold (BH) AC) techniques, including trigger AC + non MR-gated (group A), trigger AC + MR-gated (group B), BH AC + non MR-gated (group C) and BH AC + MR-gated (group D). A 4-point visual scale was proposed (on the coronal T2WI, score the mismatch degree of liver anatomic image and PET image, from 0 to 3 points reflect well match to obvious mismatch) to evaluate the respiratory artifacts by 2 doctors independently. The quantitative analysis was assessed by SUV metrics and signal-noise ratio (SNR). **Results:** The patient-based analysis showed significant differences in visual respiratory artifact scores among 4 groups, with higher proportion of 0 point in group B ($p=0.000$). The lesion-based analysis demonstrated significant differences in SUV metrics and SNR. Group B showed significant higher SUVmax (7.49 ± 3.37 , 8.45 ± 3.82 , 6.90 ± 3.24 and 7.69 ± 3.50 in A, B, C and D groups, respectively, $p=0.000$), SUVmean (3.90 ± 1.60 , 4.34 ± 1.84 , 3.67 ± 1.61 and 4.03 ± 1.81 , in A, B, C and D groups, respectively, $p=0.000$), SUVpeak (5.60 ± 2.50 , 6.10 ± 2.80 , 5.22 ± 2.40 and 5.65 ± 2.68 , in A, B, C and D groups, respectively, $p=0.000$) and SNR values (136.06 ± 90.58 , 136.24 ± 81.63 , 99.52 ± 53.16 and 107.57 ± 69.05 , in A, B, C and D groups, respectively, $p=0.000$). **Conclusion:** The MR gated reconstruction combining with triggered AC could improve the PET image quality and reduce the mismatch between MR and PET images for the thoracic-upper abdomen imaging in simultaneous PET/MR system. **References:** None

OP-837

Comparison of data-driven gating and external hardware-gating for ^{18}F -FDG PET/MRI in patients with esophageal tumors

S. Kvernby, N. Korsavidou Hult, J. Sigfridsson, H. Ahlström, T. Bjerner, M. Lubberink;
Akademiska hospital, Uppsala, SWEDEN.

Aim/Introduction: Respiratory motion during PET imaging reduces image quality, resulting in decreased lesion detection and quantitative accuracy by introducing an underestimation of the standardized uptake value (SUV) and an overestimation of the lesion volume. Data-driven gating (DDG) based on principal component analysis (PCA) can be used to identify respiratory signals, similarly as external hardware-gating does, and sort data into respiratory phases containing no respiratory motion. The use of DDG,

without need for external devices, would greatly increase the feasibility of using respiratory gating in a routine clinical setting. The objective of this study is to evaluate data-driven gating in relation to external hardware-gating and regular static image acquisition on PET-MRI data. **Materials and Methods:** Ten patients with esophageal tumors underwent a 6 min PET scan on a Signa PET-MRI system (GE Healthcare) 1.5 hours after injection of 4 MBq/kg ^{18}F -FDG. External hardware gating was done using a respiratory bellow device (GE Healthcare) and DDG was performed using MotionFree (GE Healthcare). The DDG raw data files and the external hardware-gating raw files were created on a Matlab-based toolbox (Duetto v02.03, GE Healthcare) from the whole 6 min scan LIST-file. For comparison, a 3 min static raw file was also created for each patient. Images were reconstructed using TF-OSEM with resolution recovery with 2 iterations, 28 subsets and 3 mm post filter. SUV_{max} and lesion volume, based on a 41% SUV_{max} threshold, were measured in all visible lesions. **Results:** A total number of 20 lesions (up to 4 lesions per subject) were included in the study. Both DDG and external hardware-gating demonstrated significantly ($p<0.05$) higher SUV_{max} (9.2 % for DDG; 9.6 % for external hardware-gating) and smaller lesion volume (-4.2 % for DDG; -8.6 % for external gating) in comparison with non-gated static images. No significant differences and a high correlation between DDG and external hardware-gating SUV_{max} values or lesion volumes were found, $R^2=0.967$. **Conclusion:** Data-driven gating with MotionFree for PET-MRI improves image accuracy in comparison with non-gated static acquisition by increasing SUV_{max} and reducing lesion volume. A high agreement between SUV_{max} based on DDG and on external hardware-gating was found. **References:** None

OP-838

Effect of a motion correction algorithm on malignant lung nodule uptake: in comparison to ordinary and breath-hold PET/CT

M. Jreige¹, S. Gnesin¹, P. Schleyer², M. Conti³, J. O. Prior¹;
¹Lausanne University Hospital, Lausanne, SWITZERLAND,
²Siemens Healthineers UK, Frimley, Camberley, UNITED KINGDOM,
³Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Functional imaging by F-18-fluorodeoxyglucose (FDG) SiPM PET/CT is considered an important tool for lung cancer detection and staging, with promising application for screening. We aimed to evaluate the use of a motion correction reconstruction algorithm (Siemens OncoFreeze) for malignant lung characterization in comparison to non-motion-corrected reconstructions and breath-hold PET/CT at full and up to 10% decimated dose. **Materials and Methods:** Six patients investigated for lung nodules were enrolled in this study and underwent a standard-activity (2 MBq/kg) PET/CT (Siemens Biograph

Vision 600) with standard free-breathing trunk acquisition (FB) with an ordinary non-motion-corrected reconstruction (ORD) and the motion-corrected reconstruction (EM), in addition to a dedicated lung Breath-Hold (BH) acquisition lasting between 20–40 s. Low-activity emulations were reconstructed to simulate scans with 10%, 25%, 50% and 75% of the standard injected activity (2MBq/kg) using ordinary and motion correction-algorithms. SUVmax, SUVmean, and Signal-to-Background-Ration (SBR) of malignant nodules were measured across scans. **Results:** Six malignant lung nodules, measuring 15.3 ± 7.6 mm, showed increased FDG uptake with SUVmax, SUVmean (g/mL) and SBR of 7.6 ± 3.7 , 4.6 ± 2.3 and 16.3 ± 6.8 for ORD; 8.0 ± 3.6 , 4.7 ± 2.2 and 17.1 ± 6.4 for EM; and 10.2 ± 5.1 , 5.1 ± 2.6 and 22.1 ± 9.7 for BH respectively. EM and BH increased SUVmax by 23% and 34% in comparison to ORD, respectively. At low-activity simulation scans of 10%, 35%, 50% and 75% the injected activity, EM led to a minimal increase of SUVmax of 2.0%, 0.3%, 3.8% and 2.8% in comparison to ORD, with no effect on SBR, except a slight increase of 1.6% and 1.8% for 50% and 75% of the decimated activity, respectively. **Conclusion:** This study shows that the motion correction reconstruction algorithm can increase FDG uptake measured in malignant lung nodules with standard injected activity. The combination of breath-hold PET/CT and motion correction algorithm may optimize PET/CT performance in lung cancer evaluation. **References:** None

OP-839

Application of a generic dynamic reconstruction algorithm on PET whole-body pharmacokinetic studies

Z. Chalampalakis¹, S. Stute^{2,3}, M. Filipovic¹, S. Marie^{1,4}, M. Bottlaender¹, N. Tournier¹, C. Comtat¹;

¹Service Hospitalier Frédéric Joliot, CEA, Inserm, CNRS, Univ. Paris Sud, Univ. Paris Saclay, Paris, FRANCE, ²Nuclear Medicine Department, Nantes University Hospital, Nantes, FRANCE, ³CRCINA, INSERM, Nantes University, Nantes, FRANCE, ⁴Hôpital Bicêtre, Assistance Publique des Hôpitaux de Paris, Le Kremlin Bicêtre, Paris, FRANCE.

Aim/Introduction: Dynamic PET is an ideal tool to study in vivo pharmacokinetics. When applied to the whole-body with regular scanners, however, large temporal gaps in the acquisition result to low count statistics, making whole-body parametric imaging very challenging. The aim of this study is to improve whole-body parametric imaging, using a generic 4D reconstruction algorithm adapted for dynamic whole-body protocols that does not assume a specific kinetic model. Its application is demonstrated on a research protocol that studies the function of Organic Anion Transporting Polypeptides (OATP, SLCO) transporters in drug delivery to tissues. **Materials and Methods:** The acquisition protocol was implemented on a PET/MR scanner, with whole-body passes of five

bed positions each. The data were reconstructed with a regular 3D-OSEM algorithm and a novel 4D reconstruction algorithm, adapted for imaging with overlapping beds and incorporating the dynamic spectral model [1]. From this model, whole-body images were estimated for each time frame in addition to the K_1 parametric map, assumed to reflect the activity of OATP transporters at the blood-tissue interface. **Results:** Visual comparison of the whole-body dynamic frame images shows clearly lower noise and higher contrast for the 4D reconstruction compared to 3D. The two reconstructions provide similar quantification over large organs/regions of interest in the body. In the liver the root mean square difference (RMSD) of the time activity curves of the two reconstructions is 50 Bq/cc, with an average reduction of variance across frames of 50% for the 4D reconstruction compared to 3D. **Conclusion:** The 4D reconstruction method using the spectral model has shown to greatly improve image quality in whole-body dynamic imaging while maintaining quantification. It also shows the feasibility of doing whole-body parametric imaging with currently available scanners, based on the proposed 4D reconstruction algorithm and minimum assumptions on the underlying kinetics. In the protocol demonstrated here, whole body parametric images provide a tool for direct detection of organs with OATP expression, such as the liver. Further work is required for improving quantification of regions in the field of view that are not completely modeled with the spectral model, like the bladder, using additional dynamic models. **References:** 1) Reader, A. J. & Verhaeghe, J. Phys. Med. Biol. 59, R371–R418 (2014).

OP-840

Voluntary body motion in WB dynamic PET imaging

J. Trinckauf¹, C. Weyermann¹, F. Kotasidis², M. Hug¹, V. Schober¹, V. Treyer¹, D. Ferraro¹, M. Huellner¹, K. Kudura¹, M. Messerli¹, I. Burger¹;

¹University Hospital Zürich, Zurich, SWITZERLAND,

²GE Healthcare, Zurich, SWITZERLAND.

Aim/Introduction: Recent introduction of high sensitivity SIPM-based PET systems provides the ability to acquire WB dynamic protocols, leading to images of improved image quality and allowing the estimation of WB parametric maps. In such studies, patient body motion (BM), can manifest itself both across and within dynamic frames. Therefore understanding its prevalence in clinic and optimizing acquisition protocols, is of particular interest in order to maximize clinical potential. **Materials and Methods:** 37 WB dynamic ¹⁸F-FDG patient datasets, were prospectively acquired on an 25cm FOV PETCT system (Discovery MI). Patients were injected on the scanner's bed (2 ± 0.5 MBq/kg) and dynamic acquisition over a large blood pool was initiated simultaneously (10 ± 4 min), followed by multiple (11 ± 3 frames) sequential WB passes (35sec/bed) for up to 60 ± 10 min post-injection. Data were reconstructed using

BSREM image reconstruction in a 256x256 image matrix. BM was then assessed qualitatively and quantitatively to investigate prevalence and was categorized. **Results:** In 73% (27/37) of the patients, some type of motion was visible in at least 1 dynamic frame with 13.5% having a stepped BM in less than 3 frames and 59.5% having stepped or slow drift motion in 4 frames or more. Slow drift was visible in 30% (11/37) of patients which involved mostly the head and neck region. 63% of patients which were involved in some kind of BM, exhibited a sustained step motion, while 37% were involved in a motion around a mean position. In patients that did move, 74% involved some motion in the head and neck region, either sustained or around a mean position. Extremity motion was seen also in 74% of the motion affected patients and these were mostly step movements. Lastly 6 subjects initiated a motion involving the torso either as a translation or rotation. **Conclusion:** Understanding motion types most frequently encountered in WB dynamic imaging, can guide mitigation strategies both during acquisition, reconstruction and analysis. Based on this interim analysis, BM mainly involved either the head or the extremities at the beginning or end of the acquisition but crucially less so involving the torso. Motion associated with any and injection associated procedures or other patient intervention, appears to have limited impact on the observed BM and subject to staff experience. These findings are indicative of this kind of protocols, while more clinically applicable dynamic protocols, starting after a normal uptake time, are expected to exhibit similar BM as in clinical static acquisitions **References:** None

Impact of Point Spread Function (PSF) reconstruction on ⁶⁸Ga-DOTATOC PET/CT Quantitative Imaging Parameters - a patient and phantom pilot study

A. McCann^{1,2}, S. Liddy², D. Maguire², E. Loughman², A. Dowling², L. Harris², L. L. Vintro³, S. Cournane^{1,2}, J. Lucey²;
¹Centre for Physics in Health & Medicine, School of Physics, University College Dublin, Dublin, IRELAND, ²St Vincent's University Hospital, Dublin, IRELAND, ³School of Physics, University College Dublin, Dublin, IRELAND.

Aim/Introduction: The aim of this pilot study was to assess the influence of PSF Reconstruction on ⁶⁸Ga-DOTATOC PET/CT quantitative parameters. **Materials and Methods:** Eight ⁶⁸Ga-DOTATOC PET/CT patient studies, with a total of 16 lesions were included in this study. The administered activity ranged from 94-127MBq, with patient weights ranging from 54-81 kg. Following a one hour uptake period, wholebody images were acquired on a Siemens Biograph Horizon PET/CT scanner. All images were iteratively reconstructed with Time of Flight (TOF), and with and without PSF modulation (True X UltraHD-PET). For each lesion, the SUV_{max}, SUV_{mean}, SUV_{peak}, tumor volume and

total lesion somatostatin avidity (TLSA) were measured. Uptake in the Liver and Spleen were analysed and their SNR calculated. Tumour-to-normal tissue uptake was analysed using both the Liver and Spleen as the background organ. Phantom studies were performed to determine the impact of PSF reconstruction on SUV accuracy and fixed threshold defined volume accuracy for varying target sizes using the NEMA IEC body phantom. All Images were analysed with Siemens Syngo.Via image software. **Results:** Comparing the PSF to non-PSF reconstruction, the Lesion SUV_{max} (SUV-bw), SUV_{mean} (SUV-bw) and volume(cm³) were all found to be statistically significantly different (p<0.05). TLSA was not found to be statistically different (p>0.05). All quantitative values in the Liver, with the exception of SUV_{peak} were found to be statistically different (p<0.05). PSF modulation did not have a statistically significant impact on any metrics in the spleen with all metrics having a p-value >0.05. Tumour-to-normal tissue ratios were found to be statistically different for both the liver and the spleen (p<0.05). In the phantom study volume accuracy was improved with PSF modulation for all sphere sizes. However, even with PSF reconstruction the measured sphere volume was still >50% of the actual volume for spheres ≤ 2.8cm³. PSF modulation resulted in improved SUV accuracy for all spheres compared to non-PSF reconstruction. However, even with PSF reconstruction the SUV_{mean} and SUV_{max} values were underestimated by >40% and >25% respectively, for volumes ≤ 2.8cm³. **Conclusion:** Our results demonstrated that PSF-based reconstruction significantly impacted quantitative PET values, emphasising the need for a consistent, well informed approach when applying PSF techniques in clinical practice. Even when PSF reconstruction was employed partial volume effects were still apparent for volumes ≤ 2.8cm³. Further results will be presented and their clinical significance discussed. **References:** None

LM-MLEM for an Ultra-High VoR density PET

P. Encarnação¹, P. M. M. Correia¹, I. F. Castro², I. Mohammadi¹, F. M. Ribeiro¹, A. L. M. Silva¹, J. F. C. A. Veloso¹;
¹IBN - Universidade de Aveiro, Aveiro, PORTUGAL, ²RI-TE, Radiation Imaging Technology, Aveiro, PORTUGAL.

Aim/Introduction: EasyPET.3D is a cost-effective benchtop PET system using a patented method based on a 2-axes rotation of 2 detector modules achieving a very high spatial resolution and sampling with only a small number of cells. Since modules are always face-to-face, parallax errors are strongly reduced achieving high uniformity[1]. Due to its unique scanning method, a fine sampling granularity is achieved and more than 2600 million different positions can be detected, which requires new image reconstruction algorithm and computation strategies. List-mode (LM) based image reconstruction, implemented on graphical

processing units (GPU), has been achieving a significant importance in the last few years mainly due to its speed gain. Compared with other methods LM has several advantages, such as preserving the temporal sampling and ensuring the highest spatial sampling available for a given detector geometry[2]. This work aims to develop a dedicated LM-MLEM/OSEM image reconstruction algorithm capable of ensuring a correct detector geometry description and speed reliability. **Materials and Methods:** A dedicated GPU-based LM-MLEM/OSEM algorithm was developed using a GPU GTX 1060 and a CPU core i7(8700) for EasyPET.3D data. In this algorithm, the correct modelling of the PET system is a critical factor for its imaging performance. Due to the uncommon large size of the EasyPET.3D system response matrix, the probability density function of each VoR (volume of response) is calculated on the fly. The system sensitivity and attenuation corrections were also included. In order to validate the algorithm, real and simulated (GATE) data from quality control phantoms (NEMA NU 4-2008) were used and filled with ^{18}F -FDG, as well as phantoms consisting of uniform cylinders filled with ^{18}F -FDG and ^{22}Na point-like sources. All data was reconstructed with different iterations and voxel sizes and was filtered with a 340-720 keV energy window. **Results:** A spatial resolution of about 1 mm, uniform in all the FOV, was obtained according to NEMA standards. The algorithms performance is currently being evaluated to define the best set of parameters for mice imaging. This includes image quality measurements such as SNR, PSNR, NCC and MSE. Image reconstructed results of the mentioned phantoms together and with in vivo Balb/c mice (20g) injected with ^{18}F -NAF bone tracer and ^{18}F -FDG will be presented. **Conclusion:** The reconstruction method was successfully applied to the complex geometry of easyPET.3D, resulting in high quality images of phantoms and Balb/c mice in preclinical studies. **References:** 1 - Patent WO2016/147130A12 -Autret, A et al, hal-01006117

Evaluation of Monte Carlo based reconstruction concerning visual assessment of liver metastases in ^{111}In -octreotide SPECT/CT imaging

E. Wikberg¹, M. van Essen², T. Rydén¹, J. Svensson³, P. Gjertsson², P. Bernhardt¹;

¹Institute of Clinical Sciences, Gothenburg, SWEDEN,

²Department of Clinical Physiology, Sahlgrenska University Hospital, Gothenburg, SWEDEN, ³Department of Oncology, Sahlgrenska University Hospital, Gothenburg, SWEDEN.

Aim/Introduction: Early cancer detection is crucial for patients' survival. Improvement of the image quality in ^{111}In -octreotide SPECT imaging can be accomplished using Monte Carlo (MC) based reconstruction. The aim of this observer study was to determine the detection rate of simulated liver metastases for MC based OSEM reconstruction compared to

conventional attenuation corrected OSEM reconstruction. **Materials and Methods:** 37 SPECT/CT examinations with ^{111}In -octreotide (Octreoscan) were randomly chosen. The inclusion criteria were no liver metastases at the time of examination and three years forward. 26 SPECT images of spheres, radii 2.21 mm, representing metastases were simulated using MC. Raw data of the spheres were added to rawdata of the established healthy patients in 26 of the examinations (the remaining 11 patients were unchanged) and thereafter reconstructed using two different methods. The conventional reconstruction method was iterative reconstruction with attenuation correction, AC-OSEM. The other method was Sahlgrenska Academy Reconstruction Code where MC simulations were used in the forward projection of the OSEM algorithm (MC-OSEM). Two filters were used, a butterworth low-pass filter for AC-OSEM and a gaussian low-pass filter for MC-OSEM. MC-OSEM was also used unfiltered. Hence 37 SPECT/CT examinations (26 with a simulated liver metastasis and 11 healthy) were reconstructed and placed in three groups (AC-OSEM+filter, MC-OSEM+filter and MC-OSEM without filter). The 111 (37x3) images were visually evaluated by a nuclear medicine specialist, unaware of whether or not the patient had liver metastases or what type of reconstruction method or filter was used. Criteria evaluated were liver metastasis yes or no with confidence level 1-3. The image quality was evaluated on a scale of one to five and the presence of artifacts was evaluated as yes or no. If liver metastasis was judged being present the coordinates were requested so that the accuracy of the position could be evaluated. **Results:** The sensitivity and specificity were 30.8% and 81.8% for AC-OSEM+filter, 42.3% and 54.5% for MC-OSEM+filter and 50.0% and 63.6% for MC-OSEM. The observer's confidence level was highest in AC-OSEM+filter. Regarding the image quality it was rated higher in AC-OSEM+filter and MC-OSEM+filter than in MC-OSEM. **Conclusion:** One in two metastases were found using MC-OSEM versus one in three using conventional reconstruction. However, the specificity, confidence level as well as image quality were all lower for MC-OSEM. New reconstruction methods generate different-looking images and it is important that there is time to get used to these images before eventual method modification. **References:** None

Towards a comprehensive validation of a Monte Carlo simulation for clinical SPECT acquisition protocol optimisation and image correction

S. Pells^{1,2}, D. M. Cullen¹, A. P. Robinson^{2,1,3}, B. Pietras¹, N. Calvert³, D. Deidda², A. Fenwick^{2,4}, K. Ferreira², D. Hamilton³, W. Heetun², P. Julyan³, G. Needham¹, E. Page^{1,3}, E. Price¹, J. Tipping³;

¹The University of Manchester, Manchester, UNITED KINGDOM,

²The National Physical Laboratory, Teddington, UNITED

KINGDOM, ³The Christie NHS Foundation Trust, Manchester,

UNITED KINGDOM, ⁴Cardiff University, Cardiff, UNITED KINGDOM.

Aim/Introduction: Monte Carlo (MC) simulations are a valuable tool for the optimisation of acquisition protocols and image corrections in Single-Photon Emission Computed Tomography (SPECT). Simulations allow direct gamma tracking and show all interactions that occur during acquisition. They offer an unparalleled insight into processes that are not directly experimentally observable such as scatter and attenuation within the acquisition. As the need for quantitative SPECT becomes increasingly important for dosimetry calculations, accurate image corrections are essential, and their methodologies are increasingly based on results from MC. Whilst MC is often used to provide a 'ground-truth', this is only the case if the simulation is fully validated against experimental data. This is a vital part of confirming the performance of new scanners. This work aims to establish a validation protocol for MC SPECT simulations. **Materials and Methods:** A full MC simulation of the triple-head SPECT system installed at the National Physical Laboratory has been developed in the GATE (Geant4 Application for Tomographic Emission) [1] tool-kit. The simulation extensively models the components of each detector head and a range of collimators according to technical specifications provided. The simulation can run in both dual- and triple-head acquisition modes. Validation data has been collected in a range of geometries, including commercial and 3D-printed phantoms, for multiple therapeutic and diagnostic isotopes. **Results:** Experimental and simulated data have been compared for both the dual- and triple-head acquisitions, providing validation for all key experimental observables for a range of therapeutic and diagnostic isotopes. **Conclusion:** The validation procedure has demonstrated that the MC simulation accurately reproduces SPECT data. The validated simulation will be used to optimise clinical imaging protocols and image corrections, including for novel radioisotopes such as Tb-155 and Tb-161 where low availability of isotopes limits experimental studies. **References:** [1] Jan S. 2004, 49:4543-61 Phys. Data-Driven Respiratory SPECT-Gating for Pre-Radio-Embolization Determination of Liver-Lung-Shunt Fraction

P. Ritt¹, K. Seidl¹, M. Cachovan², A. H. Vija³, T. Kuwert¹;

¹Clinic for Nuclear Medicine, Erlangen, GERMANY, ²Siemens Healthcare GmbH, Molecular Imaging, Forchheim, GERMANY,

³Siemens Medical Solutions USA, Inc., Molecular Imaging, Hoffman Estates, MI, UNITED STATES OF AMERICA.

Aim/Introduction: In hepatic radio-embolization, lungs are at risk of substantial radiation damage if resulting in a too high deposition of radioactive particles in lungs. For assessing

this risk, each patient undergoes pre-therapeutic simulation with e.g. Tc-99m-macro-aggregated albumin in order to determine liver-lung-shunt fraction (LLSF). Depending on extent of LLSF, injected activity could be adapted or therapy even be precluded. **Materials and Methods:** As part of pre-radio-embolization work-up, n=12 patients (age 65 ± 11 , BMI 24.8 ± 3.6) underwent SPECT/CT scans on a Siemens Symbia T2 system after intra-hepatic injection of Tc-99m-MAA (~150 MBq). SPECT was carried out in step-and-shoot fashion (60 views, 2 projections per view, 15 s dwell time per view) using LEHR collimators and a body-contouring scan. Patients were allowed to breathe freely during SPECT acquisition. Immediately following SPECT, a CT scan was carried out (130 kVp, 30 mAs effective). SPECT/CT consisted of a single bed-position (~40 cm axial field of view) and was set to include whole liver and as much of lungs as possible. Using research software, SPECT projection data was acquired in listmode format and retrospectively framed into four time bins representing different respiratory states. Gated SPECT data were reconstructed using ordered-subset conjugate-gradient algorithm (1 subset, 24 iterations). Only corrections for scattered radiation (dual energy window) were applied. Additionally, also ungated SPECT data was reconstructed, which represents projection data averaged over the whole acquisition time. Liver and lung compartments were manually segmented on CT. SPECT counts were extracted for gated and ungated data and LLSFs were computed. **Results:** Average segmented liver and lung volumes were 2111 ± 695 mL (ranging 980 - 3433 mL) and 1707 ± 657 mL (954 - 2769 mL). Average LLSF was 5.4 ± 2.9 % (1.5 - 11.2 %) for gated and 6.2 ± 2.3 % (2.1 - 9.6 %) for ungated data. The span, which here is the range from maximum to minimum LLSF of gated data for one individual patient, was 2.6 ± 3.0 % (0.2 - 9.1 %) in absolute units, which is equivalent to 46.1 ± 43.0 % (4.0 - 141.1 %) when expressed in percentages relative to mean LLSF. **Conclusion:** Data-driven respiratory gating of SPECT data is feasible. Respiratory movements lead to a bias, which could potentially lead to under- or overestimation of LLSF. Studies with an increased patient number will be carried out in order to determine relevancy in clinical practice. **References:** None

Efficacy and Safety of ²²⁵Ac-PSMA-617 Targeted Alpha Therapy in Metastatic Castration-Resistant Prostate Cancer Patients

M. Yadav, S. Ballal, C. Bal;

All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Metastatic castration-resistant prostate cancer (mCRPC) patients develop disease progression in spite of several current standard of care treatment offered. Managing these patients are currently challenging. Thus, there is need of new therapy options that induce anti-tumor activity and improve survival. The objective of this study was to assess the safety and therapeutic efficacy of ²²⁵Ac-PSMA-617 targeted alpha therapy (TAT) in mCRPC patients in real world conditions. **Materials and Methods:** All consecutive mCRPC patients refractory to therapy options, including first and second-generation anti-androgen therapies, taxane-based chemotherapies, and ¹⁷⁷Lu-PSMA-617 therapy, were treated with ²²⁵Ac-PSMA-617 TAT (100 KBq/Kg body weight) at an 8-weekly interval. The

primary endpoint included the assessment of biochemical response by measuring the serum prostate-specific antigen (PSA) response rate as per the PCWG3 criteria. Secondary endpoints comprised the estimation of overall survival (OS), progression-free survival (PFS), molecular tumor response assessment (PERCIST 1 criteria), disease control rate, toxicity according to CTCAE v5.0, and clinical response evaluation. **Results:** Total 28 patients were recruited for this cohort study. The mean age was 69.7 years (range: 46-87 years). All patients, except one, had extensive skeletal metastases on baseline ⁶⁸Ga-PSMA-11 PET/CT scan; one patient had lymph node dominant disease and advance primary prostatic tumor. The mean activity administered was 26.5 ± 12 MBq (range: 9.25 - 62.9 MBq) [715.5 ± 327 μCi, range: 250 - 1700 μCi] with a median of 3 cycles. After the initial follow-up and the end of the assessment, >50% decline in PSA was observed in 25% and 39%, respectively. The median PFS and OS were 12 months (95% CI: 9 - 13 months) and 17 months (95% CI: 13 - 16 months), respectively. Molecular tumor response by PERCIST 1 criteria could be conducted in 22/28 (78.6%) patients, which revealed complete response in 2/22 (9%), partial response in 10/22 (45.4%) patients, 2/22 (9%) with stable disease, and 8/22 (36%) with progressive diseases. The disease control rate, according to the biochemical and molecular tumor response criteria, was 63.4%. Multivariate analysis revealed PSA progression and any PSA decline as prognostic indicators of OS and PFS, respectively. There was no Grade III/IV toxicity noted in this series. **Conclusion:** ²²⁵Ac-PSMA-617 TAT showed promising disease control rate, even when all other therapeutic options were exhausted, with low treatment-related toxicities **References:** None

Effects of one cycle of Actinium-225-PSMA-617 (AcPSMA) on the salivary glands compared to Lu-177-PSMA (LuPSMA)-preliminary results

B. Feurecker^{1,2}, A. Gafita¹, R. Tauber³, C. Seidl¹, F. Bruchertseifer⁴, M. Retz³, J. E. Gschwend³, W. A. Weber¹, C. D'Alessandria¹, A. Morgenstern⁴, M. Eiber¹;

Aim/Introduction: ²²⁵Ac-PSMA is a compassionate use treatment option in metastatic castration resistant prostate cancer (mCRPC) after failure of approved drugs and ¹⁷⁷Lu-PSMA. Xerostomia has been reported to be a relevant side effect of AcPSMA treatment impacting quality of life. The aim of this retrospective analysis was to assess the effects of one cycle of AcPSMA on the salivary glands using data from

pre- and post PSMA-PET/CT imaging and compare it to possible changes induced by previous LuPSMA treatment. **Materials and Methods:** In 18 patients with late stage mCRPC PSMA ligand uptake (16 PSMA-PET/CT, 2 PSMA/PET/MRI) and morphologic changes (CT/MRI) were retrospectively analyzed after one cycle of AcPSMA (9.0 MBq \pm 1.6) and in 11 of these patients before and after a median of 2 cycles of LuPSMA (7346 MBq \pm 529; 11 PSMA PET/CT). PSMA ligand uptake of the parotid and submandibular glands were quantified using qPSMA, the volume was measured slice based on CT/MRI. **Results:** Mean volume of the salivary glands was 50 \pm 13 ccm before and 39 \pm 11ccm after AcPSMA treatment (- 23% mean volume reduction). Mean PSMA-TV was 68 \pm 25 ccm before and 40 \pm 15 ccm after AcPSMA treatment (-40%). For LuPSMA mean CT volume of the salivary glands was 62 \pm 14 ccm before and 52 \pm 12 ccm after LuPSMA treatment (-13% mean volume reduction). Mean LuPSMA PSMA-TV of the salivary glands was ca. 89 \pm 16 ccm before and 78 \pm 21 after treatment (-11%). **Conclusion:** Volume and PSMA-uptake of salivary glands decrease both after LuPSMA and AcPSMA. However, the effect of one cycle AcPSMA is almost 4 times higher compared to 2 cycles LuPSMA which might be a potential correlate for its relevant xerostomia. Additional investigations including salivary gland scintigraphy and measurement of saliva gland production might help to further elucidate the differences between xerostomia after LuPSMA and AcPSMA. **References:** None

OP-854

Ac-225-PSMA I&T in patients with end stage mCRPC: First clinical results

M. Zacherl, F. J. Gildehaus, A. Gosewisch, P. Bartenstein, A. Todica, H. Ilhan;

University of Munich, Munich, GERMANY.

Aim/Introduction: After failure of approved therapy options, although several agents are available, end stage metastatic castration resistant prostate cancer (mCRPC) remains challenging. Radioligand therapy (RLT), using β^- and α -emitter labeled PSMA-inhibitors, have been introduced with promising results. Here we present the first early clinical data for PSMA-directed α -therapy using Ac-225-PSMA I&T. **Materials and Methods:** 17 patients receiving Ac-225 PSMA I&T RLT between 08/18 and 12/19 have been included in this retrospective analysis. All but one patient had received second line antihormonal treatment using abiraterone and/or enzalutamide. 15 patients received prior chemotherapy. In 14 patients RLT using Lu-177-PSMA-ligands was performed prior to Ac-225 PSMA-ligandtherapy (median 2 cycles, rang 1-5). PSMA PET/CT was performed in all patients prior to Ac-225-PSMA I&T therapy to assess PSMA-expression in tumor lesions. Patients were treated at 7-8 weekly intervals until progression or intolerable side effects.

Prostate-specific antigen (PSA) and blood cell count were measured every 2-3 weeks. We evaluated hematological and non-hematological side effects according to CTCAE 4.0 criteria and biochemical response. **Results:** A total of 33 cycles of Ac-225-PSMA I&T (median dose 7.8 MBq, range 6.7-8.2) were applied. 6 patients received 1 cycle, 7 patients 2 cycles, 3 patients 4 cycles and 1 patient 5 cycles. No acute toxicity was observed at the time of hospitalization. Baseline PSA was 228 ng/ml (range 13.4 - 1146). 5/17 patients had no follow-up and were excluded from the further study. 6/12 patients had a PSA-decline of more than 50%, 3/12 patients a decline of 40-50% and 2/12 patients a decline between 20-30%. Two patients had no PSA-decline at any time. Mild xerostomia (grade 1/2) was observed in 11 patients. Severe xerostomia (grade 3) was observed in 1 patient. No patient developed a new renal insufficiency. 6/12 patients had a grade 3-4 anemia. **Conclusion:** In this small cohort Ac-225-PSMA I&T RLT showed antitumor effect in end stage mCRPC even after failure of Lu-177 PSMA-ligand therapy in more than 40%. Grade 3/4 hematological side effects in 50% of patients and Grade 1-2 xerostomia in 11/12 patients indicate moderate tolerability in this heavily pretreated end stage patient group. These results are comparable to data for Ac225 PSMA-617 after failure of Lu-177 therapy.

Aim/Introduction: Since its introduction in clinical practice for metastatic Castration Resistant Prostatic Cancer (mCRPC) and bone metastasis, Radium-223 treatment has been proven to have not only a positive effect on pain but it can also increase overall survival (OS). However, several studies

are highlighting the fact that patient's baseline conditions are fundamental in order to maximize Radium-223 effects prolonging OS. Several studies tried to individuate a prognostic marker to better stratify patients eligible to Radium-223 treatment. Still, to date clinicians lack a valid and simple tool that allows a better selection of patients before starting therapy with this α -emitting radionuclide. A study conducted in 2017 proposed a 3-variable prognostic score (3-PS) using baseline Hemoglobin (Hb), baseline Prostatic Specific Antigen (PSA) and Eastern Cooperative Oncology Group Performance Status (ECOG PS) to stratify patients in five prognostic groups, each one with a different and specific predicted OS. The aim of this retrospective multicentric study was to validate the 3-PS score. **Materials and Methods:** 430 patients with mCRPC under treatment with Radium-223 were enrolled from six Italian centers. The 3-PS was firstly applied to the entire population (TOTAL group). Secondly, 92 patients from the 2017 3-PS study were subtracted from the TOTAL group (CLEAN group). The score was applied to this purified subgroup to furtherly validate the score. The prognostic significance of the scores was evaluated via time-dependent receiver operating characteristic (ROC) curves in the CLEAN GROUP. **Results:** The area under curve (AUC) estimated (0.74) falls within the confidential interval (CI) of the AUC calculated on the validation groups. In fact, the validity of the 3-PS score was confirmed on the TOTAL group as well as in the CLEAN group [95% CI 0.66 - 0.82]. **Conclusion:** This multicentric study confirms the validity, the simplicity and the applicability of the 3-PS score on patients with mCRPC. This tool can be used in clinical practice to select patients that will most probably benefit from Radium-223 treatment and to predict and assess OS. **References:** None

Do the number of previous treatments and bone metastases impact Radium-223 therapy efficacy in mCRPC patients? A multicentre study

V. Lavelli¹, V. Frantellizzi², E. Lodi Rizzini³, M. Licari⁴, L. Cindolo⁵, M. Stazza⁶, A. Nappi¹, M. Pontico², V. Dionisi⁷, C. Ferrari¹, A. Spanu⁶, M. Mascia⁸, R. Costa⁴, F. Monari⁷, G. De Vincentis², G. Rubini¹;
¹Nuclear Medicine Department, University of Bari "Aldo Moro", Bari, ITALY, ²Department of Radiological Sciences, Oncology and Anatomical Pathology, Sapienza, "Sapienza" University of Rome, Rome, ITALY, ³Nuclear Medicine Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, ⁴Unit of Nuclear Medicine, Biomedical Department of Internal and Specialist Medicine, University of Palermo, Palermo, ITALY, ⁵Department of Urology, "Villa Stuart" Private Hospital, Rome, ITALY, ⁶Unit of Nuclear Medicine, Department of Medical, Surgical and Experimental Sciences, University of Sassari, Sassari, ITALY, ⁷Radiation Oncology Center, S.Orsola-Malpighi Hospital, Bologna, ITALY, ⁸Unit of Nuclear Medicine, "Spirito Santo" Hospital, Pescara, ITALY.

Aim/Introduction: 223Radium-dichloride (Ra223)-therapy was approved for mCRPC patients with symptomatic bone metastases (BM) and no visceral involvement and scheduled with six intravenous injections every four weeks. Its clinical use was restricted since July 2018 to patients with at least two previous systemic treatments or without other therapeutic options and not recommended with a low burden of osteoblastic BM. We aimed to evaluate if the number of previous treatments and/or BM can impact Ra223-therapy completion and efficacy. **Materials and Methods:** We retrospectively evaluated 334 mCRPC patients (mean age 73y, range: 50-90), who received Ra223 between September 2013 and July 2019 in six Italian centres. We evaluated the association between two of current eligibility patient criteria (≥ 2 previous systemic treatments and ≥ 6 BM) and the completion of Ra223-therapy as well as its efficacy. Particularly, Ra223-therapy efficacy was measured as biochemical response (\leq ALP-post-therapy vs baseline), clinical response ($<$ pain post-therapy vs baseline, assessed by Brief Pain Inventory-Short Form), instrumental response (partial response or stable disease at post-therapy Bone Scan vs baseline) and survival (alive vs dead patients). Both evaluations were calculated by using contingency tables and Chi-Square test. **Results:** 141/334 (42%) patients met current eligibility criteria, of which 80/141 (57%) completed Ra223 therapy; 193/334 (58%) patients did not meet these criteria, of which 121/193 (63%) completed Ra223 therapy. There was no statistically significant association between eligibility criteria and the completion of 223Ra-therapy ($\chi^2=1.206$, $p=0.272$). As regarding treatment efficacy, the association with eligibility criteria resulted statistically significant only for instrumental response, in particular for the number of previous treatments ($\chi^2=7.570$, $p=0.006$). In addition, a statistically significant association was found between the completion of Ra-223 therapy and biochemical ($\chi^2=16.904$, $p<0.005$) and instrumental ($\chi^2=5.002$, $p=0.025$) response as well as survival ($\chi^2=19.546$, $p<0.005$). Conversely, even if no statistically significant association was found between the completion of Ra-223 therapy and clinical response ($\chi^2=1.680$, $p<0.195$), pain reduced in a significant percentage of patients who completed treatment (65%). **Conclusion:** Our multicenter experience confirmed the efficacy of Ra223-therapy in patients who completed the six scheduled doses of treatment. The current use of Ra223 allows treating mainly advanced-disease patients. Our results suggest that neither ≥ 2 previous systemic treatments nor ≥ 6 BM impacts on both Ra223-therapy completion or efficacy. However, multi-treated patients showed worse response to Ra223-therapy, regardless of the number of doses received. **References:** None

OP-857**Overall survival in elderly mCRPC patients treated with Radium-223: a national multicenter study**

V. Lavelli¹, L. Cosma², F. Monari³, M. Mascia⁴, R. Costa⁵, G. Rubini¹, A. Spanu⁶, A. Farcomeni⁷, E. Lodi Rizzini⁸, L. Cindolo⁹, A. Murabito⁵, S. Nuvoli⁶, V. Frantellizzi², V. Dionisi³, A. Nappi¹, G. De Vincentis²; ¹Nuclear Medicine Department, University of Bari "Aldo Moro", Bari, ITALY, ²Department of Radiological Sciences, Oncology and Anatomical Pathology, "Sapienza" University of Rome, Rome, ITALY, ³Radiation Oncology Center, S.Orsola-Malpighi Hospital, Bologna, ITALY, ⁴Unit of Nuclear Medicine, "Spirito Santo" Hospital, Pescara, ITALY, ⁵Unit of Nuclear Medicine, Biomedical Department of Internal and Specialist Medicine, University of Palermo, Palermo, ITALY, ⁶Unit of Nuclear Medicine, Department of Medical, Surgical and Experimental Sciences, University of Sassari, Sassari, ITALY, ⁷Department of Economics & Finance, University of Rome "Tor Vergata", Rome, ITALY, ⁸Nuclear Medicine Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, ⁹Department of Urology, "Villa Stuart" Private Hospital, Rome, ITALY.

Aim/Introduction: The purpose of this multicentre retrospective study is to analyze metastatic castration-resistant prostate cancer (mCRPC) patients treated with Radium-223 evaluating whether there are differences in overall survival (OS) between young and elderly and verifying efficacy and safety in the very elderly population (patients >75 years old). **Materials and Methods:** In our study 430 mCRPC patients treated with Radium-223 in six Italian Centres were examined. Clinical and diagnostic patients' characteristics were gathered at baseline and after each cycle of Radium-223: blood biochemical parameters, pain by Numeric Rating Scale (BPI) and ECOG-PS. Bone scintigraphy was performed before starting treatment, after the third cycle and at the end of therapy. All patients, according to their age (≤ 75 years old and > 75 years old), were divided into two groups. Moreover we considered other clinical covariates: BMI, Gleason score, ECOG-PS, baseline hemoglobin, prostate specific antigen, total alkaline phosphatase, lactate dehydrogenase, platelets, absolute neutrophil counts. Our main endpoint was the evaluation of the overall survival (OS). Survival distributions were calculated using the Kaplan-Meier product-limit estimator and compared using the log-rank test. The association of predictors with OS was evaluated by means of univariate Cox regression models. A multivariable Cox regression model was then selected using a stepwise forward procedure based on Akaike Information Criterion. **Results:** 51% of the patients were ≤ 75 years old and 49% were > 75 years old. Considering those subjects with similar basal parameters, OS did not show significant differences between the two groups. Age had no significant impact on the OS ($p=0.274$) in multivariate models. The evaluation of clinical covariates in univariate models ($p<0.05$) showed that several of the examined clinical aspects had an impact

on OS, but not age ($p=0.072$). Moreover, the toxic effects, in terms of hematological or symptomatic skeletal events, were few and similar in the two groups, continuing to guarantee the safety of Radium-223 even in very elderly patients. **Conclusion:** The management of elderly patients should not be based on age but on their health status. Radium-223 is well-tolerated and characterized by low rates of adverse effects and for these reasons it is suitable for treatment of younger and even more for older, frail and vulnerable patients. As demonstrated in our study, at the same baseline condition Radium-223 prolongs survival in both younger and older patients and is a good choice in the mCRPC setting compared to other agents, especially for men unsuitable for cytotoxic chemotherapy. **References:** None

OP-858**The effect of tumor burden in ⁶⁸Ga-PSMA-PET/CT on tracer uptake into kidneys in ⁶⁸Ga-PSMA-PET/CT and the absorbed dose per administered GBq ¹⁷⁷Lu-PSMA-617 during a following therapy**

J. Wichert, C. Happel, W. T. Kranert, D. Gröner, J. Baumgarten, C. Nguyen Ngoc, N. Mader, S. Banek, F. Grünwald, A. Sabet; Goethe University Hospital Frankfurt, Frankfurt, GERMANY.

Aim/Introduction: In patient therapy with Lu-177-PSMA-617, kidneys are regarded as dose limiting organs. We explored if the tumor load in pretherapeutic Ga-68-PSMA-PET/CT had an effect on the SUV-parameters of the kidneys and if it could be used as a predicting factor to dose to kidney/GBq Lu177-PSMA in a following therapy cycle. **Materials and Methods:** 265 kidneys in 152 patients with mCRPC who underwent a Ga-68-PSMA-11 PET/CT-baseline scan prior to the start of the Lu-177-PSMA-617 were analyzed. Tumor load was categorized as minor ($n=31$), intermediate ($n=47$) or high ($n=74$), based on miTNM classification (PROMISE). The relation of Ga-68-PSMA-uptake in the kidneys and tumorburden were checked. We evaluated the relation between SUV-parameters of each kidney and the absorbed dose / GBq Lu-177-617-PSMA after the first administration of Lu-177-PSMA-617 therapy to see if a correlation between the two parameters exists. We also compared tumorload and the dose to the kidneys/ GBq Lu-177-617-PSMA in the following cycle. The correlation was tested using nonparametric testing. **Results:** We compared the PET parameters with the kidney dose/ GBq Lu-177-PSMA in the following cycle. Looking at all patients, SUVmax (36 ± 15), SUVmean (24 ± 10), SULmax (26 ± 10) and SULmean (18 ± 7) ranged widely. All four parameters showed a strong negative correlation to the tumor burden in the PET-scan (P -values between: SUVmax/tb: 0,009; and SULmean/tb: 0,001). When comparing the groups, we found ~10% higher tracer uptake in patients with low tumor load and 30-35% lower tracer uptake in patients with higher tumor

load, both compared to intermediate load. All four PET parameters showed a strong positive correlation to the kidney dose/ GBq Lu177-PSMA in the first PET (P-values: SUVmax/Gy/GBq: <0,001; SUVmean/Gy/GBq: <0,001; SULmax/Gy/GBq: <0,001; SULmean/Gy/GBq: <0,001). Die kidney dose per GBq Lu-177-617-PSMA for all patients had an average of 0,277 Gy. When comparing the groups, we found in average a ~3,5% lower dose per GBq Lu-177-617-PSMA in patients with minor burden, and a ~9,5% lower dose per GBq Lu-177-617-PSMA in patients with high, both compared to intermediate burden. **Conclusion:** Tumor load correlates negatively with the SUV parameters in baseline PET/CT which in turn is associated with the absorbed dose/GBq Lu-177-PSMA. Further, a high tumor burden in the primary PSMA-PET-scan correlates with a lower dose to the kidneys per GBq Lu-177-617-PSMA in the following cycle. This finding encourages the consideration of higher activities of Lu177-PSMA in patients with high tumor load and low SUV-parameters in baseline PET-scan. **References:** None

OP-859

Prediction of therapy response in PSMA radioligand therapy with PSMA PET/CT

F. Völter, A. Gosewisch, L. Kaiser, F. Gildehaus, A. Todica, P. Bartenstein, G. Böning, H. Ilhan;
Ludwig-Maximilian-Universität, München, GERMANY.

Aim/Introduction: Prediction of therapy efficacy is of great importance in PSMA-based radioligand therapy (RLT). The purpose of this investigation was to assess the value of pretherapeutic Ga⁶⁸-PSMA-11 PET as a predictive marker for therapy efficacy and dosimetry in mCRPC patients receiving ¹⁷⁷Lu-PSMA-617. **Materials and Methods:** Pretherapeutic SUVmean and SUVmax in Ga⁶⁸-PSMA-11 PET were correlated with absorbed doses pre injected activity for 40 patients (age 72,9±9,7) and 211 tumor lesions. The administered activity of Lu¹⁷⁷-PSMA was 6.0 GBq in 35 and 3.7 GBq in 5 patients. Absorbed dose of the tumor lesions were analyzed with dose maps providing voxelwise dose distribution using quantitative 3D SPECT 24, 48 and 72 hours after injection of ¹⁷⁷Lu-PSMA. Correlation was analyzed with Pearson's correlation analysis. **Results:** SUVmean and SUVmax showed a broad range in bone (SUVmean 20.5±31.5; SUVmax 30,8±21.2) and lymph node metastases (SUVmean 20.9±16.0; SUVmax 37.2±53.4). Mean absorbed dose was 5.94±13.6 Gy/GBq in bone and 5.5±8.9 in lymph node metastases. There was a strong correlation of absorbed dose and pretherapeutic SUVmean (r=0.86) as well as pretherapeutic SUVmax (r= 0.7) in bone metastases. Lymph node metastases showed a strong correlation of SUVmean and absorbed dose (r=0.7) and a moderate correlation of SUVmax and absorbed dose (r=0,64). There was no correlation between PSA levels and SUVmean

or SUVmax or absorbed dose. **Conclusion:** The strong correlation of pretherapeutic SUVmean and SUVmax with absorbed dose shows that pretherapeutic PSMA-PET can be used to predict therapy efficacy in ¹⁷⁷Lu- PSMA Radioligand therapy. **References:** None

Clinical outcome of radioligand therapy with Lu-177 PSMA in metastatic prostate cancer: An initial experience from a tertiary care cancer hospital

M. Gupta^{1,2}, P. Choudhury¹, G. Karthikeyan³, V. Talwar¹, S. Rawal¹;
¹Rajiv Gandhi Cancer Institute and Research Centre, Delhi, INDIA, ²Amity Center of Radiation Biology, Amity University, Noida, INDIA, ³Amity Institute of Virology and Immunology, Amity University, Noida, INDIA.

Aim/Introduction: Metastatic castration resistant prostate cancer (mCRPC) is an inevitable stage in management of prostate cancer. Eventually, all advanced prostate cancer patients developed resistant to known standard drugs and most of them land up with rising PSA, high volume of disease and diffuse bone pain. Hence, novel drugs with better efficacy are in-desired for patients' palliation. One such possible hope to these patients is to use 'Theranostic' approach using prostate specific membrane antigen (PSMA) as target. In this study, we analysed the clinical outcome of Lu177-PSMA in mCRPC patients in Indian population.

Materials and Methods: Twenty five mPCs patients were treated with Lu177-PSMA on compassionate basis. Pre and 8-10 weeks post treatment PSA, Eastern cooperative oncology group (ECOG) performance status, Visual analogue scale (VAS) and Analgesic quantification scale (AQS) were recorded for clinical outcome. Based on three PSA response groups (partial response PR, stable disease SD, progressive disease PD), patients were categorized into responder (PR+SD) and non-responder (PD). Wilcoxon signed-rank, and Kruskal-Wallis test, Kaplan Meier with Log rank test were computed by MedCalc Statistical Software version 19.1.5. P value < 0.05 was considered statistically significant. **Results:** Twenty five mPCa patients with median gleason score 8.3 (range 7-10) with median 69 years of age (range 45-81) were treated with median 7.4 GBq (range 3.7-7.7 GBq) Lu177-PSMA. Overall PR, SD and PD were 24%, 60% and 16% respectively. Sixteen patients who received ≥ 7.4GBq Lu177-PSMA dose, PR and SD were seen in 31.2% and 68.8% respectively. We had 84% responders and 16% non-responders. Statistically significant difference (P <0.05) was seen in pre and post ECOG (Z value -2.5), VAS (Z value -3.9) and AQS (Z value -3.5) parameters on Wilcoxon signed-rank test while it was statistical in-significant for PSA (P value 0.170, Z value -1.6). We found that Lu177-PSMA dose was the only significant factor (P 0.024) on Kruskal-Wallis test for PSA response outcome. Overall median PFS was 24 weeks (95% CI: 9-52) in our study. Two years PFS of PR, SD and

PD response group was 50%, 37.3% and 0% respectively. Significant difference was seen in PFS of responder and non-responder groups (P value 0.0003 and Hazard ratio 0.16). **Conclusion:** We concluded that Lu177-PSMA was a fair palliative option in heavily per-treated mPCa patients for both pain and PSA response. It has a potential to become valid treatment option for these patients, however proper randomized studies are pending. **References:** None

OP-861

Selective Intraarterial Lu-177 PSMA Therapy for Castration Resistant Prostate Cancer: Preliminary Results of a Pilot Study

H. Sayman¹, F. Gulsen¹, S. Sager¹, E. Akgun¹, N. Yeyin¹, S. Bilgic¹, K. Toplutas¹, F. Beytur¹, R. Oklu², O. Aras³;

¹Istanbul University-Cerrahpasa, Istanbul, TURKEY,

²Mayo Clinic Arizona, Phoenix, AZ, UNITED STATES OF

AMERICA, ³Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: In patients with metastatic castration-resistant prostate cancer undergoing Lu-177 PSMA therapy, we aimed to determine the feasibility and safety of selective intraarterial administration compared with conventional intravenous administration. We further aimed to deliver the higher possible tumor dose in the primary site depending on the receptor density at first pass, without compromising uptake by any distant metastases. **Materials and Methods:** Four patients were treated in two visits whereby their total empiric therapeutic dose was divided equally between the two occasions. During the first visit, the first half of the selected dose was given through an intravenous line (IV treatment). One week after, the second half of the selected dose was administered selectively using bilateral internal iliac arteries consecutively (IA treatment); comparing the two treatments within the same patient. Accordingly, confrontation of maximum possible dose rate was established in the first pass of therapeutic agent in the primary cancer. Subsequently, the activity was circulated in consecutive cycles until it reached other possible metastatic sites. We acquired planar whole-body and SPECT/CT scans from prostate and/or metastatic bone lesion sites to calculate the absorbed doses, after both IV and IA applications. An additional acquisition was made just before the IA dose in order to obtain a baseline image that we may calculate leftover activity in tissues from the IV dose for background correction. Freehand ROIs were drawn over the composite image by adding all axial SPECT slices with increased tracer uptake, by anatomic correlation of CT in order to cover the lesions. Additionally, liver, kidneys, bone marrow, prostate and whole-body absorbed doses were also calculated. Lesion-to-liver, lesion-to-bone marrow and lesion-to-whole-body ratios were calculated. None of our patients experienced more than regularly

expected side effects within first 8-16 weeks of follow-up and intra-arterial application was tolerated very well in all patients. Student's t-test was used and $p < 0.05$ was accepted as statistically significant. **Results:** Having limited number of patients, the organs (except kidneys) and whole-body doses were not significantly different between two applications. Kidney doses, although not significant, were less in the IA Lu-177 PSMA application. The absorbed doses in bone metastases were significantly higher in IA Lu-177 PSMA than in IV Lu-177 PSMA application. **Conclusion:** This preliminary study shows that intraarterial administration of Lu-177 PSMA may serve as an alternative to the intravenous route and may be favourable in terms of absorbed doses in metastatic bone lesions. **References:** None

MIBI SPECT as first line diagnostic of hypofunctioning thyroid nodules - a long term study

M. Baehr, K. Liepe;

Klinikum Frankfurt (Oder), Dept. Nuclear Medicine, Frankfurt (Oder), GERMANY.

Aim/Introduction: Current guidelines recommend fine needle biopsy (FNB) in hypofunctioning thyroid nodules. We have postulated that ^{99m}Tc-MIBI SPECT with additional FNB of MIBI positive nodules is a safe, effective and least-invasive workflow. **Materials and Methods:** In a time-period of 69 months 705 patients with hypofunctioning thyroid nodules underwent administration of 418 MBq ± 33 MBq ^{99m}Tc-MIBI with SPECT 120 min p.i. Additional FNB was performed in high-risk nodules (EU-TIRADS 5), in symptomatic patients and in asymptomatic patients with MIBI SPECT positive nodules. Long-term follow-up ranged from 12 to 69 months with a mean of 30.7 months. **Results:** 55 patients showed positive MIBI SPECT and consequently received surgical resection. In 26% of these patients the suspected nodule was MIBI negative but another either small nodule, isthmus nodule or part of multinodous goiter was MIBI positive. 84 patients received surgical resection after negative MIBI SPECT because of strong symptoms or symptomatic high-volume multinodous goiter. Retrospectively histological diagnosis was concordant with positive MIBI SPECT and the additional FNB in 65% of cases, whereas in 32% MIBI was superior and in 3% FNB was superior. In long-term follow-up MIBI negative patients revealed malignancy in 0.6%,

three papillary carcinoma of 2–4 mm and one medullary carcinoma with Ki-67 of 5%. Statistical analysis for MIBI SPECT showed an overall sensitivity of 73%, specificity of 95%, positive predictive value of 22% and negative-predictive value of 99%. MIBI SPECT was also positive in thyroid adenomas, which nevertheless required surgical resection, like hürthle cell adenoma, parathyroid adenoma or follicular adenoma. Assessing these patients as true-positive either, the corrected predictive statistics were 80%, 98%, 76% and 99%. **Conclusion:** First line diagnostic with MIBI SPECT is safe in the assessment of low to intermediate risk hypofunctioning thyroid nodules. With a negative predictive value of 99% after up to 69 months of follow-up, MIBI SPECT has proven as an excellent screening tool. Surgical resection of only MIBI positive and FNB positive hypofunctioning nodules could reduce the frequency of thyroidectomies significantly. **References:** None

Low-dose 18F-FDG thyroid PET/CT vs. Thyroid scintigraphy in indeterminate high-risk nodules: a pilot dosimetric assessment

E. Di Giorgio¹, M. Sicignano¹, L. Evangelista², L. Mansi³, P. Sannino¹, F. Masone¹, F. Squame¹, N. D'Acunzo¹, V. Nuzzo⁴, S. Spiezia⁵, M. Klain⁶, M. Spadafora¹;

Biomedical Sciences, University of Naples Federico II, Naples, ITALY.

Aim/Introduction: Thyroid nodules suspicious at ultrasounds necessitate fine-needle aspiration cytology as confirmative test, which suffers from high indeterminate reports, up to 25%. Indeed, these lesions are addressed to surgery, resulting as benign in ¾ of cases. In this population whole body FDG-PET/CT (wb-PET/CT) has a high negative predictive value for malignancy, ranging between 81% and 100%. However, this imaging modality is not recommended in the diagnostic workup, mainly because of high radiation exposure and costs. The aim of the study is to preliminary estimate tracer dose, dosimetric and scan-time impacts of low dose FDG-thyroid-PET/CT (t-PET/CT) either versus wb-PET/CT, in patients undergoing FDG PET/CT for an oncologic query, and 99m-TcO₄—thyroid scintigraphy (t-S). **Materials and Methods:** Wb-PET/CT of 50 patients (64,7±12yy; 50% male) were retrospectively compared with t-PET/CT, defined as the cervical part (1 bed) of wb-PET/CT. The ratio between scan-length of t-PET/CT and wb-PET/CT was the basis to estimate temporal, tracer dose and radiation exposure relationship between the two modalities. Data obtained in a population matched by age and gender undergoing

t-S were also evaluated. Tracers dose (FDG or 99m-TcO₄—, expressed in MBq), radiation exposure (ED, in mSv), scan-time and additional cancer risk (ACR) were assessed. **Results:** In wb-PET/CT, the radiation exposure is determined by CT (60.4%) and 18F-FDG (39.6%). The ratio between scan-length of t-PET/CT vs wb-PET/CT was 0,20. Mean scan-time and dose of wb-PET/CT were 17,9±1,9 min and 276,1±51 MBq, respectively. Based on the time-dose equation, t-PET/CT would need a mean dose of 55,2 MBq, which is 20% of wb-PET/CT, to obtain the same counting rate. Considering a cervical scan instead of a WB, ED decreases from 4,4 to 0,88 (p<0.0001), from 6,7 to 1,34 (p<0.0001), and from 11,1 to 2,22 mSv (p<0.0001) for PET, CT and PET/CT, respectively. For t-S, using a 99m-Tc dose of 158,6±29 MBq, mean scan-time and ED were 5,4±1,7 min and 2,1±0,4 mSv, respectively. Considering prices in our Institution, tracer's cost was 9,4 euro for t-PET/CT and 5–10 euro for t-S. ACR was calculated 0,106% for wb-PET/CT vs 0,008% for t-PET/CT (p<0.0001); 0,003% for t-PET vs 0,006% for t-S (p<0.0001). Alternatively, using the same FDG dose of wb-PET/CT, the scan time of t-PET was 4,1 vs 5,4 min of t-S (p<0.0001). **Conclusion:** These preliminary data support the hypothesis that low-dose t-PET/CT is a conceivable diagnostic strategy in patients with indeterminate high risk nodules. This imaging approach would be cost/effective in clinical setting, having a potential role in limiting the rate of futile thyroid surgery. **References:** None

OP-864

Ten-Year Follow-up and Clinical Outcome in Euthyroid Patients with Thyroid Nodules in an Iodine Sufficient Area

K. Bajuk Studen¹, K. Zaletel¹, S. Gaberscek^{1,2};

¹Department of Nuclear Medicine, University Medical

Centre Ljubljana, Ljubljana, SLOVENIA; ²Faculty of

Medicine, University of Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: The initial evaluation of patients with thyroid nodules should identify a small subgroup that harbor thyroid cancer, cause compressive symptoms or progress to functional disease and therefore need further clinical management. The rest can be managed with a surveillance program. Defining optimum surveillance intervals remains a challenge. The purpose of our study was to establish a natural history of thyroid nodules in a cohort of euthyroid patients 10 years after the diagnosis. **Materials and Methods:** Patients diagnosed with unsuspected thyroid nodules in whom at the time of diagnosis no treatment was indicated and who did not have autoimmune thyroid disease were invited for re-evaluation 10 years after the diagnosis. Baseline patient parameters and ultrasound characteristics of the nodules were retrospectively collected. At follow-up, thyroid ultrasound was performed; in case of nodule growth, the patient was referred for a complete clinical evaluation. A significant change in

the size of thyroid nodule was defined as the increase or decrease that involved at least 2 nodule dimensions, each amounting to at least 2 mm and representing at least 20% of the baseline diameter. Data are presented as mean \pm standard deviation (SD). **Results:** Forty-three (39 women/4 men, aged 54.2 \pm 13.6 years) patients were included in the study, having 65 nodules with maximum diameter 11.8 \pm 7.8 mm, mean thyrothypin (TSH) 1.73 \pm 1.00 mIU/L and thyroglobulin (Tg) 27.1 \pm 46.9 μ g/l. After 10 years, 21 (32.3%) nodules significantly increased in size, 7 (10.8%) nodules significantly decreased in size, for 29 (44.6%) of nodules, no significant change in size of the nodules was noted. Furthermore, 8 (12.3%) disappeared and 16 new nodules were found. For the nodules that grew, change in nodule largest diameter was found to correlate significantly with baseline largest diameter ($p < 0.05$), but not with baseline TSH, Tg or age. Regarding the clinical outcome, no new thyroid cancers were found. For 39 (90.7%) patients no further management was indicated. Two (4.7%) patients were referred to thyroidectomy because of the growth of the nodules. Two (4.7%) patients were treated for hyperthyroidism because of toxic multinodular goiter. **Conclusion:** We report a single centre experience of the natural history of unsuspected thyroid nodules. Our results show that 67.7% of such nodules remain stable in size, decrease or even disappear and that the vast majority of the patients remain clinically stable with no treatment indication ten years after the diagnosis. **References:** None

OP-865

^{99m}Tc-3PRGD₂ SPECT/CT for predicting disease progression after initial therapy in high risk DTC patients

X. Jia, Y. Wang, Y. Liu, X. Wang, X. Yao, A. Yang, R. Gao;
The first affiliated hospital of Xi'an jiaotong
university, Xi'an, CHINA.

Aim/Introduction: This study aimed to validate the effectiveness of integrin $\alpha v \beta_3$ imaging in predicting structural progression in high-risk differentiated thyroid cancer (DTC) patients. **Materials and Methods:** DTC patients evaluated as high risk of recurrence after initial surgery were enrolled and ^{99m}Tc-3PRGD₂ SPECT/CT was performed before radioiodine ablation (RAI). Clinical data obtained during follow-up were used to assess the response and outcome. Aggressive local surgery, another RAI, or targeted chemotherapy was performed if disease progression was detected. **Results:** A total of 25 patients were enrolled in this study because of the existence of gross extra-thyroidal extension (n=10), incomplete tumor resection (n=4), extensive vascular invasion (n=2), lung metastases (n=5), and elevated Tg suggestive of distant metastases (n=24). Nineteen out of the 25 cases demonstrated RGD-avid disease and the median T/B ratio of the lesions was 3.29 (range 1.8–15.5, n=19). The serum thyroglobulin (Tg) level of

them was higher than that of the cases that showed non-RGD-avid disease, but without statistical difference (n=6; 77.30 vs. 27.75 ng/mL, $p=0.105$). Three cases demonstrated RGD-avid disease were excluded from further analysis because of loss to follow-up. During follow-up post initial treatment (median 16 months), no disease progression was detected and a decrease of Tg (ranged from 12.83% to 100%) was revealed in cases showed non-RGD-avid disease (n=6). While structural progression was detected in 11 out of the 16 (68.75%) cases demonstrated RGD-avid lesions. Among them, a second surgery was administered in four because of metastatic lymph nodes and another RAI was applied in three for progression of pulmonary disease. Kaplan-Meier curves showed a significant difference in terms of progression-free survival (PFS) between patients who demonstrated RGD-avid disease or not ($p=0.033$). **Conclusion:** ^{99m}Tc-3PRGD₂ imaging is a valuable initial predictor of treatment failure in high-risk DTC. A significant association emerged between 3PRGD₂ uptake and PFS. **References:** None

Is BRAF^{V600E} mutation a risk factor for developing contralateral lymph-node metastases in papillary thyroid cancer (PTC) patients?

A. Campenni¹, R. Ruggeri², M. Siracusa¹, A. Alibrandi³, D. Cardile¹, H. Lanzafame¹, F. Panasiti¹, F. La Torre¹, G. Giacoppo¹, A. Ieni⁴, G. Giuffrè⁴, G. Tuccari⁴, S. Baldari¹;

¹Department of Biomedical and Dental Sciences and Morpho-Functional Imaging, Nuclear Medicine Unit, University of Messina, Messina, ITALY, ²Department of Clinical and Experimental Medicine, Unit of Endocrinology, University of Messina, Messina, ITALY, ³Department of Economical, Business and Environmental Sciences and Quantitative Methods, University of Messina, Messina, ITALY, ⁴Department of Human Pathology in Adult and Developmental age "Gaetano Barresi", University of Messina, Messina, ITALY.

Aim/Introduction: Several molecular markers have been introduced to improve postoperative risk stratification of papillary thyroid cancer (PTC) patients. BRAF^{V600E} is the most common somatic point mutation in sporadic PTC and is frequently associated with aggressive behavior in intermediate-high risk PTC patients. The aim of our study was to evaluate if BRAF^{V600E} mutation was associated with more aggressive clinico-pathological features and could be considered as risk factor for developing contralateral lymph-node metastases in low-intermediate risk PTC patients with unilateral tumor. **Materials and Methods:** We reviewed the record of 354 out of 1185 patients (29.8%) affected by low or intermediate risk unilateral-PTC [pT1-T3, Nx(0/1), Mx; 269 women, 85 men; mean age (SD)=46.9 (13.6), median=47 yrs; female-to-male ratio: 3.16:1]. In all of these patients, BRAF^{V600E} mutation was evaluated and

131-radioiodine therapy (RaIT) was performed using ≥ 2220 MBq (2220–4588 MBq) with ablative or adjuvant intent. Neck-ultrasonography and laboratory test were obtained before RaIT. A post-therapy whole body scintigraphy (pT-WBS) was performed 5–7 days after RaIT. Neck-ultrasonography, computed tomography, magnetic resonance imaging were performed on request of attending nuclear medicine physician. **Results:** BRAF^{V600E} mutation was found in 170 out of 354 (48%) PTC patients (Group A) [F=126, M=44, mean age=47.2 yrs (14.4), median=47; female-to-male ratio: 2.9:1]. In the remaining patients (184/354, 52%), BRAF^{V600E} mutation was not found (Group B). The risk to have aggressive variant (eg. Tall-cell), intermediate risk PTC (2015 ATA) and disease staging II (AJCC 8th edition) was significantly higher in Group A than B patients [Odds Ratio(OR)=3.509, 3.186, 20.646, respectively]. In addition, significant differences in the prevalence of intermediate risk PTC, Hashimoto thyroiditis, multifocality, aggressive variant as well as higher tumour size and disease staging were observed between Group A and B (p=<0.001, p=0.001, p=0.026, p=<0.001, p=<0.001, p=<0.001, respectively). Forty-two out of 170 Group A patients [F=27, M=15, mean age=48.8 yrs (14.3), median=50; female-to-male ratio: 1.9:1] had omolateral (n=24, 57.2%) or contralateral (n=18, 42.8%) loco-regional metastases at pT-WBS. Interestingly, the prevalence of both loco-regional and contralateral lymph-node metastases at pT-WBS was significantly higher in Group A than B patients [42/170 (24.7%) vs 22/184 (11.9%), p=0.003 and 18/42 vs 22/22, p=0.013, respectively]. **Conclusion:** BRAF^{V600E} mutation is associated to more aggressive clinico-pathological features in our cohort of low and intermediate risk unilateral-PTC patients. Of note, BRAF^{V600E} mutation should be considered as a significant risk factor for having contralateral lymph-node metastases. pT-WBS is a useful diagnostic tool for improving postoperative risk stratification of PTC patients. **References:** None

Comparison between PERCIST criteria, Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG) in the evaluation of response to tyrosine kinase inhibitors in patients with radioactive iodine-refractory metastatic thyroid cancer

A. Miceli¹, A. Borra¹, M. Bauckneht², S. Gay³, S. Raffa¹, M. Albertelli³, M. Donegani¹, S. Marra¹, G. Ferrarazzo², G. Sambuceti¹, D. Ferone³, M. Glusti³, S. Morbelli¹;

¹DISSAL, Genoa, ITALY, ²IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, ³DIMI, Genoa, ITALY.

Aim/Introduction: Tyrosine kinase inhibitors (TKI) and, in particular, Lenvatinib, have been shown to delay disease progression and provide benefit in terms of overall survival (OS) in patients' with radioactive iodine-refractory (RAI-R) differentiated thyroid cancer (DTC). Effective methods

for evaluating response to TKI are a critical unmet need owing to their expensive costs and unique adverse events. While computed tomography have been used to evaluate response to TKI in metastatic DTC by means of RECIST criteria, no PET-based criteria have been to-date validated in this clinical settings. We aimed to explore agreement between FDG-PET-based metabolic response to TKI measured with different criteria and their relationship with RECIST-based response at last follow up. **Materials and Methods:** We interrogated our database to identify metastatic DTC patients who performed FDG-PET just before and after therapy with TKI between January 2013 and December 2019. Both first response and following responses to TKI were considered. Baseline and post-treatment maximum standardized uptake value (SUVmax), SUVmean, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were measured at baseline and after therapy to compute PERCIST and MTV-, TLG-based responses. Concordance in terms of response between PERCIST, DELTA-MTV, DELTA-TLG was computed with kappa value. Evaluation of the predictive value of early metabolic response to the final CT-based RECIST 1.0 response was also assessed. **Results:** 45 scans in 15 metastatic DTC patients were included in the analysis (five patients had been initially treated with Sorafenib and then shifted to Lenvatinib). The median OS was 32 months. Considering both first and best response 40%, 27% and 33% of patients were classified as either stable metabolic disease (SMD) or partial metabolic response (PMR) by PERCIST, MTV and TLG respectively. Substantial agreement was observed between PERCIST and DELTA-MTV (K=0.66) while only a fair agreement was documented between DELTA-TLG and both PERCIST and MTV (k=0.4). Of note, all long term (> 41 months) SD according to RECIST 1.0 criteria at last follow up had been previously classified as in PMR according to TLG within one year after initiation of therapy with TKI (while no relationship was highlighted with PERCIST and MTV). **Conclusion:** A PERCIST-based single lesion approach reaches fair concordance with more complex metabolic response based on MTV and TLG. However, TLG computation potentially provides additive information. In fact, only depth of response as highlighted by TLG was able to early identify long term responders patients. **References:** None

OP-868

Thyroglobulin doubling time independently predicts 2-[¹⁸F]-FDG-PET/CT results in Patients Affected by Differentiated Thyroid Carcinoma with Positive Thyroglobulin Level and Negative ¹³¹I Whole Body Scan

D. Albano¹, E. Cerudelli², M. Gazzilli², F. Dondi¹, A. Mazzoletti¹, P. Bellini¹, L. Camoni², F. Bertagna¹, R. Giubbini¹;
¹University of Brescia and Spedali Civili di Brescia, Brescia, ITALY, ²Spedali Civili di Brescia, Brescia, ITALY.

Aim/Introduction: Serum thyroglobulin (Tg) is considered

the most sensitive marker of disease for monitoring patients affected by differentiated thyroid carcinoma (DTC) after surgery and ablation of thyroid remnants by iodine-131 (^{131}I). In patients with positive Tg and negative ^{131}I whole-body scan (^{131}I -WBS), 2-deoxy-2-[^{18}F]fluoro-D-glucose positron emission tomography/computed tomography (2-[^{18}F]-FDG PET/CT) can be considered useful to detect sites of disease. But the effective relationship of Tg-Doubling time (Tg-DT) and PET/CT results is lacking. **Materials and Methods:** From December 2006 to December 2019, 113 patients (median age 56 years, 61 female, 52 male) affected by DTC and treated with total thyroidectomy plus ^{131}I , with last ^{131}I -WBS negative and Tg \geq 1 ng/ml without detectable Tg-antibodies, underwent 2-[^{18}F]-FDG PET/CT and were retrospectively included in this study. Tg-DT was computed on the basis of at least three consecutive Tg measurements under TSH suppression performed prior to the PET/CT scan. Receiver operating characteristic (ROC) curve analysis was used to identify the optimal cutoff point of last stimulated Tg before PET/CT and Tg-DT in the light of which interpret the results of 2-[^{18}F]-FDG PET/CT. **Results:** Among 113 2-[^{18}F]-FDG PET/CT scans, 74 (65%) resulted positive showing the presence of hypermetabolic lesions consistent of DTC disease. Of these, 72 were confirmed as true-positive, in the remaining two cases, PET/CT were false-positive. In 39 (35%) patients, PET/CT was negative showing no increased FDG uptakes in whole body: 33 was true negative and 6 false negative. Sensitivity, specificity, positive predictive value, negative predictive value and accuracy of 2-[^{18}F]-FDG PET/CT were 92% (95% CI 84–97%), 94% (95% CI 81–99%), 97% (95% CI 90–99%), 87% (95% CI 72–92%), and 93% (95% CI 87–97%) with positive and negative likelihood ratios of 16.15 and 0.08, respectively. Serum Tg and Tg-DT were significantly higher in patients with negative PET/CT than positive (for Tg-DT median 4.52 year, mean 8.9 years, vs median 1.07 year, mean 1.3, $p<0.001$) ROC curve analysis revealed an optimal Tg cut-off of 19 ng/mL (sensitivity 78%, specificity 85%, AUC 0.844) and Tg-DT of 2.5 years (sensitivity 93%, specificity 87%, AUC 0.911). Tg-DT threshold of 2.5 years correctly predicted 66 of 72 (92%) true-positive and 31 of 33 (94%) true negative PET/CT. **Conclusion:** In conclusion, in DTC patients with negative ^{131}I -WBS and positive Tg, Tg-DT may predict 2-[^{18}F]-FDG PET/CT results with an accuracy higher than Tg as absolute value. Tg-DT less than 2.5 years can be considered a valid marker for predicting PET/CT results. **References:** None

OP-869

Comparison of Lesion Detectability and Image Quality among Digital and Analog PET Systems for Recurrence in Thyroid Cancer Patients Using I-124

D. Kersting¹, M. Weber¹, M. Sraieb¹, P. Fragoso Costa¹, L. Umutlu², C. Rischpler¹, W. P. Fendler¹, M. Conti³, K. Herrmann¹, W. Jentzen¹;

¹Department of Nuclear Medicine, University Hospital Essen, Essen, GERMANY, ²Department of Diagnostic and

Interventional Radiology and Neuroradiology, University Hospital Essen, Essen, GERMANY, ³Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: I-124 PET is limited by a low positron branching ratio and low image quality, especially for low-uptake lesions and at late dosimetry time points. In this study, we assess the improvement in lesion detectability in differentiated thyroid cancer (DTC) patients with low increasing thyroglobulin (TG) levels by a digital versus an analog PET/CT system with TOF capability and, in addition, compare the results to a neck scan on a non-TOF PET/MR system at standard and prolonged emission time (ET). Moreover, different image reconstruction algorithms are evaluated. The results are used to suggest scan protocol optimisations. **Materials and Methods:** Data sets of 10 DTC patients with low increasing TG levels after total thyroidectomy and radioiodine therapy were included. PET data were acquired within 24 h after administration of 38 MBq I-124 on a digital Siemens Biograph Vision and an analog Biograph mCT PET/CT system (both whole-body, 4-min ET per bed position, image reconstruction OSEM, OSEM+TOF and OSEM+TOF+PSF) and a non-TOF Biograph mMR PET/MR system (only neck region, 4-min and 20-min ET, only OSEM). All data were interpreted by 3 blinded nuclear medicine physicians. Apart from lesion detection, the image quality was rated on a five-point-scale from 1 to 5. **Results:** Across all systems, a total of 9 lesions was detected, all located in the neck region. The detectability was significantly higher ($p<0.01$) for the digital (OSEM 5/9, OSEM+TOF 8/9, OSEM+TOF+PSF 8/9) compared to the analog PET/CT (OSEM 2/9, OSEM+TOF 2/9, OSEM+TOF+PSF 3/9) and increased for the non-TOF PET/MR from 3/9 to 8/9 with increasing ET. TOF+PSF image reconstruction on the analog PET/CT induced two additional regions (hilar lymph node and bone) with artificially elevated uptake (as not discernible in any other imaging modality). The median visual image quality increased from the analog to the digital PET/CT from 1.5 to 3 (OSEM), from 2 to 4 (OSEM+TOF) and from 3 to 4 (OSEM+TOF+PSF), the PET/MR reached values of 1 (4-min ET) and 3 (20-min). **Conclusion:** Based on this study, several protocol optimisations may be considered to improve the detectability for low-uptake lesions. If available, digital PET/CT and TOF image reconstruction are preferable and revealed at 4-min ET a detectability comparable to non-TOF PET/MR at 20-min ET. Moreover, emphasis of the mostly affected neck region by a selectively prolonged scan duration can be useful. Images reconstructed with TOF+PSF can be critical due to artificial uptakes and should be carefully considered. **References:** None

OP-870

Do Histological Patterns of Primary Tumor Predict Metabolic Patterns detected by FDG PET/CT in

Differentiated Thyroid Cancer Patients

S. Soyluoglu, E. Tastekin, U. Korkmaz, S. Orum, G. Durmus Altun;
Trakya University, Medical School, Edirne, TURKEY.

Aim/Introduction: Although differentiated thyroid cancers (DTC) generally has excellent prognosis, approximately 15% develop metastasis in follow-up. The clinical course of metastatic patients is quite variable. We aimed to investigate the relationship between primary tumor histopathological features and FDG PET/CT findings in patients with elevated thyroglobulin levels. **Materials and Methods:** DTC patients, who underwent PET/CT between January 2015 and December 2019 were scanned and all patients with accessible postoperative pathology and I-131 whole body scan (WBS) were included in the study. Primary tumor size, focality, positive surgical margin (PSM), capsule invasion (CI), lymphovascular invasion (LVI), blood vessel invasion (BVI), perineural invasion (PNI), extrathyroidal invasion (ETI), intraglandular dissemination (IGD), mitoses, peritumoral lymphocytic infiltration (PTLI) were recorded. Patients were also grouped according to the ATA risk classification and follow-up thyroglobulin values, and the relationship between these groups, histopathological patterns, I-131 WBS and FDG PET/CT findings were evaluated statistically. **Results:** Total of 75 patients, 45 female and 30 male, included in the study. The average age at the time of diagnosis was 48.9 ± 7.8 . The tumor size ranged from 0.2 to 8 cm, mean 2.3 mm (± 1.8). Multifocality, PSM, CI, LVI, ETI (56%, 60%, 39%, 39%, 55%) were frequently observed, while BVI, PNI, IGD were more rare (1%, 7%, 7%). PET/CT was positive in 54 patients (72%) and I-131 WBS was positive in 37 patients (49%). The average SUVmax in metastatic lesions was 6.2 ± 18.8 . A significant correlation was found between PET positive metastatic disease and LVI ($p = 0.04$). The presence of LVI increased the risk of PET positivity by 3.9 times (95% Confidence Interval: 1.2–13.3; $p = 0.027$). SUVmax values were significantly associated with LVI ($p = 0.04$). There was also a significant relationship between mitosis, PTLI and PET positivity. A significant correlation was found between tumor size and SUVmax ($p = 0.04$), and between thyroglobulin groups and PSM, LVI, ETI ($p = 0.037$, $p = 0.004$, $p = 0.04$). There is a significant relationship between risk classification and PET positive bone metastasis ($p = 0.03$). **Conclusion:** LVI and mitosis detected in primary tumor and tumor size is correlated with the presence of FDG PET/BT positive metastases and higher SUVmax values in patients with DTC, which associated with more aggressive tumor behavior. Patients who identified as high risk according to initial risk stratification are more likely to develop PET positive bone lesions. **References:** None

OP-871

Comparison of simultaneous ^{18}F -FDG PET/MR and PET/CT in the follow-up of patients with differentiated thyroid cancer

L. Piscopo¹, M. Klain¹, C. Nappi¹, M. Manganelli¹, E. Nicolai², V. Romeo¹, A. Giordano¹, V. Gaudieri¹, E. Zampella¹, F. Volpe¹, M. De Risi¹, L. Pace³, A. Cuocolo¹;

¹Department of Advanced Biomedical Sciences, University Federico II, Napoli, ITALY, ²IRCCS-SDN, Napoli, ITALY, ³Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, ITALY.

Aim/Introduction: ^{18}F -FDG PET/CT is the most accurate imaging method in differentiated thyroid cancer (DTC) patients with either an aggressive histology, an absence of radioiodine uptake in neoplastic foci, or an elevated serum thyroglobulin (Tg) level that progresses with time in the absence of known imaging abnormalities. We evaluated the diagnostic performance of FDG PET/MR in comparison with that of PET/CT. **Materials and Methods:** Following the injection of a single ^{18}F -FDG activity, simultaneous PET/MR and PET/CT were sequentially performed in 40 consecutive patients with DTC previously treated with total thyroidectomy and radioiodine ablation. At PET/MR imaging, all areas with abnormal FDG uptake corresponding to a MR abnormality (tissue mass or lymph node) were considered as positive. In addition, any focal increased uptake of FDG that did not correspond to normal structures was also recorded as positive. A similar procedure was applied for PET/CT interpretation. Any morphological abnormality identified as lesion on MR or CT was recorded. All patients were followed-up for at least 6 months by serum Tg, Tg-Ab and thyroid-stimulating hormone determinations and neck ultrasonography. Other imaging procedures were performed as clinically indicated, whole-body scan was obtained in case of ^{131}I therapy, and histology was recorded in case of surgery. The date of recurrence or the most recent follow-up examination was recorded, as well as the clinical status at the end of the study. **Results:** All patients were treated in a range of 6–400 months before study. According to serum Tg levels, abnormal imaging findings were found in 10/22 patients (45%) with a serum Tg ≥ 2 ng/mL (range 20–1050 ng/mL) and in only 1/18 patients (5%) with a serum Tg < 2 ng/mL. PET/MR was positive in 11 patients and PET/CT in 10 patients. PET/MR detected 33 tumor foci and PET/CT 30 tumor foci. During the follow-up of the 12 patients with negative initial PET studies and with detectable serum Tg, only one patient had a neck recurrence and the administration of an empiric high activity of ^{131}I in the other 11 patients did not reveal any unknown tumor focus. In the 17 patients with an initial serum Tg level < 2 ng/mL, no recurrence occurred. **Conclusion:** This study confirms the high diagnostic accuracy of FDG PET studies in DTC patients with elevated serum Tg levels and shows that PET/MR does

not bring significant complementary information over PET/CT imaging. **References:** None

OP-872

Clinical Impact Of [⁶⁸Ga]Ga-DOTA-TATE Imaging In Patients With Medullary Thyroid Cancer

M. Tuncel, S. Kilickap, N. Suslu;

Hacettepe University, Ankara, TURKEY.

Aim/Introduction: Medullary thyroid cancer (MTC) arises from the neuroendocrine C cells of the thyroid. There is no single diagnostic imaging method to reveal all MTC recurrences or metastases. [⁶⁸Ga]Ga-DOTA-TATE is an alternative PET-radiotracer that showed acceptable efficacy in the detection of MTC. In this study, we aimed to reveal the clinical impact of this radiotracer in the management of patients with MTC. **Materials and Methods:** [⁶⁸Ga]Ga-DOTA-TATE-PET-CT records of 38 patients with confirmed MTC were included in the study. Demographic data, the clinical indication for the scan, previous therapies, and tumor marker levels were recorded. The site and SUVmax of the disease sites were noted. Consensus reached for the additional value of [⁶⁸Ga]Ga-DOTA-TATE-PET-CT, and discordant sites with conventional imaging (CI) were recorded. Finally, changes in management after the scan were evaluated. **Results:** [⁶⁸Ga]Ga-DOTA-TATE-PET-CT outperformed CI in 14/38 (37%) patients. It has detected metastatic lymph nodes in 8, bone metastases in 4, and both bone & lymph nodes in 2 of these 14 patients. In 16/38 (42%) of patients, [⁶⁸Ga]Ga-DOTA-TATE PET-CT performed equally with CI. In 5/38 (13%) patients CI outperformed PET-CT. [⁶⁸Ga]Ga-DOTA-TATE PET-CT positivity was also correlated with tumor markers (Ctn-median; PET-positive: 743 ± 5439 vs PET-negative: 31 ± 17 (p: 0.012) CEA median; PET-positive: 41 ± 162 vs PET-negative: 2.6 ± 1.4 (p: 0.015)). [⁶⁸Ga]Ga-DOTA-TATE PET-CT had changed clinical management in 13/38 (34%) patients. **Conclusion:** [⁶⁸Ga]Ga-DOTA-TATE is an essential part of the work-up of patients with MTC. It has outperformed CI in 14/38 (37%) patients and has changed the 34% of therapy decisions. Prospective studies with image-guided therapy decisions are needed further to reveal the impact of PET imaging in patients with MTC. **References:** None

Aim/Introduction: The aim of the study was to assess survival rates and prognostic features of papillary (PTC) and follicular (FTC) thyroid cancer patients (pts) treated and followed-up up to 50 years in one institution. **Materials and Methods:** The retrospective study enrolled 1167 PTC (F/M 4:1, median age 47, range 6-83 years) and 215 FTC pts (F/M 2.8:1, median age 48, range 13-81 years) operated between 1970-2012 and followed-up till April 2020. Mean follow-up in years of PTC pts was 12.0 (0.2-48) and FTC pts 11.0 (0.4-46). In >99% DTC pts total thyroidectomy was performed and 92% PTC and 96% FTC pts underwent I-131 therapy. Prognostic factors: age gender, tumor size, TNM stage, presence of local and distant metastases at presentation and disease recurrence were evaluated with univariate (Kaplan-Meier Survival Curves, Log-rank test) and multivariate analysis (Cox Regression) (p<0.05). **Results:** At initial presentation, cervical metastases were recorded in 252 (26%) PTC and 17 (7.9%) FTC pts (p=0.033), and distant metastases (M1) in 40 (3.4%) PTC and 29 (13.5%) FTC pts (p<0.001). Median tumour size in mm in PTCs vs FTCs was 12 (1-100) vs 32 (7-90) (p<0.001). During follow-up new M1 developed in 7 PTCs (overall 47, 4.0%) and 3 FTCs (overall 32, 14.9%) and loco-regional recurrence in 70 (6%) PTCs and 14 (6.5%) FTCs. Median tumor size in PTCs vs FTCs with M1 was 25 vs 64 mm. During follow-up 14 PTCs (F/M 0.6:1) and 20 FTCs (F/M 1.2:1) died from disease. In PTCs with fatal outcome, 8 died due to distant metastases and 6 due to advanced local disease. In FTCs with fatal outcome, 17 died due to distant metastases and 3 due to advanced local disease. Overall 10-year cancer specific survival rate for PTC and FTC was 98.8% and 92.7% (80% and 37% with M1) (p<0.001). All 7 risk factors affecting outcome in PTC and FTC pts showed statistically significant correlation in univariate analysis (p<0.001). Multivariate analysis demonstrated in PTCs older age (p=0.005), stage IV, larger tumor size and M1 (p<0.001) as prognostic factors affecting outcome, but for FTCs none reached statistical significance. **Conclusion:** DTCs are malignant tumors with low mortality rate as demonstrated in this study, especially PTCs. Recurrence rate in our study was low, probably due to total thyroidectomy and I-131 therapy in most of the pts. FTCs have less favourable outcome than PTCs due to more advanced tumour stages at initial presentation. **References:** None

OP-874

Incidental lung findings suggestive of COVID-19 pneumonia in oncologic PET/CT studies

D. Monachello Araujo, M. Coronado Poggio, S. Rodado Marina, E. López Llobet, S. Rizkallal Monzón, D. Travaglio Morales, C. Lancha Hernández, L. García Zoghby, J. Cordero García, A. Guzmán Cruz, C. Escabias del Pozo, L. Domínguez Gadea; Hospital Universitario La Paz, Madrid, SPAIN.

Aim/Introduction: In Spain COVID-19 pandemia reached its outbreak in March 2020. For some weeks, patients without clinical diagnosis of COVID-19 infection underwent PET/CT studies for standard indications. The aim of this study is to report incidental PET/CT findings suggestive of COVID-19 associated pneumonia in this group of patients, who received medical attention in a third level hospital of Madrid during this “peak of infection” period. **Materials and Methods:** Whole body PET/CT studies from patients without clinical or microbiological diagnosis of COVID-19 infection, performed from March 3rd to April 14th, were retrospectively reviewed by two nuclear medicine experts. Lung findings unrelated to their oncologic process or pulmonary chronic disease were noted. CT findings were classified in three categories following COVID-19 pneumonia classification for CT (Simpson S and cols, 2020): typical, indeterminate and atypical appearance; all of them were PET positive if they presented pathological radiotracer uptake. Final diagnosis was made based on PCR results and clinical follow up. Change in the patient management was also recorded. **Results:** 230 whole body PET/CT scans were reviewed. 33 of them (14.3%) had lung findings suggestive of COVID-19 associated pneumonia (30 18F-FDG, 3 18F-Fluorocholine). Twelve patients had typical pattern, 15 indeterminate pattern and 6 atypical pattern, all of them with pathologic radiotracer uptake. Patients characteristics: 20 male, 13 female, mean age 59 years old. PET/CT indication: 30 oncologic patients -head and neck (5), breast (4), lung (5), lymphoma (3), multiple myeloma (1), colorectal (3), sarcoma (1), unknown primary tumor (1), endometrium (1), melanoma (1), prostate (3), SPN (1), thyroid (1)- and 3 patients with fever of unknown origin. Based on PET/CT findings, PCR was performed in 22/33 (66.6%) patients 0-12 days after PET/CT, with 12 positive and 10 negative results. All patients with positive PCR received specific treatment and isolation measures, and two of them had surgery delayed. From the 10 patients with negative PCR results, three of them were symptomatic a few weeks before; 1

patient had Klebsiella pneumoniae present in BAS; 6 patients don't have more clinical data. 11 patients had no PCR done; 1 of them was found to be clinically suspicious, and was prescribed to start specific treatment, isolation, and surgery was delayed; the rest don't have further clinical follow up. **Conclusion:** In the actual pandemic state, incidental PET/CT lung findings are useful to identify COVID-19 associated pneumonia, and can change patient's medical and social management. **References:** None

OP-875

Incidental Interstitial Pneumonia Suggestive Of COVID-19 In Asymptomatic Patients Undergoing 18F-FDG PET/CT In A High Prevalence Area

D. Albano, E. Cerudelli, M. Gazzilli, F. Dondi, A. Mazzoletti, P. Bellini, L. Camoni, F. Bertagna, R. Giubbini; University of Brescia and Spedali Civili of Brescia, Brescia, ITALY.

Aim/Introduction: : An aggressive acute respiratory disease caused by SARS-CoV 2, called COVID-19, occurred initially during December 2019 in Wuhan, China, and then spread globally, becoming a pandemic. After China, Europe and especially Northern Italy were severely affected, with a dramatic increase of cases of pneumonia and respiratory distress syndrome in some cities, like Brescia and Bergamo. Chest radiographs and CT are the preferred examinations for screening, diagnosis and monitoring of COVID-19 pneumonia. CT findings are typically characterized by ground-glass opacities (GGOs) or bilateral pulmonary consolidations in multiple lobular and sub-segmental areas. Instead the potential role of 18F-FDG PET/CT in this field remains unclear. Our aim was to collect the cases of interstitial pneumonia COVID-19 suspected detected at 18F-FDG PET/CT in March 2020, describe their metabolic and radiological features and compared these results with those of the same period of 2019. **Materials and Methods:** In March 2020, 145 18F-FDG PET/CT studies were performed for routine oncological indications in our Department of Nuclear Medicine in Brescia, Italy. Owing to the concurrent high prevalence and increasing dynamics of COVID-19 infections in the region, all patients were asymptomatic and carefully screened by a triage before general access to the hospital, and again before entering the nuclear medicine service unit. Accordingly, no suspicion of viral infection was present at the time of PET/CT in any patient. **Results:** Fifteen patients (10%) showed CT signs of interstitial pneumonia, suspicious for COVID-19. In most cases (73%), increased FDG uptake corresponding to areas of pneumonia were detected. RT-PCR test was performed in 12 cases and resulted positive for COVID-19 in 11. The frequency of incidental pneumonia was significantly higher when compared to PET/CT scans of the same period one year earlier (only 9 of 350 PET/CT studies performed during March 2019 had incidental pneumonia). In case of positive scans, average SUVmax

was 5.7 (range 2.6–13) and SUVmean 3.5 (1.7–8.8). FDG-avid mediastinal lymph nodes involvement was registered in 3/15 cases. **Conclusion:** COVID-19 suspected pneumonia may be detected as incidental finding in asymptomatic patients undergoing PET/CT for oncologic indications in regions with high COVID-19 prevalence, are characterized by GGO and/or consolidations FDG-avid in most cases, underlying a possible high metabolic rate of this disease.

OP-876

Estimating the incidence of asymptomatic SARS-CoV-2 infection by frequency of CT findings in patients undergoing PET/CT

I. Alberts, B. Vollnberg, C. Sachpekidis, C. Mingels, S. Weidner, A. Rominger;
Institut für Nuklearmedizin, Bern, SWITZERLAND.

Aim/Introduction: To present a method to estimate the prevalence of asymptomatic SARS-CoV-2 infection in high-risk individuals undergoing PET/CT using frequency of CT findings. **Materials and Methods:** 562 consecutive patients underwent PET/CT scanning with different radiotracers in the period between the first confirmed SARS-CoV-2 case in Switzerland and 14.04.2020. All patients were asymptomatic for respiratory infection at the time of scanning and were at increased risk for SARS-CoV-2 infection. Cognisant of recent reports showing the high sensitivity of CT for SARS-CoV-2 (98%) [1], including in asymptomatic patients [2] when compared to conventional laboratory testing [3], we observed the frequency of incidental, SARS-CoV-2 related changes in PET/CT [4]. No SARS-CoV-2 related CT findings were observed, enabling an estimate of the prevalence in the asymptomatic population using the binomial proportion confidence interval (Wilson's test). **Results:** N=562 negative tests yields a point prevalence of asymptomatic patients with SARS-CoV-2 infection in the population as 0.325% (95% confidence interval (CI) 0–0.65). By comparison, at the time of analysis the Swiss Federal Office for Public Health (FOPH) reported 25826 laboratory confirmed cases (population prevalence 0.3%, 92.7% agreement). These results find broad agreement with estimates of SARS-CoV-2 infection in other similar populations for the limited number of peer-reviewed population prevalence studies published [5]. **Conclusion:** The frequency and number of CT findings in asymptomatic patients undergoing PET/CT scanning can be used to estimate the incidence for SARS-CoV-2 in the asymptomatic population who may otherwise not present for conventional testing. Hitherto, few prevalence studies in asymptomatic populations have been conducted as a result of limited testing capacity during the pandemic. The derived model has good agreement with other empirical parameters. **References:** [1] Shi H, et al. Radiological findings from 81 patients with COVID-19 pneumonia in Wuhan,

OP-877

Incidental lung findings suspicious for SARS-CoV-2 infection in patients undergoing PET/CT during COVID-19 pandemic

R. Mei^{1,2}, L. Zanoni¹, A. Farolfi¹, C. Nanni¹, V. Ambrosini¹, P. Castellucci¹, G. Montini¹, V. Allegri¹, A. Musto³, A. Golemi³, S. Fantì¹;
¹Nuclear Medicine Policlinico S.Orsola-Malpighi, Bologna, ITALY, ²DIMES, University of Bologna, Bologna, ITALY, ³Metropolitan Nuclear Medicine, AUSL di Bologna, Ospedale Maggiore, Bologna, ITALY.

Aim/Introduction: SARS-CoV-2 infection may remain asymptomatic/false negative at pharyngeal RT-PCR, thus leading to COVID-19 underdiagnosis. Incidental pneumonia suspicious for COVID-19 in routine PET/CT examinations is reported. **Materials and Methods:** During Italian-Phase1-COVID-19-restrictions (21Feb2020–April2020), among triage-selected PET/CT performed for standard-indication in our MNM-Institution (n=2025), we retrospectively, preliminary analysed patients with findings suspicious for COVID-19 pneumonia, respectively: SARS-CoV-2 -RT-PCR-negative (at least 1) at the time of PET/CT (n=53) who unexpectedly turned out positive at subsequent RT-PCR tests (n=4/53), and asymptomatic, with incidental suspected viral pneumonia at PET/CT, immediately addressed to further investigations (n=14). All PET/CT were retrospectively reviewed by at least 2 expert readers; any lung/mediastinal potentially infectious finding was reported at PET (visual and SUVmax interpretation) and low-dose-CT (LDCT) images. Short-term clinical/laboratory/diagnostic-CT follow-up data were collected for validation. COVID-19 likelihood was finally categorized as: “certain”(RT-PCR-positive), “probable”(RT-PCR-negative but likely infected, treated), “indeterminate”(RT-PCR negative but isolated), “excluded”. **Results:** Overall 18 pts were included (M:F=16:2; mean 67[47–84] years; 6/18 inpatients). PET-clinical-indication were: FUO 4/18, oncological 14/18. Radiotracers: 18F-FDG 15/18, 11C-Choline 2/18; 68Ga-PSMA 1/18. Overall 17/18 (94%) presented tracer-avid suspicious

ground-glass(GG)/consolidations: 7/17 monolateral, 10/17 bilateral, mostly multilobar (8/17) but predominantly basal (16/17). Among the 15 18F-FDG-avid lung findings, SUVmax ranged 2-10 (median 3.7, mean 4.4±2.5). No suspicious avid/enlarged hilar/mediastinal nodes were found. Non-avid LDCT lung findings were detected in 12/18 (67%) (mainly GG/consolidation or combination, pleural-effusion, bibasal disventilation). All 18 pts were addressed to RT-PCR after PET/CT and finally classified for COVID-19 as: "certain" (5), "probable"(5), "indeterminate"(5), "excluded"(3). At least 7/18 patients were hospitalized in COVID-area. 8/18 patients presented double RT-PCR negativity and no symptoms the day of PET/CT: 4/8 however subsequently turned out positive at 3rd RT-PCR (4th in 1 case) (mean 12 days from PET[9-15]), with concordant HRCT, later hospitalized and treated; to note 1 coinfection case (Pneumococcal remission/COVID-19 progression). Among the other 4/8 persistingly negative RT-PCR cases, 1 was "probable", 1 "indeterminate", 2 "excluded" (bacterial). Among the 10/18 asymptomatic cases, only 1/10 was "certain" (RT-PCR positive 13 days after PET) and responded to hydroxychloroquine. Among the remaining 9/10 asymptomatic and RT-PCR negative patients, 4/9 presented concordant HRCT and considered "probable"(2/4 hospitalized), 4/9 "indeterminate", 1 "excluded"(bacterial). **Conclusion:** During COVID-19 pandemic, incidental PET/CT detection of asymptomatic/previously RT-PCR-negative lung infection is not infrequent and should be reported "real-time" having relevant implications for further clinical/contact exposures management. LDCT findings are reliable whereas PET-tracer avidity is not able to discriminate aetiology. Isolation and rigorous monitoring is crucial when etiology remains indeterminate. **References:** None

OP-878

Cancer and COVID-19; Report of Cases in Nuclear Medicine Department during the Pandemia in Spain

J. Ardila Mantilla, A. Rotger Regí, M. Baquero Oliveros, A. Mari Hualde, J. Orcajo Rincón, I. Gómez Fernández, C. Durán Barquero, D. Zamudio Rodríguez, Y. Henao Celada, J. Atance García de la Santa, J. C. Alonso Farto;
Hospital General Universitario Gregorio Marañón, Madrid, SPAIN.

Aim/Introduction: The association between COVID-19 and cancer, despite the limited experience available, has been described. However, there are few publications about metabolic imaging manifestations in these patients. Since the pandemic started, Spain is one of the countries that has been affected the most in terms of case numbers and deaths. During the declaration of the state of alarm, our service has only performed urgent PET/CT scans. The aim is to determine the association between cancer and COVID-19 among patients who underwent an ¹⁸F-FDG PET/CT study. **Materials and Methods:** From March 14 to April 24, 2020, we have performed 240 urgent ¹⁸F-FDG-PET/CT

examinations most of them with oncologic indication. All of them underwent PET/CT using the usual protocol, carrying out, before the examination, a questionnaire for screening for COVID-19 infection. Those without any of the following clinical manifestations were considered asymptomatic: myalgia, cough, headache, fever, dyspnea or others and oligosymptomatic those who presented only one of the above symptoms. Imaging was considered positive for infection in the presence of hypermetabolic lung infiltrates unjustified by other causes. **Results:** In 16 patients (6.6% of the total PET performed), COVID-19 infection was diagnosed by polymerase chain reaction with reverse transcriptase (PCR). Oncological indication was: 37.5% lung cancer (6/16, 4 of them with solitary pulmonary nodule), 25% lymphomas (4/16). The rest were respectively esophageal, gastric, thyroid, urothelial carcinoma, soft tissue sarcoma and a tumor of unknown origin. In 12 patients PET was requested to diagnose malignancy or tumor staging, all except 2 were without treatment; 2 were to assess response to treatment (1 with chemotherapy and 1 with radiotherapy) and 2 for disease follow up without treatment. 3 of them were asymptomatic for COVID-19 and 5 were oligosymptomatic, in these patients the PCR was requested based on the findings of the PET/CT. The mean hospitalization time was 15 days and all except 4 required oxygen therapy. There was 1 exitus in a patient with stage IV lung carcinoma. **Conclusion:** The incidence of COVID-19 infection seems to be higher in cancer patients than in the general population that is 0,29% (Cancer Incidence in the General Chinese population, Bersanelli M. Controversies about COVID-19 and Anticancer Treatment with Immune Checkpoint Inhibitors. Immunotherapy. 2020) and 0,42% according to official data in Spain. Lung carcinoma and lymphomas are the tumors most frequently associated with this infection. Strikingly, up to 50% of the cases detected are asymptomatic or oligosymptomatic. **References:** None

OP-879

The rate of incidental pulmonary ground glass opacities (pGGOs) at 18F-Choline PET/CT in prostate cancer (PCa) patients

D. Donner¹, M. Burei², S. Agostini¹, L. Picori¹, E. Bagatin¹, M. Erini¹, G. Carbone¹, A. Palermo¹, F. Chierichetti¹, L. Evangelista³;
¹Nuclear Medicine, Santa Chiara Hospital APSS - Trento, ITALY, ²Nuclear Medicine Unit, Veneto Institute of Oncology IOV-IRCSS, Padua, ITALY, ³Nuclear Medicine Unit, Department of Medicine-DIMED, University of Padua, ITALY.

Aim/Introduction: the aim of the study was to evaluate the rate of pGGOs with or without 18F-Choline uptake in PCa patients during COVID-19 outbreak. **Materials and Methods:** 18F-Choline PET/CT images of 410 patients (pts), from two different Italian PET centers, were re-evaluated by nuclear medicine physicians. In case of discordance, a third nuclear

medicine physician was involved. Two different subsets of pts were included: those who underwent 18F-Choline PET/CT from 1st November 2019 to 24th April 2020 (called Group A) and from 1st November 2018 to 24th April 2019 (called Group B). Data about the number and percentage of pts with incidental pGGOs, with and without 18F-Choline uptake, were collected for each group. Information about therapy at the time of PET/CT and the number of pts submitted to the COVID-19 test were assessed by using the Hospital Information System (SIO). Moreover, the incidence of COVID-19 symptoms in health professionals was registered. **Results:** 164 pts were included in Group A, while 246 in Group B. The number of pts with incidental pGGOs at PET/CT was 14.6% for Group A and 3.2% for Group B. In Group B none of the pts had also an uptake of 18F-Choline in pGGOs. Conversely, 12 pts (7.3%) in Group B have both pGGOs and 18F-Choline uptake. 9/83 (10.8%) pts with incidental pGGOs were under hormonal therapy in Group A and 2/93 (2.1%) in Group B. All pts were asymptomatic for lung disease, at the time of PET/CT and none of them were submitted to the COVID-19 nasopharyngeal test. The percentage of pts with incidental pGGOs and significant uptake of 18F-Choline was 4.5 times more frequent in Group A compared to Group B. However, none of the health professionals showed symptoms relative to COVID-19 in the first four months of 2020. **Conclusion:** this descriptive and retrospective work shows a different rate of pts with an incidental abnormal lung pattern in pts undergoing 18F-Choline PET/CT during COVID-19 pandemic. The relative higher percentage of pts undergoing hormonal therapy with incidental pGGOs at PET/CT, but without symptoms, seems to suggest a sort of compliance face to a possible asymptomatic infection. However, the use of personal protective equipment (surgical masks) by all patients examined and by all health professionals, together with a telephone evaluation in order to exclude the presence of symptoms relative to COVID-19 and the frequent handwashing procedures, have probably allowed avoiding contagion among the professionals. **References:** None

OP-880

Signs of a diffuse and intense tracheobronchitis are commonly observed on ventilation scans obtained with ^{99m}Tc-labelled aerosols during the disease progression of coronavirus 2019

P. Marie, A. Bahloul, S. Melki, G. Karcher, C. Selton, F. Goehring, L. Imbert, A. Verger;
CHRU Nancy, Vandoeuvre (Les Nancy), FRANCE.

Aim/Introduction: In addition to the lung parenchyma, the endothelial lining of the respiratory track is also vulnerable to SARS-CoV2 infection, due to high ACE2 receptor expression [1]. We report herein a particularly high rate of signs of intense tracheobronchitis observed on

Technegas® ventilation scans from 12 consecutive patients (age 67±17 years, 9 men) for whom a pulmonary embolism was suspected during the progression of a coronavirus disease 2019 (COVID-19). **Materials and Methods:** Ventilation images were obtained with ^{99m}Tc-labelled Technegas® and blood perfusion images obtained with ^{99m}Tc-labelled albumin macro-aggregates. Imaging was recorded using a whole-body CZT SPECT-CT camera (Veriton-CT®). **Results:** All patients had CT abnormalities highly evocative of COVID-19; 8 had positive RT-PCR tests whereas 4 did not. No mismatch indicative of PE was documented on SPECT images, but matched ventilation/perfusion defects were documented in all patients at the sites of parenchymal lung sequelae identified on CT images. Moreover, a particularly intense and symmetrical increase in Technegas® uptake was observed within the overall tracheobronchial tract in 3 patients and in the bronchi only in 2 patients. There was no difference between the 5 patients with, and the 7 patients without, such tracheobronchial abnormalities when considering all clinical and biological data, including the time duration from onset of symptoms (18±14 days vs. 12±12 days) and the rate of previous history of pulmonary disease, which was very low in both groups (20% vs. 0%). **Conclusion:** Increased tracheobronchial uptake of Technegas® has previously been observed in patients with bronchitis or chronic obstructive pulmonary disease [2] however was particularly marked here, suggesting an intense tracheobronchitis. Although the mechanism is presumably not specific of the SARS-CoV2 virus, such signs may have diagnostic applications, especially in the absence of any previous history of pulmonary disease. **References:** 1 - Ren X, Glende J, Al-Falah M, de Vries V, Schwegmann-Wessels C, Qu X, et al. Impact of the COVID-19 pandemic in Nuclear Medicine departments: preliminary report of the first international survey

S. Annunziata¹, M. Bauckneht², D. Albano³, G. Argiroff⁴, D. Calabrò⁵, E. Abenavoli⁶, F. Linguanti⁶, R. Laudicella⁷, Young Group of the Italian Association of Nuclear Medicine (AIMN);
¹IRCCS Regina Elena National Cancer Institute, Rome, ITALY, ²IRCCS Ospedale Policlinico San Martino, Genova, ITALY, ³University and Spedali Civili, Brescia, ITALY, ⁴University of Milan, Milan, ITALY, ⁵University of Bologna, S. Orsola-Malpighi, Bologna, ITALY, ⁶University of Florence, Firenze, ITALY, ⁷University of Messina, Messina, ITALY.

Aim/Introduction: COVID-19 pandemic is challenging the availability of hospital resources. Several departments are shifting their work to the management of COVID-19 patients. Healthcare professionals who work in Nuclear Medicine (NM) departments could have experienced changes and problems. The Young Group of the Italian Association of Nuclear Medicine (AIMN) developed the first international survey to evaluate different experiences in the international scenario. Aim of this study is to perform a preliminary report of the ongoing survey. **Materials and Methods:** A questionnaire of thirty questions was prepared for all healthcare professionals of NM departments (e.g., physicians, residents, technicians, nurses, researchers), addressing three main issues: 1) new scheduling praxes for diagnostic and therapeutic programs; 2) assistance of patients with diagnosed or suspected COVID-19; 3) prevention of COVID-19 spreading in the departments. Since the 1st of April 2020, an invitation to the survey was sent to the corresponding authors of NM scientific papers indexed in SCOPUS in 2019. Two reminders were mailed to non-responding recipients. Personal data were analysed per individual responder. Organization data were evaluated per single department. **Results:** Two-hundred and ninety-six individual responders from 220 departments were evaluated. The mean age of responders was of 42 years (range 22–69). Most of the responders were from Europe (199/296, 67%). At the time of the response, several departments (213/220, 97%) already changed their organization due to the pandemic. About new scheduling praxes, in most departments scheduled diagnostic and therapeutic procedures were allowed but quantitatively reduced (112/220, 51%). A significant reduction of diagnostic and therapeutic programs (more than 20%) affected 198/220 (90%) and 158/220 (72%) departments, respectively. Patients with COVID-19 or suspected symptoms were evaluated for possible NM procedures by both phone and on-site pre-triage in approximately all departments. Incidental COVID-19 signs in NM exams occurred in 106/220 departments (48%). Few departments were closed or shifted to directly assist patients with COVID-19 (36/220, 16%). About the prevention of COVID-19 spreading, most of departments ensured proper distancing and personal protective equipment for NM staff and patients (200/220, 91%), such as surgical masks and gloves. Finally, 189/296 professionals (64%) thought that pandemic would not permanently change the work of NM departments in the future. **Conclusion:** COVID-19 heavily impacted on NM departments and professionals according to the preliminary report of this first international survey. New praxes for NM scheduling, assistance and prevention of COVID-19 have been applied during the pandemic. **References:** None

OP-882

A pandemic's impact on a Nuclear Medicine Department: Contingency plan implementation and activity restrictions in a COVID-19 referral hospital

L. Torres¹, M. Monteiro², A. Oliveira¹, J. Pereira¹;

¹Centro Hospitalar Universitário São João, Porto, PORTUGAL,

²Centro Hospitalar Universitário Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: The COVID-19 pandemic has forced Nuclear Medicine departments to adjust their operating procedures, reducing activity to the context-relevant essential services, amongst other extraordinary measures. With this study, we aimed to analyze the changes in the day-to-day activity of a Nuclear Medicine Department in a COVID-19 referral hospital. **Materials and Methods:** In our department, a COVID-19 contingency plan was drafted and put into action on March 13th 2020, determining all non-urgent programmed procedures to be suspended, therefore restricting activity to hospitalized patients and oncologic or urgent exams/treatments. This plan also revised disinfection procedures, patient flow inside the department, repurposed a room for isolation in the event of a signaled or symptomatic patient, and assigned the staff to 2 mirror teams, for rotation purposes. We reviewed the exam requests and procedures performed in the department during the periods of March–April 2019 and March–April 2020, analyzing and comparing the data. **Results:** In the months of March and April 2020, 1000 requests for imaging/therapeutic procedures were received, a 42% reduction compared to the same period in 2019 (1727 requests). These requests included non-urgent patients, to be scheduled at a later date, when the contingency plan is no longer active. 322 procedures were performed in March 2020, and 101 in April 2020, versus 628 and 652 in March and April 2019, which signals a 49% and 85% decrease, respectively. These numbers translate the rescheduling of all non-urgent patients since March 13th, and do not include PET-CT's performed, which are outsourced and remained stable, with even a slight increase (186 in March–April 2020 vs 163 in March–April 2019). From March 13th to the 30th of April 2020, 89% of procedures were for oncologic diseases, and 11% for urgent cases (myocardial perfusion, pulmonary thromboembolism, kidney transplant and Meckel diverticulitis). Finally, in March–April 2020, we reported 3 members of the staff who developed symptoms, all of whom tested negative for COVID-19, and one symptomatic patient who tested positive 1 week after having performed an imaging exam in our department. **Conclusion:** Despite precipitating a sharp decrease in the workload, the COVID-19 contingency plan allowed for a safe and clean work environment, which in turn enabled our department to carefully attend to oncologic and other urgent patients, with only 1 case of a symptomatic patient, and no cases among healthcare professionals. The impact of this contingency plan on rescheduled patients will be

evaluated in months to come. **References:** None

OP-883

Usefulness of Triage in a Nuclear Medicine Unit during Covid-19 Pandemic

S. Telo, A. Farolfi, L. Muraglia, D. Bezzi, F. Serani, E. Fortunati, S. Mattoni, L. Vetrone, P. Castellucci, C. Nanni, S. Fanti; Nuclear Medicine, Policlinico S.Orsola-Malpighi, Bologna, ITALY.

Aim/Introduction: Covid-19 pandemic heavily affected Northern Italy since late February, forcing many changes to routine activities of Nuclear Medicine units. These changes included postponing non necessary/urgent exams, systematic use of personal protective equipments (PPE), modifications of patients' pathways and standard operating procedures (SOP); furthermore, we introduced a Triage of all patients accessing the department. Aim of the study was to evaluate the usefulness of Triage in a Red Zone area.

Materials and Methods: From March 9th to April 30th 2020, we daily run the Triage, aimed at identifying patients at risk of having Covid-19 infection. At the access of the building all patients were asked for possible exposure on days before; presence of symptoms on days before; temperature was also measured. We compared the data resulting from such activity to the number of cases as officially recorded by the hospital as being Covid-19 positive. **Results:** Overall, the Triage was done for 8 consecutive weeks, namely 38 consecutive working days; 2 employees/day were necessary to run it properly. 1952 patients (pts) were overall evaluated (avg: 51 pts/day), and 3 pts (0.15%) were identified as suspect for Covid-19 (all 3 due to high temperature > 38°C). All 3 cases were sent back home (as not requiring immediate hospitalization, being without further symptoms), and notified to public healthcare for further exams/therapies; 2/3 resulted not affected and then came back to have their scans regularly done, while the 3rd was lost at follow-up. Based on official hospital data, out of the 1949 patients scanned, 8 subsequently resulted Covid-19 positive and confirmed (0.4%), while other 4 resulted highly suspect, and treated for Covid-19 but not confirmed. All those 12 cases were not identified at Triage (0% sensitivity); nonetheless we received a number of congratulations for the reassuring role of Triage, either from patients and from hospitals operators. The study could have been biased because symptomatic out-patients have probably decided to not come to the unit, while symptomatic in-patients were asked to have a negative swab before being admitted. **Conclusion:** Our data indicate that Triage was ineffective at identifying Covid-19 patients in our experience; however, the Triage was perceived as useful either by patients and by caregivers. **References:** None

Teaching PET/CT to medical students under the COVID-19 lockout: Implementing a new freeware client server PET/CT viewer in the university network

M. Biermann^{1,2}, S. Kanoun³, T. Davidsen⁴, R. Gray⁵;

¹Nuclear Medicine/PET centre, Haukeland University Hospital, Bergen, NORWAY, ²Department of Clinical Medicine, University of Bergen, Bergen, NORWAY, ³Nuclear Medicine/PET centre, Institut Claudius Regaud, Toulouse, FRANCE, ⁴IT Department, University of Bergen, Bergen, NORWAY, ⁵Department of Education, University of Bergen, Bergen, NORWAY.

Aim/Introduction: Since 2017, medical students in the third and the fifth years at the University of Bergen are taught PET/CT "hands-on" by mandatory exercises in the university's learning management system (LMS) paired to a diagnostic client-server viewing system in the hospital [1]. Following the COVID-19 pandemic, students were barred access to the hospital. To give students continued access to PET/CT studies in native format including interactive image fusion, a separate client server system based on the university network had to be established at short notice. **Materials and Methods:** All 77 fifth-year students participating in the course "Nuclear Medicine in Oncology" were requested to install the open source multiplatform Fiji viewer with Beth Israel PET/CT plugin (<http://petctviewer.org/>) on their personal computers. Anonymized DICOM images are hosted by the public domain orthanc server (<https://orthanc-server.com>) running under a virtual CentOS Linux host behind the university's firewall. Students connect via virtual private network (VPN) with individual logon. Transport Security Layer (TSL/https) encryption is provided by apache2 acting as a reverse proxy. Detailed end user documentation was provided by screencasts on <https://www.uib.no/en/radioweb/nuclear> and inside the LMS. **Results:** The new client-server solution was online with complete user documentation after just six days on 19 April 2020. Regulatory approval was obtained on 21 April 2020, in time for the electronic Team-Based Learning (TBL) session on 22 April 2020. Before the TBL, we performed in-depth usability testing with the first five student adopters, four of whom had been exposed to earlier practical teaching of PET/CT as part of their objective structured Clinical Examination (OSCE) at the end of their third year [1]. All five expressed their satisfaction with the new solution. Within ten days after the TBL, 25 % of the students (19/77) passed the course's introductory PET/CT tutorial, and none requested support. **Conclusion:** The freeware Fiji/orthanc PET/CT-viewer has made it possible for medical students to receive hands-on PET/CT training even when they have no access to the hospital infrastructure. We plan a detailed student survey at the conclusion of our course to determine if these changes, which were necessitated by the pandemic crisis, provide a benefit to our teaching that should be made

permanent. **References:** 1. Gulati, Ankush; Schwarzlmüller, Thomas; du Plessis, Elsa; Softeland, Eirik; Gray Jr, Robert; Biermann, Martin. 2019. Radiopharmacy activity during SARS-CoV-2 pandemic: management and production

S. Migliari¹, A. Sammartano^{1,2}, M. Scarlattei^{1,2}, G. Baldari^{1,2}, S. Bola^{1,2}, T. Graziani^{1,2}, L. Ruffini^{1,2};

¹AZ. Osp. Universitaria di Parma, Parma, ITALY, ²Nuclear Medicine Department, University Hospital of Parma, Parma, ITALY.

Aim/Introduction: A new coronavirus causing severe respiratory diseases, called SARS-CoV-2, was described for the first time in the Hubei province of China, on late December 2019. Since then the virus has spread in several countries being declared, on 30 January 2020, from the World Health Organisation (WHO) a Public Health Emergency of International Concern. On February 21, the first cluster of 16 Italian cases have been reported in the Italian Northern region of Lombardy and then other confirmed cases were reported in several Italian regions. In this unprecedented pandemic moment, Nuclear Medicine (NM) services as integral part of multi-speciality hospitals had to face the outbreak, especially assisting cancer patients. Aim of study was to assess the impact of pandemic challenge on a hospital-based radiopharmacy, especially considering the production phase and the related diagnostic sessions during current lockdown, the protection of the work team and the susceptible patients and the maintenance of medical quality and safety. **Materials and Methods:** We have collected data about radiopharmaceutical preparations and injected doses from February 2020 to April 2020 for both conventional NM and PET, comparing data with the same period of the previous year (2019), using Microsoft Software Excel version 2007. Moreover, we have created and adapted SOPs to minimize the risk to staff and patients, while continuing to provide the essential and critical services. **Results:** Radiopharmaceutical preparations showed an increase of 7.83% in February 2020 respect to 2019. In March and April 2020 the radiopharmacy reduced the activity with a decrease of 21.59% in March and 38.58% in April 2020 compared to the same months of 2019, due to the lockdown declaration. For the injected doses it was recorded an increase of 6.53% comparing February 2020 to 2019, and a reduction of 20.43% and 44.23% in March and April 2020, respectively. Regarding PET, it was recorded an increase of 2.36% of the injected doses comparing February 2020 to 2019, and a reduction of 2.1% and 12.64% for March and April 2020. Ga-68 based radiopharmaceuticals produced in house increased of 1.88%, 29.06% and 10.82%

in February, March and April 2020 compared to 2019. No staff member have been diagnosed with infection as of April, 2020. **Conclusion:** The current COVID-19 pandemic poses many challenges for the practice of PET and NM. Nevertheless, we have successfully developed guidelines and strategies to guarantee essential services and to keep our facilities safe for patients and staff. **References:** None

Clinical value of FDG-PET and MRI coregistration in Focal Cortical dysplasia

D. Khan, A. Raj ST, M. Tripathi, A. Garg, M. Tripathi, R. Bhargavi, P. Chandra, R. Doddamani, A. Kumar, C. Bal;

All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Utility of F-18 Fluorodeoxyglucose (FDG) Positron Emission Tomography (PET) and MRI coregistration in focal cortical dysplasia (FCD). **Materials and Methods:** This was a retrospective study in which we included 40 histopathologically proven cases of FCD (17 type I and 23 type II). Each difficult to treat refractory epilepsy (DTE) patient had been extensively worked up and discussed multiple times in the epilepsy surgery meeting and a working hypothesis was generated before the decision for surgery was taken. The pre-surgical evaluation in these patients had included MRI in epilepsy protocol and resting brain FDG-PET. In all those cases when MRI was non-lesional, PET/MRI fusion was done and evaluated with reference to the vEEG and MEG localisation. Following which the neuroradiologist had a relook at the MRI. **Results:** 17 DTE patients had FCD type 1. MRI had revealed the lesion in 5 cases while both MRI and PET revealed the lesion in 6 cases. 6 patients were non-lesional on MRI (normal in 2 and equivocal in 4). PET/MRI fusion was done in all 6 cases and lesion was confirmed on MRI with corresponding hypometabolism on PET. There were 23 cases of FCD type II. MRI was localising in 5, both MRI and PET were localising in 17 and one case was non-lesional on MRI. PET/MRI fusion subsequently helped in lesion localisation in this case. Thus in a total of 7/ 40 cases (17.5%) PET/MRI coregistration enabled lesion localisation and hypothesis generation with successful surgery in this group of patients with DTE. **Conclusion:** PET/MRI coregistration is a useful non-invasive investigation that should be included in all DTE especially when MRI is non-lesional. In patients with FCD, it can lead to lesion localisation in upto 17.5 % cases. **References:** None

EPS-154**The clinical value of 18F-FDG PET/CT in assessment of STN-DBS therapy in PD patients**

Q. Zhao, H. Yang, J. Cao, R. Wang, F. Wang;

General Hospital of Ningxia Medical University, Yinchuan, CHINA.

Aim/Introduction: 18F-fluorodeoxyglucose (18F-FDG) PET/CT has been widely used in the assessment of neurodegenerative diseases. The immediate effects of deep brain stimulation (DBS) of subthalamic nucleus (STN) in PD patients on relative subcortices are still controversial. The aim of this study was to investigate the changing pattern of 18F-FDG metabolism in PD patients after STN-DBS therapy.

Materials and Methods: Resting brain 18F-FDG PET/CT imaging on baseline and 6 months after STN-DBS surgery were performed on 6 PD patients (4 male, 2 female, mean age 62 ± 6.9 years). 18F-FDG PET/CT cerebral images and raw data were analyzed using SPM8. A volumes of interest (VOIs) based change in regional glucose metabolism was obtained. An AAL template was used to perform the ROI based semi-quantitative analysis. The correlation between glucose metabolism and clinical alleviation was also investigated. SPSS17.0 was applied as the statistical software. Paired samples t-test and Pearson correlation analysis were conducted. **Results:** Compared with baseline, the glucose metabolism in parietal lobe was significantly increased ($P < 0.05$) 6 months after STN-DBS, which was also correlated with the alleviation of body rigidity. In contrast, the 18F-FDG were shown as decreased areas in putamen, pons, cerebellum and motor cortex after STN-DBS. **Conclusion:** STN-DBS can inhibit the PD-related pattern in a short time after surgery. A large number of sample is needed to the further verification. **References:** None

EPS-155**Glucose metabolic pattern using 18F-FDG PET/CT in Parkinson's disease patients**

Q. Zhao, H. Yang, J. Cao, J. Li, F. Wang;

General Hospital of Ningxia Medical University, Yinchuan, CHINA.

Aim/Introduction: Parkinson's disease (PD) is associated with the progressive loss of dopaminergic neurons in the substantia nigra, characterized by motor symptoms including tremor, rigidity, bradykinesia, and postural imbalance. 18F-fluorodeoxyglucose (18F-FDG) positron emission tomography/computed tomography (PET/CT) has been widely used in the assessment of neurodegenerative diseases. The aim of this study was to identify the brain glucose metabolic pattern in PD patients and the clinical utility of 18F-FDG PET/CT for PD. **Materials and Methods:** A total of 62 patients (33 male, 29 female, mean age 58 ± 6.9 years) with idiopathic PD and 40 normal control (NC) (20 male, 20 female, mean age 62.3 ± 8.6 years) in the control group are enrolled for the 18F-FDG PET/CT study. 18F-FDG PET/CT cerebral images and raw data were analyzed using

SPM8. A VOI based brain metabolism changing pattern image was obtained. An AAL template was used to perform the ROI based semi-quantitative analysis. SPSS17.0 was applied as the statistical software. Paired samples t-test and Pearson correlation analysis were conducted. **Results:** When compared with the NC group, the brain glucose metabolism of PD patients in thalamus, putamen, pons, cerebellum, and motor cortex were significantly increased ($p < 0.05$). In contrast, the glucose metabolism in posterior parietal, occipital, and frontal cortices showed a decrease of FDG uptake ($p < 0.05$). **Conclusion:** The PD-related pattern (PDRP) of 18F-FDG PET/CT in Parkinson's disease was characterized and reproducible globally. Multi-centered, longitudinal and specific PD subtypes studies are needed to explore the clinical utilities of 18F-FDG PET/CT. **References:** None

Aim/Introduction: Metabolic network analysis in FDG-PET has been proven to provide complementary information underlying the disease process in Parkinsonism. In other atypical parkinsonian syndromes, network expression was proposed as an additional supporting biomarker in early diagnosis (1). In Dementia with Lewy Bodies (DLB), decreasing dopamine availability correlates with decreasing metabolic connectivity in affected regions (2), but only a few cases at an early disease stage have been investigated yet (3). The goal of this study was to evaluate alterations of glucose metabolism and network connectivity in DLB subjects at early stages of dopaminergic loss. **Materials and Methods:** FDG-PETs of subjects with probable or possible prodromal DLB (4) without significant dopamine deficiency (Z-Score < 2 in DaT-SPECT compared to healthy controls) were analysed by volume-of-interest-based calculations after stereotactic normalisation and cerebellar scaling. Metabolic alterations and network connectivity were compared to healthy controls (n=28) for both subjects with (n=86) and without (n=22) significant dopamine deficiency. **Results:** Subjects without significant dopamine deficiency showed regions with significant relative hypo- (parietal- and occipital cortex) and hypermetabolism (basal ganglia, parts of the limbic system, motor cortices) compared to healthy controls. The metabolic alterations were less pronounced, but similar to those found in subjects with significant dopamine deficiency. Metabolic connectivity analyses revealed increasing connectivity between affected brain regions at early disease stages without significant dopamine deficiency when compared to healthy controls. **Conclusion:** Disease specific patterns of glucose metabolism and altered metabolic networks can be detected by FDG-PET in DLB subjects without significant dopaminergic loss. These findings underline the potential of FDG-PET to be used as a supporting biomarker at early stage DLB. **References:** 1. Ko JH, Lee CS, Eidelberg D. Value of 18F-FDG-PET in early and differential diagnosis of Frontotemporal dementia, a prospective study

I. López Villar¹, P. Paredes Rodríguez¹, D. Lourido García², A. López-Frías López-Jurado², P. Jane Soler¹, J. Bonilla Plaza¹, P. Azpeitia Hernández¹, A. Martínez Lorca¹, A. B¹, A. B¹, J. Castro Beiras¹, M. Orduña Díez¹;

¹Ramón y Cajal University Hospital, Nuclear medicine, Madrid, SPAIN, ²Ramón y Cajal University Hospital, Radiology, Madrid, SPAIN.

Aim/Introduction: Frontotemporal dementia FTD is a common type of dementia particularly in patients younger than 65, encompassing a group of neurodegenerative diseases classified into 3 clinical variants: non-fluent variant primary progressive aphasia (NFV-PPA), semantic-variant primary progressive aphasia (SV-PPA) and behavioral-variant (BV-FTD). The goal is to evaluate FDG-PET as a biomarker for early and differential diagnosis of FTD and to investigate for specific metabolic signs of the variants. **Materials and Methods:** A prospective study of 41 patients was carried out at University Hospital (July 2017-March 2019); All patients (20 men 21 women) with clinical diagnostic suspicion of FTD were consecutively evaluated with 18F-FDG-PET/CT. Age (59–87 mean 70). The data were compared with 41 controls screened by age and gender. In all cases, a careful history, detailed neurological examination, laboratory studies and neuroimaging were performed. In atypical cases (26p) the differential diagnosis of Alzheimer's disease, parkinsonisms and/or psychiatric disorders was evaluated with: cerebrospinal fluid biomarkers (14), at the dopaminergic level (9) (with pre- and postsynaptic Dopamine SPECT and transcranial sonography), amyloid PET (2) and/or genetic test C9orf72 (1). FDG-PET data was visually and semi-quantitatively analyzed using a standardized uptake value ratio (SUVr) with a reference region of the cerebellar cortex. **Results:** In 65% patients (26/41) FTD was diagnosed: (15 PPA, 9 BV-FTD, 1 SV-PPA and in 1 case PPA and Alzheimer's disease co-occurred). The remaining 35% (15/41): (10 Alzheimer's disease, 2 corticobasal syndrome, 1 mild cognitive impairment, 1 drug-induced-parkinsonism and 1 progressive supranuclear palsy). Specificity of 87% (13 True Negatives / 2 False Positives) and Sensitivity of 100% (26 True Positives / 0 False Negatives). High negative predictive value. Compared to controls, FDG-PET showed hypometabolism in frontal and temporal regions in most of the patients with

FTD. It also proves useful for discriminating FTD and early Alzheimer's disease (where hypometabolism in precuneus is especially indicative). The specific metabolic signs of the FTD variants: in primary progressive aphasia (APP) leftward asymmetry in the hemispheric brain, with hypometabolism mainly in left fronto-temporal region; In the behavioral-variant (BV-FTD) we found hypometabolism in the frontal and anterior temporal lobes, with involvement of the anterior cingulate gyrus, as more prominent metabolic findings. **Conclusion:** FDG-PET is a sensitive metabolic marker for early and differential diagnosis of FTD, with high negative predictive value. Patients with FTD have distinctive metabolic characteristics. In addition we also found specific metabolic signs in PPA and BV-FTD variants, further research is needed. **References:** None

EPS-158

Utility of 18F-FDG PET/CT based Metabolic Parameters in Differentiating Malignant Brain SOLs

A. Bedmutha, N. C. Purandare, A. D. Puranik, M. Pereira, A. Agrawal, S. Shah, V. Rangarajan; Tata Memorial Center, Mumbai, INDIA.

Aim/Introduction: Brain space-occupying-lesions (SOLs) can be neoplastic (lymphoma, glioma, metastasis, etc.) or non-neoplastic (infection, demyelination, etc.). Although MRI is standard imaging modality for characterizing brain SOLs, features of different pathologies can sometimes overlap. Fluorine-18-fluorodeoxyglucose (18F-FDG) uptake correlates with tumoral glycolytic activity, a characteristic that can be exploited to differentiate between malignant brain lesions. In this study, we aimed to determine role of different 18F-FDG PET-based metabolic parameters in differentiating malignant brain pathologies **Materials and Methods:** 147 patients with brain SOL, referred for pre-treatment 18F-FDG PET/CT scan by a multidisciplinary team, were included in this retrospective study. Following semi-quantitative metabolic parameters of brain lesions were calculated: Maximum standardized uptake value normalized by body weight (SUVmax), maximum and mean standardized uptake values normalized by lean body mass (SULpeak and SULmean), tumor-to-background activity ratios, metabolic tumour volume (MTV) and total lesion glycolysis (TLG). Histopathological confirmation was used as the gold standard in all patients. Differences between metabolic parameters of three most common malignancies were compared using rank-based nonparametric statistical tests. Receiver operating characteristic (ROC) curve analysis was used to determine diagnostic abilities of various metabolic parameters, and to establish their optimal cut-offs to differentiate between pathologies **Results:** High grade glioma (HGG, n=43), lymphoma (n=33), and metastases (n=65) were most common brain SOL pathologies (95.9%). Lymphomas showed significantly higher metabolic uptake

(Mean \pm SD: SUVmax=29.3 \pm 12.7, SULpeak=19.2 \pm 9.1 and SULmean=14.4 \pm 6.9), as compared with HGG (Mean \pm SD: SUVmax=13.1 \pm 7.4, SULpeak=8.1 \pm 4.4 and SULmean=6 \pm 2.9) and metastases (Mean \pm SD: SUVmax=15.6 \pm 12.7, SULpeak=9.5 \pm 7.5 and SULmean=7.4 \pm 5.7), with P<0.05 on non-parametric tests. The tumour-to-background ratios for lymphomas were also significantly higher, while MTV and TLG were insignificant in this regard. SULpeak>12.7 showed 83% sensitivity and 88% specificity, while tumour-to-white matter ratio (T/Wm)>5.6 showed 83% sensitivity and 85% specificity to diagnose lymphomas (AUC=0.912 and 0.900 respectively, P<0.05). In a subset analysis, MTV>19.05 cm³ (Sensitivity, specificity:71%,75%; AUC=0.747) and TLG>126.15 gm (Sensitivity, specificity:71%,71%; AUC=0.737) could fairly differentiate HGG from solitary metastasis, while only SULmean could differentiate between HGG and multiple metastases (AUC=0.700). Lung cancer was most common primary in patients with brain metastases (83%). Two cases of disseminated tuberculosis showed FDG-avid brain SOLs. **Conclusion:** CNS lymphomas demonstrate significantly higher metabolism than HGG and metastases, with SULpeak and T/Wm ratio being optimal differentiating parameters. SULmean, MTV and TLG have average ability in differentiating glioma from metastases, and could be useful in select scenarios. In patients with brain metastasis, 18F-FDG PET/CT contributes by detecting primary malignancy and extent of disease. **References:** None

Single-centre investigation on the prognostic role of semiquantitative FET PET parameters in patients with previously treated primary brain tumours

M. Celli¹, G. Ghigi², P. Caroli¹, D. Arpa³, I. Marini¹, L. Fantini¹, V. Rossetti¹, P. Cenni⁴, E. Amadori⁵, A. Romeo³, M. Belli⁶, A. Sarnelli⁶, G. Paganelli¹, F. Matteucci¹;

¹Nuclear Medicine Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, ITALY, ²Radiation Therapy Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Ravenna, ITALY, ³Radiation Therapy Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, ITALY, ⁴Neuro-Radiology Unit, "Santa Maria delle Croci" General Hospital AUSL Romagna, Ravenna, ITALY, ⁵Radiology Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, ITALY, ⁶Health Physics Unit, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, ITALY.

Aim/Introduction: treatment-induced changes (TIC) may mimic recurrent / progressive brain tumor (RP-BT) on Gadolinium-enhanced MRI (Gd-MRI) in up to 30% of primary brain tumour patients. FET PET has been increasingly utilised to assist Gd-MRI in differential diagnosis of such scenarios. We aim to investigate the potential prognostic value of FET-based semiquantitative parameters in brain tumour patients

previously treated with surgery and chemo-radiation. **Materials and Methods:** This is a retrospective analysis on the follow-up of 18 primary brain tumour patients (mean age: 49 years; range: 21–76; WHO grade II n = 5; grade III n = 5; IV n = 8) previously treated with surgery and chemoradiation therapy, referred for FET PET to help Gd-MRI differentiate TIC and RP-BT (n=15) and for systemic therapy response evaluation (n = 3). FET PETs were acquired as 40-minute dynamic brain scans and late static brain images (20–40 minutes) were generated from each FET PET. FET images were fused with Gd-enhanced T1-weighted MRI images for lesion co-registration. FET outcome (positive versus negative) was evaluated according to established criteria* and the following FET semiquantitative parameters were tested for association with 12-month overall survival (OS): 1)ROC analysis: lesion SUVmax-to-normal Brain SUVmean Ratio (LBRmax), Metabolic Lesion Volume (MLV 40% isocontour), Total Lesion Metabolism (TLM = MTV x lesion SUVmean); 2)Kruskal-Wallis: TAC patterns (1: increasing with no peak; 2: peak and plateau; 3: peak and wash-out). **Results:** the 12-month OS ROC analysis found AUC of 0,805 for MLV cut-off value of 37,2mm³ [cohort range: 3,6–138,6mm³] with sensitivity (SE), specificity (SP), positive predictive value (PPV) and negative predictive value (NPV) of, 92,1%, 81,8%, 71,4%, 81,8%, respectively (p = .005). AUC of 0,805 was found for TLM cut-off value of 119,0mm³ [cohort range: 1,2– 314,8mm³] with SE, SP, PPV and NPV of 71,4%, 90,9%, 83,3%, 83,3%, respectively (p = .0011). FET outcome (positive / negative) did not significantly distinguish patients 12-months OS (Fisher's exact Test; p = 0,59; Log-rank: 0,642; p = 0,423), nor did LBRmax (ROC analysis; p = .149) and TAC pattern (Kruskal-Wallis; p = .200). **Conclusion:** Our preliminary experience suggests that FET-derived MLV and TLM may serve as prognostic factors for 12-month OS in pretreated primary brain tumours. **References:** *Law I, Albert NA, Javier Arbizu J et Al. Aim/Introduction: Fluoroethyltyrosine (FET), an L-tyrosine amino acid analogue whose transport is independent from blood-brain-barrier status, is a well-established PET 18F-labelled agent used in the evaluation of glioma patients. Dynamic acquisitions enable to obtain time-activity-curves (TACs), able to provide information for grading assessment: low-grade-gliomas (LGG) are usually characterized by a continuously increasing uptake, vice versa high-grade-gliomas (HGG) usually shows an early peak followed by a plateau or a decreasing TACs. However, dual time-point acquisition imaging is more feasible even due to an increase in patient comfort and quicker image interpretation. This preliminary study aims to evaluate the potential clinical advantages of FET-PET/CT in the management of glioma, also in comparison with MRI. **Materials and Methods:** We retrospectively analyzed data of 20 patients (15 male and 5 female, mean age 52 years old, range 22–75) affected by glioma (6 G2, 3 G3, and 11 G4 according to WHO classification) who underwent surveillance MRI and FET-PET/CT static acquisition 10 and 50 min after administration of a mean dose of 277,5 MBq of 18F-FET. We correlated PET findings with clinical, radiological (MRI) and follow-up data for a mean period of 3 months after the FET-PET/CT scan. **Results:** 12/20 patients resulted positive for recurrence at FET-PET/CT: among them, the dual time-point acquisition showed the usual trend in 9/12 patients (75%) with 2/2 LGG showing an increasing uptake, and 7/10 HGG showing an early peak followed by a decreasing uptake. Among positive FET-PET patients, 4 of the HGG (29%) patients experienced a change of management according to FET findings .FET-PET/CT resulted negative in 4/20 patients, and doubtfully in other 4/20.Among the four doubtful PET findings, 3 HGG were negative at MRI assessment and have resulted suspicious for recurrence at FET-PET/CT; however, follow-up evaluation confirmed the PET findings. In 12/20 patients, PET findings were in accordance with MRI findings and among them 9/12 were HGG. **Conclusion:** In our preliminary experience, the evaluation with 18F-FET PET/CT resulted as a useful tool in LGG and HGG gliomas evaluation, offering an imaging method able to identify tumour progression and malignant transformation, earlier than MRI. Hence, 18F-FET findings influence clinical and therapeutic strategy.

Aim/Introduction: in treated primary brain tumours, treatment-induced changes (TIC) can mimic recurrent / progressive brain tumor (RP-BT) on Gadolinium-enhanced MRI (Gd-MRI) in up to 30% of cases. FET PET has been increasingly utilised to assist Gd-MRI in differential diagnosis of such scenarios. We aim to evaluate 1) diagnostic performance of established* FET semiquantitative parameters in distinguishing TIC and RP-BT; 2) association of FET outcome with WHO grade, IDH mutant status, MGMT methylation and Ki67%. **Materials and Methods:** 18 primary brain tumour patients (WHO grade II n = 5; grade III n = 5; IV n = 8) treated with surgery and chemoradiation underwent 25 FET PET scans to discriminate equivocal Gd-MRI findings for RP-BT and TIC. FET PETs were acquired as 40-minute dynamic brain scans and late static images (20–40 minutes) were generated. FET images were fused with Gd-MRI for lesion co-registration. FET PET was considered positive for RP-BT if lesion SUVmax-to-normal Brain SUVmean Ratio (LBRmax) was superior to cut-off values of 1,9 and 2,3 in the early (< 12 weeks) and late (> 12 weeks) period after chemoradiation therapy, respectively. Gold standard was repeat Gd-MRI within 3 months from FET PET and clinical follow-up (n = 23) and pathology (n = 2). FET PET outcome (positive / negative) was tested for dependency on prognostic features (Fisher's Exact Test; α : 0,05): WHO grade (Grade II versus III-IV), IDH status (mutant versus wild-type), MGMT methylation (methylated versus unmethylated) and Ki67 (< 10% and 10%). **Results:** Positive LBRmax ranged between 2,3 and 5,0 resulting in 17 true positives and no false positives. Negative LBRmax ranged between 1,3 and 1,7 resulting in 5 true negatives and 3 false negatives. The diagnostic performance of FET PET resulted in 85% sensitivity, 100%

specificity, 63% negative predictive value, 100% positive predictive value and 88% diagnostic accuracy. In the post-surgical and chemoradiation therapy scenario, no significant dependency of FET PET outcome was found for WHO grade ($p = 1,000$), IDH status ($p = 0,308$), MGMT methylation ($p = 1,000$) and Ki67 ($p = 0,206$). **Conclusion:** FET PET demonstrated good diagnostic performance in discriminating RP-BT and TIC. In this pre-treated cohort of patients prognostic features did not significantly associate with FET outcome. **References:** *Law I, Albert NA, Javier Arbizu J et Al. Joint EANM/EANO/RANO practice guidelines/ SNMMI procedure standards for imaging of gliomas using PET with radiolabelled amino acids and [18F]FDG: version 1.0. EPS-162

Assessment of Glioma Aggressiveness Using Dynamic FDOPA PET/CT

A. Girard¹, P. Le Reste², A. Metais³, N. Chaboub⁴, A. Devillers¹, H. Saint-Jalmes⁴, F. Le Jeune¹, X. Palard-Novello¹;

¹Department of Nuclear Medicine, Centre Eugène Marquis, Rennes, FRANCE, ²Neurosurgery, University Hospital of Rennes, Rennes, FRANCE, ³Department of Pathology, University Hospital of Rennes, Rennes, FRANCE, ⁴Inserm, LTSI – UMR 1099 research unit - University Rennes 1, Rennes, FRANCE.

Aim/Introduction: The aim of this study was to assess the diagnostic value of kinetic parameters extracted from dynamic FDOPA PET/CT for tumor grading in patients with newly diagnosed gliomas in a prospective study with biopsy validation. **Materials and Methods:** Fourteen patients with untreated gliomas were prospectively investigated with FDOPA PET/CT. Twenty minutes of dynamic PET imaging after FDOPA injection were reconstructed. Tumor volume-of-interest (VOI) were generated based on the MRI-guided brain biopsies. Static parameters (SUVmax and tumor-to-brain ratio (TBRmax)), kinetic parameters extracted using full kinetic analysis with the reversible single-tissue compartment model (K_1 = rate constant from blood to tissue, k_2 = rate constant from tissue to blood, V_B = blood volume parameter and distribution volume (DV) = K_1/k_2) and distribution volume (V_t) extracted using Logan graphical analysis were provided. Diagnostic accuracies of FDOPA PET/CT parameters for differentiating low-grade gliomas (LGG) from high-grade gliomas (HGG) were evaluated by receiver-operating characteristic (ROC) analyses (area under the curve; AUC). **Results:** Thirty-three tumoral VOI were analysed. K_1 and k_2 were significantly higher for HGG than for LGG (respectively median K_1 value 0.124 vs 0.073 ml/ccm/min, $p = 0.025$ and median k_2 value 0.093 vs 0.063 min^{-1} , $p = 0.024$). No significant difference was observed for the other kinetic parameters and the static parameters. Using ROC analyses, the diagnostic

accuracy to discriminate LGG from HGG was the highest and similar for K1 and k2 parameters (AUC values = 0.76, $p = 0.02$). **Conclusion:** The present study confirms the significant added value of FDOPA PET/CT kinetic parameters for newly-diagnosed gliomas grading. **References:** None

EPS-163

Dopamine release after fear conditioning as measured using bolus-infusion ^{11}C -raclopride PET-MRI

M. Lubberink, A. Frick, J. Björkstrand, F. Åhs, M. Fredriksson; Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Dopamine transmission is suggested to be crucial for aversive learning, as has been shown in animal studies. However, studies on the importance of dopamine release in human fear conditioning are lacking. The aim of the present study was to investigate dopamine release in striatum and amygdala during fear conditioning in healthy humans. In addition to equilibrium analysis and $\text{I}_p\text{-ntPET}^1$, a nested version of SRTM² was evaluated for assessment of dopamine release. **Materials and Methods:** Eighteen volunteers underwent 90 min ^{11}C -raclopride scans using a bolus-infusion protocol on a Signa PET/MR scanner. Fifty minutes after injection start, participants underwent a 20 min differential fear conditioning paradigm, pairing one cue (CS+) with an aversive electrical shock while another cue (CS-) was never paired with a shock. Changes in raclopride binding were assessed by equilibrium analysis, using $\text{I}_p\text{-ntPET}$, and using a nested version of SRTM (SRTMnt). In this last case, BP_{ND} , R_1 and k'_2 were estimated for the first 45 min, and then R_1 and k'_2 were fixed for a fit to the last 20 min of data after conditioning. Accuracy and precision of SRTMnt were evaluated using simulations where dopamine release was described by gamma variate functions. Skin conductance response (SCR) to CS+ minus CS- served as the autonomic fear conditioning index. **Results:** ^{11}C -raclopride BP_{ND} based on SRTMnt was significantly reduced following fear conditioning by 5.4, 5.1 and 13.4 % in putamen, caudate and amygdala, respectively ($p < 0.03$). A significant correlation between changes in BP_{ND} across all three methods was found. Simulations showed that SRTMnt could accurately measure changes in BP_{ND} provided that dopamine release was persistent to the end of the scan, without requiring equilibrium, and that results were insensitive to changes in R_1 . Changes in BP_{ND} based on SRTMnt and equilibrium analysis in amygdala correlated with SCR ($r = 0.54$, $p = 0.22$ for SRTMnt). **Conclusion:** SRTMnt provided a robust, easily implemented alternative for assessment of dopamine release induced changes in BP_{ND} provided that increased dopamine concentrations are persistent, which has previously been shown to be the case by microdialysis in amygdala in similar fear conditioning experiments in rodents. A significant correlation between dopamine release induced changes in BP_{ND} in amygdala and

fear conditioning was found. **References:** 1. Normandin MD, Schiffer WK, Morris ED, Neuroimage 2012. 2. Lammertsma AA, Hume SP, Neuroimage 1996

EPS-164

Clinical significance of 123I-MIBG and 123I-FP-CIT in patients with Parkinsonism

K. Maruyama, K. Utsunomiya, H. Kishishita, Y. Kono, Y. Ueno, N. Tanigawa; Kansai Medical University, Osaka, JAPAN.

Aim/Introduction: To evaluate the usefulness of 123I-metaiodobenzylguanidine (MIBG) myocardial scintigraphy and 123I-loflupane (FP-CIT) scintigraphy in patients with parkinsonism. We also compare the differences between Parkinson's disease (PD) and any other parkinsonism (nonPD). **Materials and Methods:** Seventy-six patients (mean age: 73, age range: 53-89 years) with parkinsonism were enrolled in this study. Myocardial MIBG uptake was evaluated as the heart to mediastinum count ratio (H/M) for early (e) and delayed (d) images, and the heart washout rate (WR). Striatum FP-CIT uptake was evaluated as (1) Striatum (S), Caudate (C), anterior Putamen (aP), posterior Putamen (pP), whole Putamen (P); (2) Caudate asymmetry index (Casy), Putamen asymmetry index (Pasy); (3) the Caudate to Putamen count ratio (C/P). **Results:** The patients have been eventually diagnosed PD ($n = 52$) and nonPD ($n = 24$) clinically. The nonPD comprise progressive supranuclear palsy ($n = 10$), corticobasal degeneration ($n = 6$), multiple system atrophy ($n = 2$), drug induced parkinsonism ($n = 3$), and unknown cause of parkinsonism ($n = 3$). For PD-nonPD differentiation using each scintigraphic approach alone, we obtained test accuracy (MIBG eH/M, 53.9%; dH/M, 69.7%; WR, 71.1%; FP-CIT S, 65.8%; C, 69.7%; aP, 65.8%; pP, 65.8%; P, 64.5%) and low accuracy using asymmetry (Casy 48.7%; Pasy, 43.4%). MIBG WR alone had a sensitivity of 82.7% for detecting PD, with low specificity of 45.8%. FP-CIT C alone had a sensitivity of 80.8% for detecting PD, with low specificity of 45.8%. For combined use, the highest test accuracy (71.1%) separated PD from nonPD resulted under the assumption that 2 of the 2 biological markers as follows: WR combined with C or dH/M combined with S, had a sensitivity of 71.2% and specificity of 70.8%. Mean MIBG uptake (H/M) in PD was significantly lower, which was greater in dH/M than in eH/M, and mean WR in PD was significantly higher than in nonPD (Mann-Whitney U test, eH/M $P = 0.018$; dH/M, $P = 0.002$; WR, $P = 0.0001$). **Conclusion:** Neuroimaging study with radiotracer (MIBG and/or FP-CIT) may help in the differential diagnosis of parkinsonism. It is important to diagnose with taking the clinical findings and the scintigraphic features into consideration. **References:** None

EPS-165**The homogeneity of beta amyloid PET: different white matter properties of [18F]Florbetaben and [11C]PiB**

M. Rullmann¹, P. L. Flender¹, V. L. Villemagne², O. Sabri¹, H. Barthel¹;

¹Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, ²Department of Molecular Imaging and Therapy, Centre for PET, Austin Health, Heidelberg, AUSTRALIA.

Aim/Introduction: The visual reading of brain beta-amyloid (A β) PET images relies on the regional evaluation of the contrast between specific gray and unspecific white matter (WM) uptake. Thus, the degree and homogeneity of the WM uptake might influence the reading results. It is known for the approved [18F]-labeled A β tracer Florbetaben (FBB) that its WM uptake is relatively higher than that of [11C] PiB. We hypothesize, however, that the homogeneity of the tracer uptake within the WM is more important than its magnitude, and investigated this feature in the present study. **Materials and Methods:** We analyzed the data of (1) two matched (for the A β -neg. vs. -pos ratio, age and gender, n=67 each) patient cohorts who underwent [11C]PiB and [18F]Florbetaben PET, and those of (2) a head-to-head PiB vs. FBB comparison (10 young controls: 32.6 \pm 9yrs, 3 males; 25 elderly: 71.7 \pm 6yrs, 12 males) from the GAAIN database. For both tracers, we assessed the homogeneity, energy and contrast as WM uptake texture characteristics using the Radiomics toolbox in Matlab. **Results:** For (1), homogeneity, energy and contrast showed no tracer differences, but a smaller variance (p<0.001) for FBB independent of the A β status. Here, no age effect on the WM uptake texture parameters was seen. For (2), the FBB WM uptake data showed higher homogeneity (p<0.001), energy (p<0.001) and lower contrast (p<0.001) as compared to the PiB data. Here, the FBB data had a lower variance in homogeneity (young controls: p=0.02), energy (young controls: p=0.006) and contrast (elderly: p=0.009). While, in this cohort, for both tracers the WM uptake homogeneity correlated with age (FBB: r=0.45, p=0.007; PiB: r=0.6, p<0.001), only in the PiB data the WM uptake energy (r=0.57, p<0.001) and contrast (r=-0.59, p<0.001) was age-correlated. **Conclusion:** For PiB and FBB, the texture characteristics homogeneity, energy and contrast of the WM uptake differ, with favorable results for FBB. Further, an age effect on the WM uptake was evident for PiB, but not for FBB data. Further investigations on the expression of this feature over different patients and on its effect on the gray matter A β diagnosis are, thus, warranted. **References:** None

EPS-166**Myelin imaging with [11C]MeDAS PET**

C. W. J. van der Weijden, J. F. Meilof, R. A. J. O. Dierckx, E. F. J. de Vries;

UMCG, Groningen, NETHERLANDS.

Aim/Introduction: Magnetic resonance imaging (MRI) is important for the diagnosis of Multiple Sclerosis (MS), but lacks the specificity needed for evaluating demyelination and remyelination. Anti-inflammatory therapies are not able to treat MS adequately, therefore new therapies aim to stimulate remyelination. To determine the efficacy of remyelination therapies, it is necessary to have an accurate myelin imaging method. [11C]MeDAS Positron Emission Tomography (PET) scanning was found to be a promising method for in vivo myelin quantification in animal models, but has not been used in humans yet. Our study aims to evaluate the feasibility of myelin imaging with [11C]MeDAS PET in MS patients. **Materials and Methods:** A total of 10 MS patients will be included in the study. Following intravenous injection of [11C]MeDAS, patients will receive a 60-min dynamic brain PET scan and subsequently a 10 min static spinal cord PET scan. Concomitant arterial blood sampling will be performed to obtain a metabolite-corrected plasma input function. Regional time-activity curves will be generated from the PET images using pMOD (version 4.004). These curves will be analysed using several pharmacokinetic models. Some preliminary results will be presented. **Results:** So far, 5 patients have been included. The data from these patients was analysed. Visual assessment of tracer binding in the first patients indicates that the tracer primarily binds to white matter. This was confirmed by quantitative analysis, showing a higher binding potential in white (4.02 \pm 1.37) than in grey matter (1.49 \pm 0.43). Furthermore, rapid metabolism of [11C]MeDAS was observed, with 73% of the tracer being metabolized after 10 min. The kinetics of the tracer was best described by a reversible two tissue compartment model (AIC -15.9). Different amounts of tracer was observed per lesion. **Conclusion:** The first in human [11C] MeDAS scans were successfully performed. No adverse events occurred and both the scan protocol as the scan itself were well tolerated. Preliminary results indicate that [11C]MeDAS binds primarily to white matter and is rapidly metabolised, which leads to a fast clearance from the body. [11C]MeDAS kinetics are well described by a reversible two tissue compartment model. The data suggests that [11C] MeDAS might have the potential to determine the efficacy of remyelination therapies. More precise data will follow after more inclusions. **References:** None

EPS-167**Alterations in cerebral blood flow in patients with secondary progressive and stem cell-treated multiple sclerosis - a perfusion study with ¹⁵O-water-PET**

M. Lubberink, L. Appel, A. Tolf, T. Danfors, E. Larsson, A. Landtblom, G. Antoni, J. Sörensen, J. Burman; Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Multiple sclerosis (MS) is an autoimmune and degenerative disorder where the immune system

malfunctions attack the central nervous system, leading to demyelination and neuronal/axonal loss. Impaired cerebral blood flow (CBF) has been associated with disease progression in neurodegenerative disorders. Chemotherapy combined with haematopoietic stem cell transplantation (HSCT) was introduced as an alternative treatment in 2004 at our hospital. Nowadays there is a growing evidence that HSCT is a successful treatment, but the question remains whether it is an ultimate cure for MS. This study aimed to investigate differences in CBF between three cohorts: patients with secondary progressive MS (SPMS), treated patients (HSCT) and healthy controls (HC). **Materials and Methods:** ^{15}O -water-PET scans with arterial blood sampling were acquired at rest for 10 SPMS, 9 HSCT (10 years after treatment), and 10 HC (age and gender matched). Arterial input functions were corrected for delay and dispersion. CBF and distribution volume (V_T) values were generated using a standard single-tissue compartment model including a fitted blood volume parameter. T1-weighted MR images were used for segmentation and automated definition of volumes of interest. Nonparametric tests were used to detect significant differences between cohorts ($p < 0.05$). **Results:** Global CBF, including gray and white matter, was significantly lower in SPMS compared to HSCT (0.36 ± 0.08 versus 0.50 ± 0.11 mL/g/min, $p = 0.005$), whereas no significant differences were found between HSCT (0.46 ± 0.09 mL/g/min) and HC ($p = 0.47$). Regional CBF revealed similar patterns for SPMS, and significant differences with HC and HSCT were especially found in subcortical regions. Further, V_T was significantly higher in HSCT and HC compared to SPMS, both globally and regionally, but not significantly different between HC and HSCT. **Conclusion:** These preliminary results revealed an impaired CBF and decreased V_T in SPMS. Similar levels of CBF and V_T for HSCT and HC indicates that HSCT treatment might restore overall brain functionality. In part, the current findings also confirm the outcome of clinical investigations/observations^{1,2}. Specific CBF and V_T alterations in gray matter suggest a relationship with various disabilities in MS patients. **References:** 1 Burman J et al. J Neurol Neurosurg Psychiatry. 2014, 85(10):1116. 2 Tolf A et al. Acta Neurol Scand. 2019, 40(5):320-327.

EPS-168

Brain SPECT perfusion and PET metabolism as discordant biomarkers in major depressive disorder

E. Guedj¹, R. Richieri¹, L. Boyer¹, T. Korchia², G. Fond², C. Lançon¹, M. Tastevin¹;

¹Aix Marseille Univ, Marseille, FRANCE, ²APHM, Marseille, FRANCE.

Aim/Introduction: Brain SPECT perfusion and PET metabolism have been, most often interchangeably, proposed to study the underlying pathological process in major depressive disorder (MDD). It is hypothesized that the two biomarkers characterize the global synaptic activity through the

neurovascular coupling. The objective of this study is to document similarities and inconsistencies between brain SPECT perfusion and PET metabolism according to global characteristics of the disease (number of previous episodes and illness duration) in patients with MDD. **Materials and Methods:** We conducted a retrospective pilot study in 16 patients suffering from unipolar depressive disorder who underwent a cerebral SPECT with $^{99\text{mTc}}$ -HMPAO and $^{18\text{F}}$ -FDG PET with an interval delay of less than 18 months (mean delay of 4.37 months ± 4.89). Whole-brain voxel-based SPM(T) maps were generated in correlation with the number of depressive episodes and in correlation with the depression duration, separately for the two exams (p -voxel < 0.005 uncorrected, p -cluster < 0.05 uncorrected). **Results:** No significant correlations were found between brain PET metabolism and either the number of depressive episodes or the duration of the disease. On the contrary, significant correlations were found with SPECT perfusion: the increased number of depressive episodes was correlated with decreased perfusion of the right insula ($k=515$); the increased depression duration was correlated with bilateral decreased perfusion of the anterior cingulum ($k=236$). **Conclusion:** The study demonstrates that brain perfusion and glucose metabolism are not equivalent biomarkers in MDD, highlighting the value of brain perfusion SPECT despite less favorable instrumentation detection compared to metabolic PET. **References:** None

EPS-169

Effect of Statins on Brain Perfusion in Major Depression as an Addition to Standard Therapy. SPM Analysis of Inflammation, Platelet Activation, Endothelial Dysfunction and Neurocognitive Parameters

T. Massardo¹, J. Quintana², J. Pereira², C. Sáez², L. Risco¹, S. Corral¹, N. Olivares², J. Spuler¹, G. Castro¹, D. Vicentini², B. Riedel¹, G. Valenzuela², C. Villa³;

¹Hospital Clínico Universidad de Chile, Santiago, CHILE,

²Pontificia Universidad Católica de Chile, Santiago, CHILE,

³Instituto Psiquiátrico Dr. Horwitz, Santiago, CHILE.

Aim/Introduction: Major depressive disorder (MDD) is a prevalent condition, with a close bidirectional relation with cardiovascular disease and a significant proportion of relapse with serious quality of life and social impact. Statins may have some effect on MDD as observed in coronary heart disease and other vascular conditions. Aim: evaluate the effect of Rosuvastatin in MDD comparing changes in regional cerebral blood flow (rCBF), in neurocognitive performance and in serum biomarkers, affected by statins action. **Materials and Methods:** We studied 20 MDD patients free of specific therapy; 59% females; median age: 34 years; HAM-D 17 items greater than 15 and self-applied Beck's Questionnaire greater than 12. All received specific serotonin receptor inhibitors; half rosuvastatin (10 mg/d)

and half placebo, randomized. We performed a rest brain perfusion SPECT with ^{99m}Tc -ECD at baseline and at 3 months of therapy. SPM12 analysis was employed to compare the differences in both groups between 3 months and baseline (perfusion deltas). Applied covariances (CoV) were the deltas from: Neurocognition Cambridge Battery CANTAB tasks; platelet activation, endothelial dysfunction, general inflammatory serum markers, Rho A / Rho kinase pathway and oxidative stress parameters, obtained the same days than the SPECT images. **Results:** HAM-D and Beck's scores decreased ($p=0.0001$); Beck's presented a larger decrease with statins. Seven out of ten placebos were responders and 8/10 statins ($p=ns$). SPM12 analysis demonstrated significantly larger rCBF changes in the pregenual / subgenual anterior cingulate plus orbitofrontal cortex and a small area in the posterior cingulate gyrus in the statins group, not observed with placebo, when using HAM-D and Beck's scores as CoV. Similar pattern of rCBF changes, when used as CoV, were observed with: A) emotion recognition, attentional, paired associates learning, spatial planning and working memory tasks; B) platelet activation markers: P-Selectin, RANTES, NAP-2 and Brain-derived Neurotrophic Factor; C) endothelial dysfunction markers: circulating endothelial cells, ICAM-1, VCAM and Monocyte Chemoattractant Protein; D) General inflammation markers: ESR, CRP and IL-6; E) Rho kinase pathway and F) oxidative stress: malondialdehyde; those changes were no present with placebo. **Conclusion:** Short-term use of low dose statins in MDD patients under standard therapy, results in important rCBF changes in key mood and cognitive control areas, associated to improvement in neurocognitive performance, platelet activation, oxidative stress and diverse inflammatory and endothelial function markers. These findings could open a new therapeutic approach to this relevant mood disorder. FONDECYT 1160885 **References:** None

OP-898**Standardisation and Validation of ¹⁷⁷Lu Quantitative SUV-SPECT/CT**

T. Alkahtani^{1,2}, J. Johnson², K. Adamson², V. Lewington^{1,2}, L. Livieratos^{1,2};

¹King's College London, London, UNITED KINGDOM,

²Guy's & St Thomas' Hospitals NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: Imaging as part of the patient workup for molecular radiotherapy (MRT) is often used in evaluation, verification and follow-up of treatment. Beyond its role as a visual assessment tool, image quantification may have a role in monitoring change as part of MRT. Recent advancements in SPECT imaging, such as improved image reconstruction and scatter and attenuation correction, allow for precise quantitative analysis and the calculation of standardised uptake value (SUV). This study aims to investigate optimal protocols for quantitative ¹⁷⁷Lu SPECT/CT by evaluating the accuracy of absolute SUV-SPECT/CT quantification. **Materials and Methods:** As part of setting the optimal 3D quantitative SUV-SPECT/CT protocol, since there are different quantitative tools proposed, phantom imaging was conducted to develop and validate image quantification method using ¹⁷⁷Lu including: · Cylindrical homogeneous phantom to assess scintillation camera calibration factor (CF) (cps/MBq) for planar and SPECT imaging. CF value was used by HERMES to estimate the SUV in the volume of interest (VOI). · The NEMA IEC Body Phantom consisting of a body/thorax-size compartment and six spherical inserts of various sizes (from 10mm to 37mm in diameter) was used to validate the accuracy of quantitative SUV by calculating the concentration recover coefficients (cRC) at various object sizes. **Results:** HERMES Hybrid3D 3.01 software (HERMES Medical Solutions, Sweden) was used to estimate CF and SUV values. An optimal CF of 11.1 cps/MBq results in most accurate activity estimates (1124MBq) with -1% difference from the actual activity (national primary standard calibrated well-counter) compared to a 16% difference reported with manually calculated CF (9.4 cps/MBq). With regard to OSEM iterations for optimised activity concentration values, good precision

was observed over 80 sub-iterations as coefficient-of-variation became less than 3%. Relative error reached a plateau of minimum value above 80 sub-iterations. Activity concentration showed a minimum relative error of -4%. SUV-SPECT values presenting optimal SUVmean equal to 1 and measured activity concentration with less than 5% difference from the actual value for a Philips PRECEDENCE system and less than 2% for a Siemens INTEVOBOLD systems. **Conclusion:** SUV-SPECT/CT quantification can be optimised with implemented calibrations. CF and cRC are the primary aspects to be addressed with high accuracy and precision. Reliable estimation is achievable when attenuation, scatter, collimator-detector resolution, energy window, and OSEM iterative reconstructions are compensated. **References:** None

OP-899**An international quantitative SPECT/CT imaging exercise for assessment of Ba-133 as surrogate for I-131**

Aim/Introduction: In nuclear medicine imaging, commissioning and quality control are typically performed based on hollow containers manually filled with radionuclide solutions. Most associated sources of uncertainty (e.g., filling volume, activity concentration) can be overcome by sealed, long-lived surrogate sources containing a radionuclide of comparable energies and emission probabilities, traceable to a primary standard. This study presents the results of a quantitative SPECT/CT imaging comparison exercise performed within the MRT Dosimetry project to assess the applicability of Ba-133 sources as a surrogate for I-131 and to determine a cross-calibration factor. **Materials and Methods:** Cylinders of four

different dimensions (active volumes of diameters 7.5, 15, 30, and 60 mm and 38 mm height, resulting in volumes of 1.68, 6.72, 26.9 and 107.4 cm³) and two different caps (one for complete closure, one with filling hole) were fabricated with a stereolithography 3D printing system (Formlabs Form 2, Tough resin). Optimal source placement in 216-mm Jaszczak cylinder was ensured by a laser-cut attachment baseplate designed based on simulations of spilled-out counts (Gaussian convolution with 20-mm FWHM). Solid Ba-133 surrogate sources were produced at two metrology institutions: CEA (activity concentration [206.2±5.8] kBq.mL⁻¹) and CMI ([99.8±1.6] kBq.mL⁻¹), with leakage and contamination tests according to ISO9978. The comparison exercise included eight SPECT/CT systems (3×Siemens, 5×GE). Each site had to perform three measurements with different sources attached in a water-filled Jaszczak cylinder: 1) Ba-133 CEA sources, 2) Ba-133 CMI sources, 3) identical containers filled with liquid I-131. Parameters: High-energy collimator, 2×60 projections of 30s, Ba-133: 356.0keV [5%-15%-10% scatter-main-scatter], I-131: 364.5keV [6%-20%-6%], low-dose CT, OSEM with standard corrections. A CT-based VOI analysis was carried out to compare differences in pseudo-ICF (image calibration factor including partial-volume related errors: counts in VOI per activity and scan duration). A regression analysis was performed to determine a cross-calibration factor. **Results:** Iodine-131 pseudo-ICFs were higher than Ba-133 pseudo-ICFs for all reconstructions and systems. Equivalent setups (camera and reconstruction) yielded comparable pseudo-ICFs (average relative error 5.6% between three equivalent GE setups). The regression analysis resulted in a cross-calibration factor of 0.70±0.02. This value is in agreement with the ratio 0.764±0.005 of the emission probabilities (62.05±0.19)% (Ba-133) and (81.2±0.5)% (I-131) [1]. **Conclusion:** Although this international comparison exercise was challenging due to varying transport regulations between countries, we could show that traceable solid Ba-133 sources can be used as surrogate for liquid I-131, thus potentially reducing inherent problems with on-site activity measurement and phantom preparation. **References:** [1] http://www.nucleide.org/DDEP_WG/DDEPdata.htm.

OP-900

Computer Aided Imaging Analysis software for SPECT/CT protocol comparisons

C. Jaudet, E. Quak, K. Weyts, A. Corroyer Dulmont, C. Lasnon, R. Ciappuccini, J. Saviny, G. Foucras, A. Batalla, S. Bardet; Centre François Baclesse, Caen, FRANCE.

Aim/Introduction: Robust methodology to compare SPECT/CT protocol performance is lacking. Generally, a fillable phantom is used to create reproducible measurements and a simple recovery coefficient is used for comparison. We developed a new freely available software solution

to extract more complex image features from SPECT/CT acquisitions, allowing for more accurate comparisons. This software solution was then used to reduce acquisition time and optimize image quality of ¹⁷⁷Lu SPECT/CT scans.

Materials and Methods: We created a new module named Computer Aided Image Analysis in simpleITK in python [1]. It was implemented in 3dSlicer software in order to optimize this already usable graphical interface [2]. With this module, recovery coefficients, noise, spatial resolution and a shape index can be extracted from SPECT scans based on an ideal image created from CT[3]. Firstly, the module was validated and optimized on simulation data, by varying the spatial position and resolution of a SPECT degraded image in reference to an ideal one. Secondly, it was used on NEMA IEC phantom data (spheres to background ratio=10) to compare two ¹⁷⁷Lu SPECT/CT acquisition protocols for different activity concentration. The standard protocol of 32 projections of 30s in a step and shoot mode was compared to a new protocol of 60 projections of 15s in a continuous mode. **Results:** For simulation data the software was able to compare the recovery coefficient, noise, spatial resolution and form index with an accuracy of 100% for 3 different simulations. For the phantom data, the recovery coefficient, noise, spatial resolution and form index for the standard versus the new protocol were [42.2%, 54.9%], [8.7%, 10.2%], [22.5mm, 17.5mm], [70.4%, 83.8%] respectively for a sphere of 5.57ml (rod diameter=22mm) and a background activity of 150kBq/ml. Acquisition time was reduced from 35 to 30 min for a two bed position acquisition. Except for noise, the new continuous SPECT/CT protocol improved the recovery coefficient, spatial resolution and shape index in phantom data. **Conclusion:** Our program was successfully deployed in a clinical environment and allowed us to choose a faster and optimized ¹⁷⁷Lu SPECT/CT protocol. **References:** [1]Lowekamp BC et al., (2013) ,Front. OP-901

Development and characterisation of a PET “painting” robotic phantom to generate pseudo-anthropomorphic brain and geometric test objects under digital computer control

A. Paramithas, A. Britten;

St. George's University Hospitals NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: Moving radioactive source systems have been used for gamma camera and PET test objects in air (Forgacs et al., 2019). This work aims to extend the capability

to in-water objects to produce pseudo-anthropomorphic test objects to optimise brain PET. **Materials and Methods:** A computer controlled electro-mechanical system allows 3D positioning of a source (5 MBq ^{18}F), and control of the time spent at each location over a 12cm^3 volume in a water filled cylinder. The relative distribution of activity is achieved by varying the source dwell time, derived from MRI images or geometry files. Basic performance was characterised and a geometrical test object was defined representing the cerebellum and inferior temporal lobe with a clinically relevant SUVR of 1.8, as found in Alzheimer's patients imaged with novel tau tracer PI-2620. Another test object representing the 28 mm IEC sphere was digitally defined and imaged on GE Discovery 710 series scanners. **Results:** Simulated point sources had image locations measured within ± 1.2 mm of those set. A linear relationship between dwell time and image counts was obtained (97% r^2 over 0.5 s to 2.5 s). The IEC sphere image matched the set 28 mm diameter. SUVR was in agreement with the set value. Painting of test objects took 40–60 minutes. Operators could change between test objects in under 15 minutes, with the only change being the digital control files. **Conclusion:** This first in-water robotic "painting" phantom shows the potential to produce pseudo anthropomorphic and geometric shape test objects, under highly flexible digital control. Further investigation of the inclusion of random counts is required and the painting speed needs to increase to allow larger organ or shape volumes to be produced. **References:** Forgacs A, Kallos-Balogh P, Nagy F, Krizsan AK, Garai I, Tron L, et al. OP-902

Printing 3D Heterogeneous Activity Distributions for Quality Control of SPECT and PET

J. Gear, G. Flux;

The Royal Marsden NHSFT, Sutton, UNITED KINGDOM.

Aim/Introduction: Quality control tests of molecular imaging systems are hampered by the complexity required to prepare phantoms. It is proposed that radioisotopes can be directly incorporated into photo-polymer resins. Use of the radio-polymer in a 3D printer allows phantoms with complex and reliable activity distributions to be produced whilst simplifying source preparation. **Materials and Methods:** Initial tests have been performed to determine the practicality of integrating Tc-99m into a photo-polymer and example phantoms produced to test suitability for quality control. Samples of build and support resins were extracted from the print cartridges of an Objet30Pro Polyjet 3D printer. The response of the resin to external factors including ionising radiation, light and dilution with Tc-99m pertechnetate were explored. After success of the

initial tests the radio-polymer was used in the production of different phantoms. Radionuclide dose calibrator and gamma camera acquisitions of the phantoms were used to test the accuracy of activity concentration, print consistency, uniformity and heterogeneous reproducibility. Tomographic phantoms were also produced including a uniform hot sphere, a complex configuration of spheres and interlacing torus's and a hot rod phantom. **Results:** The coefficient of variation between repeat prints of a 12 g disk phantom was 0.08%. Measured activity within the disks agreed to within 98 ± 2 % of the expected activity based on initial resin concentration. Gamma camera integral uniformity measured across a 3D printed flood field phantom was 5.2 % compared to 6.0 % measured with a commercial Co-57 flood source. Heterogeneous distributions of activity were successfully reproduced for both 2D and 3D imaging phantoms. Count concentration across regions of heterogeneity agreed with the planned activity assigned to those regions on the phantom design. **Conclusion:** 3D printing of radioactive phantoms has been successfully demonstrated and is a promising application for quality control of PET and SPECT systems. **References:** None

OP-903

Retrospective Quantitative Harmonization in PET Using Deconvolution and Optimal Filtering

D. Huff¹, M. Namias², A. J. Weisman¹, T. J. Bradshaw³, M. R. Albertini⁴, R. Jeraj^{1,5};

¹Department of Medical Physics, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA, ²Department of Medical Physics, Fundación Centro Diagnóstico Nuclear, Buenos Aires, ARGENTINA, ³Department of Radiology, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA, ⁴University of Wisconsin Carbone Cancer Center, Madison, WI, UNITED STATES OF AMERICA, ⁵Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: Quantitative analysis in longitudinal clinical assessments using PET imaging can be negatively impacted if multiple PET scanners are used. In this work, we describe a retrospective harmonization method that can be implemented to enable accurate, quantitative PET analysis across scanners which were not harmonized before the baseline PET assessment. **Materials and Methods:** Clinical reconstruction protocols for each scanner were identified from PET/CT image DICOM headers. NEMA phantom scans were acquired on each scanner using the identified reconstruction settings. Phantom images were deconvolved with the post-filters declared in the headers using Wiener deconvolution, giving unfiltered images as a result. Then, optimal isotropic 3D Gaussian filters were determined for each reconstruction setting combination by minimizing the dispersion in NEMA phantom contrast recovery coefficients

(CRC_{max}) via a downhill-simplex optimizer. Dispersion was defined as the root-mean-square sum over NEMA phantom spheres of the standard deviation of CRC_{max} values. After optimal filters were established, clinical PET images were also unfiltered using Wiener deconvolution, and then re-filtered with the optimal filters. The impact of the harmonization process was assessed by tracking SUV metric changes in 184 lesion response observations from 138 ^{18}F -FDG whole body scans of 20 patients with metastatic melanoma treated at the University of Wisconsin Carbone Cancer Center. **Results:** Seven unique sets of reconstruction settings from three GE PET/CT scanners (Discovery IQ, Discovery 710, Discovery VCT) were identified. Harmonization reduced the dispersion in CRC_{max} values by a factor of 3.4. After harmonization, 7/7 reconstruction setting combinations complied with EANM/EARL specifications, where only 1/7 had complied prior to harmonization. The optimal post filters for harmonization ranged between [7.6–8.1] mm FWHM. The harmonization process changed lesion response category as defined by $\pm 30\%$ change in lesion metric for at least one lesion in 11/20 patients. Lesion response assessment via SUV_{max} was changed by harmonization more frequently (18% of lesion observations) than assessment via SUV_{mean} (5%) or SUV_{total} (4%). **Conclusion:** The proposed method for quantitative harmonization can reduce differences due to imaging hardware and reconstruction settings for a retrospective PET dataset. Performing harmonization with this method had a significant impact on lesion response observations in more than half of a cohort of metastatic melanoma patients. **References:** None

OP-904

A realistic Phantom of the head for the Validation of attenuation corrections methods in PET-MRI

J. Harries^{1,2}, T. H. Jochimsen², T. Scholz², T. Schlender², H. Barthel², O. Sabri², B. Sattler²;

¹Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY; ²Department of Nuclear Medicine, Leipzig University Hospital, Leipzig, GERMANY.

Aim/Introduction: The combination of positron emission tomography (PET) and magnetic resonance imaging (MRI) (PET-MRI) is a unique hybrid imaging modality mainly used in oncology and neurology. The MRI-based attenuation correction (MRAC) is crucial for correct quantification of PET data. A suitable phantom to validate quantitative results in PET-MRI is currently missing. In particular, the correction of attenuation due to bone is usually not verified by commonly available phantoms. The aim of this work was to develop such a phantom and to explore whether such a phantom can be used to validate MRACs. **Materials and Methods:** Various materials were investigated for their attenuation and MR properties. For the substitution of bone, water-saturated gypsum plaster was used.

The attenuation of 511 keV annihilation photons was regulated by addition of iodine. Fatty tissue was imitated by silicone and brain tissue by agarose gel, respectively. The practicability with respect to the comparison of MRACs was checked as follows: A small flask inserted into the phantom and a large spherical phantom (serving as a reference with negligible error in MRAC) were filled with the very same stock solution. The activity concentration was measured and compared using clinical protocols on PET-MRI and different built-in and offline MRACs. The same measurements were carried out using PET-CT for comparison. **Results:** The phantom imitates the human head in sufficient detail. All tissue types including bone were detected as such so that the phantom-based comparison of the quantification accuracy of PET-MRI is possible. Quantitatively, the activity concentration in the brain, which was determined using different MRACs, showed a mean deviation of about 5% and a maximum deviation of 11% compared to the spherical phantom. For PET-CT, the deviation was 5%. **Conclusion:** The comparatively small error in quantification demonstrates that the phantom can be used to validate MRAC methods. Hence, a cross-system comparison towards standardization of the overall quantification performance of various PET-MRI systems, including their MRAC methods, seems to be possible for the first time for brain imaging. **References:** None

OP-905

A PET/MRI phantom study using MRI based attenuation correction to account for attenuation of the phantom material

I. Rausch, A. Valladares, T. Beyer, E. Unger;
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: PET/MRI phantom studies are challenged by the need of a phantom specific attenuation template to account for the attenuation of the phantom material. In this study we present a PET/MRI phantom built from MRI visible, 3D printable material for which attenuation correction (AC) can be performed using the standard MRI based AC. **Materials and Methods:** A water fillable phantom was 3D printed with a commercially available, MRI visible polymer. The phantom had a cylindrical shape and the fillable compartment consisted of a homogeneous region and a region with solid rods of different diameters. The phantom was filled with a solution of water and [^{18}F]FDG. Sodium chloride (0.9%) and MR contrast agent was added to avoid MR artefacts. The phantom was placed in the FOV of a PET/MRI system and a 30 min PET acquisition including the standard Dixon based MR-AC method was performed. In addition, a CT scan of the Phantom was acquired on a PET/CT system. From the Dixon in-phase, opposed-phase and fat images, a phantom specific AC map (Phantom MR-AC) was produced by separating the phantom material from the water compartment using a thresholding-based

method and assigning fixed attenuation coefficients for water and the polymer to the individual compartments. The PET data was reconstructed using the original Dixon MR-AC, the Phantom MR-AC, an MR-AC just containing the water compartment (noWall-AC) to estimate the error of ignoring the phantom walls and a CT based AC as reference. We calculated average percent differences in measured activity between the CT corrected PET and the PET corrected with the other AC methods for the whole water compartment as well as for a 5 pixel wide region along the phantom material in a slice of the homogeneous- and the rod containing region. **Results:** Compared to the CT-AC PET, average differences in measured activity of 8.9%, 4.5% and -27.2% were found for Dixon MR-AC, Phantom MR-AC and noWall-AC based PET, respectively. Average differences near the phantom wall in the homogeneous region were 6.7%, 6.6% and -34.4%, respectively. Around the rods, activity differed from the CT-AC PET by 9.7%, 4.8% and -21.9%, respectively. **Conclusion:** The presented phantom material is visible using standard MR sequences, and thus, can be incorporated in the MR-AC. PET quantification was substantially improved when accounting for the phantom material. However, the presented MR-AC approaches did not show full equivalence to CT based AC. **References:** None

OP-906

Automated acceptance calibration and quality control for a compact benchtop SPECT system

P. Mollet, S. Neyt, K. Braeckman, K. Deprez;
Molecubes NV, Ghent, BELGIUM.

Aim/Introduction: Routine quality control measurements are often lacking in preclinical research, but are of paramount importance to standardize the use of high-performance imaging systems(1,2). In this study, we present automated QC for the γ -CUBE (MOLECUBES). To the best of our knowledge, these automated procedures do not exist in preclinical μ SPECT. **Materials and Methods:** Daily QC (<1min) measures detector temperature and response, based on background activity. Monthly QC (<1min) evaluates the energy spectrum and uniformity of each detector using a 1ml syringe containing 35-50 μ Ci ^{99m}Tc . Energy resolution and photopeak location are calculated using an automatic Gaussian fitting algorithm. The average standard deviation of detector flood maps is used as uniformity measure. An automated procedure using the syringe phantom has been included to allow acceptance calibration. This protocol will collect data at every position for all detectors. For each position on a 0.5 by 0.5mm pitch, an energy histogram is collected and the energy peak location is determined by fitting the spectrum using a Gaussian model. Using the new energy peak locations, the data is energy filtered and the detector flood maps are used to correct for detector gain variations. GPU acceleration is used to speed up the

process. **Results:** Using the standard user interface, any user can start the procedures without specialized knowledge. All measurements and analyses are done automatically and results are reported in the GUI. The daily QC will evaluate whether a detector temperature between 20 and 26°C is measured, and whether counts are collected. The Monthly QC will report energy resolution (to be below 11%), maximum energy peak shift (<1.5 keV) and detector uniformity (<5%). The procedure was tested on an uncalibrated system leaving the production facility. After passing daily QC, monthly QC showed an energy peak at 124 keV, energy resolution of 10.8% and detector uniformity of 7.96%. After applying the automated calibration, the energy peak was centered at 140 keV and a resolution of 10.6% and a uniformity of 3.45% were obtained. **Conclusion:** We demonstrated the possibility to automatically evaluate detector stability, energy spectra and detector uniformity in combination with automated system calibration. This is a step forward in providing easy and straightforward QC procedures in preclinical imaging to improve standardization in the daily use of microSPECT and to ensure uniform performance over time. All procedures can easily be extended towards other isotopes. **References:** 1. Osborne et al. Mol Imaging Biol 2. Vanhove et al. EJNMMI Physics

OP-907

Performance Evaluation of a compact benchtop SPECT system for ^{99m}Tc , ^{111}In and ^{177}Lu

K. Deprez, K. Braeckman, S. Neyt;
MOLECUBES, Ghent, BELGIUM.

Aim/Introduction: The γ -CUBE is a compact high-sensitivity, high-resolution preclinical SPECT system for whole body mouse and rat imaging. The detectors of this system are based on SiPMs coupled to NaI(Tl) scintillators. The collimators use the lofthole geometry [1] and are produced by additive manufacturing [2]. In this study we evaluated the imaging capabilities for three isotopes using the methods published in [3]. **Materials and Methods:** The performance evaluation consists of spatial resolution, energy resolution and sensitivity measurements using ^{99m}Tc , ^{111}In and ^{177}Lu [3]. Spatial resolution measurements were done both with capillary tubes and with hot rod phantoms, scanned for one hour. Reconstructions were done using 500 or 300 iterations (mouse and rat respectively) and a voxel size of 250 μm or 500 μm (mouse and rat respectively). A low volume source (50 μL , 3.7-37MBq) was used to perform the sensitivity and energy resolution measurements, scanned for 20 seconds. **Results:** The ^{99m}Tc measurements show a resolution of 456 μm and 956 μm and a sensitivity of 0.10% and 0.05%, for the mouse and rat collimator respectively. Using ^{111}In and the mouse collimator we obtained a spatial resolution of 503 μm and 801 μm for the 171 keV and 245 keV photon peak respectively and a similar sensitivity of

0.07%. With the rat collimator a resolution of 980 μ m and 1.57mm, and a sensitivity of 0.05% and 0.06% is obtained for the 171keV and 245keV photon peaks respectively. Results of the Lu177 measurements are reported for the 113keV and 208 keV photon peak respectively. A resolution (sensitivity) of 410 μ m (0.12%) and 564 μ m (0.08%) was measured for the mouse collimator and a resolution (sensitivity) of 898 μ m (0.07%) and 1.3mm (0.06%) was obtained for the rat collimator. The energy resolutions were: 9.7% (99m-Tc, 140keV), 9.3% (111-In, 171keV), 9.4% (111-In, 245keV), 10.5% (177-Lu, 113keV) and 9% (177-Lu, 208keV). **Conclusion:** This performance evaluation of the MOLECUBES γ -CUBE demonstrates that the system has ideal imaging capabilities for in vivo imaging of both rats and mice, and for a variety of radiopharmaceuticals. The high energy resolution also opens up possibilities for multi-isotope studies. **References:** 1. Deprez et al. Physics in Med & Biology 2. Deprez et al. Medical Physics 3. Deleye et al. Performance of a Novel Small-Animal SPECT System with Two Stationary Detectors: A Comparison of Multi-Pinhole Collimators for Mouse Imaging

J. Hoffmann^{1,2}, J. Janssen^{1,2}, T. Kanno^{2,3}, T. Higuchi^{1,2,4};

¹Department of Nuclear Medicine, University Hospital of Würzburg, Würzburg, GERMANY, ²Comprehensive Heart Failure Center, University Hospital of Würzburg, Würzburg, GERMANY, ³Department of Quantum Medical Technology, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, JAPAN, ⁴Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, JAPAN.

Aim/Introduction: Small-animal SPECT systems with multi-pinhole collimation and three large stationary detectors have been shown their superiority when compared to systems with moving small detectors [1]. Recently an economically attractive version with two large stationary detectors has been introduced. We investigated the performance to analyze the capabilities of this novel SPECT system. **Materials and Methods:** A newly developed small-animal SPECT with two stationary detectors (size of detectors: 47.2 cm x 59.5 cm) and multi-pinhole collimation was used for acquiring data with point source, mini-Derenzo hot-rod and uniformity phantoms, filled with ^{99m}Tc (energy window centered at 140 keV), to analyze sensitivity, spatial resolution, uniformity and contrast-to-noise-ratio (CNR). Three dedicated mouse collimators with 75 pinholes each and diameters of 0.25 mm; 0.6 mm and 1.0 mm for extra ultra-high resolution (XUHR-M), general-purpose (GP-M) and ultra-high sensitivity (UHS-M) imaging were examined. Activity concentration was 309.7 \pm 20.4 MBq/ml and scan time was 45 min. For CNR analysis, four different activity ranges representing low- and high-count setting were investigated. Raw data was reconstructed by

using the novel SR-OSEM algorithm with 3 iterations and 128 subsets [2]. **Results:** The peak sensitivity achieved 237 cps/MBq (XUHR-M); 847 cps/MBq (GP-M); 2054 cps/MBq (UHS-M). Resolution in the visually analyzed sections of the reconstructed hot-rod phantom was 0.35 mm (XUHR-M); 0.50 mm (GP-M) and 0.70 mm (UHS-M). Uniformity for maximum resolution records 40.7% (XUHR-M); 29.1% (GP-M) and 24.5% (UHS-M), respectively. UHS-M reaches highest CNR values for low-count images, for rods smaller than 0.45 mm acceptable CNR was only achieved by XUHR-M. GP-M was superior for imaging rods sized from 1.5 - 0.6 mm for intermediate activity concentrations. To achieve the best possible image quality considering contrast and noise, each collimator showed its advantage close to its maximum spatial resolution. **Conclusion:** Although the investigated SPECT scanner uses only two stationary detectors instead of conventional three detectors, the system's performance records no significant deficits regarding the highest possible image quality. The effects of the lower sensitivity on the noise level might be improved by increasing either scanning time or injection dose, but further validation especially concerning animal models is necessary. **References:** 1. Multi-pinhole SPECT Imaging of Rat Hearts and Bones: Image Quality under In Vivo Conditions

J. Janssen^{1,2}, J. Hoffmann^{1,2}, T. Kanno^{2,3}, T. Higuchi^{1,2,4};

¹Department of Nuclear Medicine, University Hospital of Würzburg, Würzburg, GERMANY, ²Comprehensive Heart Failure Center, University Hospital of Würzburg, Würzburg, GERMANY, ³Department of Quantum Medical Technology, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, JAPAN, ⁴Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, JAPAN.

Aim/Introduction: Preclinical multi-pinhole SPECT enables sub-half-millimeter spatial resolution, whereby the loss of sensitivity and its dependency on the scanned volume must be taken into account [1]. We investigated the capabilities of a new micro-SPECT, equipped with two large stationary detectors, to visualize rat hearts and bones using clinically available ^{99m}Tc tracers by maintaining high image quality. **Materials and Methods:** Sensitivity, count linearity, spatial resolution, uniformity, contrast-to-noise-ratio was measured by point source, hot-rod, and uniform phantoms for a small-animal SPECT with 2 stationary detectors using

an ultra-high-resolution rat and mouse multi-pinhole collimator. The phantoms filled with ^{99m}Tc were scanned for a high-count performance assessment and count levels equal to the animal scans. Reconstruction parameters were set to 4 iterations 128 subsets using the SR-OSEM algorithm with Gaussian smoothing [2]. Rats were injected with ~ 100 MBq ^{99m}Tc -MIBI or ~ 150 MBq ^{99m}Tc -HMDP and imaged with multiple frames in a 60-min scan after the tracer distribution (25 and 190 min, respectively). Phantom and in vivo scans, with different Gaussian filters to optimize image quality, were compared. Dependency of resolution on the injection dose and scan time was examined. **Results:** Sensitivity was 567 cps/MBq, count loss was less than 5% for up to 191 MBq (425 MBq/ml). Hot-rods as small as 1.2 mm were resolved, uniformity was 55.5 %. Resolution was 2.2 mm in the heart for 60 min acquisition time, 2.8 mm, for 30 min and 3.5 mm for 10 min, respectively. Left ventricle and bone structures of the rats were successfully visualized in the reconstructed SPECT images of the 60-min scans. The high image quality (visual observation) was maintained by Gaussian filtering with a minimum of 2.2, 2.8 and 3.5 mm FWHM for the 60, 30 and 10-min-measurement, validated by the corresponding phantom measurement. **Conclusion:** Optimizing the study design regarding injection dose, acquisition time, post-filtering and collimator choice is essential to maximize the potential of small-animal SPECT imaging. The algorithm SR-OSEM with fixed reconstruction parameters is simplifying the study planning, although there are still challenges concerning the low system sensitivity, limited injection dose and acquisition time in in-vivo settings especially concerning dynamic scans. **References:** 1. Is PSMA-PET/CT cost-effective for disease staging in men with high-risk prostate cancer? An analysis of the proPSMA randomised controlled trial

R. De Abreu Lourenco¹, R. de Fera Cardet¹, T. Segard², J. Yim¹, S. Williams³, R. Francis², M. Frydenberg⁴, N. Lawrentschuk⁵, D. G. Murphy⁵, M. S. Hofman³;

¹University of Technology Sydney, Sydney, AUSTRALIA, ²Sir Charles Gairdner Hospital, Perth, AUSTRALIA, ³Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, ⁴Monash University, Melbourne, AUSTRALIA, ⁵University of Melbourne, Melbourne, AUSTRALIA.

Aim/Introduction: The recently published proPSMA clinical trial demonstrated increased accuracy of PSMA-PET/CT compared with conventional imaging (CI; computed tomography plus bone imaging) in men with high risk prostate cancer. It is important to assess whether the additional benefits of increased accuracy are justified by potential differences in the use of resources of these two imaging approaches. Thus, we determined the cost-effectiveness of PSMA-PET/CT when compared with CI in men with high risk prostate cancer. **Materials and Methods:** This analysis was informed by data collected as part of the proPSMA study conducted in Australia. Patients in proPSMA had high-risk prostate cancer (PSA ≥ 20 ng/mL or International Society of UroPathology grade group 3-5, or clinical stage $\geq T3$). A total of 300 patients were assigned to CI or ^{68}Ga -PSMA-11 PET/CT, with planned health economics data collected (including time required for scan delivery). These data informed a cost-effectiveness decision tree analysis to estimate the cost per accurate diagnosis for PSMA-PET/CT compared to CI. Cases detected flowed into a Markov model to assess longer-term costs and outcomes of lifetime treatment following initial disease staging. Treatment pathways for the Markov model reflected local Australian practice and costs, with probabilities for disease outcomes in terms of metastatic disease, quality of life and survival informed by the literature. Results from the Markov model were expressed as cost per quality adjusted life year (QALY) gained. **Results:** Analysis of data from proPSMA

resulted in a cost per scan of AUD\$1,203 for PSMA-PET/CT and AUD\$1,412 for CI. proPSMA showed that PSMA-PET/CT was more accurate, largely due to improved sensitivity of PSMA-PET/CT in nodal disease. Thus, PSMA-PET/CT was dominant, being more effective (accurate) and less costly. When analysed as part of the Markov model, improved diagnostic accuracy resulted in a higher proportion of men receiving the appropriate treatment for their disease, accumulating estimated improvements in survival and quality of life. This resulted in a cost per QALY of AUD\$10,629. The results were most sensitive to variations in the accuracy of CI and the number of men that could be scanned for each ^{68}Ga -PSMA production. **Conclusion:** This analysis shows that PSMA-PET/CT is a cost-effective technology; based on the results of proPSMA it dominates CI for initial staging and translates into a cost-effective longer-term management strategy when combined with standard clinical pathways. **References:** None

Aim/Introduction: EAU guidelines recommend abdominopelvic computed tomography (CT) for primary nodal staging of intermediate to high-risk prostate cancer (PCa), although CT has low sensitivity for detection of pelvic lymph node metastases. We have studied two potentially more accurate imaging modalities, prostate-specific membrane antigen positron emission tomography/CT

(PSMA PET/CT) and whole-body MRI (wbMRI) with diffusion-weighted imaging (DWI), comparing in a prospective study their diagnostic performance with clinical standard-of-care CT. **Materials and Methods:** This prospective, registered (NCT03537391), single-center trial enrolled 80 patients with newly diagnosed unfavorable intermediate or high-risk PCa according to the EAU risk group classification. After consent, patients underwent contrast-enhanced abdominopelvic and chest CT as a clinical standard for nodal staging. Research scans included ^{18}F PSMA1007 PET/CT and 1.5 T wbMRI/DWI. Two separate modality-based specialists reviewed independently each modality blinded for other modalities. Regional lymph nodes were reported as either benign, equivocal or malignant and recorded using the REDCap electronic data capture tool. Pessimistic analysis (equivocal considered malignant) was performed in cases with an equivocal modality status. Histology from pelvic lymph node dissection (n=17 patients), follow-up imaging (n=63 patients) and clinical data were used as reference standards and the ground truth was defined at a patient-level in multidisciplinary consensus meetings. **Results:** Seventy-nine patients (mean age: 70 years) completed all the imaging modalities, with an eight-day median interval between the first and last imaging study (IQR 7). Median PSA was 12 ng/ml (range: 3–2000). Twenty-five patients (32%) presented with unfavorable intermediate and 54 (68%) with high-risk PCa. Twenty patients (25%) had distant metastatic disease and pelvic nodal metastases were found in 31 (39%) patients. In patient-level pessimistic analysis, the sensitivity of CT (reader 1 and reader 2), wbMRI/DWI (reader 3 and reader 4) and PSMA PET/CT (reader 5 and reader 6) were 0.44/0.36, 0.48/0.56 and 0.92/1 (p<0.01), respectively. The corresponding specificity and accuracy values were 0.89/0.93, 0.94/0.85, 0.91/0.89 (p>0.05) and 0.75/0.75, 0.79/0.75 and 0.91/0.92 (p<0.05), respectively. Inter-reader agreement values (κ = Kappa) were 0.86 for PSMA PET/CT, while the corresponding values for CT and wbMRI/DWI were 0.51 and 0.40, respectively. Furthermore, PSMA PET/CT detected regional lymph node metastases in 8/31 (26%) patients, in whom the other modalities were negative. **Conclusion:** In this prospective clinical trial ^{18}F -PSMA-1007 PET/CT demonstrated superiority in sensitivity and accuracy to wbMRI with DWI and CT in primary nodal staging of unfavorable intermediate and high-risk PCa, while maintaining optimal specificity and showing the highest inter-reader agreement. **References:** None

OP-915

A Prospective Study to Compare the Role of ^{68}Ga -PSMA-11 PET-CT and ^{68}Ga -GUL-NOTA-PSMA PET-CT in the Evaluation of Prostate Cancer

S. Prakash, C. S. Bal, A. Seth, M. Tripathi, S. Ballal, M. P. Yadav;
 All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: • ^{68}Ga -PSMA-11 has proven to be highly sensitive and specific for detection of prostate cancer and its metastasis but its drawback is that it cannot bind to therapeutic radiometals, such as ^{177}Lu or ^{225}Ac . (1) A new PSMA ligand GUL-NOTA-PSMA can be feasibly linked to both ^{68}Ga and ^{177}Lu . This study compares the role of ^{68}Ga -PSMA-11 PET-CT and ^{68}Ga -GUL-NOTA-PSMA PET-CT in the evaluation of prostate cancer keeping in mind the potential for future theranostics with ^{177}Lu -GUL-NOTA-PSMA.

Materials and Methods: 26 patients with histopathologically proven prostate cancer (age: 49-87 years, mean: 68 years) underwent ^{68}Ga -PSMA-11 PET-CT and ^{68}Ga -GUL-NOTA-PSMA PET-CT with a maximum gap of 2 weeks between the two scans. Radiotracer uptakes in the prostate cancer primary and its metastases to lymph nodes and bones were semi-quantitatively analysed by measuring the maximum standardised uptake values (SUV_{max}). SUV_{max} of physiological uptake in liver, mediastinum, parotid glands and kidney were measured. Comparison between the two tracers was done on a per lesion and per patient based analysis. Paired T test and Wilcoxon signed-rank test were used as statistical tests for significance. **Results:** Among a total of 26 patients, 25 patients had primary prostatic lesions, 23 had lymph nodal metastasis and 21 had skeletal metastasis. Both tracers detected lesions in all patients. In total, PSMA-11 PET-CT detected 738 lesions (394 skeletal, 319 lymph nodes, 25 in prostate bed) while GUL-NOTA-PSMA PET-CT detected 735 lesions (393 skeletal, 317 lymph nodes, 25 in prostate bed) ($p=0.33$) showing no significant difference in the lesion detection rate between the two tracers. There was no significant difference in the SUV_{max} of the lesions in the prostatic bed ($p=0.9$), lymph nodes ($p=0.9$) or bones ($p=0.3$) between the two tracers. Furthermore, the physiological radiotracer uptake (SUV_{max}) in liver ($p=0.001$), salivary glands ($p=0.001$) and kidneys ($p=0.002$) was significantly lower in GUL-NOTA-PSMA but mediastinal uptake ($p=0.0003$) was significantly lower in PSMA-11. **Conclusion:** There is no significant difference in the detection of prostate cancer lesions and its metastasis between ^{68}Ga -GUL-NOTA-PSMA and ^{68}Ga -PSMA-11 PET-CT. The physiological uptake in salivary glands, kidney and liver is lower with ^{68}Ga -GUL-NOTA-PSMA signifying potentially less toxicity when used as a theranostic agent which needs to be pursued with further studies. **References:** 1. Aim/Introduction: Analysis of novel [^{18}F]siPSMA14 at different time points to assess biodistribution and the optimal time point for staging primary and metastatic prostate cancer. **Materials and Methods:** 47 prostate cancer patients (69 ± 7 y; GS 6-9, median (range) PSA 3.195 (0.09 - 1000) ng/ml) referred for PSMA PET/CT were scanned at three different time points T1 (n=7; 60min), T2 (n=40; 90 minutes), T3 (n=7; 120 min). PET/CT (with contrast enhanced CT, if not contraindicated) images were acquired after injection of [^{18}F]siPSMA14 (344.08 ± 11.7 MBq, without furosemide), from head to mid-thigh (T1,T2) or from lower thorax to upper thigh (T3). SUV_{mean} were measured for normal organs and malignant lesions (intraprostatic tumor/residual tumor (prostatic lesion(PL)), bone(BM), lymph(LM) and adrenal gland(AM) metastases). For analyzing changes between early and late uptake T1 and T3 were examined. Target / non target ratios (TnTR) were calculated by comparing SUV_{mean} of tumor lesions with background activity. T-test was performed to compare the differences in the mean of SUV_{mean} in normal organs. **Results:** In all patients examined no side effects occurred. In high PSMA expressing organs mean $\text{SUV}_{\text{mean}} \pm \text{SD}$ (kidney cortex, duodenum) increased significantly at T1/T3 (kidney cortex $22.9 \pm 5.2/26.7 \pm 8.8$; duodenum $7.8 \pm 1.8/8.9 \pm 2.7$) whereas in liver, spleen and pancreas [^{18}F]siPSMA-14 uptake remained stable (liver $7.4 \pm 3/7.2 \pm 2.8$; spleen $8.4 \pm 5.6/7.9 \pm 5.4$; pancreas $2.2 \pm 0.9/1.9 \pm 0.9$). The mean SUV_{mean} of PL and metastatic lesions (ML) at T1/T3 were $6.9 \pm 4.2/14.6 \pm 6.2$ and $12.6 \pm 7.3/14.4 \pm 8.1$. Mean SUV_{mean} TnTR at T1/T3 for PL (n=6); LM (N=2); BM (n=2) and AM (n=1) were 13.8/28.2; 21.4/24.2; 5.3/5.8; 41.2/46.8. The mean SUV_{mean} of PL and ML at T2 were 9.6 ± 10.6 and 23.8 ± 9.6 . Mean SUV_{mean} TnTR at T2 for PL (n=11); LM (N=17); BM (n=11) and AM (n=1) were 16; 14.3; 18.6 and 30.2. SUV_{mean} PL and bladder ratio at T1/T3 and T2 were 0.7/0.9 and 1.9. **Conclusion:** Novel [^{18}F]siPSMA-14 was well tolerated in all patients. All lesions were observed at all the time points and showed high [^{18}F]siPSMA-14 uptake. SUV_{mean} in primary as well as in metastatic locations increased with time. Distribution in normal organs was similar to other known PSMA PET radiotracers. Without furosemide PL could be clearly delineated at 90min p.i., which seems to be the optimal time point. **References:** None

OP-917**Temporal accumulation patterns of ⁶⁸Ga-PSMA in primary prostate cancer: stable or steep?**

J. olde Heuvel¹, M. Sinaasappel¹, M. P. M. Stokkel¹, C. H. Slump², B. J. de Wit-van der Veen¹;

¹Netherlands Cancer Institute, Amsterdam, NETHERLANDS,

²University of Twente, Enschede, NETHERLANDS.

Aim/Introduction: Understanding the day-to-day variability of an imaging biomarker is key when using it to characterize lesions or quantify response to treatment. So, the objective of this study was to assess pharmacokinetics of ⁶⁸Ga-PSMA in patients suffering from primary prostate cancer in both tumour lesions and normal tissue. **Materials and Methods:** Five patients were enrolled in this prospective study. Before standard clinical PSMA-PET/CT, dynamic acquisitions were made for 30 minutes (Vereos, Philips). Acquisitions started directly after intravenous bolus injection of ~100MBq [⁶⁸Ga] Ga-PSMA-11. The same protocol was repeated ~four weeks later, without therapeutic interventions in between. List-mode data was binned in 1 minute frames, and reconstructed with 4mm voxel size (3it5sub, no PSF). Time-activity curves (TACs) were derived for the prostate tumour, gluteal muscle and common iliac artery. Intra-patient variability was expressed by median SUV_{mean} and coefficient of variation (CoV). **Results:** Median intra-patient CoV was within 3.3% for artery, 1.1% for tumour, and 0.3% for gluteal muscle. The median difference in SUV_{mean} of the common iliac artery and gluteal muscle was 0.08 and 0.04; these TACs plateaued after 8 and 5 minutes, respectively. Tumour TAC profiles showed marked differences between patients; in two patients uptake stabilized already after 5 minutes ('stable'-group), whereas in three patients the uptake kept increasing over time ('steep'-group). This resulted in a marked 3.0 times higher SUV_{mean} in the 'steep'-group (SUV_{mean} 2.8) compared to the 'stable'-group (SUV_{mean} 8.5) after 30 minutes, which was reproducible on the second PET/CT four weeks later ('steep'-SUV_{mean} 2.9; 'stable'-SUV_{mean} 8.6). No differences in systemic blood supply and perfusion were observed on PET. The only relevant distinction between these patients was tumour volume, which was on average 3cc vs. 36cc for stable and steep group, respectively. **Conclusion:** Dynamic ⁶⁸Ga-PSMA-PET/CT scans in a test-retest setting revealed that accumulation patterns are highly repeatable over time. Tumour accumulation is already visualized 5 minutes p.i., but marked difference between TAC-profiles are present. These temporal differences in tumour uptake might be beneficial for selecting patients for PSMA-targeted radionuclide therapy. **References:** None

OP-918**Is the increased ⁸²Rubidium uptake in prostate cancer explained by underlying Na⁺/K⁺-ATPase density?**

M. Jochumsen^{1,2}, J. Sörensen^{1,2}, J. R. Nyengaard³, S. R. P. Krag⁴,

B. G. Pedersen^{5,2}, M. Borre^{6,2}, J. Frøkiær^{1,2}, K. Bouchelouche^{1,2}, L. P. Tolbod^{1,2};

¹Aarhus University Hospital, Dept. of Nuclear Medicine and PET-Centre, Aarhus, DENMARK, ²Aarhus University, Dept. of Clinical Medicine, Aarhus, DENMARK, ³Department of Clinical Medicine, Core Centre for Molecular Morphology, Section for Stereology and Microscopy, Centre for Stochastic Geometry and Advanced Bioimaging, Aarhus University, Aarhus, DENMARK, ⁴Aarhus University Hospital, Dept. of Pathology, Aarhus N, DENMARK, ⁵Aarhus University Hospital, Dept. of Radiology, Aarhus N, DENMARK, ⁶Aarhus University Hospital, Dept. of Urology, Aarhus, DENMARK.

Aim/Introduction: ⁸²Rubidium is clinically used as perfusion tracer for PET, as the cellular ⁸²Rubidium uptake is proportional to blood flow. However, as a potassium analogue, ⁸²Rubidium is also dependent on active transport by the Na⁺/K⁺-ATPase for cellular uptake. In recent studies, we found ⁸²Rubidium uptake and hence blood flow in prostate cancer (PCa) correlated with cancer aggressiveness [1]. The aim of this study was to examine the role of underlying Na⁺/K⁺-ATPase density in determining PCa ⁸²Rubidium uptake. **Materials and Methods:** One-hundred-and-two patients underwent pelvic ⁸²Rubidium PET prior to magnetic resonance imaging (MRI)-guided in-bore prostate biopsy. PCa was confirmed in 100 lesions in 86 patients, and 25 lesions in 16 patients were benign. Tumours were delineated on MRI and transferred to ⁸²Rubidium PET for SUV analysis. Immunohistochemical α1/α2-Na⁺/K⁺-ATPase staining was subsequently performed on biopsies. No expression of the α2-isoform was found. Quantification of the α1-Na⁺/K⁺-ATPase antibody staining intensity was performed using ImageJ. Additionally, cell profile density was calculated. **Results:** ⁸²Rubidium SUVmax and International Society of Urological Pathology (ISUP) Grade Group (GG) were moderately correlated (rho=0.68, p<0.0001), inflamed lesions excluded. ⁸²Rubidium SUVmax separated GGG2-5 from GGG1 and benign lesions with 96% sensitivity and 59% specificity with 2.92 as cut-off. Na⁺/K⁺-ATPase optical density per cell profile in benign prostate cells was 38% (1.38 with 95% CI [1.28; 1.49]) (p<0.0001) higher than in malignant cells. Na⁺/K⁺-ATPase density per cell was significantly lower in "high" grade tumours (ISUP GG≥2) (6.4E-5 [6.0E-5; 6.9E-5]) than in low grade tumours (ISUP GG=1) (7.7E-5 [6.5E-5; 8.9E-5]) (p=0.02). Mean cell density was 24% (1.24 with 95% CI [1.17; 1.33]) higher in PCa glands than in benign glands, corresponding to 96% higher (1.96 with 95% CI [1.83; 2.09]) (p<0.0001) in malignant areas than in benign areas. Driven by this higher cell density, malignant areas has 58% higher Na⁺/K⁺-ATPase optical density than the benign areas (p<0.0001). Still, no correlations between ⁸²Rubidium SUVmax and Na⁺/K⁺-ATPase density nor cell profile density were found. A near-significant positive correlation between cell density and GG was found (rho=0.21, p=0.06). **Conclusion:** Blood flow

in PCa measured with simple ^{82}Rb SUV correlates with ISUP GG independent of underlying $\text{Na}^+/\text{K}^+\text{-ATPase}$ density. Consequently, the interpretation of ^{82}Rb uptake as a reflection of tumour blood flow is further consolidated. $\text{Na}^+/\text{K}^+\text{-ATPase}$ density is reduced in PCa cells compared to benign cells, and slightly reduced in high-grade tumours compared to low-grade tumours. **References:** [1] MR Jochumsen et al., *J Nucl Med* 60(8), 1059 (2019).

 Montevideo, URUGUAY, ²Nuclear Medicine Centre, Clinical
 Hospital, University of Uruguay, Montevideo, URUGUAY.

Aim/Introduction: ^{68}Ga -PSMA-HBED-CC (^{68}Ga -PSMA-611) PET/CT represents a clinically relevant and commonly used technique for the evaluation of prostate cancer (PCa) patients whereas [^{18}F]AIF-PSMA-HBED-CC (^{18}F -AIF-PSMA-11) is a novel tracer produced in our centre, with suitable radiochemical purity for clinical purposes. The aim of this study was to prospectively compare the diagnostic values of ^{18}F -AIF-PSMA-11 versus ^{68}Ga -PSMA-11 for the detection of metastatic disease in a sample of patients with intermediate and high-risk PCa at initial staging. **Materials and Methods:** We enrolled 66 patients (mean age: 63 years; range: 52-78 years) with medium and high-risk biopsy proven PCa prior therapy (Gleason \geq 6; mean PSA: 26.45 ng/mL, median PSA: 14 ng/mL, range: 1.7-152 ng/mL). They prospectively underwent routine ^{68}Ga -PSMA-11 and ^{18}F -AIF-PSMA-11 PET/CT scanning within a time window of 1-2 weeks. Studies were performed with a 64-slice PET/CT scan with TOF correction. We measured the SUVmax in all coincident lesions. Open prostatectomy and pelvic lymph-node dissection were performed in non-metastatic patients. Histopathology, correlative imaging and/or clinical follow-up were considered as reference standard, with a follow-up of at least 4 months after PET/CT scanning (median 6.4, range 4-11 months). Sensitivity and specificity with their 95% C.I. were calculated. **Results:** Overall detection rate was 85% (56/66) for both ^{68}Ga -PSMA-11 and ^{18}F -AIF-PSMA-11 PET/CT. At least one suspicious lesion for prostate cancer metastasis was detected in 20 (30%) and 21 (32%) of 66 patients, for each tracer respectively. A total of 145 extra-prostatic lesions were detected in bone (n=56), lymph-nodes (n=88), and lung (n=1) by at least one radiopharmaceutical: 131 (90%) for ^{68}Ga -PSMA-11 and 123 (85%) for ^{18}F -AIF-PSMA-11. In concordant lesions a significant correlation was found between the SUVmax of both radiopharmaceuticals ($r=0.90$, $P<0.001$). ^{18}F -AIF-PSMA-11 SUVmax was higher in bone foci

(n=39) compared to ^{68}Ga -PSMA-11 (7.2 vs 8.9, $P=0.002$), while no significant differences were found for lymph node and prostate lesions. On a per patient basis the sensitivity values were the same for both techniques: 0.90 (0.68-0.98). We calculated a specificity of 0.96 (0.85-0.99) and 0.94 (0.82-0.98) for ^{68}Ga -PSMA-11 and ^{18}F -AIF-PSMA-11, respectively. **Conclusion:** ^{68}Ga -PSMA-11 and AIF- ^{18}F -PSMA-11 PET/CT seem to be clinically equivalent imaging techniques for the assessment of primary medium to high-risk PCa with great potential for the detection of metastatic spread that would impact patient management. **References:** None

The clinical value of ^{68}Ga -PSMA-11 PET/CT in patients with newly diagnosed prostate cancer, ISUP grade 5 and no metastases based on standard imaging

H. Zacho^{1,2}, S. Nalliah¹, A. Petersen¹, L. J. Petersen^{1,2};
¹Aalborg University Hospital, Aalborg, DENMARK,
²Aalborg University, Aalborg, DENMARK.

Aim/Introduction: To evaluate the clinical value of ^{68}Ga -PSMA-11 PET/CT in patients with newly diagnosed prostate cancer, ISUP grade 5 (Gleason score \geq 9), and no metastases based on standard imaging. **Materials and Methods:** We initiated a new clinical strategy for the clinical use of PSMA PET/CT for staging of patients with prostate cancer, which was based on the following eligibility criteria: 1) Newly diagnosed prostate cancer, 2) no prior treatment for prostate cancer, 3) ISUP grade 5 (Gleason score 9 or 10), 4) suitable for treatment with curative intent (radical prostatectomy or radiation therapy) based on co-morbidity and life expectancy, and 4) No definitive metastases on standard of care (SoC) imaging, which was contrast-enhanced CT (ceCT) and bone scintigraphy (BS). We present the results from the first 6 months of this new staging procedure. **Results:** During six months, 50 patients complied with the eligibility criteria and underwent a PSMA PET/CT (mean age 69.6 years, range 55-78). Median PSA was 14.0 ng/mL, and 28 patients (56%) had localized cancer, 22 patients (44%) had locally advanced prostate cancer according to the criteria from the European Association of Urology. Five patients had indeterminate findings on SoC imaging (three equivocal bone scans, two ceCTs suggesting lymph node metastases). Visual uptake of PSMA in the prostate was seen in all (50/50, 100%) patients. PSMA PET/CT showed pathological PSMA-uptake outside the prostate in 23 patients (46%); pelvic lymph node metastases in 13 patients (26%) and lymph node metastases outside the pelvis and/or bone metastases and/or visceral metastases in 10 patients (20%). Among the five patients with indeterminate findings on SoC imaging, PSMA PET/CT showed malignant findings in three patients (two patients with lymph node metastases and one with bone metastases). The result of the PSMA PET/CT changed the treatment strategy in 19 (38%) patients from curatively

intended treatment to palliative treatment, e.g. androgen deprivation therapy. **Conclusion:** PMSA PET/CT revealed metastatic disease in 46% of high-risk patients with no definitive metastases on SoC imaging and led to change of patient management in 38% of patients. **References:** None

Investigation of 68-Ga PSMA PET and Multiparametric MRI imaging Radiomics based models in the prediction of ISUP score in prostate cancer patients

G. Feliciani¹, A. Savini¹, G. Bellomo¹, M. Celli¹, F. Ferroni¹, E.

Menghi¹, M. Costantini², D. Barone¹, A. Sarnelli¹, G. Paganelli¹;

¹Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, ITALY, ²Departement of Pathology Azienda Ospedaliera-Universitaria Policlinico di Modena, Modena, ITALY.

Aim/Introduction: The present study proposes a new model for predicting Epstein ISUP/WHO grade groupe based on the analysis of textural features on T2w, ADC and 68-Ga PSMA PET images. The first objective is to investigate the diagnostic performance of textural features to distinguish between well-differentiated and poorly differentiated forms and to improve accuracy of low-risk prostate cancer patients stratification. **Materials and Methods:** In this retrospective study, a dataset of T2w (MRI), ADC (MRI) and 68Ga-PSMA-PET images from 20 patients was analyzed. After the prostatectomy, the Pathology provided us with confirmation of histological diagnosis though Gleason score and ISUP/WHO grade group for each lesion. Therefore, we analysed 40 prostate lesions in T2w, ADC and 68GaPET images. Multiple patient lesions were treated as standalone after performing their direct comparison between histology and imaging location. The PIRADS associated to the patients by radiologists was assigned to the patient's corresponding lesions in MRI. All the MRI images were acquired in our department on a Philips Ingenia 3T MR scanner. All MRI study protocols included T2w sequences in the axial, coronal and sagittal plane and Apparent Diffusion Coefficient (ADC) maps, derived by DWI sequences, with *b* ranging from 0 to 1000. Patients injected with 68Ga-PSMA were then imaged on a PET/CT scanner. First-order, second-order and higher order imaging features were extracted with the open source software Lifex Ver 5.10 from each imaging modality contours. LASSO algorithm was used to select the best performing features in order to build an internally cross-validated statistical model. **Results:** Features extracted employing LASSO algorithm were used to build a model for each imaging modality. All the models were cross validated with 5-fold cross validation. The 68-Ga-PET-based model is based on a decision tree composed of 2 features (3rd Quartile of SUV histogram and Entropy) with a final accuracy of 80% to discriminate low-grade forms of prostate cancer with ISUP/WHO grade groupe 1 from others. The ADC-based model is a linear discriminant

with an accuracy of 82% employing 3 features (mean, entropy and zone uniformity). Finally, the T2w-based model, another linear discriminant, produced an accuracy of 74% employing entropy and zone uniformity. **Conclusion:** The results of this study are in line with previous published data on the prediction power of ADC sequences. PET-PSMA in combination with MRI techniques can improve accuracy in diagnosis and patient treatment stratification. **References:** None

⁶⁸Ga-PSMA PET/CT for Primary Staging of High-Risk Prostate Cancer: A High-Volume Center Study

S. Klingenberg^{1,2,3}, M. R. Jochumsen^{1,2}, B. P. Ulhøi⁴, J. Fredsøe^{2,3}, K. D. Sørensen^{2,3}, M. Borre^{2,5}, K. Bouchelouche^{1,2};

¹Department of Nuclear Medicine & PET-Centre, Aarhus University Hospital, Aarhus N, DENMARK, ²Department of Clinical Medicine, Aarhus University, Aarhus C, DENMARK, ³Department of Molecular Medicine, Aarhus University Hospital, Aarhus N, DENMARK, ⁴Department of Pathology, Aarhus University Hospital, Aarhus N, DENMARK, ⁵Department of Urology, Aarhus University Hospital, Aarhus N, DENMARK.

Aim/Introduction: We present the largest cohort of high-risk prostate cancer (PCa) patients undergoing ⁶⁸Ga-PSMA PET/CT for primary staging to date. We aimed to investigate the metastatic spread of PCa and the relation to primary tumor ⁶⁸Ga-PSMA uptake and the D'Amico classification. Furthermore, we described the undetected lymph node metastases (LNMs) in the primary staging setting. **Materials and Methods:** We assembled a cohort of 691 consecutive newly diagnosed, D'Amico high-risk PCa patients primary staged by ⁶⁸Ga-PSMA PET/CT from April 2016 to March 2019 at our facility. PSMA maximum standardized uptake value (SUV_{max}) and advanced disease findings were compared to the traditional stratification parameters PSA level, International Society of Urologic Pathology (ISUP) grade, and clinical stage. In addition, ⁶⁸Ga-PSMA PET/CT findings were compared with lymph node histology in radical prostatectomy patients. Furthermore, six undetected lymph nodes above 5.0 mm in size was immunohistochemically stained with anti-PSMA. **Results:** Advanced disease (N1/M1) was observed in 35.3% of patients (244/691) and was associated with increasing PSA levels, ISUP grades, and clinical stages. Advanced disease frequencies in patients with ISUP grade 2 and 3 were 10.8% (11/102) and 37.1% (33/89), respectively, yet the risk of advanced disease for cT2a/cT2b/cT2c tumors were almost equal (24.2%, 27.9%, and 22.4%, respectively). We observed a weak positive correlation between SUV_{max} and biopsy ISUP grade ($\rho = 0.21$; $p < 0.001$) and a modest positive correlation between SUV_{max} and post-prostatectomy ISUP grade ($\rho = 0.38$; $p < 0.001$). The area under the receiver operating characteristic curve for SUV_{max} to predict ISUP grade ≤ 2 or > 2 was 0.65

(95% CI 0.56 to 0.74). With an optimal cut-off of SUV_{max} of 11.4, the sensitivity and specificity were 51.2% and 77.4%, respectively. Sensitivity, specificity, positive and negative predictive value, and accuracy for LNMs detection on ⁶⁸Ga-PSMA PET/CT were 30.6%, 96.5%, 68.8%, 84.5%, and 83.1%, respectively. Undetected LNMs were either micrometastases located in the border of the lymph node cortex or had no PSMA expression. **Conclusion:** We identified advanced disease in 35.3% of high-risk PCa patients at diagnosis in this cohort with ISUP grade being the superior predictor of advanced disease at diagnosis. Likewise, we observed a major difference in frequency of advanced disease between ISUP grade 2 and 3, which supports the subdivision of Gleason Score 7. However, no significant differences in risk when comparing the different cT2 stages were demonstrated. The undetected LNMs on PSMA PET/CT were either PSMA-negative or micrometastases. **References:** None

OP-923

The impact of dual time point ⁶⁸Ga-PSMA PET/CT imaging on PSMA uptake of primary tumor in prostate cancer

D. Has Simsek;

Istanbul University, Istanbul Faculty of Medicine, Istanbul, TURKEY.

Aim/Introduction: The goal of this study was to investigate the impact of early and late ⁶⁸Ga-PSMA PET/CT on PSMA uptake of primary tumor in prostate cancer (PCa). **Materials and Methods:** A total of 313 patients who were performed 1h. and 2h. ⁶⁸Ga-PSMA PET/CT scan for staging PCa were enrolled to this study. Median PSA was 13.59 ng/ml (X-X ng/ml) and median Gleason score (GS) was 8 (6-10). All clinical and histopathological data were documented. Early and late ⁶⁸Ga-PSMA PET/CT scans were interpreted, and PSMA uptake in primary tumors were recorded separately by using SUVmax value based on the guidance of TRUS biopsy results. SUVmax values were correlated with GS. Statistical analysis was performed for patients who had increased PSMA in primary tumor on both 1h. and 2h. scans and more than 10% differences in primary tumor SUVmax value between 1h. and 2h. scans. SPSS version 24 was used for analyses. **Results:** According to histopathological results, 32 patients had GS:6, 114 patients had GS:7, 75 patients had GS:8, 92 patients had GS:9-10 tumors. Increased PSMA uptake in primary tumor was detected in 295 (94.2%) patients, while 18 patients (5.8%) had no PSMA uptake in primary tumor in 1h. or 2h. ⁶⁸Ga-PSMA PET/CT imaging. PSMA uptake in primary tumor was increased in late imaging in 239 patients (76.4%), and in 158 of them (50.4%) the difference was more than 10%. In remaining 74 (23.6%) patients, PSMA uptake in primary tumor was decreased in late imaging and in 33 of them (10.5%) the difference was more than 10%. There was no statistical correlation between the differences of

SUVmax values and GS (Pearson $r = -0.125$; $p = 0.084$). GS and SUVmax values were correlated for both early ($p < 0.001$) and late ($p < 0.001$) imaging, according to Kruskal Wallis test. However, no statistical differences was found in SUVmax values between GS:3+4 and GS:4+3 patients for both 1h. ($p = 0.192$) and 2h. imaging ($p = 0.117$). **Conclusion:** Our results shows that early and late PSMA uptake in primary tumor is varied independently from GS, and mostly increased in late ⁶⁸Ga-PSMA PET/CT imaging. PSMA uptake in primary tumor were well correlated with GS for dual time point imaging. **References:** None

Diagnostic performance of the novel PSMA-specific PET radiotracer [F-18]siPSMA-14 in staging and restaging of prostate cancer

J. Miksch¹, V. Prasad¹, D. DiCarlo², F. Zengerling³, C. Bolenz³, C. Solbach¹, M. Beer⁴, T. Wiegeler⁵, H. J. Wester², A. J. Beer¹;

¹Department of Nuclear Medicine, University Hospital Ulm, Ulm, GERMANY, ²Pharmaceutical Radiochemistry, Technical University Munich, Garching, GERMANY, ³Department of Urology and Pediatric Urology, University Hospital Ulm, Ulm, GERMANY, ⁴Department of Radiology, University Hospital Ulm, Ulm, GERMANY, ⁵Department of Radiation Oncology, University Hospital Ulm, Ulm, GERMANY.

Aim/Introduction: F-18 labelled Prostate Specific Membrane Antigen (PSMA) radiotracers offer logistic and potential diagnostic advantages over Ga-68 PSMA. We evaluated the diagnostic performance of the novel F-18-labelled silicone fluorine acceptor based PET radiotracer [F18]siPSMA-14 in staging and restaging of patients with prostate cancer (PCa). **Materials and Methods:** 108 PCa patients (70 ± 7 y; GS 69) referred for PET/CT at our center were retrospectively analyzed. The indications for PET/CT were primary staging ($n = 21$); restaging due to biochemical recurrence (BCR) ($n = 57$) or progressive disease under systemic therapy ($n = 30$). Median PSA value of patients referred for primary staging was 8.7 (2.36 - 1000) ng/ml and for restaging 1.06 (0.02 - 1500) ng/ml. PET/CT images were acquired 90 minutes after i.v. injection of [F18]siPSMA14 (345.8 ± 9.1 MBq, without furosemide) with contrast enhanced CT scans from head to mid-thigh, if not contraindicated. **Results:** In primary staging, all biopsy proven primary prostate cancer lesions were visualized (21/21). In 33% (7/21) of the patients metastatic findings occurred: lymph node metastases in 33% (7/21) and bone metastases in 24% (5/21). The overall detection rate in patients referred for restaging was 84% (73/87). In the PSA subgroup analyses (0-0.5 ng/ml, 0.5-2 ng/ml, 2-10 ng/ml and > 10 ng/ml) detection rates were 61% (17/28), 88% (24/26), 93% (13/14) and 100% (19/19) respectively. In patients referred for restaging, the frequency of local recurrence, lymph node metastases and bone metastases was 45% (39/87), 62% (54/87), and 37

% (32/87) respectively. Low bladder activity provided an excellent contrast for visualization of lesions in the prostate bed. **Conclusion:** The novel [F18]siPSMA14 PET radiotracer showed high detection rates comparable to the reported data of other Ga-68 and F-18 labelled PSMA radiotracers with the advantage of a low urinary excretion and low bladder activity even without administration of furosemide.

Role of [¹⁸F]FDG-PET/CT in the diagnosis of spondylodiscitis

R. Vigliani, R. Zanca, A. Marciano, F. Bartoli, P. Erba, E. Lazzeri; Regional Center of Nuclear Medicine, Department of Translational Research and New Technology in Med, Pisa, ITALY.

Aim/Introduction: Spine can be infected by pathogens through haematogenous spread (primary spondylodiscitis (SD)) or directly by contiguous tissues (secondary SD). Diagnosis of SD is based on clinical, laboratory and imaging findings. We evaluated the role of [¹⁸F]FDG-PET/CT, comparing with MRI, in primary and secondary SD diagnosis. **Materials and Methods:** Forty patients (pts), (14 women, 26 men; mean age 66±13 years) with suspected SD (26 primary and 14 secondary) presented back pain and increased flogosis indexes. All pts were retrospectively evaluated with [¹⁸F]FDG-PET/CT and MRI, performed within 30 days. 10/40 pts were ongoing antimicrobial treatment. Qualitative analysis of [¹⁸F]FDG- PET/CT was used, [¹⁸F]FDG uptake patterns were scored in 5 Hungenbach grades, grade 0 and 1 (normal or slightly enhanced uptake of FDG in the inter/ paravertebral region) were negative for infection, score 2 (clearly enhanced uptake of [¹⁸F]FDG with linear or disciform pattern in the intervertebral space) was consistent with discitis, scores 3 and 4 (enhanced uptake of [¹⁸F]FDG with linear or disciform pattern in the intervertebral space with the involvement of adjacent vertebrae or paravertebral tissues) were consistent with SD. Final diagnosis was based on microbiological culture and/or clinical follow-up for at least 10 months. Statistical analysis was performed using McNemar's test and MedCalc. **Results:** 33 pts had spine infection (8/33 with positive microbiological culture, 25/33 with clinical follow-up diagnosis), 7 pts were not infected. In primary SD [¹⁸F]FDG-PET/CT showed positive results in 22 pts (22 TP, 0 FP) and negative results in 4 pts (3 TN, 1 FN), MRI showed positive results in 25 pts (23 TP, 2 FP) and negative results in 1 pt (1 TN, 0 FN). [¹⁸F]FDG-PET/CT

and MRI showed the same diagnostic accuracy of 88%. In secondary SD [¹⁸F]FDG-PET/CT showed positive results in 10 pts (10 TP, 0 FP) and negative results in 4 pts (4 TN, 0 FN), MRI showed positive results in 4 pts (4 TP, 0 FP) and negative results in 10 pts (4 TN, 6 FN). The diagnostic accuracy of [¹⁸F]FDG-PET/CT was 100% and of MRI was 57%. McNemar's test was P=0.25. **Conclusion:** Despite the small number of patients population, our data confirm that MRI is the imaging of choice in patients with primary SD and [¹⁸F]FDG-PET/CT should be performed in pts with contraindications to MRI. [¹⁸F]FDG-PET/CT shows higher diagnostic accuracy in secondary SD compared with MRI, confirming its crucial role in the diagnostic algorithm of secondary SD in adults.

⁶⁴Cu-DOTA-Ubiquicidin 29-41 PET/CT in patients with suspected infectious process: Initial experience in a single center in Mexico

O. Garcia-Perez^{1,2}, P. Munguia¹, H. Valdovinos¹, J. Vargas-Ahumada¹, F. Lemus¹, I. Soldevilla¹, N. Becerra¹, M. Acuña³; ¹Instituto Nacional de Cancerología, Mexico City, MEXICO, ²Imagenus - Diagnostics in Healthcare, Mexico City, MEXICO, ³Clinica FOSCAL, Bucaramanga, COLOMBIA.

Aim/Introduction: Molecular imaging has played a very important role in the management of infectious processes, the development of antimicrobial peptides such as ubiquicidine (UBI29-41) a fragment of a cationic synthetic peptide capable of binding to the anionic microbial cell membrane that has allow to improve decision making. In conventional nuclear medicine, radiolabelling is done with ^{99m}Tc with quite encouraging results, however, in the field of PET/CT, ⁶⁸Ga has been used but its short half-life limits the acquisition of late images, the use of radiometals with favorable physical and chemical characteristics such as Cooper ⁶⁴(⁶⁴Cu) (T 1/2 = 12.7 hrs; beta+: 17.6%) allows an efficient and accessible alternative for the study of infectious processes by molecular imaging. **Materials and Methods:** Fourteen patients were included in a period between November 2019 and March 2020 with suspected infectious process in the extremities. PET/CT was performed 4 hours after intravenous injection of 5 mCi of ⁶⁴Cu-DOTA-UBI 29-41. All patients were cultured after the PET study. ⁶⁴Cu was produced in a IBA twin cyclotron, wich was produced in a silver disk wich was electroplated into solid target (Nirta Solid Target), the purity of the radiopharmaceutical was corroborated with HPLC analysis and mass spectrometry. **Results:** 9 women and 5 men were included, mean age was 45 years (+/-8,2). 9 patients were positive by ⁶⁴Cu DOTA UBI 29-41 and 8 by culture, the most commonly bacteria found was staphilococcus epidermidis (n=5), escherichia coli (n=2), pseudomonas aeruginosa (n=1). The mean SUV_{max} for the positive studies by culture and by PET was 1.6 (+/-

0.65), compared to 0.33 (+/-0.57) of the negative studies for infectious process. When estimating the lesion/background ratio in the patients with a positive study, the mean SUVmax was 4.58 (+/-5.2) compared to 0.95 (+/-1.0) for patients with a negative study. ROC curves were performed to estimate the cutoff values between positivity and negativity using SUVmax values and lesion/background ratio, finding a statistically significant association of 1.2 (p 0.02) and 1.5 (p 0.003) respectively. The false positive by PET was secondary to a recent surgical intervention with high inflammatory reaction. **Conclusion:** Imaging of UBI 29-41 radiolabeled with ^{64}Cu is a reliable alternative to assess active infectious processes, it allows us to define the infection sites with better spatial resolution, also the ability to acquire late images can improve the lesion/background ratio. **References:** None

OP-927

Could Hypermetabolism of the spleen or bone marrow improve the FDG-PET/CT diagnosis of Infective Endocarditis as indirect signs?

M. Gazzilli¹, D. Albano², E. Cerudelli¹, A. Mazzoletti³, F. Dondi³, P. Bellini³, F. Bertagna², R. Giubbini²;

¹Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY, ²Università di Brescia e Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY, ³Università di Brescia, Brescia, ITALY.

Aim/Introduction: In the latest update of the European Society of Cardiology (ESC) [18F]FDG-PET/CT are been included in the diagnostic flow chart for the management of infective endocarditis (IE). FDG-PET may provide direct but also indirect signs of infections and/or inflammation, notably a diffuse increase in spleen and/or bone marrow (BM) uptake. In fact, the host defence against IE involves the activation of polymorphonuclear cells, macrophages and lymphocytes leading to an increase in the glycolytic metabolism, which could be documented in BM and spleen. The aim of our study was to determine whether hypermetabolism of the spleen and/or BM (HSBM) could help in the FDG-PET-based diagnosis of IE. **Materials and Methods:** We included 108 patients who underwent 18F-FDG-PET/CT scan for suspicious of IE, all patients were prepared with a low carbohydrate, high fat and high protein diet. Nine patients were excluded because PET/CT's visual analysis demonstrated other inflammatory diseases. PET/CT images were analysed qualitatively, by experienced physicians, and semi-quantitatively by measuring maximum and mean Standardized Uptake Value (SUVmax and SUVmean) of the suspected valve lesion and liver by a ROI in the right lobe, SUVmean of the spleen was obtained from a ROI positioned in the center of the spleen and SUVmean of the BM was obtained from a ROI on the bodies of the five lumbar vertebrae. BM and spleen SUVmean

values were normalized to those of the liver, and HSBM was defined as a BM or spleen-to-liver ratio >1. **Results:** Among the 99 patients enrolled in the study, 54 had a clinical final diagnosis of IE. HSBM was a predictor of IE (p <0,05), independently of the criterion of abnormal cardiac FDG uptake. A definite IE was documented in 83% (40/48) of patients showing both HSBM and abnormal cardiac uptake, 44% (4/9) of patients with only abnormal cardiac uptake, 28% (9/32) of patients with only HSBM and 10% (1/10) of patients with neither one. **Conclusion:** Our preliminary results demonstrated that HSBM is good indirect sign of IE and could strengthen the suspicion of IE, especially in the absence of any other infections, inflammatory or malignant disease. **References:** None

OP-928

A Qualitative Assessment System Proposed to Improve the Diagnosis of Infective Endocarditis with 18F-FDG PET/CT

M. Gazzilli¹, D. Albano², E. Cerudelli¹, A. Mazzoletti², F. Dondi², P. Bellini², F. Bertagna², R. Giubbini²;

¹Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY, ²Università di Brescia, Brescia, ITALY.

Aim/Introduction: Infective Endocarditis (IE) is a disease associated with high mortality rate and highly variable clinical history. ^{18}F -FDG-PET/CT was introduced in the latest update of the European Society of Cardiology (ESC) guidelines as a new tool for the diagnosis of IE, especially in patients with prosthetic valve and Implanted Cardiac Device (ICD). The use of a simple qualitative criteria with good interpreter reliability, easy reproducibility and good diagnostic performance will be of immense value in the diagnosis of this disease; for this reason we proposed a 3-point score, similar to Deauville score to estimate the accuracy of 18F-FDG PET/CT in detecting IE. The aim of our study was to evaluate the value of this 18F-FDG PET/CT-based interpretation system to assess the diagnosis of IE and to validate the reproducibility of this criterion. **Materials and Methods:** We retrospectively included 108 patients (M:F=57:51, mean age 62 years, range 18-88) who underwent ^{18}F -FDG-PET/CT for suspected IE. After clinical assessment and echocardiographic exams, the patients underwent to FDG PET/CT imaging after adequate preparation to reduce the physiological myocardial uptake of ^{18}F -FDG (a low carbohydrate, high protein, high fat (LCHPHF) diet starting 72 hours prior the scan). PET/CT scans were interpreted by two nuclear medicine physicians with experience in this field and were evaluated according to a 3-point scale like-Deauville score criteria (score 1=uptake in suspect lesion lower than blood-pool activity; score 2=uptake higher than blood-pool but lower than liver activity; score 3=uptake higher than liver). PET/CT was considered positive when like-Deauville score 3; negative like-Deauville score

1 and 2. Inter-reader variability was assessed using percent agreement and kappa statistics. **Results:** Of the 108 patients enrolled in the study, 54 had a clinical final diagnosis of IE. Comparing the score criteria results with the clinical final diagnosis the sensitivity, specificity, positive predictive value, negative predictive value and accuracy of like Deauville score criteria were 92.8% [95% confidence interval (CI) 82.7–98%), 80.7% (95% CI 67.4–90.3%), 83.8% (95% CI 74.7–90.1%), 91.3% (95% CI 80.1–96.4%) and 87% (95% CI 79.2–92.7%), respectively. There was a high agreement between the two readers applying our criteria ($k=0.902$). **Conclusion:** The proposed 3-point scale criteria is a simple, qualitative method with substantial inter-interpreter agreement and high positive predictive value and accuracy, and may have a significant impact in the diagnosis of IE with PET/CT. **References:** None

OP-929

Identification Of Brain 18F-FDG PET Metabolic Profile Of Encephalitis In Patients With Infective Endocarditis (IE): Relationships With Clinical/Biological Features And Prognosis

M. Philip, E. Kaphan, L. Tessonnier, M. Mulatero, S. Cammilleri, F. Gouriet, J. Casalta, S. Hubert, A. Riberi, G. Habib, E. Guedj; Hôpital La Timone, Marseille, FRANCE.

Aim/Introduction: IE is associated with severe morbidity and mortality. ^{18}F FDG PET/CT is now included in ESC Guidelines for the IE positive diagnosis and peripheral complications detection. Among them, cerebral damages are frequent and break IE's prognosis. We observe strokes, hemorrhages, abscesses, usually diagnosed by MRI. In addition, some patients present with an impairment of cognitive or psychomotor functions, consistent with encephalitis, and inconsistent findings on brain morphological imaging. ^{18}F FDG PET is increasingly used for the diagnosis and the follow-up of encephalitis, with a specific metabolic profile characterized by global hypometabolism possibly associated with hypermetabolism of striata and of the medial temporal cortex. The primary objective of this study is to describe the metabolic brain PET profiles of patients with IE. We secondarily aim at determining the relationships between the PET profile of encephalitis and clinical/biological features and the prognosis. **Materials and Methods:** From November 2017 to July 2019, all patients admitted in the Cardiology Department of Timone Hospital in Marseille for IE suspicion were included and benefitted from a global evaluation and a whole-body PET including cerebral study. A first visual analysis was performed in order to determine the several brain metabolic profiles. Then we performed a quantitative whole-brain voxel-based analysis using SPM12, searching for correlation between cerebral metabolic rate of glucose and rate of C Reactive Protein using multiple comparison correction Family Wise Error method ($p\text{-voxel}<0.05$), and

secondarily with clinical/biological features. **Results:** Were included 129 patients, among which 97 with definite IE according to an Expert Consensus were analyzed. Cerebral PET visual analysis permitted the identification of usual complications in 57 patients, already highlighted by morphological imaging, and mostly a new metabolic profile in 21 patients consistent with encephalitis. In quantification analysis, hypermetabolism of the left medial temporal was correlated with CRP increase. This quantitative metabolic profile of encephalitis was statistically ($p<0.05$) associated with clinical (age, neurological events history), biological (particularly inflammatory syndrome), microbiological (Staphylococcus aureus infections) features and prognosis events such as embolism. A positive trend is revealed as well concerning mortality (OR 2.23). **Conclusion:** This study describes, for the first time, cerebral ^{18}F -FDG PET/CT findings in a cohort of patients with suspected IE. We reveal in a proportion of these patients a metabolic brain PET entity similar to those reported in encephalitis, correlated to clinical/biological features and prognosis. Further studies will be needed to specify the possible impact on the clinical management of these patients. **References:** None

Aim/Introduction: This explanatory study aimed at determining whether the detectability of infective endocarditis (IE) on ^{18}F -fluorodesoxyglucose Positron

Emission Tomography (FDG-PET) images is enhanced when recorded with an ECG-triggered cine mode (gated-PET). Conventional FDG-PET exams are poorly sensitive for detecting IE, which may be partly explained by the small size and high mobility of certain IE foci. **Materials and Methods:** Twenty-eight patients, 15 of whom had a cardiac prosthesis, and all having undergone a 10-min cardiac gated-PET recording after a whole-body FDG-PET in 4 centers involved in a multicenter IE study, were included. Static-PET images, as well as the gated-PET images reconstructed with an additional temporal Fourier filter, were analyzed by three blinded observers with the additional diagnostic criterion that the FDG-activity from IE foci should be nearly constant during cardiac contraction at gated-PET, contrary to myocardial areas of FDG-uptake. **Results:** IE was ultimately classified as definite in 19 cases, possible in 6 and rejected in 3. In these 3 groups, the pooled observers' rates of a positive PET for IE were respectively 44%, 11% and 0% with static-PET, compared to 70%, 39% and 0% with gated-PET ($P < 0.001$). Gated-PET but not static-PET was positive for IE in 6 patients, whereas the converse was observed in none. At gated-PET, the FDG foci of definite IE exhibited a high mobility with systole-to-diastole displacements ranging from 6 to 18 mm (mean: 11 ± 4 mm), and their mean activities, expressed relative to blood activities at end-diastole (2.48 ± 0.96) and end-systole (2.60 ± 1.02), were higher than corresponding values from static-PET images (2.05 ± 0.89 , both $P < 0.005$). **Conclusion:** The detectability of IE is markedly enhanced for cardiac FDG-PET images displayed in an ECG-triggered cine mode and reconstructed with an adapted temporal filtering, in keeping with lower image blurring and with an easier differentiation from areas of myocardial FDG uptake. **References:** None

Diagnostic Performance Of 18FDG-PET/CT In Discriminating Patients With/Without Cardiac Implantable Electronic Device Infection: A Case-Control Study

R. Mei¹, V. Marinelli², R. Bonfiglioli¹, L. Calderoni¹, G. Massaro², S. Fanti¹, I. Diemberger²;

¹Nuclear Medicine Policlinico S.Orsola-Malpighi, Bologna, ITALY, ²Cardio-Thoracic and Vascular Building, Department of Experimental, Diagnostic and Specialty Medicine, Bologna, ITALY.

Aim/Introduction: Diagnosis of cardiac implantable electronic device infection (CIEDI) represents a real challenge for clinicians, radiologists and nuclear physicians. Modified Duke criteria gained higher accuracy with recently implementation of ¹⁸F-FDG-PET/CT scan in the diagnostic management for suspected CIEDI. However, literature data about its real efficacy is still lacking. We aimed to explore the potential role of ¹⁸F-FDG-PET/CT in general, asymptomatic CIED population, expanding this procedure to patients

with CIED and without a suspected infection of the device. **Materials and Methods:** We have retrospectively analyzed 68 patients (Group 1, G1) with CIED who underwent ¹⁸F-FDG-PET/CT scan (corrected for attenuation) for different reasons than suspected CIEDI (i.e. oncology or non-cardiovascular infection). A second control-group of 105 patients (Group 2, G2) with confirmed CIEDI who underwent ¹⁸F-FDG-PET/CT prior to transvenous lead extraction (TLE) was considered. For both Group 1 and 2 general population characteristics, along with maximum standardized uptake value (SUVmax) and target to background ratios (TBRs) related to pocket, leads and heart were collected. Clinical outcomes (mortality and all-cardiovascular complications) were also evaluated with an up to 3 years follow-up. **Results:** 9/68 patients (13.2%) in G1 had an ¹⁸F-FDG-PET/CT report suspected for CIEDI. SUVmax on pocket and leads, as well as pocket/blood pool TBR, were statistically superior than G1 negative scans. Of positive G1 patients, no one developed CIEDI or any cardiovascular complications at follow-up. In pocket and/or lead SUVmax cut-off value of 3.5 (corresponding to 25th percentile with 82/105 patients, 79%) was assessed for G2 and then applied to G1. 14/68 patients (20%) of G1 had pocket and/or lead SUVmax higher than 3.5. According to these figures use of a cut-off value of 3.5 for SUV max in patients with suspect of CIEDI seems to provide an acceptable diagnostic performance with a sensitivity of 80% and a specificity of 79%. **Conclusion:** ¹⁸F-FDG-PET/CT in patients with CIED demonstrated a potential key-role in detecting possible asymptomatic or silent infection of the device with round to 80% of sensibility and specificity. This procedure might be useful to rule out the possibility to assess early diagnosis of CIEDI in patients without any other diagnostic standard (imaging or laboratories) tool or even asymptomatic. **References:** None

OP-932

Semiquantitative Analysis Of 18F-FDG PET/CT Results In Patients With Cardiac Implantable Electronic Device Infection

D. Pursanova, I. P. Aslanidis, O. V. Mukhortova, I. V. Shurupova, I. V. Ekaeva, T. A. Trifonova, D. A. Popov;

A.N. Bakulev Scientific Center for Cardiovascular Surgery of the Ministry of Health of the Russian F, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: to investigate the semi-quantitative assessment of 18F-fluorodeoxyglucose (18F-FDG) PET/CT in patients with infection of cardiac implantable electronic devices (CIED) and without it. **Materials and Methods:** The analysis included results of 18F-FDG PET/CT examinations performed in 50 patients (54+16 y.o.) with CIED (32+27 months after implantation) - with surgically confirmed infection (n = 20) and with malignancies used as control group (n = 30). PET/CT results were assessed visually

and semi-quantitatively with calculation of parameters of 18F-FDG uptake intensity - SUVmax and SUVratio - in whole device, pocket, extra- and intracardiac portions of leads. SUVratio was calculated as SUVmax in the CIED to SUVmean in the reference zone - aorta, liver and lung. **Results:** Visual analysis of PET/CT results revealed abnormal 18F-FDG uptake in all patients with CIED infection (n = 20) in different regions of interest: in pocket (n = 8), along extra- (n = 15) and intracardiac (n = 9) portions of leads. In control group (n = 30) 18F-FDG uptake was normal in all 90 regions of interest (n = 30 in each). In semiquantitative analysis all parameters - SUVmax and three types of SUVratios - in the CIED pocket and extracardiac portion of leads were higher in patients with confirmed infection, compared to patients without it (p<0.05). Along intracardiac portion of leads two types of SUVratios (using aorta and liver) were higher in patients with confirmed infection (p<0.02), but there was no statistical difference in the SUVmax and SUVratio using lung parenchyma (p>0.05). ROC-curve analysis for optimal thresholds of SUVmax and three types of SUVratios for the diagnosis of CIED infections (for whole device) by PET/CT was performed: SUVmax = 3.3 (AUC = 0.847), SUVratio (aorta) = 1.8 (AUC = 0.947), SUVratio (liver) = 1.2 (AUC = 0.881), SUVratio (lung) = 6.8 (AUC = 0.783). **Conclusion:** According to the obtained data visual analysis in combination with semi-quantitative assessment of 18F-FDG PET/CT images showed a good diagnostic performance in the detection of CIED infection. 18F-FDG uptake around non-infected CIED was low. SUVratio using aorta - in whole CIED, as well as in each of its various parts - pocket, extra- and intracardiac portions of leads - was found to give the greatest AUC. **References:** None

OP-933

PET-MRI in acute gastrointestinal graft versus host disease

W. Roll¹, G. Evers², P. Schindler³, R. Strotmann¹, B. Noto³, M. Masthoff³, M. Stelljes², M. Schäfers^{1,4};

¹Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY, ²Department of Medicine A, Hematology, Oncology and Pulmonary Medicine, University Hospital Münster, Münster, GERMANY, ³Institute of Clinical Radiology, University Hospital Münster, Münster, GERMANY, ⁴European Institute for Molecular Imaging, Münster, GERMANY.

Aim/Introduction: Allogeneic stem cell transplantation (alloSCT) is considered the only curative treatment option in numerous relapsed or refractory hematologic malignancies. Following alloSCT gastrointestinal Graft-versus-Host disease (GI-GvHD) is a common complication significantly increasing morbidity and mortality. There are only limited data on molecular (FDG-PET) or contrast enhanced (CE) morphological imaging assessment of GI-GvHD. The objective of this retrospective study was to further elucidate

the diagnostic value of a combined FDG-PET/MR approach in patients with acute GI-GvHD. **Materials and Methods:** Between 2/2015 and 2/2019, 21 patients with suspected acute GI-GvHD underwent FDG PET-MRI. PET- (dataset 1), contrast enhanced MRI- (dataset 2) and PET-MR datasets (dataset 3) were independently reviewed by two nuclear medicine physicians (dataset 1 and 3) and two radiologists (dataset 2 and 3). In case of disagreement a consensus reading was performed. Readers assessed the certainty of the diagnosis on a 5-point likert scale (from "1=definitely no GvHD" to "5= definitely GvHD") and the number of affected segments of the lower GI-tract. Semi-quantitative (number of affected segments) and quantitative PET-parameter (SUVmax, SUVpeak and metabolic volume (MV)), as well as quantitative parameters from CE-MRI (wall thickness) were correlated with clinical parameters (stage and grade of acute GvHD). **Results:** Likert scale values were significantly different between the tree datasets, underlining the higher reliability of imaging based diagnosis with PET-MR (median: 5; range: 4-5) compared to PET (median: 4; range: 2-5; p=0.007) and compared to MRI (median: 4; range: 3-5; p=0.002). The correlation between affected segments in PET-MRI ($r_s=0.677$; p=0.001) and MV ($r_s=0.692$; p=0.001), to clinical stage were significant. SUVmax ($r_s=0.345$; p=0.14), SUVpeak ($r_s=0.276$; p=0.24) and wall thickening ($r_s=0.174$; p=0.17) did not show any significant correlation to clinical stage. **Conclusion:** Combined FDG PET-MRI contributes to a more sensitive detection and a more reliable diagnosis of acute GI-GvHD compared to single PET or MRI. Metabolic volume adds information indicating the clinical severity of acute GI-GvHD. Before implementation into clinical routine, FDG-PET-MRI should be further evaluated in prospective studies. **References:** None

Association between residual FDG metabolic activity and CT features of active tuberculosis on end-of-treatment [¹⁸F]F-FDG PET/CT in patients treated for pulmonary tuberculosis

I. Lawal^{1,2}, M. Mathebula³, I. Moagi³, T. Lengana¹, N. Moeketsi³, M. Nchabeleng³, G. Popoola⁴, C. Hikuam⁵, E. Douglass⁶, J. Ellner⁶, M. Hatherill⁵, B. Fourie¹, M. Sathekge¹;

¹University of Pretoria, Pretoria, SOUTH AFRICA, ²Nuclear Medicine Research Infrastructure (NuMeRI), Pretoria, SOUTH AFRICA, ³Sefako Makgatho University of Medical Science, Pretoria, SOUTH AFRICA, ⁴University of Ilorin, Ilorin, NIGERIA, ⁵University of Cape Town, Cape Town, SOUTH AFRICA, ⁶Boston University, Boston, MA, UNITED STATES OF AMERICA.

Aim/Introduction: Residual metabolic activity (RMA) on [¹⁸F]F-FDG PET/CT in the lungs of patients treated with a standard course of anti-tuberculous therapy (ATT) and declared cured based on the current standard of care including negative culture has been shown to be predictive

of disease relapse. Certain CT features including nodules, consolidation, and pleural effusion are also known to be suggestive of active pulmonary tuberculosis (PTB). We aimed to determine the association between RMA on PET and CT features of active tuberculosis in patients who completed a standard course of ATT for PTB. **Materials and Methods:** We prospectively recruited patients who completed a standard course of ATT and were declared cured based on clinical and microbiological assessments. All patients underwent [^{18}F]-FDG PET/CT within two weeks of completing ATT. We determined the proportion of patients who had RMA in the lungs as well as CT features suggestive of active PTB including lung consolidation, pulmonary nodules, lung changes in tree-in-bud pattern, hilar/mediastinal lymphadenopathy, and pleural effusion. We determined the association between RMA and CT features of active PTB. **Results:** A total of 75 patients with a mean age of 30.09 ± 10.49 years were included. There were 47 males and 50 patients were HIV-infected. Forty-one patients had RMA. No significant difference in the prevalence of RMA in patients with HIV versus those without ($p=0.01$). Nodules, consolidation, tree-in-bud pattern, lymphadenopathy, and pleural effusion were seen in 53, 10, 29, 17, and 2 patients, respectively. CT features of active PTB that were significantly more prevalent among patients with RMA were nodules (Odds ratio, OR=10.41; $p<0.001$), consolidation (OR=9.28, $p=0.018$), tree-in-bud pattern (OR=30.86, $p<0.001$), and lymphadenopathy (OR=3.48, $p=0.040$). The Odds of having RMA in any patient with the combined CT features of active PTB was 24.97 (95%CI: 6.39 - 97.56), $p<0.001$. **Conclusion:** Residual FDG metabolic activity, a risk factor for relapse, is prevalent in the lungs of patients considered cured for PTB based on the current standard of care. There is a strong association between RMA and CT features suggestive of active PTB. **References:** None

OP-935

Visual 4-point scoring scale improves the yield of FDG PET/CT in the diagnosis of cyst infection in patients with autosomal dominant polycystic kidney disease

P. Lovinfosse, M. Neuville, A. Jadoul, F. Jouret, R. Hustinx;
CHU of Liege, Liege, BELGIUM.

Aim/Introduction: FDG PET/CT proved useful in the diagnosis of cyst infection (Cyl) in patients with autosomal dominant polycystic kidney disease (ADPKD). However, the definition of Cyl by FDG PET/CT remains unclear. Here, we characterize the FDG uptake in case of Cyl in ADPKD patients in order to infer a visual 4-point diagnostic scale. **Materials and Methods:** All ADPKD patients who were hospitalized between 2007 and 2019 and who underwent an FDG PET/CT within the 14 days preceding or following their admission, were identified. All files were systematically reviewed. Cyl was defined on the basis of a constellation of 5 concomitant

criteria: (i) fever $\geq 38^\circ\text{C}$; (ii) abdominal pain; (iii) peak plasma C-reactive protein (CRP) levels ≥ 70 mg/L; (iv) no other cause of inflammation; and (v) favorable outcomes after antibiotics for ≥ 21 days. First, all FDG PET/CT images were classically studied by 2 board-certified physicians in nuclear medicine unaware of the clinical and biological parameters, independently of the initial diagnosis. Next, the uptake of FDG around the suspected Cyl was scored using a 4-point scale, in comparison to the physiological FDG blood-pool activity and liver uptake. ANOVA, Kruskal-Wallis test and Fisher exact test were used to compare clinical, (micro-) biological, and PET parameters between groups. Sensitivity, specificity, positive predictive value and negative predictive value of FDG PET/CT for the diagnosis of hepatic or renal cyst infection were calculated. The logistic regression was used to study the risk of cyst infection with respect to visual scale. Differences in P-values of less than 0.05 were considered statistically significant. **Results:** Sixty-one FDG PET/CT were performed for suspected Cyl in 39 ADPKD patients. The mean age was 59, with a man/woman ratio of 33/28 and a history of kidney transplantation or nephrectomy in 72.1% and 27.9% of cases, respectively. Among these, 30 episodes met the gold-standard criteria for Cyl. The first classical assessment of FDG PET/CT images reached a sensitivity of 74% and a specificity of 71%. Using the 4-point scale scoring system, the specificity of FDG PET/CT increased to 85%, with no significant change in sensitivity. **Conclusion:** In conclusion, the use of the visual 4-point visual scale of FDG uptake improves the specificity of FDG PET/CT in Cyl diagnosis in ADPKD patients, thereby reaching positive and negative predictive values of 79% and 78%, respectively. External validation is required. **References:** None

OP-936

Automated Quantification of Bowel ^{18}F -FDG PET/CT Uptake for Early Detection of Immune-Related Colitis in Cancer Patients Receiving Immune Checkpoint Inhibitors

D. Huff¹, H. Enamekhoo², S. B. Perlman³, R. Jeraj^{1,4};

¹Department of Medical Physics, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA,

²Department of Medicine, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA, ³University of Wisconsin Carbone Cancer Center, Madison, WI, UNITED STATES OF AMERICA, ⁴Faculty of Mathematics and

Physics, University of Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: Immune-related colitis (irColitis) is a common and clinically impactful side effect of immune checkpoint inhibitors that benefits from early detection to expedite appropriate intervention and avoid unintended complications. Our purpose was to develop a biomarker for the prediction of irColitis onset from standard of care ^{18}F -FDG PET/CT. **Materials and Methods:** We retrospectively analyzed ^{18}F -FDG PET/CT scans of 40 patients receiving

ipilimumab and/or nivolumab for melanoma, lymphoma, or lung cancer. A convolutional neural network was trained to segment the bowel (small and large intestine) from low dose CT and was used to quantify bowel ^{18}F -FDG uptake. SUV metrics extracted from the bowel (SUV_{max} , SUV_{mean} , $\text{SUV}_{\text{total}}$, percentiles of the SUV histogram) were compared to clinical diagnoses of irColitis confirmed with colonoscopy and biopsy. Differences in metric between irColitis and non-irColitis groups were assessed with Wilcoxon sign-rank tests and Receiver Operating Characteristic (ROC) analysis. **Results:** Immune-related colitis was clinically diagnosed in 7/40 (18%) of reviewed patients. The median time to clinical diagnosis was 140 days after treatment start (range: 13–302). The most predictive biomarker of irColitis was the 95th percentile of the bowel SUV histogram ($\text{SUV}_{95\%}$). Patients who later received a clinical diagnosis of irColitis had a significantly higher increase in $\text{SUV}_{95\%}$ from baseline to first on-treatment PET than patients who did not experience irColitis ($p=0.023$). ROC analysis revealed that an increase in $\text{SUV}_{95\%}$ of greater than +40% indicated pre-colitis bowel change with a sensitivity of 75% and specificity of 88%. For these patients, elevated bowel ^{18}F -FDG uptake was seen a median of 115 days prior to clinical diagnosis (range: 30–206). However, in 2/7 irColitis patients, the clinical diagnosis occurred prior to the first on-treatment PET. **Conclusion:** Increased ^{18}F -FDG uptake in the bowel is a useful early indicator of immune-related colitis in patients receiving immune checkpoint inhibitors. Although standard of care ^{18}F -FDG PET/CT scans obtained for response evaluation provided sufficient information for early prediction of irColitis, an earlier timepoint scan after treatment initiation might further improve the predictive power. **References:** None

EPS-170

Is It Safe Enough to Follow-up Patients Only with Post-therapy Whole-body Scan After PRRT?

T. Telli, M. Tuncel, P. Ozgen Kiratli;

Hacettepe University Faculty of Medicine, Ankara, TURKEY.

Aim/Introduction: There is an ongoing debate over the optimal post-peptide receptor radionuclide therapy (PRRT) imaging strategies. This study aimed to compare therapy response patterns of Ga-68-DOTATATE-PET/CT with post-PRRT whole-body scans (PT-WBS) and evaluate whether PT-WBS alone could play a decisive role in therapy response. **Materials and Methods:** Ga-68-DOTATATE-PET/CT and PT-

WBS images of 60 patients (F/M:32/28, median age: 60 (IQR: 51–69), median tumor grade: 2 (IQR: 1–2)) treated with at least two cycles of Lu-177-DOTATATE (37/60) or combination of Lu-177-DOTATATE and Y-90DOTATATE (23/60) were evaluated retrospectively. Ninety-four scan pairs of Ga-68-DOTATATE PET/CT and PT-WBS were compared for therapy response by three nuclear medicine physicians. SPECT/CT was also available in 23/94 (25%) pairs. Pre-therapy PET/CTs were compared with PETs obtained six weeks after the second cycle of PRRT and PETs obtained 8–12 weeks after four cycles. Similarly, PT-WBSs after the first therapy were compared with PT-WBSs after the second and fourth therapy. For response assessment, EORTC criteria for Ga-68-DOTATATE-PET/CT and tumor/background ratios for Lu-177-DOTATATE-WBSs (PT-WBSs) were used. Critical differences between PET/CT and PT-WBS responses causing a change in the management were recorded. Tumor grade, total number of lesions, tumor volume, total lesion Ga-68-DOTATATE uptake, SUVmax of the most avid lesion, size of the largest avid lesion on pre-therapy Ga-68-DOTATATE-PET/CTs were analyzed as baseline predictor factors for the critical difference. **Results:** There was a moderate agreement between PET/CT and PT-WBS responses (kappa value: 0.44, $p < 0.001$). Critical differences were seen in 9/60 (15%) patients. Among these nine patients, eight patients were classified as PD with PET/CT, while SD/PR was reported on PT-WBS. Lastly, one patient who had PR with low tumor burden with mild uptake on PT-WBS accepted as CR with PET/CT. Overall PET/CT prevented further PRRT cycles in eight patients with PD and one with CR. Among the predictive factors analyzed for critical difference, only pre-therapy total lesion number was found to be statistically significant ($p: 0.03$, RR: 1.1, CI: 1–1.1). Patients with PD on PET/CT but SD/PR on PT-WBS, had discordant lesions with a median size of 11 mm (IQR: 8–24 mm) and a median SUVmax of 6.1 (IQR: 2.7–10.7). Progressive lesions that were not detected with PT-WBS were mostly in the abdominopelvic region compared elsewhere (81% and 42.6% respectively, $p: 0.003$). **Conclusion:** Agreement between PET/CT and PT-WBS responses was moderate, and critical inconsistencies were observed. PT-WBS can be insufficient, especially in patients with numerous lesions and may overlook progression of abdominopelvic lesions. **References:** None

EPS-171

Clinical outcome of 177Lu-PSMA-IT Therapy in Advanced metastatic prostate cancer patients in Asia

T. Bu, F. Yu, L. Zhang, F. Wang;

Nanjing First Hospital China, Nanjing, CHINA.

Aim/Introduction: The aim of this study to evaluate the safety and efficacy of metastatic castration-resistant prostate cancer (mCRPC) patients in Asia after several cycles of 177Lu PSMA-IT therapy, and to explore the factors that affect the

prognosis of treatment. **Materials and Methods:** From August 2018 to March 2020, 42 patients (mean age: 68.3 years old) with mCRPC were consecutively enrolled for one cycle of Lu-177-PSMA therapy, institutional review board approval and informed consent was obtained for this study. 68Ga-PSMA-11 PET/CT showed multiple PSMA-avid lesions in all patients before the therapy. 177Lu-PSMA-I&T radioligand therapy with 2.0–7.7 GBq were performed. Hematological status, liver and kidney function, and serum prostate specific antigen (PSA) levels were documented before and after treatment. Visual Analogue Scale/Score (VAS) was used to record changes in bone metastasis pain. The efficacy was evaluated by the changes of PSA, Eastern Cooperative Oncology Group (ECOG), maximum standardized Uptake Value (SUVmax) and tumor size on 68Ga-PSMA-11 PET/CT, and clinical follow-up. Paired t test and rank-test was used to analyze the data. **Results:** Significant PSA reduction was associated with 177Lu-PSMA-I&T treatment ($P=3.6 \times 10^{-4}$). Of the 42 patients, 10 had elevated PSA levels and disease progression, while 32 patients had variable reduction of PSA, of which 11/32 decreased by <30% and 20/32 decreased by >50%. No evident hematotoxicity, hepatorenal toxicity was observed during the follow-up after treatment. The ECOG, VAS scores and SUVmax of metastatic lesions showed significant differences in pre and post treatment ($P < 0.05$). This analysis determined that the average intensity of the mean of PSMA standardized uptake value (SUVmean), tumor burden, lactate dehydrogenase (LDH), and alkaline phosphatase (ALP) were closely related to the prognosis. **Conclusion:** The present study in Asian population validated 177Lu-PSMA-I&T treatment achieve better response in the treatment of mCRPC, which is easy tolerable and safe. In addition, both biomarkers (ALP / LDH) and PSMA PET / CT parameters have important implications for the prognosis of men receiving LuPSMA. **References:** None

EPS-172

The Role of Ga-68 PSMA PET / CT in Predicting Lu-177 PSMA Effectiveness: Can We Project the Ga-68 DOTA PET / CT and Lu-177 DOTA Treatment Experience to PSMA?

U. Korkmaz, F. S. Soyluoglu, G. Durmus-Altun;
Trakya University, Edirne, TURKEY.

Aim/Introduction: Prostate cancer is the most common type of cancer in men, and the second most common cause of cancer death. Prostate Specific membrane antigen (PSMA) is expressed in prostate epithelial cells and highly expressed on prostate cancer. PSMA levels are directly related to androgen independence, metastasis and prostate cancer progression. Therefore, it is a good target for the diagnosis and treatment of prostate cancer. Lu 177-PSMA therapy is an effective type of “targeted therapy” used in the treatment of castration-resistant prostate cancers. Despite data showing significant clinical responses obtained with Lu 177-PSMA

therapy, predictors of the treatment response in imaging were not clearly characterized yet. In this study, we evaluated the relationship between Ga68-PSMA imaging parameters and the therapeutic response obtained after Lu177-PSMA treatment, and analyzed the differences and similarities of Ga68-DOTA / Lu177-DOTA pair. **Materials and Methods:** Ga-68 DOTA and Ga 68-PSMA PET/CT images of patients who applied to the Nuclear Medicine Department and received Lu177-radiopeptide (DOTA and PSMA) treatment between January 2016 and January 2020 were included in the study. Pre-treatment, mid-treatment and post-treatment Ga68 (DOTA/PSMA) PET/CT images and also 177Lu whole body images taken after each treatment dose, which were all taken on the same system, were found from archive. Data of the patients were collected from the patient files. The patients were grouped as DOTA and PSMA according to their primary diagnosis and the peptide used in 68Ga-PET/CT. Metabolic PET parameters, 177Lu uptake, biochemical parameters and treatment response findings of both group were compared and evaluated separately. **Results:** Of the 46 patients included in the study, 14 were in the DOTA group and 32 were in the PSMA group. Most patients had widespread metastatic disease prior to the treatment. In the DOTA group, the liver was the most frequently metastatic site with the highest metabolic activity (36%), while bone was in the PSMA group (68%). TmSUVmax was similar for the DOTA and PSMA group after treatment ($p=0.11$). $\Delta TmMTV$, $\Delta Tm / TotalMTV$ values were significantly different ($p=0.04$ and $p=0.03$). At the end of the treatment, the number of foci decreased in both groups. The highest treatment efficacy was achieved in soft tissue. The metabolic response of both groups to treatment was similar. **Conclusion:** 177Lu-radiopeptide therapy is an effective treatment method for both NET and prostate cancer. Tumor burden is significantly reduced and the most pronounced effect occurs in soft tissue. **References:** None

Peptide receptor radionuclide therapy (PRRT) for neuroendocrine tumors (NET): A single institution experience in the USA

H. Duan, V. Ferri, P. L. Kunz, G. A. Fisher, F. Moradi, G. A. Davidzon,
B. L. Franc, A. H. Iagaru, C. Aparici Mari;
Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Neuroendocrine tumors (NET) are a rare and heterogeneous group of tumors with a rising incidence. NETs are often times indolent leading to a late diagnosis at an advanced, metastatic stage, making these patients ineligible for surgery, the only curative treatment. Peptide receptor radionuclide therapy (PRRT) with radiolabeled somatostatin analogues is an encouraging systemic treatment modality. It is not only known to reduce tumor burden but also leads to symptomatic relief and thus increases quality of life with

minimum side effects. Here we present our initial experience with PRRT since FDA approval in May 2018 in patients with NET and other somatostatin receptor (SSTR) positive tumors. **Materials and Methods:** Seventy-seven patients (38 males and 39 females; 37 - 81-year-old, mean \pm SD: 63.1 \pm 10.7 years), thereof 72 with progressing NETs (37 pancreas, 25 small intestine, 1 cecum, 1 appendix, 1 gastric, 1 atypical lung and 6 of unknown primary), 3 paragangliomas, and 2 pheochromocytomas underwent PRRT with ^{177}Lu -labeled Dotatate (Lutathera[®]) at our institution. ^{68}Ga -Dotatate PET/CT was performed at baseline, after 2 cycles, and following completion of treatment. RECIST and SSTR density based on change of SUV_{max} were used to evaluate response to therapy. Laboratory tests were obtained at baseline and 1 week before each cycle and every 2 months at follow up. Progression-free survival (PFS), objective response rate (ORR). Considering the short follow-up time, an interim overall survival (OS) analysis was performed. **Results:** 46/77 (59.7%) patients completed all 4 cycles of PRRT, 19/77 (24.7%) patients are still in treatment. 12/77 (15.6%) patients had to discontinue PRRT (5 after the 1st cycle, 4 after the 2nd cycle, and 3 after the 3rd cycle) due to worsening comorbidities. The 3-month PFS rate was 79% and the 6-month PFS rate was 84%. The ORR at 3-month follow-up was 56.1% and at 6-month 21.7%. Interim OS was 74% at 22 months. Patients had on average 3.4 ± 1.39 treatment lines prior to receiving PRRT. **Conclusion:** Our preliminary data show overall good results of PRRT with Lutathera[®] in patients with NETs. However, our results seem to be inferior to the NETTER -1 trial which is most likely due to the extensive pre-treatment before PRRT. **References:** None

Early change of ^{68}Ga -HA-DOTATATE uptake during PRRT prognosticates duration of response in patients with metastatic NET

F. Fiz¹, H. Dittmann², G. Centurioni³, C. la Fougère²;

¹Humanitas Clinical and Research Center - IRCCS,

Milan, ITALY, ²Nuclear Medicine Unit, Department of

Radiology, University of Tübingen, Tübingen, GERMANY,

³University of Tübingen, Tübingen, GERMANY.

Aim/Introduction: Peptide-receptor radiotherapy (PRRT) is an effective treatment of metastatic neuroendocrine tumors (NET); however, time-to-progression (TTP) after PRRT varies significantly among patients. Moreover, early posttreatment PET/CT might not identify variation in lesion size or visual tracer uptake, thus identification of response is challenging. In this study, we assessed whether semiquantitative analysis of liver and bone metastases could prognosticate response duration in NET patients. **Materials and Methods:** Seventy-six NET patients underwent ^{68}Ga -HA-DOTATATE PET/CT before and after the first two cycles of PRRT with ^{177}Lu -HA-DOTATATE (7400 MBq per cycle, four cycles total). Mean,

max, and peak target-to-background ratio (TBRmean, TBRmax, TBRpeak) was computed on the liver and bone metastases as the ratio between metastases and blood pool SUV (assessed in a 10-slices VOI, manually drawn on the inferior vena cava). Variation trend in TBR between the first and the second PET was defined as increasing (>10% TBR increase), decreasing (>10% TBR drop), or stable (all other cases). Patients were stratified according to the TTP median as long- or short-time responders (LR and SR). TBR, grading (G1, G2, and G3), histology (midgut, pancreatic, bronchial, or other), and presence of bone metastases were used to stratify TTP in a Kaplan-Meier (KM) model. **Results:** Median TTP was 22 months (range 5-39). At KM analysis, patients with increasing, stable, or decreasing TBRmean (n= 35, 12, and 29, respectively) had a TTP of 31, 26, and 14 months, respectively (p<0.001 for increasing Vs. decreasing; p<0.05 for stable Vs. decreasing). When comparing the first and second PET, LR patients displayed a more positive variation in TBRpeak than SR (+30 \pm 49% Vs. -18 \pm 32%, p<0.01); the same difference was observed for TBRmean and TBRpeak as well (p<0.05 and p<0.01, respectively). KM identified a shorter TTP in G3 NET (n=9, 7 months, p<0.001 Vs. both G1 and G2) but found no difference between G1 and G2 tumors. Moreover, histology and the presence of bone metastases purported no differences in TTP. **Conclusion:** Decreasing SSR-Expression after 2 cycles of PRRT appears to be related to a shorter duration of response. This phenomenon might indicate the growth of less differentiated tumor components. **References:** None

EPS-175

Incidence of raised HbA1c and correlation with Somatostatin analogue therapy (SSA) in patients with Neuroendocrine Tumours (NET) receiving peptide receptor [^{177}Lu]Lu-DOTA-TATE radionuclide therapy (PRRT)

N. Eftychiou¹, H. Ilyas¹, H. Ahmed¹, F. Hassan¹, A. Eccles¹, V. Lewington^{1,2};

¹Guy's and St Thomas Foundation Trust, London, UNITED

KINGDOM, ²King's College London, London, UNITED KINGDOM.

Aim/Introduction: Administration of short course corticosteroids (dexamethasone) post peptide receptor radionuclide therapy (PRRT) is recommended for selected patients to mitigate radiation-related oedema. Hence, pre-assessment of HbA1c in patients with no previous diagnosis of impaired glucose tolerance (IGT) or diabetes mellitus (DM) is considered important. As Somatostatin Analogues (SSA) are widely used in patients with Neuroendocrine Tumours (NET) and have been associated with possible changes in glucose metabolism, we investigate the incidence of raised serum HbA1c in patients with NET receiving PRRT in combination with SSA. **Materials and Methods:** This is a retrospective study. We included all NET

patients who received [¹⁷⁷Lu]Lu-DOTA-TATE treatment at our centre between 01/01/2017 - 31/12/2019. Patient data were obtained from electronic patient records. Raised serum HbA1c was defined as ≥ 42 mmol/mol. **Results:** 138 patients were treated, of whom 19 were excluded as their baseline HbA1c was not recorded. Of 119 patients, 13% (16/119) had a prior diagnosis of DM or IGT while the majority, 87% (103/119) had no history of altered glucose metabolism. Of the 103 patient cohort, 46% (47/103) had raised HbA1c at baseline (54% (56/103) being within normal limits). 83% (85/103) were on SSA therapy. To determine the significance of SSA therapy upon mean HbA1c values in patients with no known history of DM or IGT, we performed t-test. The results show no significant difference between the 2 groups (43.3 ± 6.3 Vs 44.1 ± 11.0 , p-value: 0.779). Of patients with a raised HbA1c (including both diagnosed and undiagnosed patients with DM or IGT) the commonest primary tumour origin was gastroenteropancreatic (GEP-NETs) 70%, (gastroenteric 51% and pancreatic 19%), followed by lung 13%, unknown primary 6%, pheochromocytoma 5%, paraganglioma 3%, mesenteric 1.5% and thymic 1.5%. **Conclusion:** The relatively high incidence (46%) of HbA1c ≥ 42 mmol/mol in NET patients undergoing PRRT with no known prior history of DM or IGT confirms the clinical relevance of documenting pre-treatment HbA1c status. No significant difference was observed between mean HbA1c levels among patients on SSA therapy vs those not on SSA. The most common primary site of origin among patients with raised HbA1c was GEP-NET. Statistical analysis will be performed to investigate whether an increased incidence of raised HbA1c is linked to certain primaries. **References:** None

EPS-176

Single-institution real-life experience of ¹⁷⁷Lu-DOTATATE treatment in progressive, well differentiated GEPNETs

F. Scalorbi, A. Lorenzoni, E. Seregni, V. Fuoco, G. Argiroffi, N. Prinzi, S. Pusceddu, G. Aliberti, E. Garanzini, J. Coppa, F. De Braud, V. Mazzaferro, M. Maccauro; Istituto Nazionale Tumori Milano, Milan, ITALY.

Aim/Introduction: To evaluate safety, toxicity and interim efficacy of ¹⁷⁷Lu-DOTATATE treatment (PRRT) in patients with progressive G1-G2 GEPNETs. **Materials and Methods:** We prospectively evaluated GEPNET patients treated with at least one PRRT cycle at our Institution from April 2019 to April 2020. PRRT treatment was given as 4 separate infusions, 7.4 GBq each, with 8-week interval. To evaluate the interim response, CT or MRI were performed after the second PRRT administration. Side effects were assessed applying NCI-CTCAE criteria meanwhile RECIST 1.1 criteria were applied to evaluate interim response to PRRT. **Results:** We evaluated 55 patients (21 males, 34 females; mean age 62.5, range 38-84) diagnosed as G1 (25, 44.6 %) or G2 (30,

53.6%) progressive metastatic GEPNETs. In the majority of cases the primary tumour was located in the ileum (60%) followed by pancreas (32.7%) and other sites (7.3%). PRRT was administered as fifth/sixth-line in 25 cases (45.4%) followed by third/fourth-line in 20 (36.4%) and second-line therapy in 10 (18.2%). Forty-four patients (80.3%) were treated with two, 35 (62.5%) with three and 22 (44.6%) completed the four administrations. PRRT was suspended in eight patients (14.5%), previously treated with two (4 cases), three (3 cases) and five (1 case) systemic therapeutic lines, due to toxicity (4 cases, 50%), radiological (2 cases, 25%) and clinical progression (2 case, 25%). The lasting two cases consisted of intestinal occlusion and progression of neoplastic ascites that needed medical intervention. The toxicity that caused PRRT interruption were: two G2 persistent thrombocytopenia, one G4 hyperbilirubinemia and one G4 renal failure. The lasting two cases were known to have G2 hyperbilirubinemia and G2 renal failure before the start of PRRT. In the remaining 51 patients, we observed hematological toxicities G1-G2 in 14 patients and G3 in one. Furthermore, G1 renal toxicity was shown in 1 patient and G3 in another one. Two patients experienced G1 hepatic toxicity. Data from 31 available interim CT or MRI scan showed stable disease in the majority of cases (90.3%), progression in two (6.5%) and partial response in one (3.2%). **Conclusion:** Considering our real-life experience, PRRT is a safe treatment option even in patient previously treated with numerous systemic therapeutic lines. PRRT is effective in early disease control, reaching stability in more than 90% of interim evaluations. However, effectiveness and safety could be improved if PRRT is early performed after disease progression. Further clinical studies are needed to confirm this hypothesis. **References:** None

EPS-177

Four-years experience in ¹⁷⁷Lu-oxodotreotide therapy for patients with Neuroendocrine Tumors (NETs)

A. Cardozo Saavedra, A. García-Burillo, D. Villasboas-Roscoles, M. Simó-Perdigó, J. Hernando-Cubero, J. Capdevila Castellón, E. M. Carrillo-Villamizar, S. Menendez Sanchez, J. Castell-Conesa; Hospital Universitari Vall D'Hebron, Barcelona, SPAIN.

Aim/Introduction: Our aim is to evaluate our results with ¹⁷⁷Lu-oxodotreotide therapy for patients with somatostatin-receptors-overexpressing NETs. **Materials and Methods:** We performed a descriptive and retrospective analysis in patients with a diagnosis of a disseminated NET in progression who underwent treatment with ¹⁷⁷Lu-oxodotreotide from June 2016 to April 2020 at our center. The patients still ongoing treatment were excluded. We assessed the clinical and imaging response to treatment after the fourth dose, besides the presence of adverse effects. **Results:** A total of 21 patients (15 men and 6 women), with a mean age of 57.9 years (22-85) were

included. 17/21 patients had Gastroenteropancreatic-NETs (GEP-NET), 2/21 had Non-GEP-carcinoids and 2/21 had paragangliomas. 14/21 patients completed our standard treatment of 4 doses (ST4D) of 7.4GBq; of these, 12/14 had a GEP-NET. The post-therapeutic evaluation (PTE) showed: PR in 7/14, SD in 5/14 and PD in 1/14, it is pending in 1/14. Among the GEP-NETs the PTE showed: PR in 6/12, SD in 5/12 and in 1/12 it is pending (interim-SD). 7/21 patients received less than 4 doses, the causes were: complication directly related with treatment (DRT) in 1/7 (GEP-NET), complications not-DRT in 5/7 (4/7 GEP-NET) and voluntary resignation in 1/7 (Non-GEP-NET). The PTE showed: PR in 2/7, PD in 1/7, death in 2/7 and unknown in 2/7. Among the 5/7 patients with GEP-NETs, the PTE showed: PR in 2/5 (including the patient with relevant toxicity), death in 2/5 (Not-DRT) and unknown in 1/5. The mean progression-free survival (PFS) of the 19/21 patients with known outcome was of 15.6 months (2-41). The PFS for the GEP-NETs with ST4D was of 19.8 months (6-41) and for the Non-GEP-NETs it was of 9.5 months (9-10). Of the total, 11/21 patients reported symptomatic improvement, 9/21 showed no changes (2/21 asymptomatics) and 1/21 worsened. Of the 21 patients, 10/21 presented haematological toxicity, 3/10 required transfusion and 1/10 discontinued treatment for significant pancytopenia. None of them presented significantly renal toxicity. Of the 12 patients with GEP-NETs who received 4 doses, 4/12 died during follow-up (overall survival of 12, 19, 22 and 33 months); of these, 1/12 GEP-NET patient underwent a re-treatment and died after the fifth (accumulated) dose, for an intracranial hemorrhage of unclear etiology: traumatic versus unconfirmed metastasis. **Conclusion:** Benefits in PFS, symptomatic relief and an adequate tolerance was observed in patients with GEP-NETs treated with 4 doses of ¹⁷⁷Lu-oxodotreotide. Benefits in Non-GEP-NETs are not clear. **References:** None

Treatment of Neuroendocrine Tumors with Lutetium-177 Oxodotreotide: First Results in our Institution

Á. Galiana, A. Gardellini, M. Marín, E. Martínez, A. La Salvia, R. García-Carbonero, M. Tabuenca, S. Ruiz, V. Godigna, J. Pilkington, D. Vega, J. Estenoz;
Hospital Universitario 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: Theranostics is a powerful tool with enormous potential in the management of neoplasm. We analyze the first steps of our hospital in using Peptide Receptor Radionuclide Therapy with ¹⁷⁷Lu-oxodotreotide in neuroendocrine tumors (NET), its effectiveness and security in our practice. **Materials and Methods:** Nineteen patients (9 women, average age 60,4±12,6 years) were included, all of whom received at least one dose of ¹⁷⁷Lu-oxodotreotide (standard protocol of 4 doses of 7400MBq every 8 weeks) between March 2016 and November 2019.

Thirteen patients completed the treatment (68,4%), 2 patients did not, due to toxicity/death, and 4 patients were pending completion. Fourteen patients had their primary tumor located in the digestive system (6 small intestine, 5 pancreas, 2 rectum,1 stomach), 13 of which were well differentiated (5 G1, 8 G2) and 1 was poorly differentiated; 5 were located in lungs (3 typical carcinoids, 2 atypical). We analyzed clinical characteristics during the treatment, biochemical and image response 2 months post-treatment with CT (progression criteria RECIST 1.1) and SPECT-CT Octreoscan (Krenning score and appearance of new lesions), and adverse effects (hematologic and nephrologic toxicity). Average follow-up time: 18,3±12,8 months. **Results:** All patients received previous treatments (11p: 3 or more lines of treatment, 6p: 2 previous treatments, and 2p: 1 treatment). Localization of metastasis were: 16p hepatic, 3p peritoneal, 6p osseous. Seven patients had functioning tumors (5p presented carcinoid syndrome and 2p insulinoma). Adverse reactions included gastrointestinal: nausea 13p, vomits 6p, abdominal pain 4p; hematological: anemia 3p, thrombocytopenia 4p, leukopenia 5p, neutropenia 3p and lymphopenia 15p. No significant variations were observed in renal function before and post-treatment. Treatment response of the 13p receiving full dosage was evaluated with CT and SPECT-CT Octreoscan, showing stable disease in 9p(69,2%) with CT and in 3p(23,1%) with Octreoscan, partial response was shown in 2p(14,3%) with CT and in 9p(69,2%) with SPECT-CT, finally progression of the disease was observed in 2p(14,3%) and 1p(7,7%) respectively. During follow-up, disease progressed (average 20,8 months) in 5p(38,5%), and stable disease (16,6 months) 8p(61,5%). One patient died due to hemoptysis 7 months post-treatment. **Conclusion:** Treatment of NET with ¹⁷⁷Lu-oxodotreotide is a safe option with favourable outcomes in patients with previous treatments. The results obtained are similar to published bibliography¹. **References:** ¹Strosberg, J., El-Haddad, G., Wolin, E., Hendifar, A., Yao, J., Chasen, B., ... & Yao, J. (2017). EPS-179

Evaluation of toxicity in peptide receptor radionuclide therapy (PRRT) for neuroendocrine tumors (NET)

H. Duan, V. Ferri, P. L. Kunz, G. A. Fisher, F. Moradi, G. A. Davidzon, B. L. Franc, A. H. Iagaru, C. Aparici Mari;
Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with radiolabeled somatostatin analogues is an encouraging systemic treatment modality for neuroendocrine tumors (NET). PRRT is generally safe and possesses little side effects. Renal toxicity and hematotoxicity have already been reported but little is known about liver

toxicity. **Materials and Methods:** Seventy-seven patients (38 males and 39 females; 37 - 81-year-old, mean \pm SD: 63.1 \pm 10.7 years) underwent PRRT with ^{177}Lu -labeled Dotatate (Lutathera[®]) at our institution. Thereof 72 had progressing NETs (37 pancreas, 25 small intestine, 1 cecum, 1 appendix, 1 gastric, 1 atypical lung and 6 of unknown primary), 3 had a paraganglioma, and 2 had a pheochromocytoma. Blood work was obtained 1 week before each cycle and every 2 months at follow up. Hematological parameters were determined with Common Terminology Criteria for Adverse Events (CTCAE) V5.0. The hematological guidelines for starting PRRT at our institution are based on the package insert. **Results:** 46/77 (59.7%) patients completed all 4 cycles of PRRT. 19/77 (24.7%) patients are still being treated. 12/77 (15.6%) patients did not finish all 4 cycles. Out of the patients who finished, we observed in regard to liver toxicity: One patient (2.2%) had an albumin value of 2.9 g/dl which is below the cut off for PRRT. We decided to treat for his overall benefit. Albumin increased shortly after the first cycle to 4.5 g/dl at last cycle and remained at that level. At 7-month follow up, this patient showed partial response to PRRT. 3/46 (6.5%) patients initially had albumin values within the limits for PRRT but decreased during treatment from 3.53 ± 0.61 (range 3 - 4.2) g/dl at first cycle to 2.6 ± 0.1 (range 2.5 - 2.7) g/dl at last cycle. At 6-month post-treatment follow up, 2 patients showed persistent hypoalbuminemia with 2.35 ± 0.07 (range 2.3 - 2.4) g/dl with one of them improving to normal limits at 1-year follow up (3.6 g/dl). Imaging follow-up showed that 1 patient had stable disease while the other 2 had an initial partial response and remained with a stable disease at 7 months post-treatment evaluation. All patients with a decreased albumin had previous liver-directed treatments (transarterial chemoembolization and radioembolization). **Conclusion:** Our preliminary data show that PRRT is overall a safe treatment. Hypoalbuminemia is the only liver related side effect observed. In our small cohort it appears to not affect response to treatment. **References:** None

EPS-180

Real-time MR imaging of holmium-166 microsphere distribution during SIRT in salvage patients: proof of principle

J. Roosen, M. A. Arntz, M. Janssen, K. G. Overduin, M. W. Konijnenberg, J. J. Fütterer, F. W. Nijsen;
Radboud University Medical Center, Nijmegen, NETHERLANDS.

Aim/Introduction: Selective internal radiation therapy (SIRT) is a local treatment for liver tumours during which radioactive microspheres are injected in the hepatic arterial system. To create better understanding of the distribution patterns in relation to the number of microspheres administered, we prospectively studied the microsphere distribution with radioactive holmium-166 poly(L-lactic

acid microspheres, using real-time MRI. **Materials and Methods:** Ethical committee approval was obtained for this feasibility study, in which 6 patients with unresectable liver tumours are treated. The SIRT procedure is split up: the catheter is placed under X-ray guidance as per usual, after which the patient is moved to an MRI scanner which is positioned directly adjacent to the hybrid OR. The total activity for each of the identified catheter positions is split in predefined fractions. MRI is performed during and after the administration of each fraction. All fractions for one catheter position are injected within one hour. Quantitative imaging is performed after each fraction and converted to dose maps using Q-Suite software to establish the T/L ratio and perform voxel-based dosimetry. **Results:** Recruitment is ongoing, with 3 out of 6 patients enrolled and treated successfully. The quantitative dose distributions provide promising insight into microsphere distribution in relation to the amount of microspheres administered. The intrahepatic distribution of microsphere fractions is not necessarily consistent between different fractions. **Conclusion:** This study is an important first step to better understand SIRT fundamentally and this may lead to improving the therapy by increasing the T/L ratio, ultimately resulting in better patient outcomes. **References:** None

EPS-181

Absorbed Dose in "Black Hole" as a predict of complete MRI response in HCC patients treated with Y-90 TARE

M. Meyer, S. Boughdad, J. O. Prior, M. Da Mota, N. Schaefer, A. Hocquelet;
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: Transarterial radioembolization (TARE) for hepatocellular carcinoma (HCC) induces various post-treatment radiologic changes, and it can take several months for evidencing tumor response. The lack of contrast enhancement or Black Hole (BH) on post-TARE Magnetic Resonance Imaging (MRI) is strongly associated with complete histological response. The aim of this study was to assess the absorbed dose associated with BH at 3-months post-TARE MRI. **Materials and Methods:** We retrospectively included all HCC patients treated by selective TARE (Y-90 glass microspheres) with a post-TARE Y-90 Positron Emission Tomography (PET) and a follow-up contrast enhanced MRI (06-2018 to 02-2020). BH was defined by the absence of contrast enhancement on MRI at arterial, venous and delayed (2-minute) phases. Using Simplicity software (BTG Biocompatibles Ltd, Farnham, UK), MRI was co-registered with Y-90 PET. Then, Y-90 PET perfused volume (PV) and MRI BH were semi-automatically segmented using thresholding by two experienced nuclear physician and radiologist. Enhanced-Perfused volume (E-PV) was defined by PV minus BH. We also defined margins volume (MV) corresponding to a 5-mm volume around the BH. Based

on a per-treatment analysis and considering the normal distribution of analyzed variables, absorbed dose of each volume were compared using T-test. **Results:** We included 13 treatments in 11 patients (2 patients have been treated with 2 consecutive TAREs in two different arterial territories with a few months interval): 5 lobar, 3 sectoral and 5 segmental. The mean injected activity was 2.3 ± 0.85 GBq. No specific toxicities according to high-dose Y-90 TARE have been reported. The mean delay between Y-90 TARE and follow-up MRI was 2.9 ± 0.8 months. BH was found in 11 treatments (84.6%). The mean volumes were 567.8 ± 408.6 cm³ for PV and 30.9 ± 31.9 cm³ for BH. The mean absorbed doses were 695.1 ± 372.1 Gy for BH, 425.9 ± 235.0 Gy for MV and 195.6 ± 97.0 Gy for E-PV. Absorbed dose in BH was significantly higher than in MV ($p=0.049$) and in E-PV ($p<0.0001$). No BH was found below 306 Gy, which corresponded to D_{BH_min} . **Conclusion:** The response pattern after Y-90 TARE is dose dependent and complete lack of contrast enhancement in MRI ("Black-Hole") is associated with a high-absorbed dose. This observation adds to the ongoing debate on response assessment using MRI after Y-90 TARE. **References:** None

EPS-182

The effect of metabolic tumor volume and total lesion glycolysis on prognosis of pancreatic adenocarcinoma patients in staging with FDG PET/CT

O. Ekmekcioglu¹, M. Batta², O. Bostanci², P. Arican¹, B. Yilmaz Ozguven³;

¹Nuclear Medicine Dept, Sisli Etfal Education and Research Hospital, Istanbul, TURKEY, ²General and Hepatobiliary Surgery Dept, Sisli Etfal Education and Research Hospital, Istanbul, TURKEY, ³Pathology Dept, Sisli Etfal Education and Research Hospital, Istanbul, TURKEY.

Aim/Introduction: FDG PET/CT has shown to be useful staging in pancreas cancer especially illustrating the distant metastases. The prognosis of pancreatic adenocarcinoma is correlated with stage and the resectability of the tumor. SUVmax, Metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of the primary tumor are the datas that has been shown to correlate with prognostic parameters in pancreas cancer. In this study, we aim to investigate FDG PET/CT findings with prognostic factors in our patient group with pancreatic adenocarcinoma. **Materials and Methods:** The patients with pancreas adenocarcinoma that were referred to our department between 2013 and 2020 for staging evaluated retrospectively. After at least 6 hours fasting FDG has been injected. Head to mid thigh images were revealed one hour after injection. The patient demographics, follow-up data including overall survival and reports from pathology of 39 patients, who were operated after PET/CT imaging, were gained. All the primary metabolic tumor volume, SUVmax, background SUVmax and total lesion glycolysis datas have been

measured with GE Healthcare PET/CT workstation. **Results:** The images of 57 patients; 21 female and 36 male; mean age of 67,6(41-84) with pancreatic adenocarcinoma were evaluated. Twenty-seven patients has shown positive findings for distant metastases either in lung, liver or bone. The mean values of SUVmax, metabolic tumor volume (MTV 40%) and total lesion glycolysis (TLG) of primary tumor in pancreatic tissue were 7,3 (2,1-18,5), 24,3cm³ (1,4-77,9) and 98,5 g/ml 5,3-478,4) respectively. The average survival after diagnosis of the disease 17,7 (1-55) months. TLG values have demonstrated a significant relation with positive findings for distant metastases; SUVmax was significantly related with positivity for lymph node and distant metastases. The overall survival was significantly related with perineural invasion and distant metastases. **Conclusion:** FDG PET/CT is useful for staging and detecting distant metastases in pancreatic cancer. Furthermore, total lesion glycolysis and SUVmax could be helpful to understand the prognosis of pancreatic cancer before surgery or treatment decision. However, results of metabolic tumor volume analysis of our study was not compatible with the data published before which could be related to low number of our patients. Additionally, we did not exclude the metastatic patients from the survival analysis. From this point of view we are planning to investigate MTV and TLG as independent factors in a patient group without metastases. More patients without metastatic disease could give more accurate results for correlating MTV and TLG with survival. **References:** None

Automated Production of [⁶¹Cu]CuCl₂ at UW-Madison

C. Kutyreff¹, J. Pettersson², K. Seeley¹, T. Barnhart¹, J. Engle^{1,3}, K. Gagnon²;

¹University of Wisconsin-Madison, School of Medicine and Public Health, Department of Medical Physics, Madison, WI, UNITED STATES OF AMERICA, ²GEMS PET (GE Healthcare), Uppsala, SWEDEN, ³University of Wisconsin-Madison, School of Medicine and Public Health, Department of Radiology, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: We sought to improve methods for isolating ⁶¹Cu from irradiated ^{nat}Ni, ⁶⁰Ni, and ⁶¹Ni targets to avoid high acid concentrations and large volume

formulations. We developed a cassette-based automated method for ^{61}Cu purification and Ni recovery using commercial extraction chromatography resins. **Materials and Methods:** Briefly, 99 ± 23 mg of ^{nat}Ni was electroplated (or recovered and re-plated) on silver discs following [1] and automatically transferred to/from the cyclotron (QIS). Targets were irradiated at $30 \mu\text{A}$ with 8.4 MeV deuterons for 30 minutes ($n=5$ [3 @ singly recycled; 2 @ doubly recycled]) or 200 minutes ($n=1$ [new target]) and dissolved in 1:1 7 M HCl:30% H_2O_2 . The HCl concentration was adjusted to ≥ 6 M, and transferred to a FASTlab chemistry module whereby $^{61}\text{Cu}[\text{CuCl}_2]$ was isolated with a two-column process using TBP (as an Fe guard column) and TK201 resins. In short, the ^{61}Cu was trapped on the TK201, washed with 6 M and 4.5 M HCl to remove nickel and cobalt, and finally washed with 5 M NaCl prior to elution with 0.05 M HCl. **Results:** The isolated $^{61}\text{Cu}[\text{CuCl}_2]$ was collected 65 ± 3 minutes post EoB in ~ 2 mL of 0.057 ± 0.002 M HCl ($n=5$, assessed by titration). An overall radiochemical yield (including both the dissolution and separation chemistry) of $85 \pm 4\%$ ($n=6$) is reported. The measured saturation yield of the isolated $^{61}\text{Cu}[\text{CuCl}_2]$ was 166 ± 31 MBq/ μA ($n=6$), consistent across fresh and recycled targets. HPGe and MP-AES of the isolated $^{61}\text{Cu}[\text{CuCl}_2]$ (values decay corrected to EoB) measured Ni separation factors of $\geq (6.0 \pm 3.3) \times 10^5$ ($n=5$, noting that the nickel content in the final products was below the minimum detectable limit), ^{58}Co content of $(8.3 \pm 0.6) \times 10^{-5} \%$ ($n=5$) vs. ^{61}Cu activity, molar activities of 119 ± 32 MBq/nmol ($n=5$) for the 30 minute irradiations, and apparent molar activities of 31 ± 8 MBq/nmol ($n=5$) and 201 MBq/nmol using NOTA for the 30 and 200 minute irradiations, respectively. **Conclusion:** A cassette-based, automated method of producing high purity $^{61}\text{Cu}[\text{CuCl}_2]$ from recycled Ni targets has been developed that does not require dry-down for formulation. Molar and apparent molar activities are suitable for subsequent preparations of ^{61}Cu -based radiopharmaceuticals and are expected to increase with isotopically enriched Ni targets. **References:** [1] Piel H, et al. *Radiochim Acta* 1992; 57:1–6. doi:10.1524/ract.1992.57.1.1. **Acknowledgment:** Authors acknowledge support and collaborative efforts with Swiss Nuclides.

OP-954

Cyclotron-based ^{68}Ga production with dual liquid targets

K. Gagnon¹, M. E. Rodnick², C. Parr¹, M. Clark², S. A. Grosch¹, P. J. H. Scott²;

¹GEMS PET Systems, Uppsala, SWEDEN, ²University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: At the University of Michigan, due to ongoing uncertainty in generator costs and delivery timelines, the clinical production of $^{68}\text{Ga}[\text{Ga-PSMA-11}]$ using cyclotron-produced ^{68}Ga from a liquid target was validated and implemented in early February 2019, with routine production of 1.3–1.7 GBq (35–45 mCi) final product

demonstrated [1]. Aiming for further scale-up while maintaining liquid target infrastructure, we investigated, and present the preliminary results on the cyclotron-production of $^{68}\text{Ga}[\text{GaCl}_3]$ and $^{68}\text{Ga}[\text{Ga-PSMA-11}]$ using simultaneous production of ^{68}Ga in two liquid targets by dual beam irradiation. Following bombardment, the contents of both targets were combined and used for the production of $^{68}\text{Ga}[\text{Ga-PSMA-11}]$. **Materials and Methods:** ^{68}Ga was produced by proton irradiation of 1.0M $^{68}\text{Zn}[\text{Zn}(\text{NO}_3)_2]$ in dilute (i.e. 0.3M) HNO_3 on a PETtrace cyclotron per our previous report [1], albeit using dual targets. For these initial tests, targets were irradiated at 25–30 μA (port 3), and 30–35 μA (port 6) for ~ 60 minutes at a nominal proton energy of 14.3 MeV. Target solutions were delivered to the lab one at a time, with beam maintained on the second target while the first was being emptied. The target solutions were combined into an external vial which was connected to a FASTlab synthesis module. This vial was pre-loaded with 6 mL of metal free H_2O to ensure the HNO_3 concentration was $\leq 0.1\text{M}$ prior to column loading. The resulting solution was then either processed to isolate $^{68}\text{Ga}[\text{GaCl}_3]$ ($n=2$), or, for single cassette production of $^{68}\text{Ga}[\text{Ga-PSMA-11}]$ which includes also the $^{68}\text{Ga}[\text{GaCl}_3]$ purification ($n=1$) [1]. **Results:** The total time from EOB (counting from EOB of the 2nd target) to EOS was 42 and 43 min for the two $^{68}\text{Ga}[\text{GaCl}_3]$ runs, and following slight adjustments to delivery and column loading times, only 40 minutes from EOB to EOS for the single $^{68}\text{Ga}[\text{Ga-PSMA-11}]$ run. Yields were, 4.6 ± 0.1 GBq (125 ± 3 mCi) and 3.1 GBq (85 mCi) at EOS for $^{68}\text{Ga}[\text{GaCl}_3]$ ($n=2$) and $^{68}\text{Ga}[\text{Ga-PSMA-11}]$ ($n=1$), respectively. Both products met quality control criteria previously established in UM's $^{68}\text{Ga}[\text{Ga-PSMA-11}]$ IND application approved by the US FDA. **Conclusion:** Following modifications on dilution and column loading, successful combination of two simultaneously irradiated ^{68}Ga liquid targets to produce high quality $^{68}\text{Ga}[\text{GaCl}_3]$ and $^{68}\text{Ga}[\text{Ga-PSMA-11}]$ has been demonstrated, with > 3.7 GBq (> 100 mCi) of $^{68}\text{Ga}[\text{GaCl}_3]$ isolated. Further optimization efforts are underway with a goal of producing > 3.7 GBq (> 100 mCi) of $^{68}\text{Ga}[\text{Ga-PSMA-11}]$ from a single production run. **References:** [1] Rodnick et al., *J. Label. Compd. Radiopharm.* 62 (2019), S123–S588, P149.

OP-955

Selective, stable chelation of radioantimony for Sb-119 Targeted Radionuclide Therapy

A. Olson¹, Y. Feng², P. A. Ellison¹, E. Aluicio-Sarduy¹, T. E. Barnhart¹, R. J. Nickles¹, S. S. Jurisson³, J. W. Engle¹;

¹Department of Medical Physics, University of Wisconsin Madison, Madison, WI, UNITED STATES OF AMERICA, ²Department of Radiology, Duke University, Durham, NC, UNITED STATES OF AMERICA, ³Department of Chemistry, University of Missouri, Columbia, MO, UNITED STATES OF AMERICA.

Aim/Introduction: Antimony-119 ($t_{1/2}=38.5\text{h}$, $EC = 100\%$)

emits a cascade of 23 - 24 low energy high LET electrons and no photons with energy above 30 keV [1], making it an ideal candidate for targeted radionuclide therapy (TRT). It is produced by the $^{119}\text{Sn}(p,n)^{119}\text{Sb}$ reaction but has not been chelated for practical medical applications [2]. We aim to develop antimony separation from tin through implementing direct radioantimony chelation in unseparated target solutions using a conjugatable chelator.

Materials and Methods: Radioantimony was produced by 16 MeV proton irradiation of electroplated Sn [3]. The target (mass exceeding 350 mg/cm²) was dissolved in 3 mL concentrated HCl (3h/90°C), and without purification, reacted in situ with a trithiol chelator developed at the University of Missouri [4]. HPLC was implemented to study reaction kinetics and resulting complex stability after C18 Sep-Pak purification (EtOH and H₂O pre-conditioning, load in diluted labelled target solution, 5mL H₂O wash). Sb-trithiol was eluted in 3mL of acetonitrile, dried, and resuspended in PBS. **Results:** The trithiol chelator rapidly (30 min) complexed no carrier added pmol of Sb in the presence of mmol of Sn (10⁸-fold excess) at ligand concentrations down to 0.01 mM. The trithiol has strong selectivity of antimony over tin. Final decay corrected radiochemical yields of Sb-trithiol were 64.5% ±20% (N=3) via HPGe activity measurements. HPLC stability studies revealed undegraded Sb-ligand in 25 mM cysteine at 24 hours (99.7% ±0.5% stability, N=3) and in fetal bovine serum at 72 hours (92.8% ±5.5% stability, N=3). **Conclusion:** We report an elegant method for radioantimony chelation, circumventing usual radionuclide isolation from dissolved accelerator targets with a functionalizable trithiol chelator. **References:** [1] K. OP-956

Automated production of Ga-68 chloride and Ga-68-Dotatate on a low energy medical cyclotron

M. Malinconico¹, C. Hollis², K. Kuan², C. Barkil², P. Takhar², A. Brunetti¹, W. Tieu²;

¹COMECER S.p.A., Castel Bolognese, ITALY, ²Molecular Imaging and Therapy Research Unit, South Australian Health and Medical Research Institute, Adelaide, AUSTRALIA.

Aim/Introduction: The demand for Gallium-68 (^{68}Ga) labelled PET radiopharmaceuticals and its source ($^{68}\text{Ge}/^{68}\text{Ga}$ generators) have increased over the past few years. To keep up with the demand, new avenues for ^{68}Ga production are needed. The present work describes a rapid and automated production of [^{68}Ga]GaCl₃ and [^{68}Ga]Ga-DOTA-TATE on a low energy medical cyclotron. **Materials and Methods:** An automated process was developed for producing [^{68}Ga]GaCl₃ on a GE PETtrace 880 with Comecer PTS and Aleco system. ^{68}Zn was prepared by electrochemical deposition over 2.5 h on a dynamic electrochemical cell. The ^{68}Zn target was irradiated at 14.5 and 12.0 MeV incident energy with 10 - 35 μA proton beam for 8.5 - 20 min. The irradiated $^{68}\text{Zn}/^{68}\text{Ga}$ was purified on automated Taddeo unit using hydroxamate/tri octyl phosphine resin (29 min) or octanol resin (26 min). The automated radiolabelling of DOTA-TATE was performed on the Taddeo (15 min). **Results:** [^{68}Ga]GaCl₃ on a low energy cyclotron at 14.5 MeV gave production yield of 61.26 GBq. $\mu\text{A}^{-1}.\text{h}^{-1}$ in 0.05 M HCl solution. The specific activity of [^{68}Ga]GaCl₃ was determined as 660 ± 164 GBq. μmol^{-1} following ICP-MS and effective specific activity of 14.6 GBq. μmol^{-1} following DOTA titration. Radionuclidic impurity 0.012 - 0.080% as determined by HPGe. Finally, the automated process was extended to include ^{68}Ga -dotatate labelling to give >3 GBq of ^{68}Ga -dotatate with RCY of >65%. The total process time from start of bombardment to [^{68}Ga]GaCl₃ (45 min) and [^{68}Ga]Ga-DOTA-TATE (<1 h). **Conclusion:** A rapid and automated solid targetry production was developed that yielded [^{68}Ga]GaCl₃ (>6 GBq) in <35 min and ^{68}Ga -Dotatate in <55 min after start of bombardment. [^{68}Ga]GaCl₃ obtained from solid targetry was found to be comparable to [^{68}Ga]GaCl₃ obtained from a $^{68}\text{Ge}/^{68}\text{Ga}$ generator. **References:** None

OP-957

Separation of Cyclotron-Produced ^{51}Mn from ^{54}Fe with DGA Resin

K. Barrett, E. Aluicio-Sarduy, T. E. Barnhart, J. W. Engle; University of Wisconsin- Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: ^{51}Mn has been isolated from target material with ion exchange and extraction chromatography and used for in vivo monitoring of pancreatic beta cell function [1]. We report a new method of isolating ^{51}Mn from isotopically enriched ^{54}Fe target material and trace stable contaminants with DGA (branched and unbranched) resins. **Materials and Methods:** Solutions containing representative masses of Fe(III) and Mn(II) were loaded onto 101±8mg resin columns equilibrated with HCl (0.1, 1.0, 3.0, 5.0M). Solutions were agitated then pushed through the resin. Metal concentrations were assayed by MP-AES to quantify masses adhered to the resin and eluted in solution. Affinity constants (kD values) were calculated from measured data.

The results of these batch studies were used to design dynamic separation experiments. A column containing 3.5g of resin was equilibrated with 30mL of 5M HCl. An ^{54}Fe target was irradiated and dissolved in 3mL of 6M HCl. To this solution, 1.8mL of H_2O_2 was added to promote oxidation of Fe(II) to Fe(III). This target solution was loaded onto the column, washed with 15mL of 5M HCl to elute the Mn(II), then washed with 15mL of 0.01M HCl to recover the Fe(III). Samples were collected in 5mL fractions and assayed to determine an elution profile. The final fraction of ^{51}Mn was complexed with DOTA, while the recovered Fe(III) was recycled and electroplated. **Results:** The produced kD values provided incentive to move to a dynamic column experiment. A target made of $51.5 \pm 10.3\text{mg}$ of ^{54}Fe was irradiated at 16MeV, producing ^{51}Mn at a saturation bombardment yield of $44.0 \pm 4.8 \text{ MBq}/\mu\text{Ah}$. At end of chemistry, a separation factor of $1.03 \times 10^6 \pm 2.0 \times 10^5$ and a radiochemical yield of $99.3 \pm 1.2\%$ (N=3) were achieved. The measured apparent molar activity of the ^{51}Mn was $5.46 \pm 0.8 \text{ GBq}/\mu\text{mol}$ of DOTA. The enriched ^{54}Fe was recovered and electroplated with a recycling efficiency of $90.4 \pm 12.6\%$. **Conclusion:** We report a rapid, high-yield, DGA-based purification of ^{51}Mn that efficiently recovers isotopically enriched ^{54}Fe material for target recycling. **References:** [1] S. A. Graves et al., "Preparation and in vivo characterization of $^{51}\text{MnCl}_2$ as PET tracer of Ca^{2+} channel-mediated transport," *Sci. Rep.*, vol. 7, no. 1, pp. 1-8, 2017.

OP-958

Re-Establishing of Production of $^{188}\text{W}/^{188}\text{Re}$ Generators Utilizing ^{188}W Activity Obtained from Irradiated $^{188}\text{WO}_3$ Ampoules and ^{188}W Solution

J. Jernstroem, M. Olmeda Palomar, J. Nikula, N. Vetter, I. Kuru, T. Nikula;
OncoBeta GmbH, Garching, GERMANY.

Aim/Introduction: Simultaneous long-term interruption in ^{188}W isotope production of the two main global manufacturers has created a shortage of $^{188}\text{W}/^{188}\text{Re}$ generators in the markets. In order to re-establish and stabilize the generator production it was necessary to develop a production chain which includes all the steps from raw material target irradiation and chemistry to loading and release of generator. Several generators were produced following the designed routes and methods. Comparison with generators loaded with commercially produced ^{188}W has given fundamental information on the quality of the developed processes. **Materials and Methods:** Enriched $^{186}\text{WO}_3$ powder packed in quartz glass ampoules was irradiated in high-flux nuclear research reactors in different irradiation cycles. After cooling, the ampoules were delivered to the production facility for chemical processing. Irradiated $^{188}\text{WO}_3$ powder was dissolved in hot oxidative alkaline conditions and chemically optimized for the loading

of $^{188}\text{W}/^{188}\text{Re}$ generators. The processes were performed in a hot cell using a technical unit designed for the purpose. Additionally, $^{188}\text{W}/^{188}\text{Re}$ generators were produced using ^{188}W activity provided by a commercial source. **Results:** Several generators were produced during the period of six months, majority of them using the activity obtained from $^{188}\text{WO}_3$ ampoules. The measured ^{188}W activities of the ampoules varied between 92.3 - 39.4 GBq* depending on reactor and number of irradiation cycles in question. The activities of the generators in terms of elutable ^{188}Re varied between 57.9 - 17.4 GBq* when loaded with $^{188}\text{WO}_3$ based activity and 128.2 - 18.6 GBq when loaded with commercial ^{188}W solution. The reported activities of the generators partly varied depending on the intended use (customer order, etc.). In the quality control the monitored gamma-ray emitting radionuclidic impurities included ^{51}Cr , ^{95}Zr , ^{95}Nb , ^{99}Mo , ^{124}Sb , ^{187}W , ^{191}Os and ^{192}Ir (raw materials), and ^{60}Co , ^{124}Sb , ^{191}Os and ^{192}Ir (generator eluates). In the specifications of the $^{188}\text{W}/^{188}\text{Re}$ generators the amount of gamma-ray emitting radionuclidic impurities including breakthrough of ^{188}W in eluate is limited to $< 1.0\text{e-}04$ in relation to ^{188}Re at calibration time, and the radiochemical purity of eluate is limited to $> 98\%$ as Re(VII). * Normalized to EOI **Conclusion:** The developed production chain utilizing irradiated $^{188}\text{WO}_3$ has made it possible to re-establish the full production of $^{188}\text{W}/^{188}\text{Re}$ generators at the time when the availability of commercially produced ^{188}W solution was scarce. In the future, this technology will be an important amendment to commercially produced ^{188}W in providing activity for generator production. **References:** None

OP-959

Development of an in-house $^{188}\text{W}/^{188}\text{Re}$ generator

M. Van de Voorde¹, A. Burgoyne¹, B. Ponsard¹, E. Dennis¹, T. Cardinaels^{1,2}, M. Ooms¹;
¹SCK CEN, Mol, BELGIUM, ²KU Leuven, Leuven, BELGIUM.

Aim/Introduction: ^{188}Re decays by emitting high-energy beta particles (E_{max} : 2.1 MeV, E_{av} : 784 keV), which can be used to kill targeted tumor cells. The short half-life ($t_{1/2} = 16.9 \text{ h}$) of ^{188}Re allows it to be used in targeted radionuclide therapy when linked to peptides or antibodies. ^{188}Re decays with a 155 keV (15%) gamma emission suitable for imaging and dosimetry. Combining these properties make ^{188}Re an ideal theranostic agent in clinical nuclear medicine. Furthermore, ^{188}Re is readily available from a $^{188}\text{W}/^{188}\text{Re}$ generator which enables the use of nca ^{188}Re in hospitals and remote locations [1]. **Materials and Methods:** In light of the recent shortage of $^{188}\text{W}/^{188}\text{Re}$ generators on the market we undertook efforts to prepare our own generator to provide a constant ^{188}Re supply for our research into ^{188}Re -based radiopharmaceuticals. Enriched ^{186}W (99.7%) was irradiated at high fluxes in the BR2 reactor to produce MBq amounts of ^{188}W ($t_{1/2} = 69 \text{ d}$) via double neutron capture. Following a

significant cooling time to allow for ^{187}W decay ($t_{1/2} = 23.72$ h), the ampoules were opened and the target dissolved and characterized. The tungsten solution was then loaded on an Al_2O_3 column from which ^{188}Re could be eluted. ^{188}W breakthrough was investigated in the initial ^{188}Re “milkings”, finding a radionuclidic purity of >99.99% for ^{188}Re . The generator eluent was successfully concentrated (~800 μl) with the aid of cation exchange and anionic exchange cartridges. **Results:** Using this protocol, we developed small-scale $^{188}\text{W}/^{188}\text{Re}$ generator that allows production of MBq amounts of ^{188}Re for radiolabeling. To show that the ^{188}Re can be used for radiolabeling, we performed proof-of-concept radiolabeling experiments with MAG3 and an in-house developed chelator. Initial radiolabeling experiments showed that high radiolabeling yields could be achieved. **Conclusion:** We have developed and optimized an in-house $^{188}\text{W}/^{188}\text{Re}$ generator to provide MBq amounts of nca ^{188}Re on a daily basis. Upscaling of our $^{188}\text{W}/^{188}\text{Re}$ generator will lead to a reliable supply of ^{188}Re for our ongoing research towards ^{188}Re -radiopharmaceuticals. **References:** [1.] B. Ponsard et al., J. Radioanal. Nucl. Chem., 2003. 257, 169-174

OP-960

Exploring a new library of ligands for [^{68}Ga]Gallium radiopharmaceutical application

E. Cazzola¹, C. De Rosa², J. Amico¹, M. Malachini¹, C. Nardon², G. Gorgoni¹, F. Piccinelli²;

¹Radiopharmacy and Cyclotron Dept, IRCCS Sacro Cuore Hospital, Negrar, ITALY, ²Biotechnology Dept, University of Verona, Verona, ITALY.

Aim/Introduction: In the last fifteen years radioactive [^{68}Ga] Gallium has gained more and more importance in Nuclear Medicine due to its favorable half-life, easy preparation and important theranostic pair in combination with [^{177}Lu] Lutetium. For this reason, many studies were focused to the design of new ligands capable to ensure more tunable radiopharmaceutical properties. Bpccd=N,N'-Bis(2-pyridylmethyl)-trans-1,2-diaminocyclohexane-N,N'-diacetic acid is an interesting diaminoacetic acid ligand that can be potentially used to coordinate a group IIIA nuclide like [^{68}Ga]Gallium. The H_2bpcd is a 6-fold coordinating ligands (which employs two acetic acid functions, four nitrogen atoms). The rotational restriction about the C-C bond of the cyclohexane ring gives rise to a pre-organized configuration, which, from a coordination chemistry point of view, is thermodynamically convenient. The final complex will be positive charged. The aim of this study is the investigation of the coordination chemistry towards for the trivalent [^{68}Ga]Gallium ion, and the stability of the relative complexes. **Materials and Methods:** The [^{68}Ga] GaCl_3 solution from generator was used to test different reaction conditions using this class of new ligands. In particular, different concentrations, pH values and reaction

temperatures have been investigated to find the optimal protocol. A kinetic study for all the samples was performed using the TLC and HPLC techniques over time. In detail, TLC analysis were performed with iTLC-SG mobile phase NH_4Ac (77 g/L; $\text{H}_2\text{O}/\text{MeOH}$). HPLC analysis were typically performed by means of Luna OMEGA 5 μm 100A Polar C18 column (250x4,6 mm) as stationary phase and a mixture of A=($\text{H}_2\text{O} + 0.1\text{TFA}$) and B=($\text{ACN} + 0.1\%\text{TFA}$) as eluent. Flow: 1 mL/min, gradient 0-3 min from 0% B to 100% B (ranging 3-25 min). **Results:** To date, most of the explored ligands show a promising reactivity in the tested temperature interval with an almost total conversion of free [^{68}Ga] GaCl_3 to the complexed one in less than 15 minutes. A complete characterization of the complexes was carried out using $^1\text{H-NMR}$ spectroscopy and HPLC-mass spectrometry using the non-radioactive counterpart. **Conclusion:** Based on the high stability recorded under the reaction conditions, the collected results pave the way to further radiochemical characterization, as well as biological in vitro studies. **References:** [1] Piccinelli, F.; De Rosa, C.; Melchior, A.; Faura, G.; Tolazzi, M.; Bettinelli, M. Eu(III) and Tb(III) Complexes of 6-Fold Coordinating Ligands Showing High Affinity for the Hydrogen Carbonate Ion: A Spectroscopic and Thermodynamic Study. *Dalt. Trans.* 2019, 48 (4), 1202-1216.

Aim/Introduction: Ac-225 has nuclear properties well suited for use in targeted alpha therapy and clinical trials have demonstrated the applicability of radiopharmaceuticals containing Ac-225 to treat various cancers. Despite promising results from recent clinical trials, Ac-225-radiopharmaceutical development has been hindered by insufficient supply for the demand. An electron linear accelerator has many advantages, its size is relatively small and a high beam current is easily achieved. Hence, we have carried out a feasibility study of Ac-225 production by using an electron linear accelerator. **Materials and Methods:** We carried out a basic examination of Ac-225 production using the electron linear accelerator of the Tohoku University Research Center for Electron Photon Science. We used $\text{Ra-226}\cdot\text{Cl}_2$ (Ra-226, 50 kBq) as a target nuclide, the electron beam energy was 35 MeV, the current was 140 μA and irradiation time was 5.25 h. Ac-225 is in radiation equilibrium with Fr-221 and Bi-213. Hence, we evaluated Ac-225 production

amount using gamma-ray counting rates of Fr-221 and Bi-213 measured with an HPGe detector. We also carried out an Ac-225 production calculation and compared calculated and experimental values of Ac-225 production amount. We derived the bremsstrahlung radiation distribution using the Monte Carlo radiation transport calculation code PHITS [1]. There are no experimental data for the Ra-226(γ, n)Ra-225 nuclear reaction, so we derived the production rate of Ra-225 using our derived bremsstrahlung radiation distribution and the theoretical reaction cross section data [2]. Ac-225 production amount was derived by calculation of radiation balance with Ra-225. Using these results, we also estimated the Ac-225 production amount in a real-scale system using the same calculation method. **Results:** We found that experimental Ac-225 production amounts were 1.42 times (using gamma-ray counting rate of Fr-221) and 1.37 times (using gamma-ray counting rate of Bi-213) larger than the calculated value. Based on these results, we evaluated the production amount of Ac-225 in the real-scale Ac-225 production system (Ra-226·Cl₂, 3.85 g; acceleration energy, 35 MeV; current, 1 mA) and found that 56.5 GBq per 20-h irradiation could be produced. **Conclusion:** The amount of Ac-225 produced using an electron linear accelerator was estimated and the system was found to have a high Ac-225 production capability. **References:** [1] T. Fluorine-18 labelling of biomolecules via disulfide rebridging for PET imaging

M. Richard, B. Kuhnast;

Université Paris-Saclay, CEA, CNRS, Inserm, BioMaps, Service Hospitalier Frédéric Joliot, Orsay, FRANCE.

Aim/Introduction: Fluorine-18 labelled biomolecules are increasingly employed in clinical imaging for diagnosis purposes. Given their fragility and complexity, it necessitates the development of site-selective labelling techniques in mild conditions. Besides, it is essential to develop labelling procedures with minimal modification of the tertiary structure, as it is fundamental for biological activity. Disulfide rebridging is a promising possibility since it allows protein modification as well as conservation of the tertiary structure (1). In this context, we have developed an original method for the radiofluorination of disulfide containing biomolecules via disulfide rebridging. We applied it to the labelling of octreotide, a somatostatin analogue employed for the imaging of neuroendocrine tumours, and to the labelling of trastuzumab, a monoclonal antibody used to treat HER2-

positive breast cancer. **Materials and Methods:** The labelling strategy relies on the preparation of a radiofluorinated prosthetic group presenting a disulfide rebridging moiety followed by rebridging of the reduced biomolecule. To this end, the synthesis of a labelling precursor presenting both a dithiophenolmaleimide group (rebridging moiety) and an activated pyridine group containing a trialkylammonium leaving group for nucleophilic substitution with Fluorine-18 was carried out. **Results:** The labelling precursor was reacted with K^{[18F]F}-K₂₂₂ complex for 30 minutes at 40°C affording the radiofluorinated dithiophenolmaleimide in a 25 % radiochemical yield (d.c.) after reformulation on a C18 cartridge. This prosthetic group was then reacted with the biomolecules previously reduced with TCEP. In the case of octreotide, radioHPLC analysis showed complete rebridging after 10 minutes at room temperature. Affinity of the rebridged octreotide was evaluated (K_i = 2.04 nM). Regarding trastuzumab, initial experiments showed the formation of the expected radiolabelled antibody with a 13 % radiochemical yield (d.c.) after 60 minutes at room temperature. **Conclusion:** The preparation of a highly reactive radiofluorinated maleimide was carried out and enabled the selective rebridging of the native disulfide bond of octreotide in 10 minutes. To test the scope of this original radiolabeling strategy, the method was also applied on a more complex biomolecule (trastuzumab) and showed promising results. To go one step further, the preparation of DFO- or DOTA-containing maleimides will be implemented and radiolabelling of biomolecules with Zirconium-89 or Copper-64 viarebridging will thus be explored in the near future. **References:** (1) Kuan, S. Aim/Introduction: [⁸⁹Zr]Zirconium is one of the emergent isotopes due to its favorable PET imaging characteristics (β^+ -max 0.395 MeV; 22.7%) and half-life (T_{1/2}78.4h) ideal for antibodies labeling. Monoclonal antibodies (MAbs) are the most approved biopharmaceutical in the word with multiple and selective targets. The immunoPET can facilitate the approval for new MAbs and can help on patient selection. Due to these needs, a robust production, purification and labelling procedure should be optimized on automatic modules in order to minimize the operator dosimetry and increase the reproducibility. Aim of this work is based on easy modifications of an automatic, cassette-

based, commercial module in order to dissolve the solid target and purify the ^{89}Zr Zirconium in oxalate form. After the formulation, in the same cassette, the ^{89}Zr ZrOx will be used to label Trastuzumab and finally purify the ^{89}Zr ZrTrastuzumab. The use of disposable cassettes reduce the possibility to accumulate metal impurities, avoids cleaning step, which are instead mandatory when working with synthesis modules based on fixed tubes technology.

Materials and Methods: A cassette-based module was used to set up an automatic dissolution, purification and labelling procedure. The solid ^{89}Y Yttrium target was bombarded on cyclotron at 12.5 MeV, without degrader, at different currents (20–60 μA) for a variable time 30–240 minutes. The coin was transferred to a dedicated coated hotcell and finally inserted on a cassette module in order to dissolve and purify the $^{89}\text{Zr}/^{89}\text{Y}$ material. A 2 N HCl solution was used to dissolve the target material, the solution was transferred to a ZR resin and recovered in the oxalate form. The ^{89}Zr ZrOx solution was used to label DFOTrastuzumab. The final purification based on PD10 was performed and the final solution, was evaluated on a standard quality control profile including immunoreactivity. **Results:** To date, all the process take place in less than 2h starting to target management up to radiopharmaceutical formulation. **Conclusion:** What we described on this work is one of the possible way to optimize the automatic ^{89}Zr Zirconium production starting from ^{89}Y Yttrium solid target including: dissolution, purification, MAb labelling, ^{89}Zr ZirconiumMAb purification and formulation. This process is based on cassette module to minimize the impurities, avoid any manual operation on radioactive material management and facilitate the regulatory process for radiopharmaceutical application.

An automated method for locating a liver reference region in PET/CT scans

A. Goddard^{1,2}, G. Platsch³, C. Gall¹, L. Sibille¹, B. Spottiswoode¹, V. Shah¹;

¹Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA, ²Illinois Institute of Technology, Chicago, IL, UNITED STATES OF AMERICA,

³Siemens Healthcare GmbH, Erlangen, GERMANY.

Aim/Introduction: A reference region in the liver is commonly used to determine threshold values for segmentation (e.g.-PERCIST) or provide disease scoring (e.g.-Deauville criteria). This work proposes an automated method to find an optimal liver reference region on PET/CT images. **Materials and Methods:** The proposed method consists of automatically segmenting the liver¹ and placing a 3-cm diameter sphere (as-per-PERCIST) at a homogenous position within the liver. The spherical VOI was placed on all voxel positions within the liver (segmented-mask-eroded-1.5cm). For each position the coefficient of variance (CoV) was separately calculated for PET and CT, and combined to determine a joint score. The VOI with the lowest joint score was selected as the optimal liver reference region. For comparison, a 3-cm sphere was centered on a liver landmark automatically detected using ALPHA-technology². Two-experienced nuclear medicine physicians [CvG-reader1,GP-reader2] reviewed the position of the ALPHA-derived landmark and if required moved the VOI to avoid vessels or liver metastases. 205,¹⁸F-FDG PET/CT scans evaluated: lung cancer[43%], lymphoma[24%], melanoma[10%], colorectal[3%], other[20%] cancers. Six-scans were excluded due to failure of automated technology (4-ALPHA landmarking,2-Liver Segmentation). Data was acquired on a range of scanners Siemens-(TruePoint[4%], mCT[52%],Horizon[18%], Vision[13%]) and GE-Discovery[13%]^{3,4}. **Results:** The reference region CoV across all patients [mean \pm stdev] for [reader1 (11.9 \pm 5.0%), reader2 (11.6 \pm 5.2%), ALPHA-Landmark (12.5 \pm 5.8%), proposed-method (9.1 \pm 3.9%)]. The landmark obtained by ALPHA-technology was moved in 68-scans[reader1-only:48, reader2-only:6, both:14]. When both clinicians corrected the reference region the SUVmean \pm SUVstdev: average of two readers: 2.2 \pm 0.4, proposed-method: 2.2 \pm 0.4, and ALPHA-method: 2.4 \pm 1.2. The percent difference in the PERCIST-threshold-value(1.5*SUVmean \pm 2*SUVstdev) compared to the average of the readers for all 14 scans was 15.5 \pm 61.8% for the ALPHA method and -1.2 \pm 4.2% for the proposed method. **Conclusion:** This study shows selecting liver reference regions based on minimum CoV in the PET CT volumes is more robust than performing landmarking only on CT scans. Early evidence is shown that the organ segmentation seems to be more robust in terms of failure in this small cohort. For subjects where both readers moved the reference region on old method, the mean SUV and PERCIST threshold values of the proposed algorithm were consistent with the clinician-placed regions. These early results are promising to provide a new tool for improving the use of PERCIST by using a hybrid approach to identify the optimal placement of the input VOI. **References:** [1]Yang.et.al.(2017)."Automatic-liver-segmentation using an adversarial image-to-image network."Proc.MICCAI,pp.207-515. Effectively Detecting Left Bundle Branch Block Artefacts With a Convolutional Neural Network (CNN) Using a Very Small Training Dataset

M. Abdi¹, Q. Naili¹, M. Habbache¹, B. Said¹, A. Boumenir¹, T. Douibi¹, D. Djermane², S. Berrani³;

¹Centre d'imagerie scintigraphique, Blida, ALGERIA,

²Cardio A2, Mustapha Bacha, Algiers, ALGERIA, ³Ecole Nationale Polytechnique, Algiers, ALGERIA.

Aim/Introduction: Left bundle branch block (LBBB) is a frequent source of false positive reports in myocardial perfusion imaging[1]. In this work, we evaluated the ability of a CNN-based solution, using transfer learning, to produce an expert-like judgment in differentiating LBBB artefacts from left anterior descending artery (LAD) perfusion defects. The study was conducted considering a very small training dataset, because collecting a larger dataset needs a proof of utility. **Materials and Methods:** The study covered two groups, collected retrospectively. (i) The LBBB group included patients with LBBB on ECG, along with mild to severe fixed anteroseptal perfusion defect, that was judged as false positive by two experts (based on clinical assessment, GATED-SPECT[1], and having no cardiovascular events after 3 years of follow-up). (ii) The LAD group included patients without LBBB, with mild to severe anteroseptal perfusion defect, that was judged as a true positive by two experts (confirmed by angiography; >70% narrowing of LAD artery). The dataset was composed of 107 perfusion polar maps (42 images in each class for training, with 29% for validation). Several CNN were tested[2], and ResNet50V2 was chosen for achieving the best results. Only the classification part of the network was re-trained, following a transfer learning approach. After 60 iterations, the reached accuracy plateau was 0.98, and the loss was 0.19 (the validation accuracy and loss were 0.91 and 0.25, respectively, demonstrating low overfit). **Results:** A set of 23 test images was used (11 LBBB, and 12 LAD). The empiric ROC Area[3] was estimated at 0.98, with 95.7% accuracy. Two blinded experts were asked to classify the testing images. The results of empiric ROC area for them were 0.97 and 0.91, respectively. Another test set (18x2 images) was collected after the final results (without follow-up for the LBBB group). The ROC area was estimated again at 0.98. The results showed that our CNN-based approach can reproduce expert-like judgment for this problem. **Conclusion:** Artificial intelligence, using CNN and transfer learning –even on a very small training dataset– could reproduce an expert-like judgment in differentiating between LBBB artefacts and LAD perfusion defects. These

results are motivating for a multicenter prospective study. **References:** 1. Metabolic tumour volume segmentation for oesophageal cancer on hybrid PET/CT using convolutional network architecture

E. Spezi¹, C. Parkinson¹, S. Berenato², W. Riviera³, S. Sobhee⁴, C. Stylianou⁵, T. Crosby², K. Foley²;

¹Cardiff University, Cardiff, UNITED KINGDOM, ²Velindre Cancer Centre, Cardiff, UNITED KINGDOM, ³Intel Corporation, London, UNITED KINGDOM, ⁴Intel Corporation, Munich, GERMANY, ⁵Intel Corporation Limited, London, UNITED KINGDOM.

Aim/Introduction: Oesophageal cancer (OC) has a particularly poor prognosis with an overall 5-year survival rate of only 15%. OC is rising in incidence and is a cancer with unmet clinical need. The segmentation of metabolic tumour volume (MTV) is time consuming and subject to intra and inter-observer variability. This study aims to increase the efficiency of MTV segmentation in OC by developing a hybrid PET/CT deep-learned model based on convolutional network architecture. **Materials and Methods:** A data set of 440 patients with biopsy-proven OC tumours was included in this study. All patients had PET/CT acquisition using a GE 690 scanner with time of flight. Details of patient selection and image acquisition parameters were published by our group ^{1,2,3}. Only primary tumours were used in this study for the development of a deep-learning model. The primary MTV was delineated on PET imaging using a previously published segmentation method^{4,5} and reviewed by a consultant radiologist. For the convolutional network architecture, we used a 2-dimensional (2D) based U-Net architecture⁶. The developed model was trained using a cluster consisting of 2 nodes. Each node contained 2 CPU's running at 2.10GHz, resulting in total of 88 threads per node. Contours delineated with the proposed deep-learned model were assessed using a Turing test including a total 376 images with associated contours for evaluation by 5 independent radiologists (Ob1 - Ob5). **Results:** The mean Dice Similarity Coefficient (DSC) of the U-net architecture, when compared to manual outlines, was 0.73. In the Turing test, Ob1 to Ob5 had accuracies of 0.55, 0.73, 0.47, 0.64 and 0.46, respectively. Sensitivity for Ob1 to Ob5 was 0.66, 0.64, 0.38, 0.56, and 0.47 respectively. Specificity for Ob1 to Ob5 was 0.44, 0.83, 0.57, 0.71, 0.46. The area under the curve values ranged from 0.46 to 0.73. **Conclusion:** We successfully trained a convolutional network to segment the metabolic tumour volume on hybrid PET/CT oesophageal cancer.

The performance of the network was confirmed to be equivalent to expert delineation. **References:** 1. Foley, K.G. et al., 2018. *Eur. Radiol.* 28, 428–436. 2. Foley, K.G., et al. 2019. *Radiother. A tool for AI-driven Organ Segmentation and quantification in SSTR- imaging - Development and external validation

P. Jackson¹, B. M. Fischer², S. F. Barrington², L. McIntosh¹, T. Kotwa², G. Krokos², J. Callahan¹, J. Korte¹, R. Alipour¹, M. Hofman¹, R. J. Hicks¹;

¹Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, ²King's College London & Guy's and St Thomas' PET Centre, London, UNITED KINGDOM.

Aim/Introduction: AI methods are showing potential for automatic delineation of organs using CT imaging. Our aim was to determine if convolutional neural networks could rapidly and reliably delineate organs on the CT component of PET/CT and SPECT/CT somatostatin receptor (SSTR) imaging, namely kidneys, spleen, bladder, & liver. These organ segmentations facilitate assessment of lesional Krenning score for radionuclide therapy, prediction of potential toxicities, discrimination between malignant and physiological uptake in somatostatin-avid tissues, or selection of novel adaptive thresholds to characterise highly avid regions in SSTR imaging. **Materials and Methods:** Organs were contoured on CT by first aligning to a reference coordinate system using a novel 2D image recognition neural network. Subsequently, organ-specific crop regions were selected and labelled by conventional 3D U-Net. Training data for kidney (n=93) and bladder (n=110) were manually contoured from clinical data. Contours for liver (n=161) and spleen (n=41) were taken from a publicly-available dataset¹. The tool was assessed in an external dataset of 20 FDG PET/CT images. Accuracy was scored visually by an independent experienced nuclear medicine physician rating reliability of automated contouring as follows: 1 good agreement, no correction needed 2- minimal correction required, 3- major editing required 4- no contour identified. **Results:** Images were rated as showing good agreement or minimal correction needed in 16/20 cases for liver, 12/20 for bladder, 18/20 for left kidney, and 13/20 for right kidney. The mean and standard deviation of accuracy scores for liver, bladder, left kidney, and right kidney were 1.7±0.7, 2.1±1.0, 1.5±0.7, and 2.0±1.1, respectively. Results were worse for splenic contouring with the fewest available training cases. Spleen was not identified in 4/20 cases, accuracy score=2.2±1.2. The algorithm was incorporated into a DICOM processing

pipeline. Contours were generated automatically as an RT-structure set on a typical desktop computer. Workflows that automated removal of labelled somatostatin-avid organs reduced the time required to remove physiological uptake and assess tumour burden in a modified PERCIST workflow for SSTR imaging. **Conclusion:** It is feasible to rapidly contour organs using an AI-driven tool for the purpose of assessment of functional imaging in neuroendocrine cancer with reasonable accuracy. Further work is warranted to refine the model with additional training cases to develop a mature tool for clinical application. **References:** ¹Simpson, Amber L., et al. Automatic Image Subtraction in Parathyroid Scintigraphy using Rotated Principal Components

I. Marikova¹, S. Balogova², J. Talbot³, M. Samal¹;

¹Institute of Nuclear Medicine, First Faculty of Medicine, Charles University and the General University Hospital in Prague, Prague, CZECH REPUBLIC, ²Department of Nuclear Medicine, Comenius University, Faculty of Medicine & St. Elisabeth Cancer Institute, Bratislava, SLOVAKIA, ³Department of Nuclear Medicine, Hôpital Tenon APHP and Sorbonne University, Paris, FRANCE.

Aim/Introduction: Image subtraction in parathyroid scintigraphy requires registration of the two images and estimation of subtraction weights reflecting different count rate produced by different radiopharmaceuticals. Pixel values in both images are usually converted to similar scales and subtraction weights derived stepwise by trials and errors under visual supervision. Our motivation was to simplify and accelerate manual procedure by using rotated principal components (RPC) where both scaling and weighting can be optimized automatically. The aim was to assess performance of RPC with perfectly registered pairs of 99mTc-MIBI and 123-Iodine images. **Materials and Methods:** Retrospective data on parathyroid scintigraphy in 26 patients were selected from the database and anonymized. MIBI and Iodine image pairs included 25 early and 22 delayed pinhole scintigrams and 24 early and 18 delayed planar images. RPC was performed with all 89 image pairs using inhouse software. Image scaling was automatic. The method resulted in two images demonstrating common and difference structures of each input pair. Subsequent rotation (analogy to image subtraction) was performed to emphasize unique structures specific exclusively for MIBI image on flat background (removing both oversubtracted and residual common image segments). Three rotation procedures were compared: (A) manual procedure under visual supervision (reference method), (B) semi-automatic procedure that required manual definition of background ROI, and (C) automatic procedure that defined background

ROI automatically. Parametric images visualizing entropy in the neighbourhood of each pixel were also calculated. **Results:** All 37 lesions found in 25 early pinhole image pairs were well reproduced by both semi-automatic and automatic procedures (100 %). While semi-automatic procedure reproduced 100 % of the lesions found in delayed pinhole reference images, automatic procedure failed in 8 % probably due to low counts in iodine scans. In early planar images, semi-automatic and automatic procedures found 96 % and 93 % of the lesions revealed by supervised manual procedure. There were only 10 lesions found in 18 delayed planar images that were reproduced in 100 %. In comparison with reference manual procedure, both semi-automatic and automatic RPC were faster and more comfortable. Parametric images supported interpretation of difference images by emphasizing positive lesions by locally lowest image entropy. **Conclusion:** In well registered images with sufficient counts, automatically rotated principal components perform as well as manual stepwise subtraction procedure under visual supervision. The advantage is the speed of the method, comfort of a user, and potential future inclusion in the procedures of machine learning. **References:** None

OP-969

A cross-scanner robust deep learning method for the recovery of full-dose imaging quality from low-dose PET
S. Xue¹, R. Guo², K. P. Bohn¹, J. Matzke³, M. Viscione¹, M. Viscione¹, B. Li², A. Rominger¹, K. Shi¹;

¹University of Bern, Bern, SWITZERLAND, ²Ruijin Hospital, Shanghai Jiaotong University, Shanghai, CHINA, ³Technical University of Munich, Munich, GERMANY.

Aim/Introduction: Despite the fact that radiation dose of modern PET imaging became much less than in early days, it still remains a major bottleneck for extensive application of this modality. Artificial intelligence has been recently developed to recover high-quality imaging from low-dose scans. However, it is not clear if the methods developed on one scanner can be applied to other scanners. **Materials and Methods:** Brain PET imaging of 245 patients scanned with scanner 1 was included for the development of the AI technology. Then the developed algorithm was tested on data of 8 patients with scanner 1, 27 patients scanned with scanner 2 and 9 patients scanned with scanner 3. All data was scanned in list mode for 15 min. In addition to the reconstruction of full dose imaging of 15 min, reduced frames of 7.5 min, 3.75 min, 1.5 min and 0.75 min were reconstructed to mimic a dose reduction fraction (DRF) of 2, 4, 10 and 20. A 2D generative adversarial network (GAN) was developed with a U-net generator and a convolutional neural network (CNN) based discriminator. For each DRF, a corresponding GAN was trained. The normalized root mean squared error (NRMSE), structural similarity index (SSIM)

and peak signal-to-noise ratio (PSNR) were calculated to evaluate the results generated by AI. Analysis of variance (ANOVA) was performed to examine the robustness and generalization ability of our algorithm, where the level of significance α is set to 0.05. Two independent nuclear medicine physicians assessed the interpretation ability towards a diagnosis. **Results:** The developed AI method can achieve a good physical performance with an average SSIM of 0.99 ± 0.004 , PSNR of 39.4 ± 3.7 , and NRMSE of $0.66 \pm 0.32\%$ for DRF=2. The performance decreased as DRF increased and for DRF=20 it achieved the average SSIM of 0.94 ± 0.018 , PSNR of 26.8 ± 3.3 and NRMSE of $2.9 \pm 1.1\%$. The ANOVA test showed no significant difference of NRMSE, PSNR and SSIM between the AI predictions on the three scanners in most cases, exception occurred to NRMSE and PSNR when DRF=2, where variation between scanner brands is the major source of difference. Clinical reading was performed in a subset of patients and after correction no significant impairment could be observed for DRF up to 20. **Conclusion:** The developed deep learning method is robust in the application on scanners of different vendors and technology. This encourages the further investigation of this method with emphasis on clinical interpretation. **References:** None

Zero-TE MRI-based Attenuation Correction for Chest FDG PET/MRI: A Feasibility Study of Deep Learning Approach Using Unpaired PET/CT Data

M. Nogami¹, H. Matsuo¹, M. Nishio¹, F. Zeng¹, J. Inukai¹, F. Wiesinger², S. Kaushik², T. Kurimoto³, K. Kubo¹, T. Murakami¹;
¹Kobe University Hospital, Kobe, Hyogo, JAPAN, ²GE Healthcare, Munich, GERMANY, ³GE Healthcare, Hino, Tokyo, JAPAN.

Aim/Introduction: Deep learning approaches using pseudo computed tomography (pCT) for attenuation correction (AC) of chest positron emission tomography-magnetic resonance images (PET/MRI) is challenging as differences in subject's respiratory phase, body position, and scanner bed shape can hamper pairing data of images for training. Moreover, conventional generative adversarial networks (GANs) using unpaired training data suffer from significant deformation of the generated pCT. Here we propose using unsupervised GANs with adaptive layer-instance normalization for image-to-image translation (U-GAT-IT) in combination with a modality independent neighborhood descriptor (MIND) to create pCT for AC in the chest. **Materials and Methods:** The data of 125 patients who underwent chest fluorodeoxyglucose (FDG) PET/MRI with zero echo time (ZTE) were retrospectively analyzed. All ZTE images were scanned with a large field of view and reconstructed in-phase by central frequency adjustment. Unpaired training image data included bias-corrected ZTE (n=100) and CT component of PET/CT (n=100), and

were utilized for training U-GAT-IT/MIND model of pCT generation. Human annotation was not performed for the construction of unpaired training image data. Twenty-five cases with paired ZTE PET/MRI and PET/CT were used to validate the model for standardized uptake values (SUV) after AC. Mean SUV (SUVmean) of bone and liver in the chest region were measured by segmentation of bone on pCT and placement of a fixed region of interest in the liver, respectively. An MRI-based AC map with bone ($MRAC_{ZTE}$) was created by merging the segmented bone map onto a conventional 2-point Dixon-based AC map ($MRAC_{Dixon}$), and was applied to PET reconstruction on the offline workstation. Bland-Altman plots and ANOVA were used to compare SUVmeans between $MRAC_{Dixon}$, $MRAC_{ZTE}$ and CT-based attenuation correction (CTAC). **Results:** Mean differences in bone SUVmeans by $MRAC_{ZTE}$ and CTAC (-0.0252; 95% confidence interval (CI), -0.1014 to 0.05104) were significantly smaller than by $MRAC_{Dixon}$ and CTAC (-0.0988; 95%CI, -0.1741 to 0.02353) ($p < 0.05$). Bone and liver SUVmean (0.918 and 2.300, respectively) by $MRAC_{ZTE}$ were significantly larger than by $MRAC_{Dixon}$ (0.844 and 2.252, respectively) ($p < 0.0001$). **Conclusion:** AC maps with bone components from pCT yield smaller differences in bone SUV with CT-based AC than do $MRAC_{Dixon}$ and larger SUVs in the bone and liver than $MRAC_{Dixon}$, supporting the feasibility of deep-learning approaches with unpaired data sets for pCT and AC map creation for chest PET/MRI. **References:** 1. Deep learning based scatter correction for PET imaging

D. Visvikis¹, T. Merlin², A. Bousse¹, D. Benoit¹, B. Laurent¹;

¹LaTIM, INSERM, UMR 1101, Brest, FRANCE, ²LaTIM, INSERM, UMR 1101, CHRU Brest, Brest, FRANCE.

Aim/Introduction: Scatter correction in PET imaging is routinely performed using a single scatter simulation (SSS) approach, where multiple scatter and scatter from outside the field of view are not accurately modeled leading to reduced qualitative and quantitative PET image accuracy. In this work we explore the potential of deep learning for the development of an accurate PET scatter correction methodology accounting for all scatter coincidences. **Materials and Methods:** The network used is based on a U-Net architecture with 5 convolutional layers. The input corresponds to emission data and attenuation sinograms, while the output corresponds to scatter sinograms of the same size as the input. The network training was performed using Monte Carlo (MC) simulated PET datasets. Multiple anthropomorphic XCAT phantoms of two different regions (lung and pelvis) were created, considering three different body sizes and different levels of statistics (1-6 minutes

acquisitions). A total of 216 simulations were performed. Each sinogram contains 553 slices, leading to a total of 120 000 simulated slices. This entire dataset was subsequently divided in 3 parts: 2/3 for the training data, 1/6 for validation and 1/6 for testing data. Moreover, to train the network and evaluate its precision and robustness among different levels of statistics, acquisitions were simulated with various dose levels and acquisition times. In addition, two patient images acquired on an mMR scanner at the level of the lung and the pelvis were used to assess the expected performance of the algorithm relative to a perfect scatter correction based on MC simulations and the standard SSS algorithm used in clinical practice. **Results:** The results of the training were independent of data statistics for the use of acquisition times of >2 minutes per bed position. The quantitative accuracy in the simulated reconstructed images corrected using the estimated scatter sinograms output from the proposed network was equivalent to that achieved by a full MC based scatter correction. The results were not dependent on the body location (lungs or pelvis). In the case of the clinical patient datasets the results in the pelvis clearly demonstrated a reduction in the artefacts related to the use of the SSS approach. **Conclusion:** In this work we developed a deep learning based approach for scatter correction in PET imaging. The results obtained demonstrate the interest of this approach relative to the standard SSS methodology used clinically, improving both qualitative and quantitative image accuracy. **References:** None

Data-driven motion compensation of [18F]FDG-PET brain imaging using conditional Generative Adversial Networks (cGANs)

D. Iommi¹, L. Shiyam Sundar¹, O. Muzik², Z. Chalampalakis³, E. M. Klebermass⁴, M. Hienert⁵, L. Rischka⁵, R. Lanzenberger⁵, A. Hahn⁵, E. Pataraiia⁶, T. Traub-Weidinger⁴, T. Beyer¹;

¹QIMP Team, Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA, ²Department of Pediatrics, Children's Hospital of Michigan, The Detroit Medical Center, Wayne State University School of Medicine, Detroit, MI, UNITED STATES OF AMERICA, ³Service Hospitalier Frédéric Joliot, CEA, Inserm, CNRS, Univ. Paris Sud, Université Paris Saclay, Orsay, FRANCE, ⁴Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA, ⁵Department of Psychiatry and Psychotherapy, Medical University of Vienna, Vienna, AUSTRIA, ⁶Department of Neurology, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: The quality of PET images and the accuracy of absolute quantification are affected by involuntary subject motion. We present here a fully-automated, motion correction (MC) approach based on conditional-generative adversarial networks (cGAN) that might promote dynamic

PET acquisitions in clinical routine. **Materials and Methods:** Ten healthy volunteers (5M/5F, (27±7) years, (70±10) kg) underwent a test-retest [18F]FDG-PET/MRI brain examination (N=20). The imaging protocol consisted of a 60-min PET list-mode acquisition with parallel MR-acquisitions including MR navigators and 3D time-of-flight MR-angiography (TOF-MRA). Arterial input function (AIF) was collected as the reference standard. A separate low-dose CT scan was used for brain attenuation correction. Training of the cGAN was performed using 70% of the total data sets (N=14, randomly chosen), which was corrected for motion using the MR navigator sequences. The PET frame corresponding to 55-60 min p.i. was considered as the target frame and all other frames (0 to 55 min p.i.) were individually paired to the target frame. cGAN training was individually applied to the image pairs (early frames to late PET frames) and the resulting cGAN models were applied to the testing data set (remaining 30%, N=6), generating artificial high-count early PET frames with increased image-quality. These volumes were then used for MC during the extraction of an image-derived input function (IDIF). Performance of the cGAN-method to carry out an accurate MC was tested by comparing the area-under-the-curve (AUC) of the so derived IDIF against the gold standard of AIF. The clinical relevance of this methodology was assessed by direct comparison of average cerebral metabolic rates of glucose (CMRGlc) values in grey matter (GM) calculated using the AIF and the IDIF. **Results:** The artificially generated images displayed excellent image quality for frames >2 min p.i., whereas the quality was suboptimal for frames <2 min p.i. Quantitative assessment of motion vector accuracy in the test data set resulted in an absolute % difference between AUCs derived using the motion-corrected IDIF and the AIF of only 1.2±0.9%. Moreover, the GM CMRGlc values determined using these two input functions differed on average by less than 5% (2.4±1.7%). **Conclusion:** A fully-automated data-driven MC approach was established and validated for quantitative [18F]FDG-PET imaging of the brain. The developed cGAN based MC scheme might be pivotal in enabling the translation of non-invasive clinical absolute quantification from PET/MR to PET/CT. **References:** None

Automatic Classification of Data-Driven Respiratory Waveforms Using AI

M. D. Walker¹, K. Su², S. D. Wollenweber², R. Johnsen², D. R. McGowan^{1,3};

¹Oxford University Hospitals NHS FT, Oxford, UNITED KINGDOM, ²GE Healthcare, Milwaukee, WI, UNITED STATES OF AMERICA, ³University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: Data-driven respiratory gating for PET has been implemented clinically^[1]. The decision to apply

gating can be made during the acquisition, modifying the protocol and affecting image quality. This is currently done using a threshold on the signal-to-noise ratio for respiratory frequencies in the respiratory waveform (R-value). We aimed to develop an AI algorithm to improve the accuracy of this decision, and compare its performance to the existing method. **Materials and Methods:** 155 ¹⁸F-FDG PET scans were used to train the AI and evaluate performance. The respiratory waveform was extracted from each of 1134 bed positions. Waveforms were previously scored by two readers using a three-point scale (0, 1, or 2)^[2]. The AI uses a pattern recognition network, designed and trained to predict the readers' scores using ten-fold cross-validation. This provided 10 separate AI predictors, each of which was trained on 90% of the data and predicted the scores for the remaining 10%. Predictions for the entire dataset were thus obtained, with each test waveform not included in the training waveforms for its corresponding AI predictor. Those waveforms with an average reader score ≥1.5 were classified as being clinically useful. This classification provided the standard for performance evaluation of the two methods. The classification accuracies, sensitivities and specificities were calculated. The optimum R-value threshold of 12, found to give maximum accuracy, was used for the comparison. **Results:** The AI outperformed the R-value method. It had higher accuracy (93% vs. 88%), sensitivity (87% vs. 78%) and specificity (96% vs. 92%). The maximum discrepancy between the AI-predicted score and the readers' mean score was small. In all cases the AI correctly classified those waveforms with reader scores of 2 or ≤0.5, corresponding to waveforms where clinical utility was unambiguous. The R-value method had greater variance, leading to some waveforms with mean reader scores of 0 or 2 being misclassified, with R≥12 or R<12 respectively. The ¹⁸F-FDG-trained AI performed well in similar, initial evaluation for ⁶⁸Ga-dotatate (24 waveforms; 96% accuracy). **Conclusion:** An AI-classifier of data-driven respiratory waveforms was developed. In the ¹⁸F-FDG data used for evaluation, the AI had greater concordance with the scores assigned by two medical physicists as compared to the existing technique. This AI approach may allow for improved automation of respiratory gating workflows in PET/CT, with improved decision making as to when motion correction techniques can be confidently applied. **References:** [1] Walker et al. *J Nucl Med* 120.242248.(2020) [2] Walker et al. *EJNMMI Res* 9,1(2019)

The effect of data preparation of small datasets to predict biochemical recurrence in prostate patients from PET/MR imaging

D. Krajnc, L. Papp, C. P. Spielvogel, M. Grahovac, M. Hartenbach, M. Hacker, T. Beyer;

Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Machine learning (ML) approaches have demonstrated potential to improve the diagnostic value of medical imaging and patient management. However, the majority of these studies does not embrace adequate data preparation to address challenges, such as imbalanced subgroups, insufficient sample count and outliers. We aim to demonstrate the importance of applying data pre-processing of small patient cohorts, in order to support ML training processes to predict biochemical recurrence from prostate PET/MRI studies.

Materials and Methods: 36 multi-parametric prostate PET/MRI cases with ^{18}F -FMC, ^{18}F -FMC+ ^{68}Ga -PSMA^{hBED-CC} (dual-tracer) PET furthermore, T2, ADC, iAUC, KEP, Ktrans and Ve MRI images were involved in our study. Each case had biochemical recurrence yes/no information as well as annotated full-mount histopathological slices. Two nuclear medicine experts delineated in consensus the most aggressive lesion on each PET/MR image using the Gleason-annotated histopathological slices. 56 radiomics features were extracted from each delineation. Ensemble learning approaches were applied to predict biochemical recurrence yes/no information in a 100-fold Monte Carlo cross-validation scheme. This step was performed twice: first, with training the predictive models on the original training datasets, and second with processing the training datasets. In training data pre-processing, we performed imbalance data correction, outlier detection as well as data oversampling and undersampling across MC folds. Predictive performance was estimated for both executions over the ML fold validation cases with confusion matrix calculations (sensitivity (SENS), specificity (SPEC) and overall accuracy (ACC)). **Results:** The validation performance including ML models built on the original training data was SENS 35%, SPEC 71% and ACC 53%. In contrast, the validation performance including ML models built on the pre-processed training data was SENS 84%, SPEC 66% and ACC 75%, where sensitivity and overall accuracy significantly increased by 49% and 22% respectively, while specificity slightly decreased (5%) due to model overfitting built on original imbalanced dataset. **Conclusion:** We have demonstrated the added value of performing adequate data preparation steps (ACC 75% vs 53%), suggesting that applying these techniques can support the establishment of ML models based on small patient cohort for prediction of biochemical recurrence in prostate PET/MRI cases.

Novel Software for Computer-aided Differential Diagnosis of Parkinsonism Using Positron Emission Tomography

E. Lindström^{1,2}, C. Widström², T. Danfors², M. Lubberink^{1,2}, M. Jonasson^{1,2};

¹Uppsala University, Uppsala, SWEDEN, ²Uppsala

University Hospital, Uppsala, SWEDEN.

Aim/Introduction: The PET tracer ^{11}C -PE2I is a selective dopamine transporter (DAT) compound that has been successfully introduced for differential diagnosis of Parkinsonism [1]. Using tracer kinetic analysis of a dynamic ^{11}C -PE2I-PET scan, DAT availability and relative cerebral blood flow (rCBF) can be measured at the voxel level. The aim was to develop an automated workflow from dynamic PET-data to statistical comparison of the patient's regional rCBF and DAT availability values to a normal control database, allowing for computer-aided differential diagnosis of Parkinsonism.

Materials and Methods: The automated workflow was based on previously validated and published methodology [2,3]. In brief, the dynamic PET images were realigned to correct for inter-frame patient motion. A volume of interest template in MNI space was projected onto an early sum image. rCBF images were generated from 40-min dynamic PET-data using a basis function implementation of the simplified reference tissue model and SUVR-1 was estimated for the 30-40 min interval, with cerebellar gray matter as reference region. Regionally average voxel values were extracted in conjunction with z-scores from comparison to a normal database (n=30). Surface projection maps of rCBF and rCBF z-score were computed after translation to MNI space. The software was written in Qt and C++ and implemented within the Hermes environment. Results in 22 subjects were compared to a previous analysis using in-house written software in Matlab. **Results:** Quantitative results of the automated software agreed well with previous analysis. Spearman rank correlation r was 0.92 (CI 0.86-0.96) and 0.84 (CI 0.79-0.88) for SUVR-1 in putamen and rCBF in the limbic area, respectively. So far, the software has been used for differential diagnosis of about 300 patients at Uppsala University Hospital. Total processing time of approximately 5 min/patient. **Conclusion:** ^{11}C -PE2I enables a differential diagnosis of Parkinsonism based on both DAT availability and general brain function (rCBF) using a single scan, replacing a dual scan approach using DATscan-SPECT and FDG-PET. The software-aided approach improves logistics and may be helpful for experienced ^{11}C -PE2I-PET readers analyzing challenging cases. The single scan approach and software have been successfully introduced as a routine clinical application at Uppsala University Hospital and the software is freely available for other interested centers. **References:** 1. Prognostic markers for overall survival and outcome to LuPSMA radionuclide treatment in patients with metastatic castration-resistant prostate cancer

A. Gafita¹, J. Calais¹, H. Wang², M. Weber³, H. Rathke⁴, C. Kratochwil⁴, R. Esfandiari⁵, W. R. Armstrong¹, S. Sandhu⁶, R. Tauber², E. S. Delpassand⁵, U. Haberkorn⁴, W. A. Weber², K. Herrmann³, J. Czernin¹, M. S. Hofman⁶, W. P. Fendler³, M. Eiber²;
¹UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, ²Technical University Munich, Munich, GERMANY, ³University of Duisburg-Essen, Essen, GERMANY, ⁴Heidelberg University, Heidelberg, GERMANY, ⁵Excel Diagnostics and Nuclear Oncology Center, Houston, TX, UNITED STATES OF AMERICA, ⁶Peter MacCallum Cancer Center, Melbourne, AUSTRALIA.

Aim/Introduction: The aim of this international multicenter retrospective analysis was to identify prognostic markers for the clinical outcome in late-stage mCRPC patients treated with ¹⁷⁷Lutetium-prostate-specific membrane antigen (LuPSMA) radionuclide treatment. **Materials and Methods:** Patients with progressive mCRPC treated with LuPSMA at six centers in Germany, USA and Australia

were considered for inclusion. Eligible patients had 24 predefined pretherapeutic covariates (demographics, prior mCRPC treatments, and PSMA PET/CT derived parameters) and survival data available. Endpoints included overall survival (OS) and PSA progression-free survival(PSA-PFS). Covariates were tested using univariate and multivariate proportional hazards regression Cox models. **Results:** 267/414 (64%) patients met inclusion criteria and were analyzed. 113 patients participated in clinical trials, while 154 were enrolled in compassionate access programs. After a median follow-up of 22.5 months, median OS was 13.0 months (95%CI 11.6-14.4); 83% of the patients died. Median PSA-PFS was 4.0 months (95%CI 3.2-4.7). In the multivariate analysis, factors associated with shorter OS were: shorter time since diagnosis of prostate cancer (HR = 2.04; p= 0.002), lower number of prior systemic therapies (≤ 3 ; HR = 1.56; p= 0.006), prior exposure to chemotherapy (HR = 1.42; p= 0.05), lower hemoglobin levels (HR = 1.13; p= 0.002), higher number of lesions (≥ 20 : HR = 1.53; p= 0.009), multiple sites of metastases (bone/LN only vs. bone + LN; HR = 1.39; p= 0.03) and visceral involvement (M1c) (HR = 1.45; p= 0.01). Factors associated with longer PSA-PFS were: longer time since diagnosis of prostate cancer (HR = 0.44; p< 0.001), higher hemoglobin levels (HR = 0.32; p= 0.03), presence of pelvic lymph nodes (LN) metastasis (N1) (HR = 0.68; p= 0.01), no distant lymph node metastases (M1a) (HR = 0.66; p= 0.01), no skeleton involvement (HR = 0.44; p= 0.01), no visceral metastases (M1c) (HR = 0.51; p< 0.001), higher PSMA-positive tumor volume (HR = 0.87; p= 0.04), and higher SUVmean (HR = 0.94; p= 0.002). **Conclusion:** This retrospective analysis identified prognostic factors for survival and treatment response to LuPSMA. Along with the conventional risk factors in mCRPC, PSMA PET/CT can be a useful tool for stratifying patients and guide patient's selection for LuPSMA radionuclide treatment. **References:** None

OP-980

Circulating androgen receptor gene amplification and resistance to 177Lu-PSMA-617 in patients with metastatic castration-resistant prostate cancer: results of a phase 2 trial

G. Paganelli¹, S. Severi¹, M. Sansovini¹, S. Nicolini¹, I. Grassi¹, F. von Eyben², V. Conteduca¹, M. Monti¹, F. Foca¹, G. Gurioli¹, M. Celli¹, F. Matteucci¹, U. De Giorgi¹;

¹Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, IRST IRCCS, Meldola (FC), ITALY, ²Center of Tobacco Control Research, Odense M, DENMARK.

Aim/Introduction: Plasma androgen receptor (AR) aberrations have been associated with resistance to hormonal therapy in prostate cancer, however their impact on the prognosis of radio ligand therapy with 177Lu PSMA is unknown. In a phase 2 clinical trial, we aimed to determine if plasma AR

gene status enable early assessment of ¹⁷⁷Lu-PSMA-617 activity in metastatic castration-resistant prostate cancer (mCRPC) progressing after standard survival-prolonging treatments. **Materials and Methods:** In this open-label, single-arm, phase 2 study mCRPC patients with a positive PSMA PET/CT scan received 3.7–5.5 GBq of ¹⁷⁷Lu-PSMA-617 repeated 4–6 times at interval of 8 weeks. We determined AR copy number by droplet digital polymerase chain reaction (ddPCR) on pretreatment plasma samples. Logistic regression was used to estimate the odds ratio (OR) and 95% confidence intervals (95% CI) in order to evaluate the independent relevance of AR status and patients without PSA response (PSA decline >50%) and those with early progressive disease defined as treatment interruption occurring within 4 months of the start of ¹⁷⁷Lu-PSMA-617. **Results:** Forty-three patients were enrolled, 40 of whom were included in the analysis, 15 (32.5%) with AR gain and 25 (62.5%) with AR normal. A PSA response was reported in 15 (37.5%) of the 40 pts, 3 of 15 (20%) with AR gene gain, and 12 of 25 (48%) with no gain ($P = 0.080$). Early progressive disease was observed in 17 (42.5%) of the 40 pts, 12 of 15 (80%) with AR gene gain and 5 of 25 (20%) with no gain ($P = 0.0002$). The OR for patients without PSA response having AR gain was 3.69, 95% confidence interval (0.83–16.36), $P = 0.085$. The OR for patients with early PD having AR gain was 16.00, 95% confidence interval (3.23–79.27), $P = 0.0007$. **Conclusion:** Plasma AR status assessment using ddPCR identifies mCRPC resistant to ¹⁷⁷Lu-PSMA-617. These data suggest potential better activity of ¹⁷⁷Lu-PSMA-617 in earlier phases of prostate cancer. **References:** None

OP-981

Overall survival after ¹⁷⁷Lu-PSMA-617 molecular radiotherapy in patients with metastatic castrate-resistant prostate cancer: Post-hoc analysis of a prospective phase II trial

J. Calais¹, W. R. Armstrong¹, J. Gartmann¹, P. Thin¹, K. Nguyen¹, V. Lok¹, L. Gosa¹, R. Slavik¹, M. Dalhomb¹, K. Herrmann², M. Eiber³, W. P. Fendler⁴, J. Czernin¹;

¹UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, ²University Hospital Essen, Essen, GERMANY, ³Technical University Munich, Munich, GERMANY, ⁴University Clinic Essen, Essen, GERMANY.

Aim/Introduction: This was an open-label randomized prospective bi-centric single-arm phase II clinical trial of ¹⁷⁷Lu-PSMA-617 molecular radiotherapy in patients with progressive metastatic castrate-resistant prostate cancer (mCRPC) conducted at University of California Los Angeles (USA) and Excel Diagnostics & Nuclear Oncology Center (Houston, TX, USA) (NCT03042312). The study was investigator-initiated under an investigational new drug approval protocol (IND#133661) with authorization of charging for investigational drug (cost-recovery, Title 21 CFR 312.8). We report here the post-hoc analysis of overall

survival (OS) in a single-study site cohort (UCLA). **Materials and Methods:** Patients with progressive mCRPC (biochemical, radiographic, or clinical) after ≥ 1 novel androgen axis drug (NAAD), either chemotherapy (CTX) naïve or post-CTX, with sufficient bone marrow reserve, normal kidney function, and sufficient PSMA-target expression by PET were eligible. Patients received up to 4 cycles of ¹⁷⁷Lu-PSMA-617 every 8 ± 1 weeks and were randomized into 2 treatment activities groups (6.0 or 7.4 GBq). Efficacy was defined as serum PSA decline of $\geq 50\%$ from baseline and served as primary endpoint (hypothesis: $\geq 40\%$ of responders after 2 cycles). **Results:** 43 patients were randomized to the 6.0 GBq ($n = 14$) and 7.4 GBq ($n = 29$) treatment arms. 11/43 (26%) were CTX naïve while 10/43 (23%), 12/43 (28%), 5/43 (12%) and 5/43 (12%) had received 1, 2, 3 or 4 CTX regimens. Median baseline PSA was 29.2 ng/ml (mean 228.8, range 0.5–2082.6). 21/43 (49%) completed 4 cycles of ¹⁷⁷Lu-PSMA-617 whereas 4/43 (9%), 13/43 (30%) and 5/43 (12%) underwent 1, 2 and 3 cycles. PSA decline of $\geq 50\%$ was observed in 11/43 of patients (26%) after 2 cycles and in 16/43 (37%) at any time (best PSA response). 9/43 (21%) had a PSA decline of $\geq 90\%$ and 23/43 (53%) had any PSA decline ($> 0\%$). After a median follow-up of 19.5 months the median OS was 14.8, 15.7 and 13.5 months in the whole cohort, the 6.0 GBq and 7.4 GBq treatment arms, respectively ($p = 0.68$). Patients showing a PSA decline of $\geq 50\%$ after 2 cycles and at any time had a longer OS: median 20.1 months vs. 13.6 ($p = 0.091$) and 20.1 vs. 11.6 ($p = 0.002$), respectively. **Conclusion:** In this post-hoc analysis of a single-site cohort of 43 patients included in a prospective phase II trial the median OS after ¹⁷⁷Lu-PSMA-617 molecular radiotherapy in patients with progressive mCRPC was 14.8 months. There was no difference of efficacy between the 6.0 GBq and 7.4 GBq treatment arms. **References:** None

[¹⁷⁷Lu]Lu-PSMA-617 in low-volume metastatic hormone sensitive prostate cancer: a prospective pilot study

B. Prive¹, S. M. B. Peters¹, C. H. J. Muselaers¹, P. Zamecnik¹, M. J. R. Janssen¹, T. W. J. Scheenen¹, M. W. Konijnenberg¹, J. Verzijlbergen¹, W. R. Gerritsen¹, N. Mehra¹, D. M. Somford², J. A. Van Basten², I. M. Van Oort¹, J. Sedelaar¹, J. O. Barentsz¹, S. Heskamp¹, M. Gotthardt¹, J. Witjes¹, J. Nagarajah¹;

¹Radboudumc, Nijmegen, NETHERLANDS, ²Canisius Wilhelmina Hospital, Nijmegen, NETHERLANDS.

Aim/Introduction: To date, [¹⁷⁷Lu]Lu-PSMA-617 (Lu-PSMA) is solely used in end-stage high-volume metastasized prostate cancer (PC) with promising efficacy. However, because of high PSMA expression in metastatic hormone-sensitive PCa (mHSPC), Lu-PSMA could also be effective in this patient cohort. Here we present the results of the first prospective study analyzing dosimetry, tolerability and treatment response of Lu-PSMA as a first-line systemic

treatment in oligometastatic mHSPC patients. **Materials and Methods:** In this prospective study (NCT03828838), 10 mHSPC patients with a maximum of 10 metastatic lesions on [⁶⁸Ga]Ga-PSMA PET (PSMA-PET) and serum-PSA doubling time <6 months received two cycles (3+6 GBq) of Lu-PSMA in an 8 week interval. Whole-body SPECT/CT and blood dosimetry was performed (1, 24, 48, 72, and 168 hours p.i.) to calculate the doses to tumor lesions and organs at risk (salivary glands, kidneys, liver and bone marrow). Adverse events (AE), toxicity (hematology, renal/liver functions and PSA) and quality of life were monitored weekly until 12 weeks after cycle two (end of treatment; EOT) and followed up until week 24 after cycle two. All patients underwent PSMA-PET at screening, 8 weeks after cycle one, EOT and 24 weeks after cycle two. **Results:** All 10 patients completed the study protocol till EOT. At baseline the median number of metastases was 3 (range 1-10) and PSA level was 1.75 µg/l (0.43-20). According to dosimetry, Lu-PSMA was safe with a mean total dose of 6.34 Gy (2.25-10.77), 7.92 Gy (5.65-10.46), 1.49 Gy (1.11-1.93), 0.16 Gy (0.12-0.21) to salivary glands, kidney, liver and bone marrow, respectively. No grade 3/4 AEs were observed during the study. None of the patients reported xerostomia at EOT. All patients had at least a stabilization of PSA. 5/10 patients had a drop of >50% in PSA. On baseline PSMA-PET, a total of 36 metastases were identified with SUVmax higher (mean 16.1 ±10.7) than liver SUVmean (mean 5.1 ±1.3). In 12 of these 36 metastases, the SUVmax dropped below liver SUVmean, with one patient having complete response. Furthermore, none of the patients showed new metastases on the EOT PSMA-PET. **Conclusion:** Lu-PSMA appears to be safe in mHSPC. Even with this relatively low dose of Lu-PSMA, all patients responded by at least stabilizing disease. 5/10 patients showed >50% PSA drop and one patient showed complete remission on PSMA-PET. Based on the results of this study, we initiated a prospective randomized multicenter phase II/III trial in oligometastatic mHSPC. **References:** None

Aim/Introduction: Treatment regimens with predefined treatment cycles of Lu-177-PSMA-617 radioligand therapy (RLT) may be suboptimal in patients with more aggressive high tumor load metastatic castration-resistant prostate

cancer (mCRPC). We assessed the outcome, toxicity and clinical response in patients receiving extended RLT with a mean cumulative activity of >45 GBq and no other promising treatment alternatives. **Materials and Methods:** Eighteen patients with high tumor burden (miTNM classification, PROMISE) and low PSA-doubling time of <2 months were treated with 6.7±1.2 GBq Lu-177-PSMA-617 at 9±8 weeks interval. Treatment was discontinued in case of 1) biochemical progression defined as a rise of >30% in PSA-Level from baseline (PCWG3), 2) progressive disease in routine Ga68-PSMA-11 PET/CT examinations done every 2-3 cycles using mPERSIST criteria, 3) new lesions in intra-therapeutic Lu-177-PSMA-617 scintigrams, 4) the onset of significant renal or hematological toxicity (grade 3/4) using maximal Common Terminology Criteria for Adverse Events (CTCAE v. 5.0), 5) xerostomia (grade 3/4, CTCAE v.5), 6) pain exacerbation, defined as >2 step increase in VAS, or 7) clinical deterioration (ECOG >2). Progression free survival analysis was performed with the Kaplan-Meier curve method. **Results:** Patients were treated with 10±2 cycles. Mean cumulative activity was 67.1±14.6 GBq, resulting in a median cumulative renal dose of 31.5±11.3 Gy. Mean eGFR declined from 90.4 ml/min/1.73 m² at baseline to 72.4 ml/min/1.73 m² after a mean follow-up period of 17±9 months (p=0.003). Moderate renal function reduction (grade 2) was observed in 4 patients (22 %) but no patient developed severe nephrotoxicity (grade 3/4). Significant pancytopenia of grade 3 occurred in 1 patient (6 %) leading to therapy cessation after 7 cycles. Eight patients (44 %) developed xerostomia (grade 1-2) after 5±2 cycles. The median progression free survival (PFS) was 31 months (CI 95 % 14-48). Five out of 7 patients with painful metastases (VAS >5) improved significantly (VAS-reduction >2 steps) throughout the treatment and no patient showed pain progression. Two of three patients starting the treatment with restricted performance status (ECOG 2) at baseline improved to grade 1. **Conclusion:** Long progression free survival times and the absence of serious adverse events in this patient group encourage further evaluation of extended radioligand therapy in patients with advanced disease. **References:** None

Early prostate-specific antigen changes and clinical outcome following ¹⁷⁷Lu-PSMA radionuclide treatment in patients with metastatic castration-resistant prostate cancer

A. Gafita¹, M. M. Heck², I. Rauscher¹, R. Tauber², C. Franz¹, L. Cala¹, C. D'Alessandria¹, M. Retz², M. Eiber¹, W. A. Weber¹;

¹Department of Nuclear Medicine, Technical University Munich, Munich, GERMANY, ²Department of Urology, Technical University Munich, Munich, GERMANY.

Aim/Introduction: The availability of multiple new treatments for metastatic castration-resistant prostate cancer (mCRPC)

mandates early treatment switch decisions in the absence of a response. Prostate-specific antigen (PSA) is widely used to monitor treatment response, however, PSA measurements are considered only after 12 wk of treatment. We aimed to evaluate the prognostic value of early PSA changes following ^{177}Lu -labelled prostate specific membrane antigen (LuPSMA) radionuclide treatment in mCRPC patients. **Materials and Methods:** Men who were treated under a compassionate access program with LuPSMA at our institution and had available PSA values at baseline, and at 6 wk after treatment initiation were included in this retrospective analysis. Patients were assigned to three groups based on PSA changes: 1) response: $\geq 30\%$ decline, 2) progression: $\geq 25\%$ increase and 3) stable: $< 30\%$ decline and $< 25\%$ increase. The co-primary endpoints were overall survival and imaging-based progression-free survival. The secondary endpoints were PSA changes at 12 wk after LuPSMA initiation and PSA flare-up. **Results:** We identified 124 eligible patients with PSA values at 6 wk, with 115 patients had available PSA levels at both 6 wk and 12 wk time-points. A $\geq 30\%$ decline in PSA at 6 wk was associated with longer overall survival (median 16.7 mo; 95%CI 14.4–19.0) compared with patients with stable PSA (median: 11.8 mo; 95%CI 8.6–15.1;) and progression (median: 6.5 mo; 95%CI 5.2–7.8; $p < 0.001$). Patients with $\geq 30\%$ decline in PSA at 6 wk also had a reduced risk of imaging-based progression compared with patients with stable PSA (HR: 0.60; 95%CI 0.38–0.94; $p = 0.02$), while patients with PSA progression had a higher risk of imaging-based progression compared with those showing stable PSA (HR: 3.18; 95%CI 1.95–5.21; $p < 0.001$). The percentage changes of PSA at 6 wk and 12 wk were highly associated ($r = 0.90$; $p < 0.001$). 29 of 31 (94%) patients who experienced early PSA progression at 6 wk achieved biochemical progression also at 12 wk. Overall, only 1 of 36 (3%) patients with PSA progression at 6 wk achieved any PSA decline at 12 wk (1% of the entire cohort). **Conclusion:** PSA changes at 6 wk after LuPSMA initiation are an early indicator of long-term clinical outcome. Patients progressing by PSA after 6 wk of treatment could benefit from a very early treatment switch decision. PSA flare-up during LuPSMA treatment is very uncommon. Prospective studies are now warranted to validate our findings and potentially inform clinicians earlier on the effectiveness of LuPSMA. **References:** None

OP-985

Risk and Concomitant Factors of Renal Insufficiency throughout Radioligand Treatment with ^{177}Lu -PSMA-617
C. Nguyen Ngoc¹, N. Mader¹, K. Davis¹, D. Groener¹, C. Happel¹, P. Mandel², N. Tselis³, F. Gruenwald¹, A. Sabet¹;

¹Department of Nuclear Medicine, University Hospital Frankfurt, Frankfurt am Main, GERMANY, ²Department of Urology, University Hospital Frankfurt, Frankfurt am Main, GERMANY, ³Department of Radiooncology, University

Hospital Frankfurt, Frankfurt am Main, GERMANY.

Aim/Introduction: Kidneys are exposed to continuous low dose radiation during radioligand therapy with ^{177}Lu -PSMA-617 (Lu-RLT) due to excretion of the ligand and specific binding. This may result in glomerular damage and gradual renal function loss. This study is to define the extent and potential risk factors of renal impairment in patients with metastatic castration-resistant prostate cancer (mCRPC) undergoing Lu-RLT using serial eGFR measurements driven from serum creatinine levels. **Materials and Methods:** 105 patients received 4 ± 1 cycles of Lu-RLT with 6.5 ± 1.4 GBq ^{177}Lu per cycle, resulting in a mean cumulative activity of 27 ± 13 GBq and a total renal radiation dose of 13 ± 8 Gy. eGFR was measured for a median of 6 ± 4 times per patient. Yearly change in eGFR was calculated using linear curve fit. Common Terminology Criteria for Adverse Events (CTCAE) v5.0 was used to classify renal toxicity. Correlation of eGFR reduction and potential risk factors like renal impairment prior to Lu-RLT, diabetes mellitus, hypertension, previous chemotherapy and cumulated administered dose was assessed using nonparametric testing. **Results:** Alterations in eGFR differed widely among the patients during the follow-up period of 13 ± 9 months. 57 patients (54 %) experienced a mild ($2\text{--}10$ ml/min/m² per year) and 35 patients (33 %) a significant (> 10 ml/min/m² per year) decline of eGFR. In 18 patients, on the other hand, eGFR increased > 10 ml/min/m² per year. Mean eGFR of the cohort decreased 4.5 ± 26 ml/min/m² per year from 83 ± 19 ml/min/m² at baseline to 72 ± 21 ml/min/m². 58 patients showed renal impairment of grade I (n=30) or II (n=28) subsequent to the treatment. 3 patients developed postrenal (sub)acute kidney injury and significant renal function loss (grade 3) due to progressive bladder infiltration and subsequent ureteral stenosis. No radiation induced nephrotoxicity of grade 3/4 was observed. However, cumulated renal dose was significantly correlated with renal function decline per year ($p < 0.01$). No other parameter including previous chemotherapy affected renal function ($p > 0.05$). **Conclusion:** Slight reduction in renal function may be expected in patients undergoing radioligand therapy with ^{177}Lu -PSMA-617 and correlates with cumulative doses. Acute kidney injury was observed only in a small number of cases with subrenal obstruction. **References:** None

Tracer kinetics in the dual time-point ^{177}Lu -PSMA post-therapy SPECT/CT scan predicts treatment outcome in prostate cancer patients

F. Fiz¹, H. Dittmann², M. Straub³, C. Ia Fougère²;

¹Humanitas Clinical and Research Center - IRCCS, Milan, ITALY, ²Nuclear Medicine Unit, Department of Radiology, University of Tübingen, Tübingen, GERMANY, ³University of Tübingen, Tübingen, GERMANY.

Aim/Introduction: ^{177}Lu -PSMA is a promising, radionuclide therapy in metastasized castration-resistant prostate cancer (mCRPC), as it can induce a PSA and clinical response in most cases. However, some patients do not respond and progress quickly in course of the ^{177}Lu -PSMA cycles, independently from the pre-therapeutic PSMA uptake on PET/CT. Kinetics of tracer uptake/elimination might indeed influence the absorbed dose. In this study, we investigated whether tracer kinetic inside the metastatic lesions is associated with the therapy outcome. **Materials and Methods:** 91 mCRPC patients were retrospectively enrolled. Every patient underwent at least two ^{177}Lu -PSMA cycles. Mean SUV on a representative lesion was calculated on the pre-therapy PSMA-PET/CT, using an isocontour method. Each patient then underwent two consecutive SPECT/CT scans the first and the second day after each ^{177}Lu -PSMA administration. The target-to-background ratio (TBR) of the same representative lesion was calculated on each SPECT/CT. Patients presenting at least a 50% PSA-drop after two ^{177}Lu -PSMA cycles were classified as responders. **Results:** Fifty-five patients (59%) were classified as responders. In these patients, mean TBR increased by $34 \pm 19\%$ from the first to the second SPECT/CT. Conversely, non-responders showed a significantly smaller mean TBR increase ($5 \pm 9\%$, $p=0,016$). Mean TBR increase showed a direct correlation with PSA decrease after two ^{177}Lu -PSMA cycles ($R=0,63$; $p<0,001$). Mean SUV, mean starting PSA, and absolute TBR were not significantly different between responders and non-responders. **Conclusion:** Effectiveness of the ^{177}Lu -PSMA seems to be related to the tracer residence time, rather than to the absolute uptake value. Increasing uptake values between the first and the second day after the ^{177}Lu -PSMA administration could be compatible with a longer biological half-life of the radiopharmaceutical within the lesions, possibly purporting a higher dose to the tumour. **References:** None

Efficacy and safety of ^{177}Lu -PSMA radionuclide treatment in patients with diffuse bone marrow involvement: a multicenter retrospective study

A. Gafita¹, W. P. Fendler², H. Wang³, S. Sandhu⁴, M. Weber², R. Esfandiari⁵, J. Calais¹, I. Rauscher³, H. Rathke⁶, R. Tauber³, E. S. Delpassand⁵, W. Weber³, K. Herrmann², J. Czernin¹, M. Eiber³, M. S. Hofman⁴, LuPSMA;

¹UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, ²University of Duisburg-Essen, Essen, GERMANY, ³Technical University Munich, Munich, GERMANY, ⁴Peter MacCallum Cancer Center, Melbourne, AUSTRALIA, ⁵Excel Diagnostics, Houston, TX, UNITED STATES OF AMERICA, ⁶University of Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: ^{177}Lu -labelled prostate-specific membrane antigen (LuPSMA) radionuclide therapy for metastatic castration-resistant prostate cancer is under

investigation in a Phase III trial (VISION: NCT03511664). However, patients with diffuse bone involvement, diagnosed with a superscan by bone scintigraphy at baseline, were excluded due to lack of efficacy and safety data. We therefore aimed to investigate the feasibility of LuPSMA in patients with diffuse bone marrow involvement on baseline PSMA-targeted PET. **Materials and Methods:** The primary end points were PSA response (PCWG3), hematologic safety profile (CTCAE), and overall survival. Secondary end points of quality of life (assessed with Brief Pain Inventory-Short Form questionnaires), and radiological response (RECIST) were assessed. **Results:** Through retrospective screening of databases, we identified 43 eligible patients across four centers worldwide who received 154 cycles of LuPSMA under clinical trials or compassionate access programs. Median baseline PSA was 1000 (IQR 431-2151) ng/ml. PSA decline of at least 50% at 12 weeks was achieved in 22 (58%) patients, while median time to pain progression was 8.3 (95%CI 4.1-12.6) months. Median overall survival was 11.6 (95%CI 8.8-14.3) months. Objective response in nodal or visceral disease was reported in seven (39%) of 18 patients with RECIST measurable disease. Grade 3 anemia, thrombocytopenia and neutropenia occurred in nine (22%), seven (17%) and three (8%) patients, respectively. Grade 4 thrombocytopenia was noticed in three (8%) patients. **Conclusion:** Patients with diffuse bone marrow involvement demonstrated similar LuPSMA efficacy and safety compared to Phase II evidence. Acceptable safety outcomes do not support exclusion of patients with a superscan from future LuPSMA treatment protocols. **References:** None

OP-988

Intermittent radioligand therapy with Lu-177-PSMA-617 in metastatic castration-resistant prostate cancer patients with favorable characteristics and early response

N. Mader¹, C. Nguyen Ngoc¹, J. Baumgarten¹, D. Gröner¹, K. Davis¹, J. Wichert¹, N. Tselis², P. Mandel³, F. Grünwald¹, A. Sabet¹;

¹Department of Nuclear Medicine, University Hospital Frankfurt, Frankfurt am Main, GERMANY, ²Department of Radiooncology, University Hospital Frankfurt, Frankfurt am Main, GERMANY, ³Department of Urology, University Hospital Frankfurt, Frankfurt am Main, GERMANY.

Aim/Introduction: Various treatment regimens have been recommended for radioligand therapy (RLT) with Lu-177-PSMA-617 in metastatic castration-resistant prostate cancer (mCRPC). Extending the time to maximal renal absorbed dose is highly desirable in patients with more favorable tumor biology, and longer life expectancy. Therefore, we assessed the feasibility of intermittent RLT in patients with an early initial response achieving a low tumor burden during the first three treatment cycles. **Materials and Methods:** RLT was discontinued in 15 responding patients with a PSA doubling time ≥ 3 months, achieving low tumor load after

only 2 ± 1 cycles RLT with 6.6 ± 3.8 GBq Lu-177-PSMA-617 per cycle. Treatment was initiated upon progression, consisting of 2 ± 1 more cycles with 6.6 ± 3.8 GBq each. The mean cumulative activity was 29.4 ± 18.4 GBq. Treatment response was evaluated using PSA sampling according to Prostate Cancer Working Group 3 criteria (PCWG3) and ^{68}Ga -PSMA-PET/CT imaging using mPERCIST criteria. Tumor load was identified as low based on miTNM classification, PROMISE. Complete blood count and estimated glomerular filtration rate (eGFR) were measured at baseline, during treatment course and follow-up period. Toxicity was classified using Common Terminology Criteria for Adverse Events (CTCAE v. 5.0). Kaplan-Meier curve method was used for survival analysis. **Results:** Re-initiation of RLT with Lu-177-PSMA-617 resulted in partial response in 5 patients (33 %), stable disease in 3 patients (20 %) and progressive disease in 7 (47 %). Median progression free survival (PFS) was 10 ± 3 months after initial treatment and 7 ± 2 after re-initiation. The cumulative renal absorbed dose during the treatment period of 18 ± 7 months was 13.3 ± 8.5 Gy. No patient developed significant renal function loss or bone marrow dysfunction (CTC grade III/IV). **Conclusion:** Intermittent radioligand therapy with Lu-177-PSMA-617 seems not to comprise the outcome of early responders with low PSA doubling time and tumor load. This treatment regime may be worth considering to prolong the time to maximal cumulative renal absorbed dose enabling further treatment cycles in patients with longer life expectancy. **References:** None

OP-989

Efficacy of Lu-177-PSMA-617 Therapy in Metastatic Castration-resistant Prostate Cancer Patients, A Single-Center Experience

T. Telli, M. Tuncel, M. Caglar;

Hacettepe University Faculty of Medicine, Ankara, TURKEY.

Aim/Introduction: Lu-177 labeled prostate-specific membrane antigen(PSMA) radioligand therapy is an emerging treatment in metastatic castration-resistant prostate cancer(mCRPC). The study aims to share our experience on clinical, biochemical, and PET response rates of the mCRPC patients treated with at least two cycles of Lu-177-PSMA-617 therapy. **Materials and Methods:** The study included 52 patients (median age: 70,5(range:56-86)) with mCRPC who received Lu-177-PSMA-617 treatment. Serum PSA levels were regularly monitored 2-weekly during the therapy and three months after completion of the therapy. Biochemical responses were evaluated according to the Prostate Cancer Clinical Trial Working Group3(PCWG3). For subjective responses, the patients were clinically followed for ECOG and Karnofsky performance scores(PS), the visual analog scale(VAS) for pain. The patients were evaluated with Ga-68-PSMA PET/CT 6-8 weeks after the second therapy

and 8-12 weeks after completion of the therapy to four. PET responses were categorized according to EORTC Response Criteria. **Results:** The patients received 163 cycles of Lu-177-PSMA-617 (median cumulative dose: 21,09 GBq, range 13,5-44,4 GBq, 24/52(46,2%) two cycles; 7/52(13,5%) three cycles; 15/52(28,8%) four cycles; 2/52(3,8%) five cycles; 4/52(7,7%) six cycles). Any PSA decline was seen in 44 patients (84,6%). Maximum PSA response rates were as follows: ≥ 90 decrease in 11(21,2%), ≥ 50 decrease in 31(59,7%), ≥ 30 decrease in 37(71,1%) patients. Eight patients(15,4%) showed PSA progression despite the therapy. PSA response rates three months after completion of the therapy(PCWG3 criteria) were as follows: ≥ 90 decrease in 7(13,7%), ≥ 50 decrease in 25(49%), ≥ 30 decrease in 26(51%) patients. Four patients (7,8%) had biochemical stable disease (SD), while 21 patients(41,2%) had progressive disease (PD). Eleven(21,2%) patients showed at least one score improvement in ECOG PS, and 15/52(28,8%) patients showed improvement at least 10 scores in Karnofsky PS after Lu-177-PSMA therapy. Among the patients with bone metastases and baseline pain score(VAS) ≥ 2 , 19/36(52,7%) of the patients showed two points or more improvement (or $\geq 30\%$) in VAS. There was a significant difference between pre and post-therapy mean VASs($4,1\pm 2,35$ and $2,8\pm 2,4$, $p: 0,03$). 5/16 patients with a regular need for non-opioid-analgesics and 2/9 patients with a regular need for opioids before Lu-177-PSMA therapy, no longer needed any analgesic after Lu-177-PSMA therapy. During the follow-up (median:10,93 months), 24/52(46,2%) patients died. Estimated median overall survival was 17 months(95% CI:15,4-18,6) and median progression-free survival was 6,7 months(95% CI:3,65-9,8). **Conclusion:** Lu-177-PSMA therapy is a promising therapy option for mCRPC patients in terms of both objective responses and pain palliation. **References:** None

OP-990

The efficacy of Lu177-PSMA treatment at chemotherapy-naive metastatic prostate cancer

F. Beytur¹, S. Sager¹, S. Bilgic¹, A. Nazari¹, L. Uslu-Besli¹, S. Asa¹, H. B. Sayman¹, D. Tural², C. Demirdağ³, K. Sonmezoglu¹;

¹Cerrahpasa Faculty of Medicine, Nuclear Medicine Department, Istanbul, TURKEY, ²Bakirköy Sadi Konuk Teaching Hospital, Medical Oncology Division, Istanbul, TURKEY, ³Cerrahpasa Faculty of Medicine, Urology Department, Istanbul, TURKEY.

Aim/Introduction: Hematotoxicity is one of the most serious side effects and also a limiting factor of Lu177-PSMA treatment in prostate cancer patients and it is seen more often in the patients who were treated with taxane-based chemotherapy regimes previously. In this retrospective study, we aimed to evaluate the efficacy and hematotoxicity of Lu177-PSMA therapy in chemotherapy-naive patients with metastatic prostate cancer. **Materials**

and Methods: Retrospectively, we recruited 12 patients with a diagnosis of metastatic prostate cancer who received Lu-177 PSMA-617 treatment without a previous taxane-based chemotherapy between December 2015 and September 2019. All patients had pretreatment serum PSA measurements and Ga-68 PSMA PET/CT or PET/MR imaging. Mean pretreatment age was 71.33 ± 11.0 (ranged 59–86). Efficacy of the treatment was assessed with serum PSA levels, clinical performance, and Ga68-PSMA PET imaging as well. **Results:** Patients received a median of 3.5 cycles (ranged 1–8) of Lu177-PSMA with an average dose of 6.98 GBq per cycle and a mean total administered activity of 23.85 GBq (ranged 7.4–65). According to the PROMISE criteria¹, the patients were categorized according to their pretreatment Ga68-PSMA PET imaging findings and there were 3 patients (25%) as miN2, 1 patient (8.3%) as miM1a, 1 patient (8.3%) as miM1b(oligo), 2 patients (16.7%) as miM1b(diss), 1 patient (8.3%) as miM1b(dmi), and 4 patients (33.3%) as miM1c. In this study, we grouped miM1b(diss) and prior stages as early-stage and miM1b(dmi) and miM1c stages as advanced-stage. Early-stage group consists of 7 patients and advanced-stage group consists of 5 patients. The median overall survival was 35.0 (ranged 4.7–49.5) months at early-stage group and 2.8 months (ranged 1.2–14.5) at advanced-stage group after emerging of Lu177-PSMA treatment. Grade 3–4 nephrotoxicity developed only in 2 patients (16.7%) and grade 3–4 hematotoxicity was not observed in any patient. In 4 patients (33.3%), PSA levels decreased >50% from baseline, but elevated in 8 patients (67.7%). Post-treatment Ga-68 PET scans revealed a regression in 4 patients (33.3%), and progression in 8 patients (67.7%). Only 5 patients (41.7%) described a symptomatic relief due to the treatment. **Conclusion:** Our preliminary data suggests that Lu177-PSMA treatment is useful and could be an alternative to taxane-based chemotherapy in early-stage prostate cancer with less severe side effects. However, it has not got a considerable positive impact on survival in advanced-stage disease. **References:** 1. Eiber, M., et al. (2018). A Positron Emission Tomography (PET) Study to Examine the Brain Binding of [¹¹C]-PXT012253 in Healthy Subjects

P. Stenkrona¹, R. Arakawa¹, H. Holst², S. Nag¹, M. Mahdi Moein¹, Z.

Jia¹, C. Halldin¹, A. Varrone¹;

¹Karolinska Institutet, Stockholm, SWEDEN,

²H. Lundbeck A/S, Valby, DENMARK.

Aim/Introduction: The metabotropic glutamate receptor 4 (mGlu4) has been proposed as a target for Parkinson's disease (1). [¹¹C]PXT012253 is a PET radioligand for mGlu4 (3.4 nM), previously characterized in non-human primates (2). This study evaluated the quantification and replicability of [¹¹C]PXT012253 binding in healthy subjects. **Materials and Methods:** Two 93-min PET measurements with [¹¹C]PXT012253 on the same day using an HRRT system were planned for 6–10 subjects. Metabolite corrected input function was measured. Regions of interests delineated using the Anatomical Automatic Labeling template on co-registered MRI. The regions with the highest binding was identified using quantification by kinetic analysis using 1-tissue (1T) and two-tissue (2T) compartment modeling (CM), Logan graphical analysis (GA) and Multilinear analysis (MA1). The outcome measure was the total distribution volumes (VT). Test-retest metrics were absolute variability (AbsVar, %) and intraclass correlation coefficient (ICC). **Results:** Six subjects (4 females, age 23 ± 3.5 y, weight 66 ± 14 kg) completed the study (373 ± 77 MBq, 1090 ± 416 GBq/ μ mol, 0.11 ± 0.4 μ g). [¹¹C]PXT012253 displayed high uptake (peak SUV whole brain 4.7 ± 0.9 kg/ml) at about 5 min, and a rapid wash-out. There was 10–20% of unchanged [¹¹C]PXT012253 in plasma at 20 min. The parent fraction curve was extrapolated by 3-exp fitting from 45–60 min and onwards. VT in subcortical regions (2TC: pons: 6.1 ± 1.0 , thalamus: 5.5 ± 0.9 , putamen: 5.3 ± 1.1) was higher than in cortical regions (frontal-cortex: 4.0 ± 0.8 , cerebellum: 3.6 ± 0.6), consistent with the known distribution of mGlu4. 2TC provided better fits than 1TC (Akaike information criterion 16 vs 85, model selection criterion 4.6 vs 2.7). VT by Logan GA and MA1 analysis were highly correlated with VT (Logan GA: $y = 0.97x + 0.36$, $R^2 = 0.95$; MA1: $y = 0.96x + 0.36$, $R^2 = 0.95$). MA1 showed better identifiability as smaller standard error than Logan GA (1.2 vs 1.7). Test-retest metrics were good for all models and regions (AbsVar 2TC: pons: $3.3 \pm 2.6\%$, thalamus: $2.8 \pm 1.7\%$, putamen: $4.2 \pm 5.5\%$, frontal-cortex: $6.4 \pm 5.3\%$, cerebellum: $8.0 \pm 5.8\%$), (ICC 2TC: (95% CI): thalamus 0.98 (-0.87, 1.0), putamen 0.93 (-0.56, 0.99), frontal-cortex 0.95 (-0.67, 0.99), cerebellum 0.83 (-0.27, 0.97), pons 0.97 (-0.78, 1.0)). Time stability analysis showed that VT values estimated using 63 minutes of imaging were within 10% of the values obtained with 93 minutes. **Conclusion:** [¹¹C]PXT012253 showed high brain uptake and rapid washout. VT was reliably estimated using 2TC, Logan GA and MA1. The test-retest metrics in pons, putamen and thalamus showed AbsVar lower than 7% and ICC higher than 0.93, indicating replicability. [¹¹C]PXT012253 is a suitable PET radioligand for mGlu4 in humans. **References:** 1. Charvin D. *Mov Disord.* 2018;33:1619–16312. Takano A. *Mol Imaging*

First-in-human PET imaging and dosimetry of [¹¹C]NOP46, a novel visualization agent of protein kinase G (PKG) pathway activation

M. Doubrovin¹, J. Kim¹, S. Oya¹, J. Castrillon¹, S. Deng¹, P. Zanzonico², M. Soffing¹, A. Molotkov¹, P. Carberry¹, D. Landry¹, A. Mintz¹;

¹Columbia University H. Irving Medical Center, New York, NY, UNITED STATES OF AMERICA, ²Memorial Sloan-Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: Protein kinase G-1α (PKG) activation controls long-term hyper-excitability (LTH) of the primary sensory neurons and has been shown to contribute to chronic pain. It is also associated with the pathogenesis of several malignancies, including in the breast, stomach and pancreas. The NOP46 protein kinase inhibitor was developed to have over 3-log higher specificity to PKG pathway compared to other PKs. We initiated a first in human clinical trial [¹¹C]NOP46 to visualize PKG related biological processes. Our objective is to establish human dosimetry to enable further clinical trial in subjects afflicted with diseases affected by the PKG pathway. **Materials and Methods:** The dosimetry and initial pharmacokinetic assessment was performed in four informed and consented healthy volunteers according to the IRB-approved protocol. The whole-body [¹¹C]NOP46 PET/CT was acquired in a dynamic mode over approximately 90 minutes following the radiotracer injection (6.2–9.8 mCi). The radiotracer uptake data analysis was performed on PMOD software generating residence times for individual organs and tissues. The dosimetry calculations were performed using OLINDA 1.1. Serum samples harvested from the patients were used to assess the [¹¹C]NOP46 stability. **Results:** The [¹¹C]NOP46 administration for PET was well tolerated and was estimated to deliver Effective Dose Equivalent (EDE) 2.8 +/-0.5 mSv or Effective Dose (ED) of 1.7+/-0.8 mSv, which represented EDE 12.3 +/- 2.4 microSv/MBq or ED 7.4 +/- 3.8 microSv/MBq. With predominantly hepatic clearance of the radiotracer, the critical organ was identified as a gall-bladder, which accumulating up to EDE 0.44+/-0.25 mSv. Appearance of [¹¹C]NOP46 degradation metabolites were identified around 30 minutes. **Conclusion:** Dosimetry evaluation of the first 4 human subjects with [¹¹C]NOP46 PET/CT demonstrated safety of the radiotracer for the human subjects. In future studies, we will assess [¹¹C]NOP46 PET/CT accumulation in chronic pain and tumors with activated PKG. **References:** Support: Study was sponsored by Medtech Innovation. The PET Center early drug development program is supported by the Columbia Dept. of Radiology and Irving Institute CTSA Translational Therapeutics Accelerator (UL1TR001873).

Functional Dynamics of Dopamine Synthesis During Reward Processing

A. Hahn¹, M. B. Reed¹, V. Pichler², P. Michenthaler¹, L. Rischka¹, G. M. Godbersen¹, W. Wadsak^{2,3}, M. Hacker², R. Lanzenberger¹;

¹Department of Psychiatry and Psychotherapy, Medical University of Vienna, Vienna, AUSTRIA, ²Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, ³Center for Biomarker Research in Medicine (CBmed), Graz, AUSTRIA.

Aim/Introduction: Although the competition model enables the assessment of dopamine release, cognitive paradigms only elicit 5–15% signal change and comparison with a control condition requires several PET measurements. We introduce a novel approach to assess rapid changes in dopamine neurotransmission during task performance in a single PET scan. The technique combines functional PET (fPET) [1] and 6-[¹⁸F]FDOPA imaging by exploiting the dynamic regulation of dopamine synthesis. Specifically, dopamine synthesis is activated by neuronal firing to refill the synaptic vesicles [2,3] and is also increased by the dopamine releasing agent amphetamine [4]. **Materials and Methods:** Dopamine synthesis was obtained in 16 healthy participants (24.8±4.8 years, 7 female) using 6-[¹⁸F]FDOPA fPET (injected dose=5.5 MBq/kg as bolus+infusion, 70x43 s frames). During the scan the monetary incentive delay (MID) task was carried out with separate evaluation of monetary gain and loss (4x5 min task blocks). Task effects were obtained by the general linear model [1] and dopamine synthesis was quantified with the Gjedde-Patlak plot. For comparison, BOLD fMRI was obtained in the same subjects (3T, TE/TR=30/2050 ms). **Results:** Compared to baseline, dopamine synthesis rates in the nucleus accumbens of men increased by 77.6±32.9% during monetary gain and 49.4±26.7% for loss (p<0.001). These task-specific effects were reversed in women with higher dopamine synthesis during loss (78.4±18.6%) than gain (51.2±16.5%, p<0.001), leading to a significant sex difference for gain vs. loss (p<0.01). Task changes in dopamine synthesis were further correlated with behavioral metrics of reward sensitivity in men (rho=-0.7, p<0.05) and punishment sensitivity in women (rho=0.89, p<0.01). Although robust activation of the nucleus accumbens for gain vs. loss was also obtained with fMRI (p<0.001), this was not different between men and women (p=0.4). **Conclusion:** Assessment of functional dynamics in dopamine neurotransmission with 6-[¹⁸F]FDOPA fPET is highly sensitive and specific to task stimulation, enabling direct investigation of dopamine action during numerous cognitive and emotional processes. Our findings provide a biological rationale for well-known behavioral sex differences in reward and punishment processing, which is usually not observed in fMRI-based neuronal activation [5]. This may have important implications in several psychiatric

conditions with sex-specific prevalence rates, altered reward processing and dopamine signaling. **References:** [1] Rischka et al., *NeuroImage* 181: 323–330 (2018).[2] Morgenroth et al., *PNAS* 71: 4283–4287 (1974).[3] Neff et al., *Prog Brain Res* 106: 91–97 (1995).[4] Kehr et al., *J Neural Transm* 40: 129–147 (1977).[5] Oldham et al., *Hum Brain Mapping* 39: 3398–3418 (2018).

⁷University of Leipzig, Department of Internal Medicine, Leipzig, GERMANY, ⁸University of Leipzig, Department of Psychosomatic Medicine and Psychotherapy, Leipzig, GERMANY.

Aim/Introduction: Cholinergic modulation of brain reward and attentional networks appears to play a crucial role in information processing about salience as a key biological mechanism in obesity (OB). Changes in acetylcholine (ACh) transmission, however, that are associated with abnormal eating behavior have not been demonstrated in vivo in human OB so far. We investigated the $\alpha 4(\alpha 6)\beta 2^*$ -nAChRs availability by applying simultaneous PET-MRI and (-)-[¹⁸F]flubatine in individuals with OB and normal-weight controls (NW) at rest and in response to salient food cues (stim).

Materials and Methods: Thirty-one individuals with OB (n=15; 10♀; age 38±14 yrs; BMI 38±3 kg/m²) and NW (n=16; 13♀; 27±7 yrs; BMI 22±2 kg/m²) underwent simultaneous PET-MRI with (-)-[¹⁸F]flubatine twice on separate days (rest and stim) using a bolus-infusion protocol (294±7 MBq) with list-mode acquisition 0–60 min and 120–165 min p.i. paralleled by anatomical MPRAGE and functional EPI sequences. Total distribution volumes VT (mL/cm³) were estimated as the ratio between mean (-)-[¹⁸F]flubatine activity in tissue between 120 and 165 min and free parent (-)-[¹⁸F]flubatine in plasma obtained from venous blood. Food pictures (stim) were shown 120–135 min p.i.. Disinhibited eating

behaviour was assessed by using the German version of the Three-Factor Eating Questionnaire (TFEQ). High TFEQ score indicates high disinhibition (cut-off 7 according to Niemeier et al., 2012). **Results:** VT_{stim} was significantly higher in OB compared with NW in the thalamus, in particular in those with high TFEQ disinhibition (left: 30.7±4.5 vs. 25.6±3.3, p=0.01; right: 29.5±4.4 vs. 25.4±3.3, p=0.03) while VT_{rest} in the ventral tegmental area and in the nucleus basalis Meynert tend lower in OB compared with NW (e.g. left: 16.4±2.2 vs. 17.5±2.3; p=0.1 and 11.7±2.0 vs. 10.3±1.8, p=0.08). VT_{stim} values compared with VT_{rest} appear only to increase in OB with high TFEQ disinhibition in the thalamus and the mesolimbic system (without reaching significance yet) but not in NW and in OB with low TFEQ disinhibition.

Conclusion: Compared with NW and low-disinhibited eaters with OB, $\alpha 4(\alpha 6)\beta 2^*$ -nAChR availability of high-disinhibited eaters with OB seems to be altered in the thalamus, the mesolimbic system and in the basal forebrain. Whether these changes are associated with an attentional bias towards incentive food cues in high-disinhibited eaters and changes in large-scale networks as markers for differences in eating traits is currently under investigation. **References:** Niemeier HM, Leahey T, Palm Reed K, et al. Brain metabolism and related connectivity after EMDR in PTSD of military veterans: a ¹⁸F-FDG PET study sensitized by virtual reality exposure to war scenes

A. Verger¹, P. Rousseau², E. Malbos³, M. Chawki¹, F. Nicolas⁴, C. Lancon³, S. Khalfa², E. Guedj⁵;

¹Department of Nuclear Medicine and Nancyclotep Imaging Platform, CHRU Nancy, Nancy, FRANCE, ²Laboratoire de Neurosciences Sensorielles et Cognitives, Marseille, FRANCE,

³Department of Psychiatry, La Conception University Hospital, Marseille, FRANCE, ⁴Department of Psychiatry, Hôpital d'Instruction des Armées Sainte-Anne, Toulon, FRANCE,

⁵Department of Nuclear Medicine, Assistance Publique Hôpitaux de Marseille, Timone University Hospital, Marseille, FRANCE.

Aim/Introduction: The prevalence of posttraumatic stress disorder (PTSD) is high among military veterans, and can lead to disastrous consequences such as suicide. Eye Movement Desensitization and Reprocessing (EMDR) is recommended in first-line psychotherapies for PTSD. The objective of this study is to identify, after EMDR therapy, the metabolic and related connectivity changes in military veterans suffering from PTSD. **Materials and Methods:** Fifteen military veterans with PTSD performed a brain ¹⁸F-FDG-PET sensitized by virtual reality exposure to war scenes, before and after EMDR treatment. Statistical parametric mapping (SPM) was used to compare brain metabolism before and after treatment, to evaluate connectivity of previously

identified areas (through inter-regional correlation analysis), and to study correlations between metabolism and evolution scores on PTSD clinical scales (PTSD Checklist Scale, PCLS; Clinician Administered PTSD Scale, CAPS). **Results:** After EMDR therapy, the metabolic activity of the precuneus was increased, and a decrease of metabolic connectivity was observed between this area and two bilateral clusters of the cerebellum (bilateral Crus I and VI cerebellar lobules, $p < 0.005$ for the voxel, $k > 180$). Moreover, the metabolic values of precuneus were associated before and after therapy with respectively the PCLS scale ($r = -0.667$ and $p = 0.006$) and the CAPS scale ($r = -0.73$ and $p < 0.001$) after EMDR. Furthermore, higher cerebellar metabolism before treatment was associated with reduced clinical PTSD scores after EMDR ($p = 0.03$). **Conclusion:** The precuneus metabolism and its related connectivity with the posterior cerebellum upon VR stress exposure are correlated and predictive of the clinical improvement after EMDR in military patients with PTSD. **References:** None

OP-996

Can ^{18}F -FDG PET be used as a surrogate marker in autoimmune encephalitis?

S. ArunRaj¹, D. Khan¹, K. Ihtisham², M. Tripathi², A. Garg³, A. Kumar¹, D. Yadav¹, M. Tripathi¹, C. Bal¹;

¹Department of Nuclear Medicine, All India Institute of Medical Sciences, New Delhi, INDIA, ²Department of Neurology, All India Institute of Medical Sciences, New Delhi, INDIA, ³Department of Neuroradiology, All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Autoimmune encephalitis (AIE) is an immune-mediated, paraneoplastic or non-paraneoplastic process of the central nervous system. Initial diagnosis is based on the clinical presentation as well as antibody profiles and MRI findings. Timely diagnosis is essential for initiation of appropriate therapy, response to which is usually good in non-paraneoplastic AIE. Though the utility of ^{18}F -FDG PET has been suggested in limbic encephalitis when MRI findings are normal it has not been included in the diagnostic algorithm of AIE.¹ This study investigates the combined potential of ^{18}F -FDG-PET and MRI in AIE. **Materials and Methods:** This was a retrospective analysis in 60 patients diagnosed and treated for AIE, 40 were antibody negative and 20 antibody positive. Patient inclusion was based on the clinical diagnosis of AIE and whether both MRI and PET had been done. All patients had undergone a dedicated brain and whole body ^{18}F -FDG PET/CT in the department of Nuclear Medicine. MRI had been done in a separate setting on a dedicated MRI scanner. The PET and MRI dataset was independently reviewed by a nuclear medicine physician and neuroradiologist. **Results:** In the antibody negative group (40 patients) MRI was positive in 23 and FDG PET in 20. Both MRI and PET were positive in 12, MRI was positive but PET

negative in 11 while MRI was negative and PET positive in 8. Thus when both PET and MRI were combined the detection rate for AIE was 77 % (31/40). In the antibody positive group (20 patients), MRI was positive in 7, PET was positive in 9. Both MRI and PET were positive in 4, MRI was positive and PET negative in 3 while MRI was negative and PET positive in 5. Thus the correct identification of AIE by both combined was 60% (12/20). Based on combined PET and MRI findings 43/60 (71 %) patients were found to show morphologic and functional changes indicative of AIE. **Conclusion:** MRI findings play an important role in the diagnostic criteria for AIE. Nevertheless the inclusion of functional information from PET along with MRI findings has definite potential to improve the imaging diagnosis of AIE. **References:** 1. OP-997

Predictive value of metabolic and perfusion beyond the seizure onset zone as predictors of postoperative outcome in patients with refractory focal epilepsy

M. Haemels¹, D. Van Weehaeghe¹, E. Cleeren², P. Dupont³, J. Van Loon⁴, T. Theys⁴, K. Van Laere¹, W. Van Paesschen², K. Goffin¹;

¹Department of Nuclear Medicine, University Hospitals Leuven, Leuven, BELGIUM, ²Department of Neurology, University Hospitals Leuven, Leuven, BELGIUM, ³Department of Neurosciences, Laboratory of cognitive neurology, KU Leuven, Leuven, BELGIUM, ⁴Department of Neurosurgery, University Hospitals Leuven, Leuven, BELGIUM.

Aim/Introduction: Interictal ^{18}F -fluorodeoxyglucose (FDG)-PET and ictal/interictal perfusion SPECT are established imaging tools to identify the seizure onset zone (SOZ) in patients with refractory focal epilepsy, who are eligible for epilepsy surgery. Functional changes beyond the SOZ may provide predictive information regarding surgical outcome. The aim of this retrospective study was to evaluate relative metabolic and perfusion changes beyond the SOZ as predictors of postoperative outcome in patients with refractory focal epilepsy. **Materials and Methods:** Eighty-six patients with refractory unifocal epilepsy underwent ^{18}F -FDG-PET prior to epilepsy surgery. Ictal and interictal perfusion SPECT was available in 65 patients (75%). Good postoperative outcome was defined as International League Against Epilepsy class 1&1a. Univariate statistical analysis quantified the predictive ability for outcome of metabolism/perfusion in composite volumes of interest (VOIs) by the area under the ROC-curve (AUC). The composite VOIs were based on the Hammers atlas (orbitofrontal, frontal, temporal, parietal, occipital and central VOIs). Results were cross-validated and a false discovery rate (FDR) correction was applied for multiple comparisons. A subgroup analysis was performed on patients with temporal lobe epilepsy

(TLE). **Results:** Increased ictal perfusion in the contralateral central region was significantly correlated with good surgical outcome both in the total population (AUC 0.79, $p_{\text{FDR}}=0.009$) and the TLE-subgroup (AUC 0.80, $p_{\text{FDR}}=0.028$). Higher ictal perfusion showed a trend to be correlated with good outcome in the ipsilateral central region (total population AUC 0.69, $p_{\text{non-FDR}}=0.012$; TLE-subgroup AUC 0.68, $p_{\text{non-FDR}}=0.048$) as well as in the ipsilateral orbitofrontal cortex (total population AUC 0.65, $p_{\text{non-FDR}}=0.046$). Also higher interictal perfusion in the contralateral central region tended to correlate with good outcome (total population AUC 0.69, $p_{\text{non-FDR}}=0.01$). Reduced ictal perfusion, on the other hand, tended to correlate with good outcome in the contralateral temporal lobe (total population AUC 0.70, $p_{\text{non-FDR}}=0.007$). No significant correlations or trends between metabolic changes and postoperative outcome were detected. **Conclusion:** Ictal perfusion in the contralateral central region significantly predicted outcome after epilepsy surgery in patients with refractory focal epilepsy, potentially reflecting a variable degree of ictal neuronal network recruitment. **References:** None

OP-998

Epileptogenic zone localization on SISCOS in drug refractory epilepsy

D. Khan, S. T. Arun Raj, S. Sagar, M. Tripathi, M. Tripathi, R. Doddamani, A. Garg, P. Chandra, C. Sarkar, N. Damle, C. S. Bal; All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Drug refractory epilepsy (DRE) can be effectively treated by surgical resection of the epileptogenic zone (EZ) if it is correctly localized. The pre-surgical work-up of such patients includes interictal and ictal SPECT followed by SISCOS (subtraction ictal spect coregistered to SPECT). We have been routinely performing SISCOS for our DRE patients. In this retrospective analysis we determined the concordance of SISCOS for localization of the EZ in DRE patients who underwent surgery. **Materials and Methods:** This retrospective analysis was conducted in 148 patients of DRE who underwent presurgical workup followed by surgical resection at All India Institute of Medical Sciences, New Delhi. During workup vEEG, MRI, FDG PET/CT and SISCOS was done for all these patients. The concordance of these modalities for localization of the EZ was compared with the reference standard which was surgical resection/biopsy and assessed along with post surgical outcomes (ILAE surgical outcome scales). **Results:** Age range of patients was 1.7 to 51 years, there were 96 male and 52 females. Seizure onset was during the first decade of life in 51 patients, with a mean duration of symptoms of 9.3+ 6 years. There were 71 cases of extratemporal epilepsy and 77 cases of temporal lobe epilepsy. FCD (n=30) was the most common histopathological diagnosis in the resected samples. Concordance for localization of the EZ on MRI,

vEEG, FDG-PET, and SISCOS was 85.8%, 64%, 71.2% and 75.8% with the surgically resected EZ. Concordance of SISCOS with MRI, VEEG, and FDG PET for lesion detection was 42.9%, 45.6% and 35.5%. Thus SISCOS had highest concordance with MRI. Good surgical outcomes (ILAE scale; Grade 1) were seen in 58% of the patients with localization on SISCOS. Localization of the EZ for SISCOS (subtraction ictal spect coregistered to MRI) has been reported as 88.2% (1) while one study in literature has similar results for SISCOS 87%(2). **Conclusion:** Localization of the EZ by SISCOS was the second highest of all modalities used in pre-surgical evaluation of DRE after MRI. This is comparable to the localization of EZ by SISCOS and can therefore be effectively used for DRE patients. **References:** (1) O'Brien et al; Subtraction ictal SPECT co-registered to MRI improves clinical usefulness of SPECT in localizing the surgical seizure focus ;Neurology. 1998 Feb;50(2). OP-999

Reduced pulmonary function is associated with global brain function on ^{18}F -FDG brain PET in lung cancer patients

S. Son, E. Kong; Yeungnam University Medical Center, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: While a growing number of studies have demonstrated a relationship between pulmonary function and brain function, especially cognition, the relationship has been only studied with clinical or structural imaging technique, such as MRI. Imaging techniques using ^{18}F -FDG positron emission tomography (PET) provide measures of true functional activation of whole brain. This study was performed to determine the relationship of pulmonary function to brain metabolic parameter and to examine the mediating factors for any relationships. **Materials and Methods:** A random sub-sample of 102 patients who were diagnosed as lung cancer, underwent ^{18}F -FDG brain PET and pulmonary function test. Pulmonary function was analyzed according to the percentage predicted values (% pred) for forced vital capacity (FVC), forced expiratory volume in the first second (FEV1), and diffusing capacity for carbon monoxide (DLCO). The semiquantitative FDG uptake (standardized uptake values [SUVs]) was calculated in brain by using the PMOD Neuro tool (version 3.6). The quantifications mostly performed by cortical-to-cerebellum SUV ratio (SUVr). **Results:** Five of 102 patients, who had brain metastasis, were excluded, therefore, 97 patients were final subjects (mean age, 67.7±10.3). Mean FVC was 80.0±15.4%; mean FEV1 was 77.6±17.8%; mean DLCO was 71.0±20.9%. There was significant correlation between

FVC or FEV1 or DLCO and SUVr in all brain regions (frontal, parietal, occipital, temporal) ($p < 0.01$). The result was also significant in cognition-related regions (posterior cingulate gyri, precuneus, and posterior temporal and parietal lobes). In multivariate regression, FVC, FEV1, and DLCO were significantly associated with SUVr in cognition-related regions ($p < 0.05$), after adjusting the data for confounding factors (age, sex, lung cancer type [NSCLC or SCLC], smoking [pack-year]). In addition, lung cancer type (NSCLC) was also associated with SUVr in cognition-related regions ($p < 0.05$). **Conclusion:** These findings suggest that reduced pulmonary function was significantly associated with decreased brain function, especially in cognition-related regions. **References:** None

OP-1000

Relation Between Amyloid Deposition and Microbleeds in CAA

Y. Chang, J. Liu, B. Xu;

Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: Our aim was to investigate the relationship between amyloid deposition and strictly lobar cerebral microbleeds (CMBs) in cerebral amyloid angiopathy (CAA), Alzheimer's disease (AD) and cognitively normal healthy controls (NC) by integrated PET/MR, and to assess the diagnostic value of PIB PET/MR in probable CAA patients. **Materials and Methods:** 8 probable CAA patients (per modified Boston criteria, $n=7$; pathologically defined CAA, $n=1$), 15 probable AD patients and 15 NC subjects underwent static head PET/MR scan using ^{11}C -PIB at 40 min after injection. Cortical PIB deposition was assessed quantitatively (standardized uptake value ratio [SUVr]) and visually classified as positive or negative. SUVr were calculated using the cerebellum as reference region. Patients with CAA and AD and NC subjects were compared for region cortical and global cortical PIB SUVr values. Brain MRI were assessed for detecting the location of CMBs. **Results:** All CAA patients had evidence of lobar CMBs, Eight of 15 AD patients (53.3%) presented with CMBs. Fourth of 15 NC subjects (26.7%) detected lobar CMBs. PIB deposition was detected at CMB sites were observed in CAA patients when compared with AD patients and NC subjects (1.72 ± 0.11 vs 1.63 ± 0.08 vs 1.17 ± 1.08 ; $p < 0.0001$). PIB deposition was associated with lobar CMBs and was greatest in occipital and temporal regions in CAA patients. The global cortical PIB deposition was significantly higher in CAA than in NC subjects (1.71 ± 0.61 vs 1.21 ± 0.60 ; $p < 0.0001$) and significantly less than in AD patients (1.86 ± 0.17 ; $p < 0.0001$). In contrast, the occipital-to-global PIB ratio was significantly increased in CAA (occipital/global cortex 1.07 ± 0.03) relative to AD patients (0.95 ± 0.02). **Conclusion:** Amyloid deposition associated with strictly CMBs, indicate CMBs occur preferentially in local regions of concentrated

amyloid and suggest underlying CAA pathology. PIB-PET can detect cerebrovascular amyloid in patients with CAA and the distribution differ from that seen in AD patients. We recommend PET/MR may serve as a noninvasive method for diagnose CAA in appropriate clinical setting. **References:** None

OP-1001

Comparison between regional cerebral blood flow estimates using different MR arterial spin labelling approaches and early-phase amyloid PET on a simultaneous PET/MR

J. Anton Rodriguez^{1,2}, J. C. Matthews³, L. Scott³, M. Lohezic⁴, K. Herholz³, L. M. Parkes³;

¹The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM, ²Division of Informatics, Imaging and Data Sciences, MAHSC, University of Manchester, Manchester, UNITED KINGDOM, ³Division of Neuroscience and Experimental Psychology, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, UNITED KINGDOM, ⁴Applications and Workflow, GE Healthcare, Manchester, UNITED KINGDOM.

Aim/Introduction: Amyloid-PET can be used as dual-phase biomarker enabling differential diagnosis between dementias by providing images of amyloid load (late-phase) and functional estimates of regional cerebral blood flow (rCBF) (early-phase) [1]. MRI arterial spin labelling (ASL) can quantify CBF and can provide similar patient classification information as [^{18}F]FDG PET [2]. Here, we compare rCBF obtained with ASL with the early-phase distribution of amyloid-PET using [^{18}F]flutemetamol (FLUT). **Materials and Methods:** Twenty participants, 70(60-80) years old, 14 cognitively normal/6 mild cognitive impairment, were scanned on a SIGNA PET/MR (GE-Healthcare). PET list-mode data were acquired for 30 minutes following the injection of $\sim 185\text{MBq}$ of FLUT. PET images were reconstructed using GE Q.Clear ($\beta=250$) for two separate time frames corresponding to 20s-80s and 120s-300s post-arrival of tracer in the brain. Enhanced-ASL with pCASL labelling and 3D spiral FSE acquisition was acquired with 6 post-labelling delays to obtain voxel-wise arrival-time-corrected CBF maps [3] (scan duration: 9min). CBF maps were calculated using either global ($\text{CBF}_{\text{global}}$) or local ($\text{CBF}_{\text{local}}$) correction for equilibrium magnetisation and also using a single time point post-labelling of 2.2s ($\text{CBF}_{2.2}$) (scan duration: $\sim 3\text{min}$). FreeSurfer brain segmentation on each participant's T1w MPRAGE image (1mm isotropic resolution) was used to estimate median CBF values for 12 'meta-regions'. Linear regression was used to compare intensity normalised early phase PET and ASL. **Results:** For PET_{20-80} vs $\text{CBF}_{\text{global}}$, $\text{CBF}_{\text{local}}$, $\text{CBF}_{2.2}$ the r (median(range)) values across the 20 participants were 0.56(0.26-0.65), 0.67(0.33-0.82) and 0.59(0.27-0.82) respectively. Removing subcortical ROIs caudate and striatum (clear outliers on the scatter-plots) improved the

r values to 0.63(0.36–0.81), 0.82(0.48–0.96), 0.85(0.42–0.96). Lower r values for PET_{120–300} were observed. **Conclusion:** For cortical regions, there is a good proportional relationship between ASL and PET measurements (improved using earlier PET (PET_{20–80}) to PET_{120–300} proposed in [1]) with this proportion not holding for the subcortical ROIs with values underestimated for ASL. ASL CBF maps with local magnetisation correction have a closer association with PET suggesting that spatial inhomogeneity in coil sensitivities cause significant errors if uncorrected. Good association is maintained with single time point ASL suggesting that 2.2s is sufficient delay for complete transit of labelled blood; enabling faster ASL acquisition. These close associations suggest that simultaneous ASL with late-phase amyloid-PET and injection of FLUT off the bed could provide excellent classification of dementia patients in a single scan. **References:** [1]Asghar M. et al. Association of Retention of [¹⁸F]-APN-1607, a Novel Tau PET Tracer, with Brain Glucose Metabolism and Cognition in Patients of Alzheimer's Disease

J. Lu¹, W. Bao¹, M. Li¹, L. Li¹, Z. Zhang¹, I. Alberts², M. Brendel³, P. Cumming², C. Zuo¹, Y. Guan¹, Q. Zhao⁴, K. Shi², A. Rominger²; ¹PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA, ²Department of Nuclear Medicine, University Hospital Bern, Bern, SWITZERLAND, ³Department of Nuclear Medicine, University Hospital of Munich, Ludwig-Maximilian-University Munich, Munich, GERMANY, ⁴Department of Neurology, Huashan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: Specific molecular imaging of tau pathologies in patients of Alzheimer's Disease (AD) with positron-emission-tomography (PET) is complicated by off-target binding properties of the first-generation of tau radioligands. We aimed to characterize the cerebral binding of [¹⁸F]-APN-1607 ([¹⁸F]-PM-PBB3), a newly developed tau tracer, in AD patients compared to normal control (NC) subjects. **Materials and Methods:** We obtained static late frame PET recordings with [¹⁸F]-APN-1607 and [¹⁸F]-FDG in patients with a clinical diagnosis of AD group (N=19), along with an age-matched NC group ([¹⁸F]-APN-1607 only, N=11). Group differences were tested by statistical parametric mapping (SPM) and volume of interest (VOI) analyses of the reference region normalized standard uptake value ratio (SUVR) maps. Relationships between both PET biomarkers as well as their associations with clinical cognition were assessed by Spearman correlation. **Results:** In the AD group, [¹⁸F]-APN-1607 binding was elevated in widespread cortical regions (P < 0.001 for VOI analysis, family wise error-corrected P < 0.01 for SPM analysis). The regional uptake in AD correlated significantly with global cognitive function (mini-mental state examination (MMSE); frontal lobe:

R= -0.632, P= 0.004; temporal lobe: R= -0.593, P= 0.008; parietal lobe: R= -0.552, P= 0.014; insula: R= -0.650, P= 0.003; cingulum: R= -0.665, P= 0.002) and cognitive functions of specific domains including memory (Delay Recall of Rey-Osterrieth Complex Figure Test (CFT-delay); frontal lobe: R= -0.725, P < 0.001; temporal lobe: R= -0.616, P= 0.005; occipital lobe: R= -0.611, P= 0.005; parietal lobe: R= -0.687, P= 0.001; insula: R= -0.669, P= 0.002; cingulum: R= -0.717, P= 0.001), visuospatial function (CFT-copy; frontal lobe: R= -0.502, P= 0.029; occipital lobe: R= -0.485, P= 0.035; parietal lobe: R= -0.510, P= 0.029; insula: R= -0.478, P= 0.038; cingulum: R= -0.526, P= 0.021), attention and working memory (Trail Making Test A (TMT-A); frontal lobe: R= 0.526, P= 0.021; occipital lobe: R= 0.536, P= 0.018; parietal lobe: R= 0.566, P= 0.012; insula: R= 0.521, P= 0.021; cingulum: R= 0.547, P= 0.015). The hypometabolism to [¹⁸F]-FDG PET in AD patients also showed negative correlations with regional [¹⁸F]-APN-1607 binding in some signature areas of AD (temporal lobe: R= -0.530, P= 0.020; parietal lobe: R= -0.637, P= 0.003; occipital lobe: R= -0.567, P= 0.011). **Conclusion:** Our results demonstrate that [¹⁸F]-APN-1607 retention differentiates patients of AD from normal subjects and the distribution of [¹⁸F]-APN-1607 matches the expected patterns of tau deposition in AD. Furthermore, [¹⁸F]-APN-1607 retention correlates with impaired cerebral glucose metabolism and cognitive function. **References:** None

Additional Diagnostic Value of Metabolic Parameters Measured by Pretreatment F-18 FDG PET/CT in patients with early stage endometrial carcinoma

J. Hwang;

Soonchunhyang University Hospital Bucheon, Bucheon, KOREA, REPUBLIC OF.

Aim/Introduction: The aim of this retrospective study was to determine whether delayed glucose metabolism assessed by pretreatment F-18 FDG PET-CT provides additional diagnostic information independent of established pathologic factors in patients with early stage endometrial carcinoma. **Materials and Methods:** We reviewed retrospectively the medical records of 54 patients (mean age 52 ± 10 years) with pathologically proven endometrioid carcinoma of endometrium. They underwent F-18 FDG PET-CT and enhanced MRI as part of a pretreatment workup from Jan 2016 to Jan 2019. For the analysis, patients were classified by age, FIGO stage, SUVmax, MRI pattern [No demonstrable

(ND), SI change or thickness (ST), mass forming (MF) and histopathology (size, lymphovascular invasion (LVI), invasion depth, LN metastasis). The relationship between FDG uptake, MRI pattern and diagnostic value was analyzed using the parametric and nonparametric tests and multiple regression methods. **Results:** Median SUVmax for all 54 study subjects was 15.9 (range: 3.5 - 35.4). The correlation of SUVmax and MRI pattern was found to be significantly related [median SUVmax of ND 8.7 ± 5.1 , ST 14.6 ± 6.0 , MF 20.8 ± 8.8 ($p = 0.0008$)] and revealed that the patients with a higher SUVmax showed mass forming MRI pattern ($p = 0.045$) than non-mass forming pattern. In univariate analysis, FIGO stage ($p = 0.01$), LN metastasis ($p = 0.001$), MRI pattern ($p = 0.003$) and LVI ($p = 0.003$) showed significant correlation with pretreatment SUVmax. Among the all patients, 6 patients showed recurrence (5 stage 3, 1 stage 2, 5 MF and 1 ST with LN metastasis). The result revealed that higher SUVmax ($p = 0.0001$), MF pattern of MRI ($p = 0.03$), higher stage ($p = 0.008$), presence of LN metastasis ($p = 0.001$) and LVI ($p = 0.003$) showed a recurrence in multiple regression analysis. **Conclusion:** SUVmax on pretreatment F-18 FDG PET-CT can provide additional diagnostic information with MRI pattern and predictive value in patients with early stage endometrial cancer. **References:** None

¹⁸F-FDG PET/CT in the Preoperative Staging of Endometrial Cancer

A. Gutta^{1,2}, W. J. Pillay¹, T. Mosehle^{1,2}, P. B. Nemataduni^{1,2};
¹SMU Health Sciences University, Garankuwa, Pretoria, SOUTH AFRICA, ²Dr George Mukhari Academic Hospital, Garankuwa, Pretoria, SOUTH AFRICA.

Aim/Introduction: The incidence of Endometrial cancer (EC) is lower in developing than developed countries. Patients in developing countries such as South Africa frequently present with advanced disease due to limited access to health care services and a lack of awareness of EC symptoms and treatment. EC prognosis and management is guided by accurate initial staging. Five-year-survival rates in early-stage EC are >95%, but drop to 20% in more advanced cases. Surgery is the mainstay of treatment, with extent of resection and the use of external beam radiotherapy and intracavitary brachytherapy directed by staging. Routine lymphadenectomy remains controversial. The aim of this study was to evaluate the diagnostic performance of ¹⁸F-FDG PET/CT in the preoperative assessment of lymph node and distant metastases in patients with EC at a South African tertiary hospital. **Materials and Methods:** A retrospective analysis of 56 women with histologically proven EC was undertaken. All patients underwent a preoperative ¹⁸F-FDG PET/CT scan (Philips Ingenuity TF) at 50-70 minutes p.i ($8,12 \pm 1,192$ mCi), followed by surgery. Scans were visually assessed by an experienced nuclear

medicine physician and a radiologist. Findings were compared with histology, complementary imaging and/or follow up. Using appropriate statistical methods, the diagnostic accuracy of PET/CT was determined. **Results:** Complete records were available for 49 patients, with a mean age of 65 years (range 52-86). 69% (34/49) were endometroid adenocarcinomas. Primary tumours were all FDG avid (mean SUV_{max}: 6,8 [range 3,22-32,1]). No correlation was determined between SUV_{max} and histologic subtype, but a statistical significance was observed between higher SUV_{max} values and histologic grading ($p=0,002$). Extra pelvic nodes were observed in 37% (18/49) of patients, with para-aortic adenopathy being the most common site. Distant metastases were present in 27% (13/49), predominantly in the lungs (54%[7/13]), followed by skeletal, liver, splenic and adrenal lesions respectively. The sensitivity, specificity, PPV and NPV of PET/CT for (1) nodal disease was 82,8%, 90%, 92,3% and 78,3% respectively; and for (2) distant metastases was 100%, 94,3%, 87,5% and 100% respectively. **Conclusion:** In this cohort, whole body ¹⁸F-FDG PET/CT demonstrated high diagnostic accuracy for the detection of nodal and distant metastases in EC. The retrospective design (and probable selection bias) may account for a higher diagnostic accuracy than is quoted in the literature, but PET/CT may be valuable in the preoperative workup of EC in a setting where advanced disease at presentation is likely. A prospective study is planned to validate our results. **References:** None

EPS-185

The Relationship Between HER-2 Expression Levels and ¹⁸F-FDG PET/CT Parameters in Gastric Cancer Patients

S. Ertürk, Z. Hasbek, H. Özer, Ö. Ulaş Babacan;
 Sivas Cumhuriyet University, Sivas, TURKEY.

Aim/Introduction: Gastric cancer is one of the most common cancers worldwide. HER-2 is a protooncogene encoded by ERBB2 on chromosome 17. The main role of HER-2 protein in these tissues is to support cell proliferation and prevent apoptosis. ¹⁸F-FDG PET/CT examination is frequently used for the detection of distant metastasis in gastric cancer imaging. Our aim in this study is to investigate the relationship between the data obtained in the ¹⁸F-FDG PET/CT examination and HER-2 expression status in gastric cancer patients. **Materials and Methods:** In our study, patients who underwent HER-2 examination with a diagnosis of gastric cancer and ¹⁸F-FDG PET / CT examination for staging purposes between 2016 and 2020 are included. All patients were staged with ¹⁸F-FDG PET / CT examination. HER-2 immunohistochemical examination was performed on all patients. SPSS 23.0 program was used for statistical analysis. **Results:** In our study, there were 115 patients, including 85 men (73.9 %) and 30 women (26.1 %). According to the HER-2 immunohistochemical examination, 71 patients (61.7%)

were negative and 44 patients (38.3%) were positive. The median SUVmax, SUVmean, MTV, TLG values of HER-2 positive patients were 9.95, 5, 30.44, 139.16, whereas HER-2 negative patients were 9.3, 5.4, 36.62 and 190.424 respectively ($p > 0.05$). The median CA 19-9 levels of HER-2 positive patients was 33.52, whereas those who were negative were 11.79 ($p = 0.016$). The mean age was 69.3 ± 9.35 in patients with distant metastases, while the mean age was 65.2 ± 10.9 in those without distant metastases ($p = 0.042$). Median SUVmax and SUVmean values in patients with distant metastases were 11.1 and 6.3, respectively, and 8.2 and 4.5 in those without distant metastases ($p = 0.002$, $p = 0.001$, respectively). The median CA 19-9 and CEA levels in patients with distant metastases were 31.34 and 9.20, respectively, whereas those without distant metastases were 11.55 and 2.26, respectively ($p = 0.011$ and $p = 0.001$, respectively). **Conclusion:** In our study, there was no statistically significant difference in terms of HER-2 status and SUVmax, SUVmean, MTV, TLG, presence of distant and lymph node metastasis, age, gender, tumor diameter, tumor grade, tumor localization, and CEA levels in gastric cancer patients. A statistically significant difference was found between HER-2 status and CA 19-9 levels. While there was a statistically significant relationship between distant metastases in the ^{18}F -FDG PET/CT examination and SUVmax, SUVmean, age, CEA levels; the relationship between distant metastasis, and MTV, TLG, tumor diameter, tumor localization, and tumor grade was not statistically significant. **References:** None

Aim/Introduction: Pancreatic cancer is one of the leading causes of cancer death with an increasing incidence. Noninvasive determination of malignancy is of major interest for patient therapeutic management. We aim to evaluate the diagnostic performance of ^{18}F -FDG PET/MRI and ^{18}F -FDG PET/CT in preoperative assessment of patients with pancreatic neoplasms. **Materials and Methods:** Forty-four Patients (18 male, 56.2 ± 11.1 yrs) with suspected pancreatic neoplasms were recruited prior to resection or biopsy. All underwent PET/CT (Biograph TruePoint 64, Siemens) and PET/MR (Signa 3T, GE) on the same day, using a single tracer ^{18}F -FDG injection. PET protocol in PET/CT included 5 bed positions (2 min/bed). PET/MR protocol included T_1 -weighted, T_2 -weighted and diffusion-weighted MR sequences and single bed position for PET scan. ^{18}F -FDG was injected with 3.7-7.4 MBq/kg averaged 95 min before PET/CT scan and 165 min before PET/MR scan. Tumor with high-grade dysplasia and invasive pattern were defined as malignance based on the histological examinations. Patients were grouped into malignant ($n = 25$) and benign ($n=19$) groups. Subjective diagnosis was made according to clinical routine process. Regions of interest (ROIs) were defined on the lesions on MRI for PET/MR. Regions of interest (ROIs) were defined as PET-positive lesions with anatomic CT correlate (if visible). The maximum standardized uptake value (SUVmax) of placed ROIs was assessed on PET. The uptake ratio (SUVr) was calculated by SUVmax of the lesion targeted to the mean of SUV on liver of 1 cm ROI (SUVmean). Diagnosis agreement between the two scans and the corresponding calculation of sensitivity, specificity, and accuracy to differentiate malignance and benign tumors were performed. Paired t tests and correlations were performed to compare the SUVmean of liver, the SUVmax of lesion and the SUVr measured on PET/CT and PET/MRI, respectively. **Results:** SUVr values in malignant group were significantly elevated than those in benign group (2.82 ± 1.97 vs. 0.71 ± 0.28 with $P < 0.001$) for PET/CT and (4.98 ± 2.98 vs. 0.99 ± 0.40 with $P < 0.001$) for PET/MR. All the SUV measurements differed ($P < 0.001$) but significantly correlated ($P < 0.05$) between PET/CT and PET/MRI. The diagnosis showed total sensitivity, specificity, and accuracy were 79.2%, 82.35% and 79.6% for PET/CT and 91.67%, 70.59% and 81.8% for PET/MR, respectively. The overall agreement between PET/CT and PET/MRI reached 77% (95% CI, 0.59-0.96). **Conclusion:** ^{18}F -FDG PET/MRI and ^{18}F -FDG PET/CT seem comparably accurate for the detection of malignant neoplasms. **References:** None

Does diffuse gastric FDG uptake infer Helicobacter pylori infection?

Z. Al Bimani^{1,2}, S. Samman³, W. Zeng¹;

¹University of Ottawa, Ottawa, ON, CANADA,

²Ministry Of Health, Muscat, OMAN, ³University of

Miami, Miami, FL, UNITED STATES OF AMERICA.

Aim/Introduction: Helicobacter pylori (H. pylori) is a common cause of peptic ulcers and may be present in more than half of the people in the world. Diffuse Fluoro-Deoxy-Glucose (FDG) uptake in the stomach is usually an incidental finding in patients referred for FDG Positron Emission Tomography (PET) scan for cancer staging. Several studies have shown good correlation between gastric FDG uptake and the presence of H. pylori infection in Asian patients. However, no studies have been done in the North American population. The aim of the study is to test if the presence of diffuse gastric FDG uptake on PET without a CT correlate is associated with H. pylori infection. **Materials and Methods:** All patients referred to our institution for FDG PET/CT for cancer staging from April 2017–Dec. 2019 were retrospectively reviewed for the presence of diffuse gastric uptake if the gastric uptake is much higher than the liver. The patients with gastroesophageal cancer or abnormal gastric findings on CT were excluded. The presence of H. Pylori infection was identified by endoscopy, C-14 urea breath test and blood test. Continuous variables are presented as mean \pm standard-deviation. P-values less than 0.05 were considered statistically significant. **Results:** There are 96 patients with diffuse gastric FDG uptake, with the activity much higher than the liver (stomach SUV_{max} : 7.6 ± 3.7 , liver SUV_{max} : 3.4 ± 0.8). 18 patients had follow-up results for H. pylori. There is no difference in FDG uptake in the stomach between the follow-up and non follow-up groups (SUV_{max} 7.1 ± 2.6 vs. 7.7 ± 3.9 , $p=0.57$). Of the patients who had follow-up results for H. pylori, 13 were negative and 5 were positive or intermediate probability for H. pylori infection, with no significant difference in gastric uptake (SUV_{max} 7.0 ± 1.9 vs. 7.4 ± 3.4 , $p=0.77$). **Conclusion:** Incidental diffuse gastric uptake on FDG PET in cancer patients is not an uncommon finding. Different from the results from the studies with Asian patients, our study from North America showed no significant association between the diffuse gastric uptake and the presence of H. pylori infection. **References:** Kobayashi S, Ogura M, Suzawa N, Horiki N, Katsurahara M, Ogura T, et al. (18)F-FDG uptake in the stomach on screening PET/CT: value for predicting Helicobacter pylori infection and chronic atrophic gastritis. BMC med imaging 2016;16(1):58.

Impacts of malnutrition on ^{18}F -FDG PET/CT measurements on healthy organs in patients with esophageal cancer

E. Deshayes¹, S. Thezenas², I. Berkane¹, N. Flori³, P. Senesse³, T. Galvez³;

¹Nuclear Medicine Department, Institut du Cancer de Montpellier, Montpellier Cedex 5, FRANCE, ²Biometrics Unit, Institut du Cancer de Montpellier, Montpellier Cedex 5, FRANCE, ³Clinical Nutrition and Gastroenterology Department, Institut

du Cancer de Montpellier, Montpellier Cedex 5, FRANCE.

Aim/Introduction: Malnutrition characterized by reduced food intake, involuntary weight loss and change in body composition is frequent in cancer patients, impairing quality of life and overall survival¹. ^{18}F -FDG PET-CT is routinely performed as part of initial staging of numerous cancers owing to its ability to detect increased glycolytic activity of cancer cells. The aim of this study was to determine, in patients with esophageal cancer (with a high incidence rate of malnutrition), whether ^{18}F -FDG uptake in healthy organs was influenced by malnutrition status (weight loss, fat and muscle wasting) and correlated to overall survival (OS). **Materials and Methods:** Patients over 18 years-old diagnosed with oesophageal cancer, who underwent an initial ^{18}F -FDG PET-CT between 2014 and June 2019, were included in this retrospective study. Patients whose brain scanning was not performed or who presented with diabetes were excluded. SUV (max, peak, mean) normalized to patient's weight (bw) or lean mass (lm) were obtained from brain, liver, spleen and bone marrow. Nutritional status and survival data were obtained from patient records. Patients were defined as sarcopenic according to cut-off values obtained from a reference healthy population² of skeletal muscle index (SMI). SMI is the Skeletal Muscle Area using CT imaging at the 3rd lumbar vertebra normalized by height squared. Group differences were tested using the Kruskal-Wallis test and correlation with overall survival (OS) was assessed using a Cox proportional hazards model. **Results:** Sixty patients (51 males), with median age of 65.5 years at diagnosis, were included. Twenty had a weight loss $WL \geq 10\%$. Median OS was 25.8 months. Nineteen showed a SMI consistent with sarcopenia. SUV(bw and lm) in brain were significantly lower in patients with $WL \geq 10\%$ compared to $WL < 10\%$ ($p < 1e-3$). No difference between SUV in these 2 groups were observed for any other normal tissues. In sarcopenic patients, SUV_{bw} were consistently lower in every tissue tested but no difference was observed when using SUV_{lm} , except for brain with values still lower in sarcopenic patients ($p = 0.003$). Patients with lower brain SUV(bw and lm) had poorer OS ($p < 0.05$). No association between SUV and OS in other organs was seen. **Conclusion:** SUV should be corrected for lean mass in malnourished patients. Brain ^{18}F FDG uptake is significantly lower in malnourished patients and correlated to poor OS. FDG uptake in other studied organs was not associated with OS. **References:** 1. Arends, J.(2017). 2. Van der Werf, A. (2018)

EPS-189

Clinical Value of ^{18}F FDG Bio-distribution in Metabolic Characterization of Pancreatic Masses on PET/CT

S. Tatlidil¹, E. Guler², B. Karasah¹, G. Hakverdi³, Z. Ozcan¹;

¹Department of Nuclear Medicine, Ege University Medical Faculty, Izmir, TURKEY, ²Department of Radiology, Ege

University Medical Faculty, Izmir, TURKEY, ³Department of Statistics, Ege University Medical Faculty, Izmir, TURKEY.

Aim/Introduction: FDG PET/CT imaging for the initial evaluation of pancreatic tumors is challenging. In the current study, we aimed to assess the possible effects of metabolic/clinical factors and bio-distribution of FDG on pancreatic tumor detectability. **Materials and Methods:** The study group included 162 patients (pts) with a pancreatic mass referred for initial metabolic characterization between July 2012 and January 2019. PET/CT was performed using non-contrast low-dose CT. Clinical records, biochemical and radiologic findings were reviewed retrospectively including biochemical profile, personal variables, and SUV measurements of reference tissues. Patients were divided into groups as benign lesions, pancreatic adenocarcinoma (AC), and liver metastasis (LM) as a subgroup of AC. Only one primary lesion and/or metastatic lesion from each patient was included for quantitative analysis. In order to assess FDG bio-distribution, SUVmax were measured in the cerebrum, psoas muscle, and liver using standard ROIs. Data were analyzed using SPSS Statistics 22.0 Program and binary logistic regression analysis was used to test variables related to lesion detectability. CI was accepted as %95 for all tests. **Results:** There were 17 benign and 145 AC pts. LM was found in 47. The median SUVmax was 4.2 (1-10.7) and 9.6 (1.5-65) respectively in benign lesions and ACs (Mann Whitney U test, $p < 0,001$). In the AC group, primary lesions > 1 cm did not show FDG uptake in 9 pts. In the LM group, 13 liver lesions could not be detected on PET/CT though they had a confirmed metastasis > 1 cm. In Pts with false (-) FDG findings, high blood glucose level was noted (Mann-Whitney U test, $p < 0,001$) which was also negatively correlated with low SUVmax cerebrum ($r: -0,571$; $p < 0,001$). The sensitivity of PET/CT for the detection of the primary lesion was 94% (CI: %88-97) and 90% (CI: 82-96) respectively in the overall group and hyperglycemic pts. SUVmax cerebrum was found to be the most robust variable which predicted the undetectability of a primary or metastatic lesion ($OR = 0,3(0,2-0,6)$; $p < 0,001$). ROC analysis showed cut-off value for SUVmax cerebrum was 8.2 ($AUC = 0,9(0,7-0,9)$, $p < 0,001$) and 7.9 ($AUC: 0,8(0,7-0,9)$; $p < 0,01$) for the overall and hyperglycemic pts (> 120 mg/dl, $n: 71$). **Conclusion:** FDG PET/CT appears to be useful in discriminating benign and malignant pancreatic lesions while SUVmax values may overlap. Detectability of pancreatic AC found to be inter-related both with high blood glucose and low cerebral FDG uptake. Therefore, in daily practice of PET/CT, reviewing cerebral uptake might improve diagnostic evaluation of pancreatic tumors in cases with high glucose levels **References:** None

FDG-PET/CT versus Conventional Imaging to Distinguish Between Benign and Malignant Pathology of the Gallbladder

A. Sabaté-Llobera¹, G. Reynés-Llompart², J. Mestres-Martí¹, J. J. Robles-Barba¹, L. M. Gràcia-Sánchez¹, P. C. Notta¹, I. Sánchez-Rodríguez¹, M. Cortés-Romera¹;

¹IDI - Hospital Universitari de Bellvitge - IDIBELL, L'Hospitalet de Llobregat, SPAIN, ²ICO - Hospital Universitari de Bellvitge - IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: Gallbladder lesions are frequent findings in routine imaging tests. Though usually benign (adenomyomatosis or inflammation), malignant lesions are sometimes found incidentally. This study aimed to determine the ability of PET/CT to distinguish between benign and malignant conditions of the gallbladder compared with the conventional imaging approach (CT or MRI), and to find cut-off values for metabolic parameters that could help the diagnosis. **Materials and Methods:** Imaging studies of 50 patients (28 men, mean age 67.5) were retrospectively reviewed. Imaging findings were considered as benign, malignant or indeterminate. PET/CT images were analyzed visually and semiquantitatively (SUVmax of the gallbladder lesion and lesion-to-liver ratio (LLR)). Agreement between conventional imaging and PET/CT was calculated (weighted kappa). Using histology or evolution as gold-standard, ROC curves were obtained to calculate the optimal cut-off values for PET semiquantitative parameters. **Results:** Conventional imaging classified 22 studies as benign, 17 as malignant and 11 as indeterminate, while for PET/CT they were 25, 21 and 4, respectively. There were 16 discordant results between both imaging procedures, obtaining a fair agreement ($k = 0,36$). Visually, PET/CT findings were dichotomized as FDG-avid (32 studies, 64%) and non-FDG-avid. Median SUVmax and LLR in FDG-avid cases were 6.15 and 2.19, respectively, while in non-FDG-avid studies they were 2.0 and 0.66, respectively. Overall, 37 patients (74%) were operated, while the remaining were considered for follow-up (all of them with suspected adenomyomatosis). Among operated patients, 28 (87.5%) were FDG-avid (proving 23 carcinomas and 5 chronic cholecystitis) and 9 were non-FDG-avid (5 cholecystitis, 2 cholelithiasis without additional pathology, 1 lymphoplasmacytic colangitis and 1 adenocarcinoma). PET/CT considered all these non-FDG-avid findings as benign, while conventional imaging considered 2 of them as malignant (the lymphoplasmacytic colangitis and the adenocarcinoma) and 3 as indeterminate. Regarding the final diagnosis (histology or clinical/radiological follow-up), PET/CT showed a diagnostic accuracy of 87% and conventional imaging of 92.3%, though indeterminate results were not considered in this analysis. Metabolic parameters showed significant differences between finally

benign and malignant lesions, with median SUVmax of 3.0 and 6.8, respectively ($p=6.4 \cdot 10^{-6}$), and median LLR of 0.86 and 2.3, respectively ($p=3.4 \cdot 10^{-6}$). Optimal cut-off values to distinguish between benign and malignant pathology were 3.7 for SUVmax and 1.16 for LLR. **Conclusion:** PET/CT shows a good performance in distinguishing benign and malignant gallbladder lesions, with less indeterminate results than conventional imaging techniques. In our study, significant differences between benign and malignant conditions were obtained for PET metabolic parameters, aiming the diagnosis. **References:** None

EPS-191

Potential Value of Quantified Metabolic Indices Obtained in ^{68}Ga (DOTATOC) PET/CT to Distinguish Between G1 and G2 Low-Grade Neuroendocrine Tumors. A Pilot Experience in a Single Center of Spain

J. Rodríguez Gomez¹, M. Ollarves Carrero¹, M. Cabrera Martín¹, F. Ferrando-Castagnetto², C. Wakfie Corieh¹, M. Meneses Navas¹, P. Romero Fernández¹, J. Carreras Delgado¹;

¹Servicio de Medicina Nuclear, Hospital Clínico San Carlos, Madrid, SPAIN, ²Departamento de Cardiología-CCVU, Hospital de Clínicas, Facultad de Medicina, Universidad de la República, Montevideo, URUGUAY.

Aim/Introduction: The detection of neuroendocrine tumors (NET) is favored by over-expression of somatostatin receptors (STTR) in tumor cells. The precision of diagnosis obtained through PET/CT with ^{68}Ga (DOTATOC) and ^{18}F -FDG depends on the STTR membrane receptor subtype and histopathological grade. The following experience explored the potential usefulness of some clinical variables and quantified indices of molecular activity in ^{68}Ga (DOTATOC) PET/CT to differentiate G1 from G2 histopathological degrees in NET patients over-expressing SSTR. **Materials and Methods:** All diagnosed/highly suspicious NET patients who underwent ^{68}Ga (DOTATOC) PET/CT between April 2019 and march 2020 were included. Patients with high-grade NET (grade G3 histological tumor according to Ki67 criteria) were excluded. The clinical data, anatomy of the primary tumor, and the indices maximum and mean standardized uptake value (SUVmax, SUVmean) in primary/metastatic lesions, metabolic tumor volume (MTV), and total lesion glycolysis (TLG) were compared between histological grades G1 and G2. All indices were correlated using the Pearson coefficient (r). Data in subjects with G1 and G2 tumors were compared using Fisher's exact and nonparametric Mann-Whitney tests. A multiple linear regression model was applied to detect possible predictors of histological G1 (p -value = 0.05). **Results:** Thirty-two patients with ^{68}Ga (DOTATOC) PET/CT results were available, 50% women, aged 40-81 years, 44% were gastrointestinal-pancreatic primary tumors. Histopathological confirmation was obtained in 19 patients; 74% of them were classified

as low-grade G1 and G2 ($n=14$). In aggregated low-grade NETs, the sensitivity of ^{68}Ga PET/CT (DOTATOC) was 91%, with a positive predictive value of 100%. There was an inverse strong correlation between VMT and TLG ($r= -0.96$) with a moderate/weak correlation among other indices. Patients in both subgroups were similar in age, anatomic site of the primary tumor, functional status, recurrence rate an treatment. Quantified parameters did not differ between patients with G1 and G2 tumors SUVmax +SEM: 67.78+21.58 vs. 30.21+10.94, $p=0.13$; SUVmean +SEM: 13.07+1.60 vs. 9.86+3.01, $p=0.49$; MTV +SEM: 42.38+14.64 vs.20.17+5.34, $p=0.41$; TLG +SEM: 607.9+297.2 vs. 226.4+82.12, $p=0.34$). The only variable associated with G1 tumors after multivariate analysis was male sex, with a non-significant trend to lower age ($p=0.06$) and bigger SUVmax ($p=0.08$) in G1 subjects. **Conclusion:** ^{68}Ga PET-CT (DOTATOC) demonstrates high sensitivity for diagnosing low-grade NETs. The quantified molecular indices measured in the primary tumor and/or metastatic lesions are similar in histological grades G1 and G2. These preliminary findings and the potential prognostic value of different parameters should be tested in larger multicenter case series. **References:** None

Impact of PET data driven respiratory motion correction of ^{68}Ga -DOTATATE PET/CT for differentiating neuroendocrine tumors (NET) and intrapancreatic accessory spleens (IPAS)

V. Liberini^{1,2,3}, F. Kotasidis⁴, V. Treyer², M. Messerli², E. Orita², I. Engel-Bicik², A. Siebenhüner⁵, M. Huellner²;

¹Department of Nuclear Medicine, A.O.U. Città della Salute e della Scienza di Torino, University of Turin, Turin, ITALY,

²Department of Nuclear Medicine, University Hospital Zürich, University of Zürich, Zürich, SWITZERLAND, ³ENETS CoE Training Fellowship Grant 2019, Berlin, GERMANY, ⁴GE Healthcare, Waukesha, WI, UNITED STATES OF AMERICA, ⁵Department of Hematology and Medical Oncology, University Hospital Zürich, University of Zürich, Zürich, SWITZERLAND.

Aim/Introduction: To evaluate whether quantitative PET parameters of motion-corrected ^{68}Ga -DOTATATE PET/CT may allow differentiating between intrapancreatic accessory spleens (IPAS) and pancreatic neuroendocrine tumor (pNET). **Materials and Methods:** A total of 498 patients underwent a clinically indicated ^{68}Ga -DOTATATE PET/CT for staging/restaging of NET. All subjects with accessory spleens ($n = 43$, thereof 7 IPAS) and pNET ($n = 9$) were included, resulting in a total of 45 scans. PET images were reconstructed using TOF PSF OSEM (OSEM_{PSF}) and TOF PSF BSREM with a beta value of 1000 (BSREM₁₀₀₀). A data-driven gating (DDG) technique (MotionFree™, GE Healthcare) was applied to extract respiratory triggers and use them for PET motion correction within both reconstructions. An R-value threshold of > 10.0 defined respiratory motion. PET

parameters among different samples were compared using non-parametric tests. Receiver operating characteristics (ROC) analyzed the ability of PET parameters to differentiate IPAS and pNETs. **Results:** SUVmax and SUVmean were able to distinguish pNET from accessory spleens and IPAs in OSEM as well as in all BSREM₁₀₀₀ reconstructions (all $p < 0.05$), except SUVmax of OSEM. This result was more reliable using DDG-based motion correction ($p < 0.003$) in both OSEM and BSREM₁₀₀₀ reconstruction. For differentiating accessory spleens and pNETs, the ROC analysis yielded an AUC of 0.742 (sensitivity 56%, specificity 100%) / 0.765 (sensitivity 56%, specificity 100%) / 0.846 (sensitivity 62%, specificity 100%) / 0.840 (sensitivity 63%, specificity 100%) for SUVmax 36.7 / 41.9 / 36.9 / 41.7 in OSEM_{PSF} / BSREM₁₀₀₀ / OSEM_{PSF} + DDG / BSREM₁₀₀₀ + DDG, respectively. **Conclusion:** An SUVmax > 42 identifies a pNET with a specificity of 100%, regardless of the reconstruction technique used. A lesion with SUVmax < 42 may need more specific imaging examinations, such as ^{99m}Tc-HDRBC, if the suspicion of IPAS is still high, in order to avoid surgery. DDG-based motion correction increases the ability of PET/CT parameters (SUVmax and SUVmean) to discriminate IPAS/accessory spleens from pNET. BSREM₁₀₀₀ leads to a significant increase of SUV parameters compared to OSEM, while data-driven gating (DDG) leads to a significant increase of SUV parameters and reduced PET volume compared to reconstructions without DDG. Hence, SUV cut-offs need to be adapted to different reconstruction settings. **References:** None

EPS-193

Image quality for two administration schedules for PET/CT-imaging of 68Ga-DOTATOC

C. Hindorf¹, A. Stenvall^{1,2}, L. Jönsson^{1,2}, B. Olsson³, A. Svensson³, U. Bitzén³, F. Hedéer³;

¹Radiation physics, Skåne university hospital, Lund, SWEDEN, ²Medical radiation physics, Lund university, Lund, SWEDEN, ³Clinical physiology and nuclear medicine, Skåne university hospital, Lund, SWEDEN.

Aim/Introduction: For 68Ga-DOTATOC PET it is attempting to administer a low fixed activity per patient to facilitate a high patient throughput since the yield per batch is limited. Guidelines for 68Ga-DOTA-conjugated peptides recommend an injected activity of 100–200 MBq. However, each examination has to provide images with an acceptable quality. The aim was to compare image quality obtained by two different administration schedules: fixed injected activity and activity injected per body weight. **Materials and Methods:** Twelve patients referred for ⁶⁸Ga-DOTATOC PET were included (mean: 59years, 83kg, 6 females). The patients were divided into three groups based on body weight (3 patients <70kg, 6 patients 70–100kg, and 3 patients >100kg). Each patient received 2 MBq/kg body weight and an hour thereafter images were acquired in list

mode (Discovery MI). Images were reconstructed with a block-sequential regularization expectation maximization reconstruction algorithm (Q.Clear, beta 900) both for our clinically used acquisition time of 3 minutes/bed position and for a shorter acquisition time/bed position to mimic an injected activity of 100 MBq. Images were assessed for image quality by one expert reader. Scores were given by a five-grade scale (1=unacceptable to 5=very high image quality). From regions-of-interest drawn in liver, muscle and fat max and mean activity concentration and standard deviation (std) were noted, and signal to noise ratios (SNR=mean/std) were calculated. Visually assessed image quality and SNR was compared for the two administration schedules and for the three patient groups. **Results:** The administration schedule of 2 MBq/kg gave a mean scored image quality of 3.7, 3.8 and 3.7 for patient groups <70kg, 70–100kg and >100kg, respectively. For a fixed activity of 100 MBq, the mean image quality decreased to 92%, 71% and 44%, respectively, of that for the 2MBq/kg-schedule for the patient groups. The SNR follows the results for the scored image quality. The administration schedule of 2 MBq/kg gave mean SNR of 19.3, 20.2 and 18.6 for patient groups <70kg, 70–100kg and >100kg, respectively. For a fixed injected activity of 100 MBq, the visually assessed image quality decreased to 94%, 92% and 65%, respectively, of that for the 2MBq/kg-schedule for the patient groups. Similar trends were seen for muscle and fat. **Conclusion:** Our study shows that an image quality independent of body weight is obtained for these patients if an administration schedule of 2 MBq/kg is applied, compared to if a schedule of 100 MBq fixed activity is applied. **References:** None

Integration of PET/MRI Hybrid Imaging into Radiotherapy Planning of Cervical Cancer Patients: First Results

S. Ahangari¹, N. Liv Hansen¹, A. Beck Olin¹, T. Jakobi Nøttrup², A. Kiil Berthelsen¹, J. Olof Löfgren¹, A. Loft Jakobsen¹, A. Kjær^{1,3}, F. Littrup Andersen¹, B. M. Fischer^{1,4}, A. Espe Hansen¹;

¹Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, University of Copenhagen, Copenhagen, DENMARK, ²Department of Oncology, Section of Radiotherapy, Rigshospitalet, University of Copenhagen, Copenhagen, DENMARK, ³Cluster for Molecular Imaging, University of Copenhagen, Copenhagen, DENMARK, ⁴The PET Centre, School of Biomedical Engineering and Imaging Sciences, Kings College London, St Thomas' Hospital, London, UNITED KINGDOM.

Aim/Introduction: The integration of multiparametric PET/MRI imaging into the radiation treatment (RT) planning process and its potential to improve local disease control is promising but remains challenging. The objective of this study is to investigate how multiparametric PET/MRI can be integrated into RT planning of patients with cervical cancer. This includes attenuation correction (AC) of MRI hardware

and dedicated positioning equipment and evaluating MRI derived synthetic CT (sCT) of the pelvis region for PET AC and dose calculation to enable a PET/MRI-only setup. **Materials and Methods:** Nine patients underwent PET/MRI (Siemens Biograph mMR) scan in RT position. Each patient had a CT available and one patient was referred for RT. The PET/MRI scan protocol included multiparametric imaging with a total scan time of 35 minutes. The PET signal attenuation and CT-based attenuation correction of the dedicated RT setup including a flat table overlay, leg fixation device, flexible surface coil, and coil holders were evaluated using both phantom and clinical measurements. A deep convolutional neural network was trained to generate sCT from the corresponding Dixon MRI by including also data of sixteen patients from another ongoing study. For one patient the sCT was evaluated by measuring the mean absolute difference between the dose distributions calculated on sCT and CT. PET images reconstructed with sCT and co-registered CT were compared by the voxel-wise relative difference. **Results:** Phantom imaging with the RT flat table overlay revealed 2.3% reduction in total prompt. The PET photon attenuation for the phantom was up to 14.6% near to the table, which was reduced to $0.5\% \pm 3.2\%$ using the generated hardware AC map. Comparable results were found in the patient study resulting in a 16% underestimation of SUV_{mean} without AC of the RT equipment. AI based sCT was inferred for each patient in less than 5 seconds. There was an excellent voxel-by-voxel correlation between CT and sCT ($P < 0.01$). The dosimetric analysis of the sCT-based dose planning showed a mean absolute error (MAE) of 0.12 Gy within the body contour and 0.18 Gy inside the planning target volume (PTV). PET image reconstructed with sCT compared to the one reconstructed with CT had relative differences of $6.2\% \pm 1.7\%$ within the tumor. **Conclusion:** These preliminary results suggest that multiparametric PET/MRI-only can be successfully integrated in the radiotherapy workflow of patients with cervical cancer. Patient recruitment is ongoing for validation of the robustness of the setup. **References:** None

EPS-195

Utility of the Sentinel Lymph Node Biopsy in Breast Cancer after Neoadjuvant Chemotherapy with Negative Axillary Lymph Nodes or Node Involvement

N. Álvarez Mena, F. Sebastián Palacid, P. Turbay Eljach, B. Pérez López, M. Alonso Rodríguez, C. Gamazo Laherrán, A. Sainz Esteban, M. Ruiz Gómez, M. González Soto, R. Ruano Pérez; Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To assess the usefulness of sentinel lymph node biopsy (SLNB) technique in patients with breast cancer after neoadjuvant chemotherapy (NAC). **Materials and Methods:** Retrospective series of 80 women with breast cancer who underwent a lymphoscintigraphy after the

periareolar/peritumoral injection of 111MBq of ^{99m}Tc -nanocolloid for the detection of the sentinel lymph node post-NAC between June 2016 and April 2020. Variables such as age, carcinoma histology, molecular subtype, BRCA gene mutations, focality, axillary staging pre-NAC (clinical, US/MRI, FNA), tumor size, type of surgery, radiological response, lymphoscintigraphy result and intraoperative SLNB result (by using OSNA method) were analyzed. **Results:** Average age was 50 years (48% between 45-60 years). The main histological type was invasive ductal carcinoma (75), followed by infiltrating lobular carcinoma (4) and metaplastic (1). Regarding tumor characteristics we found that: 29 patients were triple-negative (36%), 19 luminal B-HER2, 13 HER2neu, 16 luminal B and 3 luminal A. BRCA1 gene mutations were detected in 3 patients. 1 tumor was multifocal and 7 multicenter. Axillary involvement pre-NAC was observed in 40 patients (50%): 4 clinically+ and US/MRI/FNA-, 7 US/MRI+ and FNA-, and 29 with axillary FNA+. 33 of them (83%) showed a tumor size $< 5cm$ (T1-T2) and the remaining 7 $> 5cm$ (T3-T4). Conservative surgery (lumpectomy/quadrantectomy) was performed in 54 patients (68%). 54% showed complete radiological response. Lymphoscintigraphy detected the SLN in 76 patients (95%). 4 were not detected despite reinjection, so an axillary lymph node dissection (ALND) was performed (3 without lymphatic invasion and 1 with 5/9 macrometastases). When evaluating SLNB result, it was observed to be: 1. Negative in 61 patients: -Axillary lymph-node preservation in 42 (69%): 1 metaplastic carcinoma. 17 triple-negative (1 of them synchronous bilateral carcinoma), 5 HER2neu (1 showed partial radiological response) and 8 luminal B-HER2. 1 multifocal and 4 multicenter. 8 patients with axillary affection pre-NAC (1 clinically, 1 US/MRI+ and 6 FNA+) and 34 with negative axillary lymph nodes. 9 patients operated with a mastectomy. -ALND was performed in 19: they showed partial radiological response and/or suspicious lymph nodes intraoperatively (14 with lymphatic invasion pre-NAC). However, 73% without metastases. 2. Positive in 15 patients: -Axillary lymph-node preservation in 3 (20%) with micrometastases. -ALND in 12 with macrometastases: 9 showed axillary involvement pre-NAC. **Conclusion:** SLNB is a very useful technique in patients with NAC by avoiding a high number of unnecessary axillary lymphadenectomies, even in those with a worse prognosis, improving their quality of life. **References:** None

EPS-196

Impact Of Sentinel Lymph Node Biopsy In Breast Cancer Patients Treated With Neoadjuvant Chemotherapy

A. Roteta, D. Nogueira Souto, E. Galindo Lalana, L. Tardín Cardoso, A. Andrés Gracia, P. Razola Alba, M. Delgado Castro, T. Escalera Temprado, E. Prats Rivera, M. Abós Olivares; Clinic Hospital "Lozano Blesa", Zaragoza, SPAIN.

Aim/Introduction: To analyze how many of the patients undergoing neoadjuvant chemotherapy (NCT) may benefit from SLNB, as well as the impact on patient management, especially in those with early axillary involvement. **Materials and Methods:** We included patients with breast carcinoma candidates to NCT discussed at the Tumor Committee of our hospital (April/2017-August/2019). All of them were subjected to clinical assessment, ultrasound and, if appropriate, histological analysis, axillary pre and post-NCT. Sentinel lymph node detection was performed after periareolar injection of [99mTc]Tc-nanocoloid (74 MBq) the day before surgery. In some cases, blue dye was injected and/or a pre-NPC metal clip was placed in the affected node. **Results:** Sixty-two patients were included. NCT achieved a complete breast response in 12 patients, partial in 46 and non-response in 4. Initially, 31 patients were classified as N0 and 31 as N+ (28 N1 and 3 N2), achieving a complete axillary response in 58% of N+ (18). SLNB was performed in 49 patients (79%; 100% in N0 and 58% in N+ from baseline). The gamma detection rate of the sentinel lymph node was 91.8% (93.5% in N0 and 88.9% in N+). 28 lymphadenectomies were undergone (45.2%; 22.5% in N0 and 67.7% in N+), 11 due to positive SLNB (5 N0 and 6 N1), 13 owing to lack of axillary response and 4 caused by the non-localization of the sentinel lymph node. SLNB was performed in 58% of N+ patients, of which 44.4% were negative, avoiding lymphadenectomy. Metal clip and/or blue dye techniques were used in 31 cases (50%). **Conclusion:** SLNB is viable in a high percentage of patients with previous NCT, with a high detection rate, even in patients with early affected axilla, avoiding lymphadenectomy to patients who achieve a complete response of the axillary lymph node. **References:** None

EPS-197

Tumor Recurrence at 5 Years in Patients with Breast Cancer, Previous Surgery Treatment and Sentinel Lymph Node Biopsy

N. Álvarez Mena, F. Sebastián Palacid, P. Turbay Eljach, B. Pérez López, C. Gamazo Laherrán, M. Alonso Rodríguez, A. Sainz Esteban, M. Ruiz Gómez, M. González Soto, R. Ruano Pérez; Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To assess the probability of tumor recurrence at 5 years in patients with personal history of breast cancer in whom sentinel lymph node biopsy (SLNB) was performed. **Materials and Methods:** Retrospective series of 123 patients with breast cancer who underwent lymphoscintigraphy to detect the SLN and subsequent intraoperative exeresis between January 2014 and December 2014. Variables such as age, sex, SLNB result, tumor recurrence at 5 years and exitus until January 2020 were analyzed. Data were also collected from patients with disease recurrence: age, sex, histology and tumor size,

if triple-negative (negative estrogen and progesterone receptors and also negative HER2), percentage of nuclei with positive staining in tumor cells (Ki-67 score), SLNB result and location of recurrence. **Results:** 122 women and 1 man with average age of 55 years were studied. SLNB was negative in 76 patients (62%). Recurrence was detected in 6 patients, all of them women with mean age of 60 years. Regarding tumor characteristics in this group: histological types found were invasive ductal carcinoma (IDC) in 5 patients and carcinosarcoma in 1, and an average size of 20mm. 33% of them were triple-negative and showed Ki-67 percentage score of 70-80%. When evaluating SLNB result, it was observed to be: 1. Negative in 2 of the relapsed patients: 1 showed distant recurrence at 3 years in the liver, and 1 presented new lesion in the contralateral breast at 2 years (second SLNB also negative). 2. Positive in 4 patients, with axillary lymph node dissection (ALND) performed: 2 showed local recurrence (surgical site) and 2 presented distant disease (1 in the liver and 1 had a mass with superior vena cava thrombosis). Therefore, the recurrence of disease at 5 years is 5% in our sample (6/123): 33% (2/6) with previous negative sentinel lymph node biopsy; 66% (4/6) with positive SLNB and ALND. Until January 2020, 6 of the 123 patients deceased, but just 3 due to recurrence. **Conclusion:** The recurrence of the disease at 5 years is not relevant in patients undergoing sentinel lymph node biopsy. However, there is a higher incidence in those who showed positive SLNB and ALND was performed, probably due to some prognostic factors such as tumour size, histology, hormone receptors expression, or Ki-67 score. **References:** None

EP-001**Decision impact study on the use of PET-PSMA for the initial staging of men with high-risk localized prostate cancer (PCa)**

A. Viaouet¹, C. Verrier², S. Mengue², S. Leroux³, G. Desrez², T. Haaser¹, R. Herve², O. Couturier², P. Gustin²;

¹University Hospital of Bordeaux, Bordeaux, FRANCE, ²General Hospital of French Polynesia, Papeete, FRENCH POLYNESIA.

Aim/Introduction: The standard-of-care conventional imaging for men with high-risk localized PCa are the MRI and the 99mTc-Bone scan. We aimed to investigate to what extent the use of gallium-68 PSMA PET-CT (Prostate Specific Membrane Antigen), because of its better sensitivity, could induce a change in management during the multi-disciplinary genitourinary oncology teams. **Materials and Methods:** This monocentric retrospective study was conducted at the General Hospital of French Polynesia on 23 patients with high-risk localized PCa who underwent PET-PSMA in New-Zealand for their initial staging. The primary outcome was the frequency of staging modification. The secondary outcomes were the proportion of change in management intent (curative to palliative) or modality (prostatectomy or radiotherapy) (major change), and the proportion of change in modality delivery (minor change). **Results:** The median age was 64 years-old. The mean initial PSA was 44,26 ng/mL. 11 patients were T3a (48%), 2 were T3b (9%). The distribution between ISUP group 1, 2, 3, 4, 5 was respectively 4 (17%), 3 (13%), 8 (35%), 1 (4%) and 6 (26%). 18 were at high-risk according to D'Amico's risk classification (78%) and 5 were at intermediate risk (22%). A change in staging occurred for 13 patients (56%): 7 UP-staging (30%), including 4 on T, 2 on N, 2 on M. 6 DOWN-staging (26%), including 0 on T, 4 on N, 3 on M. 10 were stable (43%). A change in treatment intent occurred for 11 patients (48%) with 6 « major » changes and 5 « minor » changes. **Conclusion:** Despite their retrospective and their low power, these results are consistent with the recent available literature. Thus, the prospective study "proPSMA" confirmed to a lesser extent these results with a change in treatment intent occurring for 39 (27%) of the 146 patients who underwent PET-PSMA. **References:** None

EP-002**¹⁸F-NaF Uptake by Fibrous Dysplasia Lesions in the Skull is Significantly Higher in Patients with Optic Neuropathy**

G. Papadakis^{1,2,3}, G. Giannakakis², A. H. Karantanis³, K. Marias², M. T. Collins¹, A. M. Boyce¹;

¹National Institute of Dental and Craniofacial Research (NIDCR), Bethesda, MD, UNITED STATES OF AMERICA,

²Computational Biomedicine Laboratory (CBML), Foundation for Research and Technology Hellas (FORTH), Heraklion, GREECE, ³Department of Medical Imaging, Medical School, University of Crete, Heraklion, GREECE.

Aim/Introduction: Fibrous dysplasia (FD) of bone is a benign skeletal disorder characterized by the replacement of normal bone and normal bone marrow with abnormal fibro-osseous tissue leading to significant morbidity. Since the skull is a frequent site of FD lesions, aim of the current study was to explore potential association between FD-related ¹⁸F-NaF uptake in the skull and the presence of optic neuropathy. **Materials and Methods:** Forty four FD patients (26 females, 18 males) underwent whole-body ¹⁸F-NaF-PET/CT scans at the NIH Clinical Center. All study participants underwent neuro-ophthalmologic evaluation in order to determine the presence of optic neuropathy (36 patients without optic neuropathy, 8 patients with optic neuropathy). Mean age±std at the time of the scan was: 30.1±14.9 years. PET scans were obtained (mean ± SD) 61.8±5.1 minutes after intravenous administration of an average±std of 2.69±0.73mCi of ¹⁸F-NaF. Low dose, non-contrast, CT scans were acquired for coregistration and attenuation correction purposes. FD-related ¹⁸F-NaF activity in the skull was assessed by using MIM vista (version 6.5.9). Firstly, a VOI encompassing the head was drawn, and afterwards a SUVmax threshold-based approach -customized per patient- was employed in order to include all FD-related craniofacial uptake. Separate VOIs encircling all areas above the SUVmax threshold, were automatically generated, while areas with non-FD related ¹⁸F-NaF activity were manually removed. Subsequently, the following craniofacial FD-related ¹⁸F-NaF uptake parameters were automatically obtained: Total Volume (TV) of all ¹⁸F-NaF positive skull FD lesions and FD-related Total ¹⁸F-NaF craniofacial Activity (TA) determined as the product of TV multiplied by SUVmean of all craniofacial FD lesions (TA = TV×SUVmean). Finally the aforementioned ¹⁸F-NaF parameters were correlated with the presence of optic neuropathy. **Results:** T-test revealed that both TV and TA were significantly higher in FD patients with optic neuropathy in comparison to FD patients without

optic neuropathy. (TV: $t=2.37$, $p=0.022<0.05$) (TA: $t=2.04$, $p=0.048<0.05$). **Conclusion:** The significant association between craniofacial FD-related ^{18}F -NaF uptake and the presence of optic neuropathy, indicates the effectiveness of ^{18}F -NaF PET/CT in reflecting clinically relevant skeletal outcomes in patients with FD. **References:** None

EP-003

Prognostic value of ^{18}F -FDG PET/CT-based metabolic parameters in patients with bone sarcoma

L. García Belaústegui, C. Wakie Corieih, R. Valhondo Rama, A. Blanes García, M. Cabrera Martin, J. Carreras Delgado; Clinico San Carlos Hospital, Madrid, SPAIN.

Aim/Introduction: The aim of the study was to assess the prognostic significance of maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) from ^{18}F -FDG PET/CT scans performed in patients with bone sarcoma by correlating these metabolic parameters with clinicopathological features of the tumor. **Materials and Methods:** In total, 35 patients initially diagnosed with bone sarcoma and who underwent ^{18}F -FDG PET/CT with contrast enhancement at the time of initial diagnosis were retrospectively reviewed. The SUVmax, MTV (cm^3) and TLG of primary tumors were measured and correlated with tumor grade, histological subtype and presence of lymph node or distant metastasis. **Results:** Mean age was 42 years and 57.7% of the patients were women. Primary tumor was located in lower (53.85%) and upper limbs (23.07%) or pelvis (23.07%). The 7.7% of the patients presented lymph node metastasis at the time of diagnosis and the 30.8% had distant disease in lung, bone or peritoneum. Tumors histologically classified as high grade presented mean values of SUVmax 20.60, $\text{VMT}_{2.5}$ 319.67, $\text{VMT}_{40\%}$ 51.83 and TLG 1605.30; moderate grade tumors showed an average of SUVmax 8.24, $\text{VMT}_{2.5}$ 71.58, $\text{VMT}_{40\%}$ 46.80 and TLG 283.20 and mean values in low grade tumors were SUVmax 4.75, $\text{VMT}_{2.5}$ 8.32, $\text{VMT}_{40\%}$ 39.9 and TLG 25.09. Metabolic parameters were also measured according to the histological subtype of the tumor: 34.6% were osteosarcoma (SUVmax 12.80, $\text{VMT}_{2.5}$ 80.47, $\text{VMT}_{40\%}$ 27.09, TLG 463.98), 34.6% were chondrosarcoma (SUVmax 7.16, $\text{VMT}_{2.5}$ 59.07, $\text{VMT}_{40\%}$ 50.08, TLG 228.35) and 11.5% were Ewing sarcoma (SUVmax 12.02, $\text{VMT}_{2.5}$ 123.77, $\text{VMT}_{40\%}$ 59 and TLG 669.84). **Conclusion:** The pretreatment SUVmax, MTV and TLG from ^{18}F -FDG PET/CT were directly related with histologic tumor grade and aggressiveness of the tumor subtype and therefore could be useful for providing important prognostic information at initial diagnosis. However, these results need to be validated in standardized prospective studies. **References:** None

Correlation between ^{18}F -sodium fluoride uptake by PET and dual-energy X-ray absorptiometry in the second lumbar spine vertebra

R. Piri^{1,2}, P. Hermann³, H. Petersen¹, O. Gerke^{1,2}, A. B. Jespersen^{4,5}, M. Ø. Andersen^{4,5}, P. F. Høilund-Carlsen^{1,2};

¹Research Unit of Clinical Physiology and Nuclear Medicine, Department of Clinical Research, University of Southern Denmark, Odense C, DENMARK, ²Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, ³Department of Endocrinology, Odense University Hospital, Odense C, DENMARK, ⁴Center for Spine Surgery and Research, Lillebælt Hospital, Middelfart, DENMARK, ⁵Institute of Regional Health Research, University of Southern Denmark, Odense, DENMARK.

Aim/Introduction: ^{18}F -Sodium Fluoride (NaF) is a known positron emission tomography (PET) tracer used to track micro-calcification at the molecular level, i.e., “active calcification” in the body. In comparison, dual-energy X-ray absorptiometry (DXA) is common modality used to examine bone mineral density (BMD) and bone mineral content (BMC). Thus, these modalities are used to evaluate molecular and physical bone features, respectively. Focusing on the second lumbar spine vertebra (L2), we examined the potential association between results obtained by NaF-PET/CT and DXA scans. **Materials and Methods:** A total of 78 patients were included from the PARA-DESIS study, i.e., a randomized controlled trial aiming to elucidate the effect of parathyroid hormone (Teriparatide) given to patients, aged 60+ years, for three months following spondylolisthesis operation for disabling spinal stenosis. All patients underwent NaF-PET/CT and DXA scans 3 months after operation, and measured variables were obtained from L2, distant from the operation site in all patients. PET variables included volume of interest (VOI), and maximal, peak, mean and total standardized uptake values (SUVmax, SUVpeak, SUVmean, SUVtotal), including the latter two after partial volume correction (cSUVmean and cSUVtotal). Finally, the association between demographics and variables from the two modalities were examined. **Results:** The mean age of the patients was 70.49 ± 6.14 years (62 females). Weight ($r=0.31$, $p=0.007$) and height ($r=0.34$, $p=0.002$) had weak positive correlations with BMC and with total VOI uptake ($r=0.34$, $p=0.002$) and ($r=0.44$, $p<0.001$), respectively. BMC correlated with VOI volume ($r=0.51$, $p<0.001$), SUVtotal ($r=0.37$, $p<0.001$) and cSUVtotal ($r=0.34$, $p=0.002$). Similarly, BMD correlated with SUVpeak ($r=0.24$, $p=0.03$), SUVtotal ($r=0.24$, $p=0.04$) and cSUVtotal ($r=0.27$, $p=0.02$). **Conclusion:** Positive correlations between relevant SUV measures and physical features of bone, including BMD and BMC, were observed indicating that the metabolic activity of bone increases with increasing bone density and mineral content. **References:** None

EP-005**Comparison of thoracic, abdominal and pelvic SPECT/CT with wholebody bone scan in bone metastases. Can we avoid planar wholebody bone scan?**

A. Sainz Esteban, P. Turbay Eljach, N. Álvarez Mena, F. Sebastian Palacid, M. González Soto, M. Ruiz Gómez, C. Gamazo Laherrán, B. Pérez López, R. Ruano Pérez;
Hospital Clinico Universitario, Valladolid, SPAIN.

Aim/Introduction: To compare thoracic, abdominal and pelvic SPECT/CT (wSPECT/CT) with wholebody bone scan (WBS) in the assessment of bone metastases. **Materials and Methods:** A total of 32 patients with suspected or confirmed bone metastases underwent WBS and a wSPECT/CT (from the base of the cervical spine to the pelvis) after the intravenous injection of ^{99m}Tc-diphosphonates. Images were visually interpreted in two separate reading sessions. For anatomical analysis, the skeleton was divided in nine anatomical sections as skull and cervical spine, clavicle and sternum, ribs and scapula, thoracic spine, lumbar spine, sacrum, pelvis, humerus and femur. In patients with generalized bone metastases, only one dominant lesion in each anatomical section was selected for analysis. Lesions were interpreted as malignant or equivocal in WBS and malignant, benign or equivocal in wSPECT/CT. Lesions with unsuspecting morphological alterations located around the joints, degenerative changes (e.g. osteophytes), osteoporotic patterns and/or fractures detected in WBS were excluded from the study. **Results:** A total of 130 lesions were assessed, 10 were only positive on WBS (located in parts of the body not covered by wSPECT/TC) and 21 were only positive on the wSPECT/CT. WBS showed 31 equivocal lesions, 12 were benign on wSPECT/CT, 18 malignant and 1 equivocal. In a patient-based analysis, in 16 patients wSPECT/CT didn't supply additional information to the WBS: two patients showed a normal scan and 14 patients showed the same lesions presented in the WBS or more lesions but without impact on the final diagnosis. In 16 patients wSPECT/CT add crucial information to the diagnosis: in one patient wSPECT/CT showed metastatic disease not visible in WBS, in 13 patients improved equivocal lesion characterization and in two patients dismiss false positive findings on WBS. However, in all the patients the performance of a WBS and a SPECT/TC of one anatomical section would have been sufficient to provide the same data. In 8 patients showed lesions not covered in the wSPECT/CT but it didn't modify the final diagnosis. **Conclusion:** wSPECT/TC can replace the WBS in all the patients studied and add crucial information to the diagnosis in 50% of the patients. However, in all the patients the performance of a WBS and a SPECT/TC of one anatomical section would have been sufficient to provide the same data. **References:** None

EP-006**Necessity of Whole Body Bone Scintigraphy In Patients With Lung Or Breast Cancer Who Underwent Whole Body ¹⁸F FDG-PET/CT For Initial Staging**

F. Görtan¹, Z. Kaya Döner², Ö. Vural Topuz³, E. Arslan⁴, M. Halaç⁵;
¹Turkish Ministry of Health, Ankara City Hospital, Department of Nuclear Medicine, Ankara, TURKEY, ²Health Sciences University Bursa Higher Specialization Training And Research Hospital, Department of Nuclear Medicine, Bursa, TURKEY, ³Istanbul Okmeydanı Training and Research Hospital, Department of Nuclear Medicine, Istanbul, TURKEY, ⁴Istanbul Training and Research Hospital, Department of Nuclear Medicine, Istanbul, TURKEY, ⁵Neo Life Medical Center, Istanbul, TURKEY.

Aim/Introduction: The aim of our study is to analyze the necessity of performing whole body bone scintigraphy (WBS) for revealing potential metastatic bone lesions in patients with lung or breast cancer who underwent whole body fluorodeoxyglucose positron emission tomography/computerized tomography (¹⁸F FDG-PET/CT) for initial staging. **Materials and Methods:** In the study, the patients diagnosed with histopathologically proven lung or breast cancer who underwent ¹⁸F FDG-PET/CT scan at our department for initial staging were evaluated retrospectively. Among these patients, 82 of them were included in the study (41 female and 41 male; average age 57.7 (34-76); 48 lung cancer and 34 breast cancer) who had undergone also WBS within maximum 30 days (average 5.4± 6.4 days) in order to be evaluated for bone metastases before any treatment. **Results:** Either one of ¹⁸F FDG-PET/CT or WBS revealed 292 bone lesions which were evaluated to possibly be bone metastasis in 36 (43.91%) out of 82 patients. In 22 of those 36 patients, both methods revealed positive results. 7 out of remaining 14 patients had true positive results in ¹⁸F FDG-PET/CT and false negative results in WBS. The remaining 7 patients revealed false positive results in WBS and true negative in ¹⁸F FDG-PET/CT. According to the final diagnosis, all but 2 metastatic bone lesions were demonstrated in ¹⁸F FDG-PET/CT while only 122 of 292 lesions were demonstrated in WBS. In identifying bone metastasis, sensitivity, specificity, accuracy, positive and negative predictive values of ¹⁸F FDG-PET/CT and WBS were 99.32%; 100%; 99.41%; 100%; 95.92% and 41.78%; 56.79%; 45.04%; 77.70%; 15.75%, respectively. The relation between computerized tomography (CT) characteristics and ¹⁸F FDG uptake concentration indicated that SUVmax values in lytic lesions tend to be higher. **Conclusion:** Our study revealed higher values of sensitivity, specificity, positive and negative predictive values in ¹⁸F FDG-PET/CT than those in WBS for diagnosis of bone metastasis. ¹⁸F FDG-PET/CT could reveal all but two bone metastasis. These two lesions were in the upper extremity and therefore out of imaging area. Besides, there wasn't any lesion where ¹⁸F FDG-PET/CT predicted false negative results. On the other hand, WBS wasn't able to

detect all metastatic bone lesions. Furthermore, it predicted false positive lesions. Accordingly it might be concluded that it is not necessary to perform WBS for revealing other potential bone metastasis in patients who underwent ^{18}F FDG-PET/CT for initial staging. **References:** None

EP-007

Additional clinical impact of single photon emission computed tomography/computed tomography bone scintigraphy (SPECT/CT) 16 slices to planar whole body BS in evaluation of equivocal lesions

N. Kapsoritakis¹, P. Simos², O. Bourogianni¹, M. Stathaki¹, A. Tsaroucha¹, E. Papadaki¹, S. Koukouraki³;

¹Nuclear Medicine Department, University Hospital, Heraklion-Crete, GREECE, ²School of Medicine, University of Crete, Institute of Computer Science, Foundation for Research and Technology-Hellas, Heraklion-Crete, GREECE, ³School of Medicine, University of Crete, Heraklion-Crete, GREECE.

Aim/Introduction: In clinical practice, one of the most frequent diagnostic dilemmas is evaluating oncological patients in order to confirm or rule out bone metastatic disease. Despite more advanced imaging modalities, bone scintigraphy (BS) continues to play a major role. However, indeterminate lesions require further imaging with higher specificity. Nowadays, new hybrid imaging modalities SPECT/CT 16 or more slices is increasingly being used in clinical nuclear medicine practice. The aim of this study was to assess the additional value of targeted SPECT/CT 16 slices acquisition to whole body planar BS (wbPBS) in characterizing equivocal bone lesions. **Materials and Methods:** Between January 2019 and January 2020, a total of 600 pts with different types of histopathologically proven cancer were prospectively recruited for staging and restaging purposes. Inclusion criteria were bone pain, elevated tumor markers and equivocal/suspicious CT results. All 600 oncological pts underwent wbPBS and all patients with equivocal/suspected for bone metastasis lesions on wbPBS (n=265), underwent additionally a targeted SPECT/CT. Image interpretation was based on lesion and patient based analysis. According to lesion based analysis, lesions were scored as benign (score 1), malignant (score 2) or equivocal (score 3). **Results:** 215/600 pts had a negative test result (35.9%) on wbPBS. In the remaining 385 patients a total of 803 lesions of abnormal uptake of the radiotracer were found: 62 (7.7%) lesions were evaluated as metastatic (score 2), 60 (7.7%) were evaluated as lesions of benign origin (non-metastatic) (score 1) and 681 (84.8%) as unclear lesions (score 3). A targeted SPECT/CT was performed immediately after the wbPBS in 265 pts. 668 lesions considered as unclear and were reevaluated with targeted SPECT/CT. Diagnostic findings on SPECT/CT were obtained for 592/668 (88.6%) lesions and 227/265 (85.7%) of patients, 317/668 lesions (47.5%) were classified as score

1, 275/668 (41.2%) as score 2. 76/668 lesions (11.4%) in 38 patients (14.3%) were classified as score 3. The percentage of indeterminate lesions on SPECT/CT vs PBS was 11.4% vs 84.8%. Moreover, the addition of SPECT/CT provided 36 more lesions vs wbPBS. The diagnostic yield was 83% (30/36 lesions), with 8/30 (26.7%) were evaluated as score 1 and 23/30 as score 2 (76.7%). 5/36 lesions (13.9%) were classified as score 3. **Conclusion:** The introduction of SPECT/CT has further enhanced the diagnostic accuracy of wbPBS offering a better characterization of equivocal findings distinguishing metastasis from benign lesions. SPECT/CT could be a promising tool for the accurate staging and restaging. **References:** None

EP-008

Bone scan indications in patients under 30 years of age

N. Manevska, N. Bozinovska, T. Makazlieva, S. Stojanoski, V. Majstorov, D. Miladinova;
Medical Faculty, Skopje, NORTH MACEDONIA.

Aim/Introduction: Bone scintigraphy can be a useful tool in evaluating bone disorders in young adults. Although it has a low specificity, combining planar dual phase bone scan (DPBS) and hybrid imaging (SPECT/CT), can help in detecting metabolic activity of bone lesions (BL) of various etiology. **Materials and Methods:** Bone scan indications in young patients under 30 years were retrospectively evaluated in a two-year period at our Nuclear Medicine Department. The DPBS and afterwards SPECT/CT procedure on the region of interest was performed 3 hours after i.v application of $^{99\text{m}}\text{Tc}$ -MDP in dose calculated by age. **Results:** We evaluated 65 patients (27 males, 38 females), average - 15.32 ± 7.25 years. The most frequent indication was metabolic activity of primary BL of non-malignant etiology (38/65, 58.46%), followed by primary malignant BL (12/65 patients, 18.46%). In 10 (15.38%) patients the indication was to detect bone mets due to non-bone malignancies (Malignant Melanoma, Neuroblastoma, Nephroblastoma, Medulloblastoma, Hodgkin Lymphoma, Histiocytosis). The non-malignant etiology was predominantly due to primary benign bone tumors (22/38, 57.89%) including Osteoid osteoma - 8, Fibroma Non-Ossificans - 4, Enchondroma - 1, Osteochondroma - 1, followed by Aneurysmal Bone Cyst-7, Exostosis-1. Other rare indications were trauma, sacroiliitis, rheumatologic diseases and fibrous dysplasia. In suspected malignant bone tumors histopathology revealed Osteosarcoma in 4 patients, Chondrosarcoma - 2, Ewing sarcoma - 1, Histiocytosis - 3, Malignant Lymphoma - 1, NET - 1. More than 2/3 of the patients complained of bone pain and in 23% the pain was associated with an injury. In 50/55 patients, BL presented in the appendicular skeleton, mainly in the inferior extremities. DPBS was performed in all except 9 patients (with malignancy of non-bone etiology), where indication was detecting distant

mets. From 56 patients, DPBS was positive in 36.92%, while negative in the pool phase and positive only on the late phase in 27.69%. Positive both planar and SPECT/CT were detected in more than half of the patients (52.31%), while 4 patients had negative planar and positive SPECT/CT (ABC-1, Ewing - 1, Sacroiliitis - 1, Nephroblastoma - 1). **Conclusion:** Bone scintigraphy is still a valuable nuclear method complementary to other diagnostic modalities. In young adults the main clinical indication is evaluation of primary BL of non-malignant etiology. Because of its high sensitivity, it can detect metabolic activity of BL and their turnover (osteoblastic reactions) of various etiologies (benign, malignant, traumatic, inflammatory, rheumatic) and assists in further management of the patient. **References:** None

EP-009

The role of bone scan in the diagnosis of bone metastases in Ewing's sarcoma

D. Travaglio Morales, J. M. Cordero García, L. García, D. Monachello Araujo, E. López Llobet, S. Rodado Marina, M. Coronado Poggio, C. Lancha Hernandez, C. Escabias del Pozo, E. Ortiz, R. Sebastián, L. Dominguez Gadea; Hospital Universitario La Paz, Madrid, SPAIN.

Aim/Introduction: To review the experience of the conventional bone scan in the evaluation of Ewing's sarcomas metastases in a sarcomas expert center. **Materials and Methods:** A review of the bone scans performed in the last 6 years in our center was carried out, evaluating the presence of metastases in the initial assessment and follow up of Ewing's sarcoma (ES). The data concerning the age at initial diagnosis, histological type and anatomic origin of the primary tumor were collected, as well as the data of evolution of these patients. The presence of metastases in the initial diagnosis or during follow up was confirmed by CT, RM, PET-CT or biopsy. **Results:** A total of 42 patients (p) (average age: 16.8 years, 14 women and 28 men) were reviewed, in whom a total of 191 bone scan had been carried out. Eight out of 42 patients were diagnosed of soft tissue ES, and 34/42 with bone ES. The primary tumor was located in the lower extremities in 20 patients, followed by pelvis (9 patients), trunk (9), upper extremities (3) and head (1). The follow up ranged between 1 and 204 months, with a mean of 58 months. A total of 18/42 patients (43%) had metastases: 18/18 in the lungs and 5/18 (28%) in bone tissue. 15/18 patients had metastasis at initial diagnosis (16 pulmonary and 2 osseous) and 3/18 during the follow up (3 osseous and 2 pulmonary). The bone scan identified the presence of lesions in 4 of 5 patients with bone metastases. (S=83% and E=100%). The false negative case was due to diffuse bone marrow involvement. **Conclusion:** The bone scan constitutes nowadays an important diagnostic tool in the initial evaluation and follow up of Ewing's sarcomas, with a high sensitivity in the detection of bone metastases.

Bone marrow involvement may not be identified in bone scans, leading to false negative results **References:** None

EP-010

Usefulness of ¹⁸F FDG PET/CT in Ewing sarcoma In Morocco

A. Sallak, E. Iris, G. Amal;

University Hassan II of medicine, Casablanca, MOROCCO.

Aim/Introduction: This is a retrospective descriptive study done at the nuclear medicine department of the Ibn Rochd University Hospital in Casablanca, from February 01, 2015 to December 31, 2017. We analysed the 18FDG TEP-TDM exams done as part of the initial extension assessment or follow-up of patients with Ewing's sarcoma (ES). The purpose of this work is to understand the usefulness of PET / CT in these patients. **Materials and Methods:** The 18FDG PET / CT examination done in fasted patients for at least 6 h, with a fasting capillary blood glucose lower than 7mmol / l. The injected activity is 3 MBq / Kg for children and 4 to 5.5 MBq / kg of 18FDG in adults. The acquisitions made 60 minutes after the injection. The exams analyse was done by two seniors. Positive lesions are those in which the max SUV is greater than the hepatic max SUV **Results:** Fourteen patients, and 15 scans, 6 scans for initial assessment of extension, 5 for suspected recurrence and 4 for evaluation of treatment. The average age was 23.5 years [5 to 55 years]. The sex ratio F/M was 1.67. The ES was skeletal in 88 % of the cases. For the extension assessment, PET / CT was strongly positive in the initial lesion in 5/6 patients, the mean maximum SUV was 8, the hepatic max SUV [1.14, 4.42]. The mean lesion metabolic volume was 641.7 cm³. Two patients had satellite lymph node hypermetabolism, SUV max at 2.65. Three patients (50%) have osteo- medullary and pulmonary metastatic at diagnosis, the SUV max average value at 4.5. For suspected relapse, ¹⁸FDG PET / CT was positive in 5/6 patients. The initial site was hyper metabolic in 5/6 patients, the maximum mean SUV was 8.5 associated in 50 % of cases with a satellite lymph node hypermetabolic and in 83 % of cases to a distant metastasis. Four patients underwent end-of-treatment ¹⁸FDG PET / CT. The ¹⁸TEP / CT was negative in 3 patients, the disease was stable in one. **Conclusion:** The level of FDG uptake faithfully reflects the grade and aggressiveness of the tumor and remains a guiding factor in the management of Ewing's sarcomas by offering one of its great advantages, whole-body imaging and exhaustive mapping of all the targets to be treated as well as possible risk lesions. **References:** None

Differential diagnosis between progression and radionecrosis in brain metastases after stereotactic radiosurgery using hybrid FDG-PET and MRI coregistered images

H. Otman¹, J. Deverdin², N. Menjot de Chamfleur², F. Molino², M. Bilal Chawki³, F. Cachin¹, C. Bouvet¹, B. Fayçal², L. Emmanuelle², D. Mariano Goulard²;

¹Centre Jean Perrin, Clermont Ferrand, FRANCE,

²University Hospital of Montpellier, Montpellier, FRANCE,

³University Hospital of Nancy, Nancy, FRANCE.

Aim/Introduction: Dual phase 18 FDG-PET has been proven helpful to assess FDG-avid cerebral tumors as tracer will build up in metastases or tumor recurrences while its retention remains stable within normal tissue or inflammatory process. This is useful when MRI can't discriminate brain tumor recurrence (TR) from radionecrosis (RN) after stereotaxic radiosurgery (SRS) for brain metastases (BM). Many studies have sought to improve diagnostic performance by associating FDG-PET and MRI with interesting results but many bias, mostly within image post-processing. Coregistered MRI and dual phase FDG-PET images could alleviate these biases and be used to extract prognostic biomarkers. **Materials and Methods:** We retrospectively evaluated patients treated with SRS for BM which developed a contrast-enhanced MRI lesion with non-conclusive diagnosis for TR or RN. All patients underwent MRI and FDG-PET at least 3 months after their last SRS session. Dual FDG-PET comprised a one hour "based image" (H1) followed by a 4 hours "delayed image" (H4). MRI included contrast enhanced T1 (T1), FLAIR, ASL (BAT, CBF), T1 Perfusion (ktrans, SER) and T2* Permeability (k₂rBF, rBV). PET and MRI data were all coregistered on the T1 images. Semi-automated Regions of Interest (ROI) of the tumor were drawn on the T1 MRI, H1 and H4 FDG-PET images; a reference contralateral white-matter ROI (WM) was drawn for standardization. Imaging metrics were then evaluated for their association with TR or RN based on histological, radiological and clinical criteria after at least 6 months follow-up. **Results:** Eleven patients matched the inclusion criteria; 7 with TR and 4 with RN; no additional treatment was introduced. On visual analysis, FDG-PET and MRI respectively obtained 100% and 83% Sensitivity and 100% and 80 % Specificity. The two MRI-false negative diagnoses were subsequently identified on follow-up (1 patient, RN) and histology (1 patient, TR). When standardized on WM, PET SUVmax values were significantly different across groups at

H1 ($p < 0,044$) and H4 ($p < 0,00285$). Among MRI metrics, relCBF ($p < 0,02055$), T1-perfusion AUC ($p < 0,00425$), SER (Signal Enhancement Ratio, $p < 0,0195$) and Washout ($p < 0,0212$) could significantly discriminate between TR or RN. **Conclusion:** Coregistered PET-MRI images accurately discriminates between TR and RN. With FDG being the most commonly used PET radiotracer, this protocol remains easily transposable and should be encouraged to obtain non-invasive prognostic and clinically relevant biomarkers. **References:** None

EP-012

[¹¹C]Methionine Uptake In Grade II-III Diffuse Gliomas Does Not Allow To Classify Tumors According To IDH1 Mutation Status

T. Skvortsova, Z. Savintseva, D. Zakhs;

N. P. Bechtereva Institute of the Human Brain of Russian Academy of Sciences, Saint-Petersburg, RUSSIAN FEDERATION.

Aim/Introduction: The aim of the study was to assess the relationships between [¹¹C]methionine (MET) positron emission and computed tomography (PET/CT) and histomolecular markers in patients with untreated grade II-III glioma. **Materials and Methods:** We included 109 patients with histologically proven grade II-III gliomas (47 males, 62 females, age 39±11 years) who had undergone PET/CT using [¹¹C]methionine (PET-MET) prior surgery/biopsy. The sample included diffuse gliomas grade II (57 astrocytomas (AST), 27 oligodendrogliomas (ODG), n = 84) and grade III (18 AST, 7 ODG, n = 25). All were tested for the presence of a mutation in the IDH1 gene (R132H IDH1). 1p/19q status was assessed in 42 cases. On PET-MET tumor-to brain uptake ratio (TBR) was calculated by dividing the MET uptake in the tumor (hot spot 10 mm in diameter) to radiotracer uptake in the contralateral unaffected cortex. Imaging-derived parameters were compared between gliomas stratified according to glioma type, WHO grade, IDH1 status using non-parametric tests. **Results:** Diffuse astrocytic and oligodendroglial tumors grade II-III were divided into three subgroups: astrocytic gliomas with a mutation in the IDH1 gene (n = 51), astrocytic gliomas without a mutation in the IDH1 gene (n = 24) and IDH1 mutated oligodendrogliomas (n = 34). In mutated gliomas (n = 85) TBR was 1,79 ± 0,7 (mean ± standard deviation), in IDH1-wild type glioma TBR was 1,8 ± 0,97 ($p = 0,59$, Mann-Whitney test). The median TBR in grade II-III astrocytomas with and without the IDH1 mutation was 1,52 (range 0,8 - 3,8) and 1,47 (range 1,0 - 5,1), respectively ($p = 0,31$). Oligodendrogliomas showed significantly higher MET uptake values (median TBR=1,9, range 1,0 - 4,36) compared with astrocytic gliomas (median TBR=1,5, range 0,8 - 3,8) ($p = 0,0008$). Moreover, significant differences were revealed between IDH1 mutated astrocytoma and oligodendrogloma ($p = 0,0007$). Significant differences in TBR were also found between grade II and

III gliomas ($p=0,03$). **Conclusion:** MET uptake in grade II-III gliomas seems not to be dependent on the IDH1 (R132H) status of the tumor and PET-MET does not allow to classify gliomas according to their IDH1 genotype. Differences in MET uptake metrics in lower grade gliomas are associated with their histological subtypes and the grade of malignancy. Acknowledgment: The reported study was funded by Russian Foundation of Basic Researches according to the research project № 18-29-01015. **References:** None

EP-013

Initial Experience With 18F-DOPA PET/CT For Differentiating Radionecrosis From Tumour Progression In Brain Metastasis And Malignant Primary Tumors Of The Central Nervous System

V. Lopez Prior, R. Diaz Expósito, F. Manchón Adsuar; Valencian Oncologic Institution (IVO), Valencia, SPAIN.

Aim/Introduction: This study highlights our initial experience evaluating the efficacy of 18F-DOPA PET/CT for distinguishing changes post-radiation treatment (CPRT) from disease progression (DP) in patients with brain metastasis and malignant primary tumors of the central nervous system. **Materials and Methods:** In 16 patients (11 men (68.80%)-5 women (31.20%); 56.00 ± 9.93 years) with a total of 30 previously irradiated brain lesions (metastasis 10 (62.50%) or primary tumors 6 (37.50%)) 18F-DOPA PET/CT was performed. PET studies were analyzed semiquantitatively (maximum lesion uptake value (SUVLmax), lesion-to-estriatum (SUVmaxL/Smax), and lesion-to-normal brain tissue (SUVLmax/SUV Bkgmax) ratios). Diagnosis of DP was defined radiologically as an increment in lesion size on MR images or clinical follow-up. Relative cerebral blood volume (rCBV) derived from perfusion-MR was available in 10 lesions. A comparison was made between SUVmaxL/Smax, SUVLmax/SUV Bkgmax ratios and rCBV values from our results, and the results obtained by Cicone et al (Eur J Nucl Med Mol Imaging (2015) 42:103-111). **Results:** Primary tumors were lung (7 patients), breast (1 patient), colon (1 patient), melanoma (1 patient), astrocytoma (1 patient), glioblastoma (5 patients). Median maximum diameter of the lesions was 25.00 ± 11.58 mm (range 10-50 mm). All patients had undergone radiation therapy before the PET scan: whole brain radiation (WBR) 4 (26.70%), radiosurgery (RS) 4 (26.70%), stereotactic radiotherapy (SRT) 7 (46.70%). Median treatment doses were (Gy): WBR 47.50 (range 30-60), RS 19.50 (range 18-24), SRT 27.35 (range 18-60). The median time interval from the completion of radiation treatment to PET was 10.25 mo (2.00-23.00 mo). Of the 30 lesions, the diagnosis of DP was established in all of them as a definitive outcome by radiological and clinical criteria. The median of SUVLmax of the total of 30 lesions was 2.85 ± 0.87; SUVmaxL/Smax 1.04 ± 0.27; SUVLmax/SUV Bkgmax 2.10 ± 0.65. Using Cicone's best differentiating SUVmaxL/Smax cut-off value

(0,75) we have 83.33% (25/30 lesions) of accuracy in our study (Cicone: 78.2%). Using Cicone's best differentiating SUVLmax/SUV Bkgmax cut-off value (1,59) we have 79.31% (23/29 lesions) of accuracy in our study (Cicone: 91.3%). The rCBV was available in 10 lesions (6.04 ± 4.23). Using Cicone's best differentiating cut-off value (2,14) we have 90% (9/10 lesions) of accuracy in our study (Cicone: 75,6%). The mean time of follow-up after PET scan was 5.64 ± 2.92 mo. The management strategies after PET scans include RS 3/14 (21.43%); SRT 8/14 (57.14%), surgery 1/14 (7.14%); chemotherapy 1/14 (7.14%); palliative treatment 1/14 (7.14%). One patient died and a new recurrence was observed in another patient. **Conclusion:** Semiquantitative indices from 18F-DOPA PET/CT images could be used for differentiating DP from CPRT. In this specific setting, these parameters could be predictors of progression-free survival but need to be confirmed with longitudinal studies on a larger population. **References:** None

EP-014

¹⁸F-FET or ¹⁸F-FLT PET/CT in diagnosis of low-grade gliomas? A pilot study

J. Vasina¹, M. Hodolič², R. Jančálek³, Z. Mackerle³, M. Hendrych³, R. Hejnová¹, T. Kazda¹, Z. Řehák¹;

¹Masaryk Memorial Cancer Institute, Brno, CZECH REPUBLIC,

²University Hospital, Olomouc, CZECH REPUBLIC, ³St.

Anne's University Hospital, Brno, CZECH REPUBLIC.

Aim/Introduction: The diagnosis of low-grade glioma (LGG) is challenging, as conventional imaging modalities can often give inconclusive results. PET, as functional imaging modality, can provide additional metabolic information. Given that thymidine is a nucleoside encountered in DNA, 3'-deoxy-3'-[¹⁸F]-fluorothymidine (¹⁸F-FLT) was proposed as a PET marker for cell proliferation rate. ¹⁸F-FLT has a high detecting rate for high-grade gliomas (HGG) but is considered less valuable in diagnosis of LGG. O-(2-[¹⁸F]-fluoroethyl)-L-thyrosine (¹⁸F-FET) is a radiopharmaceutical approved for the characterization of glioma-suggestive lesions. The aim of this study was to determine the diagnostic accuracy of ¹⁸F-FET and ¹⁸F-FLT PET/CT in patients with primary LGG. **Materials and Methods:** Patients with MRI-suspected LGG planned for biopsy or resection surgery underwent preoperative ¹⁸F-FET and ¹⁸F-FLT PET/CT within one week. Surgery and histopathological diagnosis was performed by the next two weeks. The histopathological results were correlated to PET findings. **Results:** Six patients (22-43 years) with MRI suspected LGG underwent ¹⁸F-FET and ¹⁸F-FLT PET/CT followed by a surgery and tissue diagnostics. PET findings can be divided into three diagnostic groups according to ¹⁸F-FET and ¹⁸F-FLT PET positivity: the first group counting one patient (n=1/6) was characterized by positive ¹⁸F-FET PET (SUVmax 5.52/T5, 6.05/T40) and negative ¹⁸F-FLT PET had histopathological diagnosis of oligodendroglioma

(grade II). The second group was characterized by positive ^{18}F -FET PET but only slightly positive ^{18}F -FLT PET. This PET pattern was presented in two patients ($n=2/6$) with lower SUVmax in the one suffering diffuse astrocytoma WHO grade II (^{18}F -FET PET SUVmax 3.13/T5, 3.48/T40; ^{18}F -FLT PET SUVmax 0.84/T15) compared to the patient with final diagnosis of anaplastic astrocytoma WHO grade III (^{18}F -FET PET SUVmax 5.6/T5, 5.9/T40; ^{18}F -FLT PET SUVmax 0.96/T15). The main feature of the third PET group was marked positivity on both PET procedures. Three patients ($n=3/6$) with ^{18}F -FET (SUVmax 6.69/T5, 4.74/T40; 8.85/T5, 6.85/T40; and 13.31/T5, 9.15/T40) and ^{18}F -FLT PET (SUVmax 2.69/T15; 3.91/T15; and 1.75/T15) avid lesion had a final diagnosis of diffuse midline glioma harbouring the H3 K27M mutation (grade IV), anaplastic astrocytoma (grade III), and anaplastic astrocytoma (grade III), respectively. **Conclusion:** Preliminary results on the small number of patients document the need for appropriate diagnostic tool in patients with LGG because of the low specificity of MRI. Opposed to the MRI findings, ^{18}F -FET and ^{18}F -FLT PET were sufficient for diagnosis of HGG. However, ^{18}F -FET was superior to ^{18}F -FLT in imaging of LGG. **References:** None

EP-015

Molecular imaging $^{99\text{m}}\text{Tc}$ -CXCR4-L SPECT in brain tumors

P. Vallejo Armenta¹, G. Ferro Flores², O. Pérez-García¹, J. Soto Andonaegui³, B. Sandoval-Bonilla³, B. Nettel-Rueda³, C. Bautista-Wong³;

¹Instituto Nacional de Cancerología, Mexico City, MEXICO,

²Instituto Nacional de Investigaciones Nucleares (ININ), Mexico

City, MEXICO, ³UMAE Hospital de Especialidades. Centro Médico Nacional Siglo XXI. IMSS., Mexico City, MEXICO.

Aim/Introduction: Overexpression of the chemokine-4 receptor (CXCR4) in brain tumors (BT) is associated with high cancer cell invasiveness. $^{99\text{m}}\text{Tc}$ -CXCR4-L is a new SPECT radioligand capable of specifically detecting the CXCR4 protein. The aim of the study was to assess the feasibility of $^{99\text{m}}\text{Tc}$ -CXCR4-L (CXCR4-SPECT) for imaging BT and correlate the radiotracer uptake by BT in patients with the histological grade of differentiation and the CXCR4 expression evaluated by immunohistochemistry. **Materials and Methods:** Twenty-seven patients (age, 44.6 ± 15.8 years; 16 males, 11 females) with suspected brain tumor (20 indeterminate brain tumor [IBT] and 7 with suspected glioma recurrence detected by enhanced MRI) were evaluated with preoperative brain SPECT scan 3 hours after intravenous injection of 750 MBq $^{99\text{m}}\text{Tc}$ -CXCR4-L. Both visual and semiquantitative analyses were performed. Maximum target-to-background ratio (TBRmax) was calculated using contralateral tissue uptake as background. The expression of PSMA was analyzed by immunohistochemistry in 11 patients. TBRmax was correlated with IHC findings and pathological grade (low-grade glioma [LGG], high-grade

gliomas [HGG]). The gold standard was pathological diagnosis using specimens obtained by biopsy or surgical resection. **Results:** In vivo CXCR4 expression was seen in all patients with malignant BT and glioma recurrence ($n=24$). CXCR4-SPECT was positive in 3 LGG (astrocytoma), 14 HGG (1 anaplastic astrocytoma and 13 GBM) and 2 breast mets with TBRmax 1.8 ± 0.6 , 7.5 ± 2.1 and 5.0 ± 3.0 , respectively; while for the rest, the result was negative with a histological report of gliosis. TBRmax significantly correlated with the pathological grade (Spearman $r_s=0.90$, $p < 0.0001$). CXCR4 was highly expressed in the cancer cells of HGG and mets, while its expression in LGG was low and completely absent in gliosis. The sensitivity, specificity, PPV, NPV and accuracy with TBRmax evaluation with a cut-off value of 1.3 were 100%. **Conclusion:** The radiopharmaceutical uptake in malignant BT was significantly higher than the background brain uptake, which demonstrated the ability of the new $^{99\text{m}}\text{Tc}$ -CXCR4-L to detect tumours with CXCR4 expression. CXCR4-SPECT is a potentially useful imaging tool for assessing of glioma grading, to detect tumor recurrence (negative scan in treatment-related changes), planning treatment and biopsy guidance (the background uptake in normal brain parenchyma is absent, thus enhancing tumor detection). **References:** None

Mexico City, MEXICO, ³UMAE Hospital de Especialidades.

Centro Médico Nacional Siglo XXI, Mexico City, MEXICO,

⁴Instituto Nacional de Cancerología, Mexico City, MEXICO.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is upregulated on endothelial cells of solid tumors, including gliomas. Glioblastoma (GBM) is the most malignant glioma, the current standard therapy includes surgery followed by concurrent radiotherapy and chemotherapy with temozolomide. However, combination therapy can lead to radiation necrosis that often mimics recurrent brain tumor on MRI. PSMA-targeted imaging may potentially identify patients with disease recurrence and help direct changes in therapy. The aim of this study was to investigate the diagnostic value of $^{99\text{m}}\text{Tc}$ -EDDA/HYNIC-iPSMA (iPSMA-SPECT) in distinguishing tumor recurrence from radiation necrosis. **Materials and Methods:** Eighteen patients (age, 43.8 ± 15.0 years; 9 males, 9 females) with suspected glioma recurrence (8 low-grade glioma [LGG] and 10 high-grade glioma [HGG]) detected by enhanced

MRI after surgery and radiation therapy (median interval was 11 months) were evaluated with iPSMA-SPECT. Both visual and semiquantitative analyses were performed. Maximum target-to-background ratio (TBR_{max}) was calculated using contralateral tissue uptake as background. The expression of PSMA was analyzed by immunohistochemistry in 6 patients. TBR_{max} was correlated with IHC findings and pathological grade. The gold standard for diagnosing radiation necrosis (RN) or glioma recurrence (GR) was pathological diagnosis using specimens obtained by biopsy or surgical resection. **Results:** In vivo PSMA expression was seen in all patients with GR (n=12). iPSMA-SPECT was positive in 4 LGG (astrocytoma) and 8 HGG (1 anaplastic oligodendroglioma and 7 GBM) with TBR_{max} 7.6 ± 0.7 and 22.7 ± 4.8 , respectively; while for the rest, the result was negative with a histological report of RN. TBR_{max} significantly correlated with the pathological grade (Spearman $r_s = 0.87$, $p < 0.0001$). Immunohistochemical results corroborated that PSMA was highly expressed in the vascular endothelium of HGG, whereas its expression in LGG was low and absent in RN. Furthermore, a trend toward a positive correlation between the degree of iPSMA-SPECT uptake and PSMA expression levels in tumor specimens was observed. The sensitivity, specificity, PPV, NPV and accuracy of TBR_{max} evaluation with a cut-off value of 2.8 were 100%. **Conclusion:** The extremely low background uptake in normal brain tissue and consequently high TBR_{max} make iPSMA-SPECT highly promising for discrimination between recurrence and RN. PSMA expression in recurrent glioma opens a potential way for targeted peptide therapy as well as for prediction of treatment with antiangiogenic agents. Substantial advantages to iPSMA-SPECT were seen including low dosimetry, high availability and low cost. Further study with a larger population using external data is required for translation of the future clinical potential. **References:** None

The metabolic amyloid signature of ^{18}F -FDG PET/CT in Alzheimer's disease

S. Pacella¹, V. Isella^{2,3}, E. Preza¹, V. Polonia⁴, A. Franchini¹, C. Crivellaro⁵, C. Landoni^{2,5}, L. Guerra^{2,5}, C. Ferrarese^{2,3}, A. Formenti⁴, M. Musarra⁵;

⁴Postgraduate School of Neurology, University of Milano Bicocca, Milan, ITALY, ⁵Department of Nuclear Medicine,

ASST Monza San Gerardo Hospital, Monza, ITALY.

Aim/Introduction: Alzheimer's disease (AD) represents the most common cause of dementia in elderly patients, accounting for about 60-70% of all cases. ^{18}F -FDG-PET/CT is an important tool in the diagnostic workout of AD: the typical pattern of hypometabolism involved the posterior cingulate cortex (PC), precuneus (Pr) and temporoparietal areas (TP). The aim of our study is to determine if ^{18}F -FDG-PET/CT may predict amyloid pathology at the individual level in patients with confirmed AD using three methods of analysis of PET/CT images and comparing the three approaches. **Materials and Methods:** Two Nuclear Medicine Physicians retrospectively reviewed 101 PET/CT scans of patients referred to the Neurology Unit of our Hospital for dementia or suspect dementia, who had undergone lumbar puncture or amyloid-PET as biomarker for amyloid status, or carried a genetic mutation for AD or non-AD dementia. They used three rating methods: the visual evaluation (also named visual rating, VR) of PET/CT transaxial re-elaborated images and two semiautomatic softwares that are Cortex ID, developed and marketed by GE Healthcare (Waukesha, WI, USA) and SPM INLAB, an automated software based on Statistical Parametric Mapping (SPM; <http://www.fil.ion.ucl.ac.uk/spm>), developed by the National Research Council (<http://inlab.ibfm.cnr.it/inlab/SPM.php>). Cohen's kappa (κ) was run to determine the degree of concordance between the three rating methods in defining the presence/absence of PC-Pr-TP hypometabolism. Total accuracy, sensitivity, specificity and positive and negative predictive values (PPV, NPV) were calculated for each of the three FDG-PET rating methods. **Results:** Cortex ID showed the best sensitivity (91%), specificity (75%) trade off and highest total accuracy (83%) of all three rating methods. For VR, inter-rater reliability was also calculated and indicated near-perfect agreement between the two Nuclear Medicine physicians in defining presence/absence of PC-Pr-TP hypometabolism (Cohen's $\kappa = 0.85$ [95% CI, 0.74 to 0.96], $p = 0.000$). Cohen's κ showed substantial agreement between the two automated ratings ($\kappa = 0.80$ [95% CI, 0.68 to 0.92], $p = 0.000$). There was substantial agreement also between SPM INLAB and VR ($\kappa = 0.73$ [95% CI, 0.59 to 0.86], $p = 0.000$). **Conclusion:** Our study confirmed the important role of ^{18}F -FDG PET/CT in patients with confirmed AD. The high sensitivity of all three methods supports the idea that underlying amyloid pathology strongly correlates with a typical topography of hypometabolism. Semiautomatic softwares as Cortex ID could improve specificity in order to reduce the possibility of false positive results that could lead to overdiagnosis of amyloid-related dementia. **References:** None

EP-018**Alternatives to static F-18-FDG brain PET using early-phase F-18-FPN brain PET**H. Yoon¹, Y. Jeong^{1,2}, J. Jeong¹, H. Shin², D. Kang^{1,2};¹Dong-A University Medical Center, Busan, KOREA, REPUBLIC OF, ²Dong-A University, Busan, KOREA, REPUBLIC OF.

Aim/Introduction: Early-phase amyloid PET images represent perfusion and are known to be associated with the metabolism of F-18-FDG. F-18-Florapronal (FPN, Alzavue, FutureChem Pharma, Korea) is a newly developed radio-pharmaceutical for amyloid PET imaging that is being used clinically in Korea. The aim of this study is to find the optimal frame in early-phase F-18-FPN PET that can replace the F-18-FDG PET image, to generate perfusion images and use it for AD diagnosis. **Materials and Methods:** Seventeen AD patients (age: 69.0±9.3 yrs) and 15 age-matched normal subjects (age: 69.9±8.0 yrs) underwent F-18-FDG and F-18-FPN brain PET scans, within an interval of 4 weeks. Dynamic PET data were acquired 0-60 min after intravenous injection of F-18-FPN (370 MBq) and F-18-FDG (185 MBq). Early-phase F-18-FPN PET images were merged by frame within 15 minutes with 0-3 minutes as the start time, and voxel-wise and region-based correlation coefficients with F-18-FDG PET were calculated. Region-based correlation coefficients were calculated using the average SUVr values in 83 brain regions using Hammer's brain atlas of PMOD 3.6. Optimal frames were determined by considering the correlation coefficient, noise in the initial state, image quality, and personal similarities between early-phase F-18-FPN perfusion PET images and F-18-FDG delayed static PET images. **Results:** The voxel-wise correlation coefficient of early-phase F-18-FPN PET and static F-18-FDG brain PET images was 0.934 at 1.5-2 min, and the region-based correlation coefficient was 0.984 at 2.7-4.5 min. Considering the PET image quality, and voxel-wise and region-based correlation coefficients, the early-phase F-18-FPN image generated in 1.5-4 minutes was optimal to replace the static F-18-FDG brain PET image. Early-phase F-18-FPN images were generated for each patient for 1.5-4 minutes and compared to static F-18-FDG PET images. The two images were visually similar. Correlation coefficients of minimum value 0.873 or higher were observed. The regions for classifying AD and HC in early-phase F-18-FPN images were anterior orbital gyrus, lateral orbital gyrus, and amygdala, and SUVr thresholds were 0.900, 0.889, 0.763 using ROC. **Conclusion:** We found an early-phase F-18-FPN image with a high correlation coefficient to replace the static F-18-FDG brain PET image. In this study, the threshold value of SUVr, which can be classified as AD and HC, was proposed using a time-optimized early-phase F-18-FPN brain PET image. Now, quantitative diagnosis of amyloid negative AD patients will be possible. **References:** None

EP-019**Severe Obstructive Sleep Apnea and Increased Cortical Amyloid-beta Deposition**T. Laitinen¹, S. Ylä-Herttua², M. Hakulinen¹, P. Poutiainen¹, T. M. Laitinen¹, A. Koivisto³, A. Remes⁴, M. Hallikainen³, J. Lehtola³, T. Saar², M. Könönen¹, R. Vanninen¹, H. Mussalo¹, E. Mervaala¹;¹Diagnostic Imaging Center, Kuopio University Hospital, Kuopio, FINLAND, ²Institute of Clinical Medicine, University of Eastern Finland, Kuopio, FINLAND, ³KUH Neurocenter, Kuopio University Hospital, Kuopio, FINLAND, ⁴Research Unit of Clinical Neuroscience, University of Oulu, Oulu, FINLAND.

Aim/Introduction: Human studies have suggested that sleep deprivation may act as a risk factor of Alzheimer's disease (AD) via brain amyloid- β (A β) burden. Patients with obstructive sleep apnea (OSA) have poor quality of sleep, insufficient sleep, and chronic partial sleep deprivation. The suggested association between severe OSA and risk of Alzheimer's disease (AD) needs further study. So far only few reports exist on associations between brain A β burden and severe OSA. **Materials and Methods:** The study cohort was collected retrospectively from a routine diagnostic patient population from the years 2011-2018 that was evaluated in our hospital due to a clinical suspicion of OSA. Inclusion and exclusion criteria were 1) severe OSA (Apnea-Hypopnea Index > 30/h) in diagnostic polygraphy, 2) age 30-50 years, 3) no medical history of major neurological or psychiatric diseases, 4) diabetes, when present, had to be in good treatment balance, 5) no use of medication influencing on the central nervous system or any substance abuse, 6) no subjective or objective symptoms or signs of any cognitive difficulties. We performed detailed multimodal neuroimaging in 19 cognitive intact middle-aged patients with severe OSA. Brain A β uptake was studied with [¹¹C]-PiB -PET, glucose metabolism with [¹⁸F]-FDG-PET, and structural imaging was performed with 3.0 T MRI. **Results:** Increased cortical grey matter [¹¹C]-PiB uptake (Z-score >2 in any of the regions of interest) was found in 6 out of the 19 patients (32 %). Two of these 6 patients showed Z-scores above 3. The increased A β uptake was seen individually in precuneus/posterior cingulum regions (5 patients), sensorimotor regions (2 patients), and prefrontal, temporal mesial, anterior cingulum, and occipital regions (1 patient in each, respectively). Cortical glucose hypometabolism in [¹⁸F]-FDG-PET was seen in only two patients and localized to primary visual cortices in both of them. MRI did not show structural changes suggestive of AD-related pathology. **Conclusion:** OSA may predispose to cerebral A β burden, which reflects a future risk for AD, or a possible preclinical prevailing pathology. In OSA patients findings of increased [¹¹C]-PiB uptake were less pronounced and regional compared with more pronounced and widespread A β burden typically seen in AD. In OSA patients A β clearance may be compromised without simultaneous

evidence of metabolic or structural alterations. Our results emphasize the importance of early diagnostics and proper treatment of severe OSA in cognitively intact subjects, possibly diminishing the individual risk for later cognitive dysfunction. **References:** None

¹⁸F-FDG PET/CT study on the changes of brain FDG metabolism in patients with DLBCL after chemotherapy

H. Yang¹, Q. Zhao², J. Cao¹, J. Tian¹, J. Ren¹;

¹Ningxia Medical University, Yinchuan, Ningxia, CHINA, ²General Hospital of Ningxia Medical University, Yinchuan, Ningxia, CHINA.

Aim/Introduction: The aim of this study was to illustrate the glucose metabolism changing pattern of “chemo-brain” in patients with diffuse large b-cell lymphoma (DLBCL). The relationship between brain glucose metabolism and clinical staging and chemotherapy cycles were also explored. **Materials and Methods:** Forty-five patients with DLBCL were retrospectively included. All patients received standard CHOP or R-CHOP chemotherapy. A baseline before chemotherapy and follow-up ¹⁸F-FDG PET/CT whole-body imaging were performed in all subjects (9 after 4 cycles, 26 after 6 cycles, and 10 after 8 cycles). Clinical data, such as staging, was recorded. ¹⁸F-FDG PET/CT cerebral images and raw data were analyzed using SPM8 and ScAnVP. AVOI based brain metabolism changing pattern image was obtained. An AAL template was used to perform the ROI based semi-quantitative analysis. SPSS17.0 was applied as the statistical software. Paired samples t-test and Pearson correlation analysis were conducted. **Results:** After chemotherapy, the glucose metabolism of bilateral temporal pole, bilateral hippocampus, bilateral parahippocampal gyrus, bilateral pons, , bilateral amygdala, left inferior frontal gyrus, right gyrus rectus, vermis, bilateral olfactory cortex, right thalamus and bilateral cerebellum were significantly decreased ($p < 0.05$). In contrast, bilateral inferior occipital gyrus, bilateral middle occipital gyrus, right middle frontal gyrus, right inferior frontal gyrus, bilateral precuneus, bilateral superior occipital gyrus, bilateral cuneus, right precentral gyrus, bilateral postcentral gyrus, bilateral supramarginal gyrus and bilateral angular gyrus showed an increase of FDG uptake after chemotherapy ($p < 0.05$). The changes of glucose metabolism in bilateral pons positively correlated with chemotherapy cycles ($p < 0.05$). No correlation was found between the changes of glucose metabolism and clinical staging ($p < 0.05$). **Conclusion:** Chemotherapy changed the brain glucose metabolism in DLBCL patients, especially in frontal lobe, temporal lobe, collapse and cerebellum. The change of glucose metabolism in bilateral pons was associated with chemotherapy cycles. **References:** None

EP-021

Brain amyloid load assessed by ¹¹C-PIB PET/CT for predicting long-term severity of cognitive impairment in patients with amnesic mild cognitive impairment. A comparison with ¹⁸F-FDG PET/CT scan

J. Jiménez-Bonilla¹, R. Quirce¹, M. De Arcocha-Torres¹, I. Martínez-Rodríguez¹, S. López-García², C. Lage², M. García², A. Pozueta², E. Rodríguez-Rodríguez², P. Sánchez-Juan², A. Sánchez-Salmón¹, N. Martínez-Amador¹, S. Ruiz-Llama¹, G. Molina¹, O. Cuenca-Vera¹, J. Andrés¹, A. Gutiérrez-González¹, I. Banzo¹;

¹Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Research Group. University of Cantabria, Santander, SPAIN, ²Neurology Service. Marqués de Valdecilla University Hospital, Santander, SPAIN.

Aim/Introduction: To study in patients with amnesic mild cognitive impairment (A-MCI) if brain amyloid load (BAL) is associated with the severity of cognitive impairment after 5-year follow-up and to compare it with the prognostic value of regional glucose metabolic findings. **Materials and Methods:** We prospectively studied 45 consecutive A-MCI patients (all Stage 3 on Global Deterioration Scale [GDS]) with ¹¹C-PIB and ¹⁸F-FDG PET/CT at diagnosis. Five years later, 33 patients were clinically re-evaluated; re-evaluation was not possible in 12 patients (5 died, 7 lost to follow-up). Clinical status was evaluated using the GDS. PIB-PET was acquired 60-90 minutes after iv 555MBq ¹¹C-PIB, and FDG-PET 30 minutes after iv 185 MBq ¹⁸F-FDG. In PIB-PETs, regional SUV indices were obtained in cerebellar, temporal, occipital, frontal, parietal, anterior cingulate and posterior cingulate cortex. Using the cerebellar cortex as reference region, regional SUV ratios (SUVr) were obtained. BAL was obtained as an average of these regional SUVr in each patient. FDG-PET was visually analyzed considering temporo-parietal hypometabolism as key finding to consider the scan as positive or negative for AD. **Results:** At diagnosis, 7/33 A-MCI patients were PIB+/FDG+ (Group A); 14/33 were PIB+/FDG- (Group B); 3/33 were PIB-/FDG+ (Group C), and 9/33 were PIB-/FDG- (Group D). In the group A, the averaged BAL was 2.2034+0.441 (range: 1.664-2.7677), and in group B was 2.2191+0.3582 (range: 1.779-3.0175) ($p = ns$). Five years later, in the Group A 3/7 patients were GDS 6-7, 1/7 was GDS 5, and 3/7 were GDS 3-4; and in the Group B, 3/14 patients were GDS 6-7, 5/14 were GDS 5, and 6/14 were GDS 3-4 for AD. In the Group C and D, none of them developed Alzheimer's disease dementia (ADdm). When the proportion of patients who developed a severe-severe ADdm (GDS 6-7) was compared between A and B groups, statistically significant differences were not found. However, when only BAL was considered, we found that the cut-off value to predict a deeper cognitive impairment was 1.96. Above 1.96, (n=11) 6/11 patients were GDS 6-7 and 5/11 were GDS 4-5; and below 1.96, (n=10) 1/10 patient was GDS 6-7 and 9/10 were GDS 4-5 ($p < 0.05$). **Conclusion:** BAL in

A-MCI patients may be a better predictor of the long-term severity of cognitive impairment than FDG PET/CT findings. BAL may play a role in the progressive neurodegeneration beyond initial regional FDG abnormalities. It may deserve more studies focussed on anti-amyloid therapies. **References:** None

EP-022

Concordance between amyloid PET imaging and CSF biomarkers in clinical setting

G. Marotta, L. Sacchi, G. G. Fumagalli, A. M. Pietrobboni, A. Arighi, L. Ghezzi, A. Colombi, T. Carandini, M. Scarioni, F. Buffoni, M. Rognoni, D. Galimberti, E. Scarpini; Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ITALY.

Aim/Introduction: Increased uptake of A β tracers in the brain on PET and decreased concentrations of amyloid β (A β) in the cerebrospinal fluid (CSF) are considered the most specific biomarkers of Alzheimer's disease (AD). Despite a high rate of concordance, results show discrepancies. Our aim was to investigate concordance between amyloid PET scans and CSF amyloid measurements. **Materials and Methods:** We included 76 subjects from a mixed cohort of demented and non-demented patients, who had undergone a lumbar puncture for CSF analysis and an amyloid PET with either florbetapir (N=49) or florbetaben (N=27) compounds. CSF specimens were assayed for A β , total Tau and phosphorylated Tau, using cut-offs for positivity of <600 pg/mL, >450 pg/mL and >61 pg/mL, respectively. Amyloid-PET scans were subdivided into positive and negative on the basis of quantitative measurement of global amyloid uptake in the brain. **Results:** 45 out of 76 (59%) subjects showed concordant results between amyloid PET scans and CSF A β levels. Of these, 38 (84%) were positive and 7 (16%) negative exams. Among discordant cases, the majority (23/31 or 74%) had a positive PET scan in spite of normal CSF-A β levels (F+/A-). Interestingly, mean CSF concentration of A β in the F+/A- group was significantly different from F-/A- cases (683.3 vs 963.7 pg/mL). **Conclusion:** In our cohort, overall concordance was 59% (florbetapir 61%, florbetaben 56%). According to our results, PET and CSF-A β measurements cannot be used interchangeably and PET imaging is particularly helpful for settling uncertain cases near the CSF-A β threshold. **References:** None

Differences of Perfusion Correlates between Apathy and Depression in Patients with Alzheimer's disease. A Brain SPECT Study with Brodmann Areas Mapping

V. Valotassiou¹, N. Sifakis², C. Tzavara¹, E. Lykou³, N. Tsinia⁴, V. Kamtsadeli⁵, D. Sali⁵, G. Angelidis¹, D. Psimadas¹, I. Tsougos¹, A. Ziaka¹, E. Theodorou¹, C. Tzioumerka¹, C. Ziangas¹, S. Papageorgiou⁶, P. Georgoulas¹, J. Papatriantafyllou^{3,7};

¹Dpt of Nuclear Medicine, University Hospital of Larissa, Larissa, GREECE, ²Dpt of Nuclear Medicine, "Alexandra" University Hospital, Athens, GREECE, ³IASIS Third Age Center, Athens, GREECE, ⁴1st University Psychiatric Department, Aeginition Hospital, Athens, GREECE, ⁵Neurology Dpt, Evrokloniki, Athens, GREECE, ⁶2nd University Neurological Dpt, Attikon Hospital, Athens, GREECE, ⁷Memory Disorders Clinic, Medical Center, Athens, GREECE.

Aim/Introduction: Apathy and depression are among the most clinically important neuropsychiatric symptoms (NPSs) in Alzheimer's disease (AD). The prevalence of apathy and depression ranges from 19% to 88% and from 19% to 78%, respectively. Apathy is characterized by lack of initiative and interest and emotional blunting, while loss of interest is also a core feature of depression. Apathy and depression often co-occur, which results, in combination with the similarity of symptoms, in misdiagnosis. The aim of this study was to evaluate differences of perfusion correlates between apathy and depression in AD patients using SPECT with Brodmann areas (BAs) mapping and comparison with healthy controls, in order to reveal BAs associated specifically with these NPSs. **Materials and Methods:** We studied 65 consecutive patients (20 men, 45 women, age \pm SD 69.9 \pm 8.1 years, duration of disease \pm SD 3.4 \pm 2.4 years, education \pm SD 9.4 \pm 4.7 years) from an outpatient Memory Clinic. We used the established DSM-IV criteria for the diagnosis of dementia and the specific established criteria (NINCDS-ADRDA) for the diagnosis of AD. All the patients had a neuropsychological evaluation with a battery of tests including the mini-mental state examination (MMSE, mean \pm SD 19.6 \pm 5.5) and the Neuropsychiatric Inventory. All the patients underwent a brain SPECT scan 20 min after the intravenous administration of 740MBq of ^{99m}Tc-HMPAO. We applied the NeuroGamTM software on the reconstructed data, for the comparison of brain perfusion in BAs in the right (R) and left (L) hemispheres with the software's normal data base consisted of healthy subjects of the same age. **Results:** Compared with normal subjects, we found a statistically significant correlation of apathy with hypoperfusion in right anterior prefrontal cortex (BA 10R), dorsolateral prefrontal cortices (BAs 8L, 9LR, 46R), ventral posterior cingulate cortices (BA 23LR), left dorsal anterior cingulate cortex (BA 32L), right entorhinal and perirhinal cortices (BAs 28R, 36R). Depression was correlated with hypoperfusion in primary motor, primary somatosensory and dorsolateral prefrontal cortices, on the left (BAs 1L, 2L, 3L, 4L, 8L). **Conclusion:** Apathy and depression in AD are mediated through different underlying neural mechanisms. Functional nuclear imaging may contribute significantly in the differential diagnosis between them and the improvement of patients' management. **References:** 1. Brain Perfusion SPECT Imaging with Brodmann Areas Mapping in the Evaluation of Eating Disorders in Frontotemporal Dementia

V. Valotassiou¹, N. Sifakis², C. Tzavara¹, V. Kamtsadelis³, N.

Tsinia⁴, E. Lykou³, D. Sali⁵, G. Angelidis¹, I. Tsougos¹, D. Psimadas¹, E. Theodorou¹, A. Ziaka¹, C. Tzioumerka¹, C. Ziangas¹, S. Papageorgiou⁶, P. Georgoulis¹, J. Papatriantafyllou^{3,7};

¹Dpt of Nuclear Medicine, University Hospital of Larissa, Larissa, GREECE, ²Dpt of Nuclear Medicine, "Alexandra" University Hospital, Athens, GREECE, ³IASIS Third Age Center, Athens, GREECE, ⁴1st University Psychiatric Department, Aeginition Hospital, Athens, GREECE, ⁵Neurology Dpt, Evroklini, Athens, GREECE, ⁶2nd University Neurological Dpt, Attikon Hospital, Athens, GREECE, ⁷Memory Disorders Clinic, Medical Center, Athens, GREECE.

Aim/Introduction: Eating disorders (ED) represent a prominent feature in frontotemporal dementia (FTD), and especially in the behavioral variant of FTD (bvFTD), where the prevalence of ED ranges from 60% to 80%. In bvFTD, the spectrum of ED involves overeating, changes in food preference with a craving for sweets and inappropriate eating behaviors. In semantic dementia (SD), ED include stereotypical eating, alterations in food preference and hyperorality, characterized by oral exploration of inappropriate objects. The aim of this study was to reveal hypoperfused Brodmann areas (BAs) implicated specifically in the manifestation of ED in FTD. **Materials and Methods:** We studied 56 consecutive patients (18 men, 38 women, age±SD 65.5±9 years, mean duration of disease 3.6 years, education±SD 10.1±4.6 years) from an outpatient Memory Clinic. We used the established DSM-IV criteria for the diagnosis of dementia and the Nearsy criteria for the diagnosis of FTD. Twenty-seven patients received the diagnosis of bvFTD and 29 patients the diagnosis of SD. All the patients had a neuropsychological evaluation with a battery of tests including the mini-mental state examination (MMSE, mean 17.7±8.5) and the Neuropsychiatric Inventory (NPI, ED score 5.4). All the patients underwent a brain SPECT scan 20 min after the intravenous administration of 740MBq of ^{99m}Tc-HMPAO. We applied the NeuroGam™ software on the reconstructed data, for the comparison of brain perfusion in BAs in the right (R) and left (L) hemispheres with the software's normal data base consisted of healthy subjects of the same age. **Results:** Compared with normal subjects, we found statistically significant correlation of ED with hypoperfusion in bilateral anterior prefrontal and right dorsolateral prefrontal cortices (BAs 10LR, 46R), orbitofrontal cortices bilaterally (BAs 11LR), orbital part of inferior frontal gyrus (posterior lateral) on the right (BA 47R) and left parahippocampal gyrus (BA 36L). **Conclusion:** Our

findings suggest that neurodegeneration of an integrated network which involves the orbitofrontal and prefrontal cortices, especially in the right hemisphere, and other connected areas in temporal cortices, is the underlying cause of ED and their sub-syndromes in FTD. These brain regions are implicated in the organization of feeding in response to internal and external behavioral signals and in cognitive control on appetite. **References:** 1. Optimization of ¹⁸F-Fluorocholine PET/CT protocol in parathyroid imaging

I. Bossert¹, M. Hodolic^{2,3}, S. Chytiris⁴, D. D'Ambrosio⁵, A. Marchetto¹, C. Vellani¹, A. J. Mallia⁶, M. Boniardi⁷, L. Chiovato⁴, G. Trifirò¹;

¹Nuclear Medicine Unit, Istituti Clinici Scientifici Maugeri SpA SB IRCCS, Pavia, ITALY, ²Nuclear Medicine Department, Faculty of Medicine and Dentistry, Palacký University, Olomouc, CZECH REPUBLIC, ³Nuclear Medicine Research Department, Iason, Graz, AUSTRIA, ⁴Endocrinology Unit, Istituti Clinici Scientifici Maugeri SpA SB IRCCS, Pavia, ITALY, ⁵Medical Physics Unit, Istituti Clinici Scientifici Maugeri SpA SB IRCCS, Pavia, ITALY, ⁶Division of Nuclear Medicine, Department of Medical Imaging, Mater Dei Hospital, Msida, MALTA, ⁷Department of Endocrine Surgery, Niguarda Hospital, Milan, ITALY.

Aim/Introduction: Identification of pathological parathyroid glands in primary hyperparathyroidism, based on neck ultrasound (US) and/or ^{99m}Tc-SestaMIBI (MIBI) scintigraphy, is challenging. With respect to MIBI scan, ¹⁸F-Fluorocholine (FCH) PET/CT improve detection rate of pathological parathyroid glands thanks to its better spatial resolution and lesion-to-noise ratio. Different authors proposed different protocols, with variations in administered activity, scanning time and bed time duration. Our aim was to propose a protocol for FCH PET/CT imaging, optimizing every variable and preserving the good quality of the exam. **Materials and Methods:** On the basis of published literature and the characteristics of our PET/CT scanner (Discovery 690 VCT, GE Healthcare) we decided to inject less than 2,5 MBq/kg of FCH, perform a dual-time point acquisition (15 and 60 min after FCH injection) with a duration of 3 minutes per bed (neck and upper mediastinum), and to skip dynamic acquisition. To test our method we plan to enroll 50 patients

with primary or tertiary hyperparathyroidism and negative or inconclusive MIBI scan. FCH PET results will be confirmed with cito-hystological examination whenever possible. **Results:** We prospectively enrolled 41 patients. The median injected FCH dose was $2,3 \pm 0,13$ MBq/kg (range 1,79–2,55). The median injected FCH per patient was $172,9 \pm 45,5$ MBq (range 108,9–283,6). FCH PET/CT was positive in 35 out of 41 patients. One patient had bilateral lesions (then sent for genetic evaluation) and 1 patient had a focal FCH uptake in the superior-anterior mediastinum. So far 15 patients had a cito-hystological confirmation of FCH PET result. We obtained a perfect correlation between PET and the gold standard evaluation results, even in case of a very small lesion or uncommon localization (i.e. para-esophageal). **Conclusion:** Although we have a relatively small number of patients, our method showed a good sensitivity allowing a reduction in patient's dose and exposure, bed time duration and avoiding dynamic acquisition, resulting in an easier patient's management. **References:** - PET/CT with ^{18}F -Choline localizes hyperfunctioning parathyroid adenomas equally well in normocalcemic hyperparathyroidism as in overt hyperparathyroidism. Brain FDG PET/CT in Patients with Epilepsy : Single Center Experience

A. Arçay, F. Aydın, E. Apaydin Doğan, M. Akyüz, U. Şenol, K. Karaali;
Akdeniz University, Antalya, TURKEY.

Aim/Introduction: The aim of this study is to determine the consistency between visual and quantitative evaluation in brain FDG PET/CT which are performed to seek epileptic focus and assess surgical therapy options in epilepsy patients. We also aim to investigate the correlation between brain PET findings, brain MRI and clinical findings. **Materials and Methods:** 42 epilepsy patients who underwent brain FDG PET/CT in our hospital between April 2016 and January 2020 were included in the study. The 42 PET/CT scans

were evaluated visually without quantitative results by the experienced nuclear medicine specialist. The correlation between the quantitative values which were obtained from the workstation by comparing to the data in normal individuals and the visual evaluation results were examined. In addition, the consistency of PET data with the clinical course of the patients and brain MRI findings was determined. **Results:** In 29 of 42 PET/CT scans, visual and quantitative evaluation were found compatible. Out of the remaining 13 incompatible scans, in 11 scans epileptic focus could be determined by visual evaluation while the quantitative evaluation was within normal limits. In 7 of these patients, visual evaluation was compatible with the clinical and MRI findings and contributed to treatment planning. Visual PET and MRI findings were compatible in 28 patients while they were incompatible in 14 patients. Out of these 14 patients, in 8 patients epileptic focus could be determined with PET but not with MRI. Total 13 patients underwent epilepsy surgery and 10 of these patients (8 patients with mesial temporal sclerosis, 1 patient with cortical dysplasia and 1 patient with diffuse astrocytoma) have been followed up without post-operative seizures. While visual and quantitative PET evaluation, MRI and clinical findings were compatible in 8 of these patients who were followed-up without seizures after successful surgery, 2 patients had quantitative values within normal limits, and epileptic focus was determined by visual PET evaluation and this guided the surgery option. While the compatibility rate between clinical (seizure semiology and EEG findings) and visual PET evaluation was 56%, this rate was determined as 54% with MRI and 50% with quantitative evaluation. **Conclusion:** Although the quantitative data contributes to the evaluation of brain FDG PET/CT, visual evaluation should be as effective as quantitative evaluation on PET/CT interpretation, as it appears that collective assessment of visual evaluation, MRI and clinical findings will provide additional benefits to the clinical course of epilepsy patients. **References:** None

Description of the typical patient with suspected cardiac amyloidosis due to transthyretin deposits and a positive result on the $^{99\text{mTc}}$ DPD scintigraphy in our health area

F. Sebastián Palacid, N. Álvarez Mena, P. Turbay Eljach, B. Pérez López, C. Gamazo Laherrán, M. Alonso Rodríguez, A. Sáinz Esteban, M. Ruiz Gómez, M. González Soto, R. Ruano Pérez;

Hospital Clínico Universitario Valladolid, Valladolid, SPAIN.

Aim/Introduction: Describe the clinical, epidemiological and scintigraphic characteristics of the typical patient with suspected cardiac amyloidosis due to transthyretin deposits (TTR) with a positive result on the ^{99m}Tc -DPD scintigraphy in the population of our health area. **Materials and Methods:** A retrospective study carried out between February 2017 and April 2020. We have evaluated 152 patients (95 men and 57 women) aged between 51 and 90 years, with suspected TTR cardiac amyloidosis by pathological echocardiography with diagnostic ^{99m}Tc -DPD scan (60 positive and 92 negative results). Variables such as the result of the scintigraphy, the degree of uptake intensity of the radio tracer in the myocardium, the distribution pattern, as well as demographic and clinical variables of each patient were analyzed. **Results:** The results obtained allow us to characterize the typical patient with a positive result on the ^{99m}Tc -DPD scintigraphy as a male patient (91.7% $p=0.000$), with a mean age of 81.5 years ($p=0.000$), with or without arrhythmias ($p=$ not statistically significant (nss)), non-pacemaker carrier (76.7% $p=$ nss), with no history of infarction (95% $p=$ nss), and without alterations in the proteinogram (63.3% $p=$ nss). Regarding the scintigraphic pattern of radiotracer uptake, 91.7% of patients with amyloidosis present a type 3 pattern and, in 88.3% of patients, a biventricular distribution pattern is evident. Finally, regarding the rest of the complementary diagnostic techniques, 10% of patients with a positive scintigraphic result have a histological study, 28.3% have a genetic study (100% with a negative result), 76.3% present signs of left ventricular hypertrophy in echocardiography ($p=0.000$) and 26.7% present a late subendocardial enhancement pattern typical of TTR amyloidosis on cardiac magnetic resonance imaging ($p=0.000$). **Conclusion:** A positive ^{99m}Tc -DPD cardiac scintigraphy is more common in older men, with echocardiographic signs of left ventricular hypertrophy and a pattern of late subendocardial enhancement on cardiac MRI. We have not been able to demonstrate any other clinical or demographic variable that allows us to predict which scans will be positive before being performed. We find that in clinical practice, ^{99m}Tc -DPD scan obviates the need to perform a biopsy for the diagnosis of TTR amyloidosis. **References:** None

EP-028

^{99m}Tc PYP planar and SPECT bone scan in the diagnosis of transthyretin cardiac amyloidosis

M. Garcheva-Tsacheva¹, M. Gospodinova², G. Kirova³, A. Todorova⁴;

¹Acibadem City clinic, Sofia, BULGARIA, ²Clinic of Cardiology, Medical Institute, Ministry of Interior, Sofia, BULGARIA,

³Clinic of Medical Imaging, Acibadem City clinic Tokuda, Sofia, BULGARIA, ⁴Department of Medical Chemistry,

Biochemistry, Medical University Sofia, Genetical Medical-Diagnostics Laboratory, Genica, Sofia, BULGARIA.

Aim/Introduction: Transthyretin cardiac amyloidosis (ATTR-CA) is a devastating disease, more common than previously thought. Early diagnosis is vital for timely treatment and better prognosis. Endomyocardial biopsy with histology for amyloid typing is an invasive procedure with potential risks. The aim of the study is to determine the value of combined planar and SPECT ^{99m}Tc PYP bone scan in the noninvasive diagnostic algorithm of the disease. **Materials and Methods:** Forty patients (29 males, 11 females, aged 39–88 y) with suspicion for cardiac amyloidosis from clinic, echocardiography, or cardiac magnetic resonance) were submitted to ^{99m}Tc -PYP bone scan for evaluation of eventual myocardial uptake. Two planar projections (anterior and left lateral) were registered at the 1st hour after injection of 10–15 mCi of ^{99m}Tc -PYP followed by SPECT/CT imaging. Beside visual assessment of planar cardiac uptake (according to Perugini score) and semiquantitative evaluation by the ratio heart to contralateral region (H/CL), a visual assessment of SPECT images was also done to prove myocardial deposition of radiotracer. Serum and urine electrophoresis with immunofixation and free light chain assays were performed to rule out light chain amyloidosis (AL) as well as genetic analyses for differentiation of hereditary from wild type ATTR-CA. **Results:** Eleven patients had score ≥ 2 , in 10 of them in combination with $H/CL \geq 1.5$, suggesting ATTR-CA. Parallel test results suggested AL amyloidosis in 11 patients, only 3 of them with score ≥ 2 , two - with $H/CL \geq 1.5$, accepted to be false positive for ATTR-CA. The visual evaluation of SPECT images confirmed myocardial deposition in all, but one of patients with $H/CL \geq 1.5$, and did not show myocardial deposition in patients positive for AL and the rest of the patients ($n=21$), which were referred for further diagnostic assessment. Bone scan with additional SPECT images evaluation correctly identify 8 patients to have ATTR-CA, with only one false positive result. The further genetic analysis confirmed hereditary type in 6 of them, 2 were with wild type of the disease. **Conclusion:** Bone scan by ^{99m}Tc PYP is a reliable method for the diagnosis of the Transthyretin cardiac amyloidosis with low rate of false positive results. SPECT/CT helps the differentiation of myocardial deposition from blood pool persistence of radiopharmaceutical. This noninvasive examination reduces significantly the percentage of patients with unclear diagnosis, which need EMB. **References:** None

EP-029**Evaluation of technetium-99m DPD uptake in cardiac amyloidosis using myocardial perfusion imaging quantification software**

M. O'Connell^{1,2}, F. Delaney¹, M. Dore³, M. Coyne², G. Giblin¹, D. O Sullivan¹;

¹Mater Misericordiae University Hospital, Dublin, IRELAND, ²University College Dublin, Dublin, IRELAND, ³Mater Private Hospital, Dublin, IRELAND.

Aim/Introduction: Multiple technetium 99m (Tc99m)-labelled bone avid radiotracers, such as 3,3-diphosphono-1,2-propanodicarboxylic acid (DPD), reliably identify myocardial amyloid deposition, facilitating the non-invasive diagnosis of cardiac transthyretin (ATTR) Amyloidosis. We aimed to map the distribution and extent of myocardial DPD uptake in ATTR amyloidosis using commercially available myocardial perfusion imaging (MPI) quantification software. The polar plot data which is produced may enhance understanding of the distribution of DPD uptake and help quantify severity over serial studies. MPI quantification software has not previously been validated in the assessment of myocardial DPD uptake. **Materials and Methods:** Tc99m-DPD radionuclide studies to evaluate for cardiac ATTR amyloidosis in 26 patients who demonstrated significant uptake (graded as Perugini Score 2 or 3) on planar thoracic imaging were included. Additional SPECT/CT imaging was performed in all cases. Images were analysed using AutoQUANT® software (Cedars Sinai, CA) and polar plot maps were produced based on the 20-segment model with relative uptake quantified in each segment from 0-100. Segments were grouped into five anatomical regions to evaluate relative uptake in the left ventricular myocardium. Data was compared to echocardiographic and MRI findings. **Results:** Quantification was successful in all patients. The average relative left ventricular myocardial uptake values across the 26 cases in each segment were: anterior = 56, inferior = 58, anteroseptal = 66, inferoseptal = 69, anterolateral = 56, inferolateral = 58, apical = 60. Follow-up imaging to date in one patient on Patisiran treatment showed an overall increase in DPD uptake with clear increase in 12 out of 20 individual segments. **Conclusion:** This study demonstrates the ability to re-purpose standard commercially available software to assess left ventricular myocardial uptake of Tc99m DPD in a deposition disease. While formal validation is required, there is the possibility to greatly improve the quantification of DPD uptake and map its distribution in cardiac ATTR Amyloidosis. This may allow assessment for disease progression on serial studies in patients undergoing novel treatments, such as Patisiran ATTR gene silencer. **References:** None

EP-030**Left ventricular ejection fraction improvement predicted by postoperative gated blood pool SPECT performed on CZT camera**

V. Shipulin, K. Zavadovsky, S. Andreev, A. Pryakhin, V. M. Shipulin; Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: To assess the value of gated blood pool SPECT (GBPS) carried out on CZT camera in early postoperative period in term of prediction of left ventricular (LV) ejection fraction (EF) improvement after 1 year follow-up period in patients with ischemic cardiomyopathy (ICM). **Materials and Methods:** Thirty six patients with ICM were enrolled. Before and within 2 weeks after surgery all patients underwent GBPS and 2D echocardiography. The values of LV and right ventricular (RV) volumes, global contractile function and LV mechanical dissynchrony were calculated. In the follow-up period (476 ± 36 days), patients were divided into two groups based on 2D echocardiography data. Group 1 (n=12) - patients with improving of LV ejection fraction (EF) $\geq 5\%$ in comparison to early postoperative period study. Group 2 (n=24) - without improving of LV EF. **Results:** According to univariate U-test there were no statistically differences between two groups in clinical variables as well as GBPS indices before surgery. Early postoperative study showed significant differences between groups in terms of LV end diastolic volume index (EDVI) (109,6 (94,2; 129,5) vs. 146 (89,8;232,8), $p < 0,0001$), end systolic volume index (ESVI)(69,7 (45,6; 94,4) vs. 107,7 (47,3; 200,6), $p = 0,001$), LV EF (40 (35; 49) vs. 30 (26;39), $p = 0,02$) as well as dissynchrony indices like LV Entropy (64 (60;70) vs. 74 (69; 77), $p = 0,003$), RV SD (13 (8;17) vs. 69 (57; 102), $p < 0,0001$), RV bandwidth (45 (36;60) vs. 69 (57; 102), $p = 0,0008$), and interventricular dissynchrony (IVD) (8,5 (5;17) vs. 24 (8;40), $p = 0,01$), respectively. It had been shown that long-term LV EF has a strong negative correlation ($r = -0,7$, $p < 0,05$) with postoperative LV Entropy indices, middle negative correlation with RV SD indices ($r = -0,66$, $p < 0,05$) and RW Bandwidth indices ($r = -0,64$, $p < 0,05$). Multivariate logistic regression analysis showed that all of this variables were independent predictors of LV EF improvement.: LV EDVI (OR = 0,93; 95% CI 0,88; 0,98; $p = 0,0001$), LV ESVI (OR = 0,95; 95% CI 0,92; 0,99; $p = 0,004$), LV EF (OR = 1,06; 95% CI 1,02; 1,14; $p < 0,003$), LV Entropy (OR = 0,85; 95% CI 0,76; 0,95; $p < 0,002$), RV SD (OR = 0,7; 95% CI 0,56; 0,88; $p < 0,0001$); RV bandwidth (OR = 0,7; 95% CI 0,56; 0,88; $p < 0,0001$), IVD (OR = 0,92; 95% CI 0,87; 0,98; $p < 0,0001$). **Conclusion:** The values of LV and RV indices, obtained from GBPS carried out in early postoperative period after surgical ICM correction, are associated with LV EF improving in 1 year follow-up period. **References:** None

EP-031**Diagnostic accuracy of bone scintigraphy in the assessment of cardiac amyloidosis: comparison among different methods of evaluation**

C. Cottignoli, C. Romagnolo, F. Fringuelli, G. Biscontini, A. Palucci, L. Burroni;
Nuclear Medicine, Ancona, ITALY.

Aim/Introduction: Cardiac transthyretin-related amyloidosis (ATTR) is a severe and progressive cardiomyopathy. Bone scan with bone-seeking radiotracers is able to detect myocardial amyloid deposits, especially in ATTR patients. In all previous studies, several different tracers (Tc99m-DPD, -PYP, -HMDP, -MDP and -HDP) and different acquisition times are used for bone scan. The scintigraphic images were analyzed qualitatively (Grade 0-3) by means visual analysis and also semi-quantitatively in about 75% of studies. For the semi-quantitatively analysis different methods were also described in literature. Aim of our work is to compare these different methods of analysis to identify the most simple and accurate method for diagnostic use. **Materials and Methods:** Bone scintigraphy (Tc99m-HDP; 740 MBq) was performed in 28 patients (8 females and 20 males; mean age: 76 yrs) with 3 age-related groups of cardiomyopathy: cardiac TTR Amyloidosis (ATTR; n=10, qualitative grade 2), other Infiltrative Cardiac Disease (ICD; n=4) and Hypertensive Cardiomyopathy (HC; n=18). For the semi-quantitative analysis, we used the anterior image (ANT) and the geometric mean of anterior and posterior images (GM), drawing ROIs to obtain: hearth/contralateral lung count ratio (H/CL), hearth/skull count ratio (HS) and heart/iliac bone count ratio (H/IB). The values obtained were compared between groups with statistical evaluation tests for unpaired data. **Results:** The results obtained by comparison (p value) between the groups and the methods are shown in the table below. Non-significant p values were found in the comparison between ICD and HC with all the methods used. **Conclusion:** Our data confirm that bone scintigraphy represent a non-invasive tool for the assessment of cardiac ATTR with high sensitivity and specificity values. To differentiate infiltrative from hypertensive cardiomyopathies, any method has proven to be accurate, but if you want to distinguish ATTR from other infiltrative cardiomyopathies, it is better to perform the measurements with the calculation of the geometric mean between the anterior and posterior acquisition. The most reliable reference regions of interest were the iliac wing and the contralateral thoracic region. The skull region is the least reliable, probably because it is most affected by individual bone metabolic activity. **References:** None

EP-032**Volumetric Evaluation of ^{99m}Tc-pyrophosphate SPECT/CT in the Diagnosis of Transthyretin Cardiac Amyloidosis**

S. Watanabe, K. Nakajima, H. Yoneyama, H. Wakabayashi, A. Inaki, T. Konishi, J. Komatsu, S. Yoshida, S. Kinuya;
Kanazawa University Hospital, Kanazawa, JAPAN.

Aim/Introduction: Quantitative evaluation of ^{99m}Technetium-pyrophosphate (PYP) uptake using standardized uptake value (SUV) has been reported in the diagnosis of transthyretin cardiac amyloidosis (ATTR-CA). However, SUV changes depending on volume of interest because blood pool PYP uptake is relatively high. The aim of this study was to evaluate a feasibility of a volumetric PYP parameter, which can be calculated more objectively, for differentiating ATTR-CA patients from control patients. **Materials and Methods:** We retrospectively evaluated all patients who underwent PYP SPECT/CT at our hospital between October 2018 and February 2020. Among them, 35 patients who underwent endomyocardial biopsies (29/35) and/or TTR gene tests (18/35) were included in this study. Seventeen patients were diagnosed as ATTR-CA (9 variant types and 8 wild types) and 18 patients were diagnosed as non-ATTR (control: 1 light chain cardiac amyloidosis, 1 cardiac sarcoidosis, and 16 other myocardial disorders). There was no significant difference in age between two groups. First, we evaluated blood pool PYP uptake by SUVmean in the ascending aorta at the level of the main pulmonary artery and defined as Amean. Then, we objectively evaluated the total volume of the region with PYP uptake above 1.5 times of Amean within the left and right ventricular myocardium and defined as a cardiac metabolic volume (CMV, i.e., a volume of voxels with abnormal PYP uptakes). SUVmean and CMV were calculated using xSPECT Quant. Accuracy of determining abnormal or normal volume was examined by receiver operating characteristic analysis and the area under the curve (AUC) was calculated. **Results:** The average CMV was 130.8 ± 118.2 cm³ in the ATTR-CA group and 0.4 ± 0.5 cm³ in the control group. CMV was significantly higher in the ATTR-CA group than the control group (p = 0.0003, AUC = 0.96). Using the cutoff value of 1.6 for diagnosing ATTR-CA, CMV showed sensitivity and specificity of 94% and 94%, respectively. There was no significant difference in CMV between patients with variant type ATTR-CM and patients with wild type ATTR-CM. **Conclusion:** A novel volumetric assessment of PYP SPECT/CT could accurately differentiate ATTR-CA patients from control patients, which should be studied in a larger prospective manner. **References:** 1) Ramsay SC et al. EP-033**Conduction disturbances in cardiac amyloidosis patients and ^{99m}Tc-HDP bone scintigraphy**

A. Scarale¹, C. Dolci¹, A. Capozza¹, A. Franchini^{1,2}, I. Gotuzzo^{1,2}, E. Gay¹, G. Cabrini¹, M. Milella¹, C. Rossetti¹;

¹ASST Grande Ospedale Metropolitano Niguarda, Milano, ITALY, ²Nuclear Medicine School, University of Milan-Bicocca, Milan, ITALY.

Aim/Introduction: Cardiac amyloidosis is a disorder caused by extracellular protein fibril accumulation in the myocardium leading to restrictive heart failure. Both atrial and ventricular arrhythmias, along with conduction disease are common in cardiac amyloidosis. Planar imaging alone or with single-photon emission computed tomography (SPECT) using bone-seeking radiotracers (e.g. ^{99m}Tc-DPD, ^{99m}Tc-HDP) have been found to be more effective in detecting transthyretin (TTR) myocardial deposits. Aim of this study is to evaluate the prevalence of conduction disease in cardiac amyloid population in relation to ^{99m}Tc-HDP heart uptake. **Materials and Methods:** ^{99m}Tc-HDP scans performed, between 01/2015 and 04/2020, in patients with suspected or known cardiac amyloidosis were retrospectively reviewed. All underwent clinical evaluation, trans-thoracic echocardiography (TTE), electrocardiography (ECG), and total-body scintigraphy with ^{99m}Tc-HDP. Perugini visual score and semiquantitative analysis of cardiac uptake normalized to background activity (H/CL), defined as [total counts (myocardial ROI) / total counts (right hemithorax background ROI)] were performed. ROIs dimensions were identical in the same patient. TTE assessed LV volumes, function and mass. Final diagnosis was obtained by biopsy (28/77), or clinical follow-up. To compare differences between moderate/high and absent/low tracer's uptake, the unpaired t-test or Mann-Whitney was performed for normally or non-normally distributed variables, respectively for continuous variables and Pearson chi-squared for categorical ones. To evaluate the magnitude effect of the moderate/high and absent/low heart uptake and the presence of atrial fibrillation (AF) or other arrhythmias standardized mean differences (SMD) for each variable were computed. **Results:** Seventy-seven patients (63 males, 14 females) were enrolled. Population had median age of 77.0 (IQR: 70-83) years, 39/77 TTR cardiac amyloidosis patients and 38/77 AL-amyloidosis or other forms. The population was divided in two groups: patients with moderate/high or absent/low ^{99m}Tc-HDP heart uptake. Thirty-eight (49%) patients (35 males, 3 females) resulted with moderate/high heart uptake, significantly older (79.8±6.4 years; p-value<0.001) and with a significantly higher number of AF (n=28, 70%; p-value<0.001) respect to the absent/low heart uptake group (n=39, 51%). The sample was homogeneous for BMI and TTE and ECG measures. Among patients with AF higher SMDs were found for age

(0.83) and FE% (0.65). **Conclusion:** These preliminary data on a small cohort suggest an higher prevalence of arrhythmias in cardiac amyloidosis patients with high heart ^{99m}Tc-HDP uptake than in low or absent one. **References:** None

EP-034**^{99m}Tc-DPD SPECT/CT Quantification In Cardiac Transthyretin Amyloidosis. A Pilot Descriptive Study**

Aim/Introduction: Scintigraphy with ^{99m}Tc-bisphosphonate derivatives (^{99m}Tc-DPD, ^{99m}Tc-HMDP and ^{99m}Tc-PYP) provides critical information on transthyretin cardiac amyloidosis (ATTR-CA). Unlike ^{99m}Tc-HDMP, a detailed quantification about myocardial distribution of amyloid transthyretin (ATTR) has not been evaluated so far with ^{99m}Tc-DPD. While it is suggested that can be used interchangeably, there is also no comparison between both tracers. This pilot experience quantified the myocardial distribution of ^{99m}Tc-DPD on of SPECT/CT in ATTR-CA patients. **Materials and Methods:** Eleven patients with Perugini score 2 and 3 diagnosed with ATTR-CA were consecutively selected between September 2019 and February 2020. All of them underwent planar and cardiac SPECT/CT images. ^{99m}Tc-DPD uptake through left ventricle (LV) was analyzed by obtaining the number of counts over each cardiac wall (anterior, septal, inferior, lateral and apex), both in non-corrected (NC) images and after applying iterative reconstruction with attenuation correction (IRAC). **Results:** Mean age was 83.8 years, 90.9% were men. Tracer distribution over LV walls tended to be more intense in septal-inferior walls and through basal segments, reflecting a lower amyloid accumulation in the apex. In NC images, ATTR deposit in LV walls was distributed, in decreasing order, as follows: septal, inferior, anterior, lateral and apex (23.3±4.4, 21.0±3.0, 19.8±3.6, 19.3±3.0 and 16.6±5.1%, respectively, p=0.002 for ANOVA and Bonferroni posthoc test for septal vs. apex). After IRAC, regional amyloid distribution tended to be higher in inferior than in septal walls, with a more prominent apex-to-base gradients. The decreasing uptake order obtained in IRAC images was: inferior, septal, lateral, anterior and apex (23.3±2.8, 23.1±4.4, 20.9±2.8, 19.0± 3.2 and 13.9±4.2%, respectively, p<0.05 for multiple comparisons: anterior vs. inferior, anterior vs. apex, septal vs. apex, inferior vs. apex and lateral vs. apex). **Conclusion:** In ATTR-CA subjects with high Perugini scores, ^{99m}Tc-DPD SPECT/CT allows to quantify the distribution and extension of regional amyloid burden. These results agree with recent findings provided by ^{99m}Tc-HDMP SPECT/CT. The image activity obtained after IRAC could be derived

from soft tissue attenuation (described in patients with CA) and from ribs and sternum uptake related with DPD bone avidity. Clinical diagnostic and prognostic impacts of different attenuation correction algorithms should be evaluated in larger series, head-to-head with other noninvasive diagnostic techniques. **References:** None

¹²³I-Metaiodobenzylguanidine Cardiac Scintigraphy In Patients With Clinical Suspicion Of Parkinson's Disease

L. García Zoghby, S. Rizkallal Monzón, C. Lancha Hernández, D. Monachello Araujo, D. Travaglio Morales, E. López Llobet, S. Rodado Marina, C. Escabias del Pozo, J. Cordero García, M. Coronado Poggio, L. Domínguez Gadea; Hospital Universitario La Paz, Madrid, SPAIN.

Aim/Introduction: The aim of our study is to determine the heart / mediastinum ratio cutoff value for Parkinson's disease (PD) diagnosis in our population, and also determine which image has more correlation with the final diagnosis (early vs delayed vs both). **Materials and Methods:** We retrospectively analyzed 51 patients (29 females, 22 males; mean age 66.6 years) with clinical suspicion of PD studied in our nuclear medicine department from January 2016 to October 2019. All of them underwent a ¹²³I-MIBG cardiac scintigraphy: anteroposterior and left oblique thorax planar images, 15 minutes and 4 hours after intravenous administration of the tracer (370 MBq). These images were quantitatively evaluated with the heart / mediastinum ratio. Patients were followed up for a mean of 20 months (range 3 to 48). We divided our sample (51 patients) into two groups according to final diagnosis: PD or non-PD. Final diagnosis was achieved with clinical findings, laboratory and imaging tests, treatment response and follow-up. The optimal e-H/M ratio cutoff and d-H/M ratio cutoff were determined by Receiver Operating Characteristic (ROC) curve analysis. We compared the delayed heart / mediastinum (d-H/M) ratio capability vs the early heart / mediastinum (e-H/M) ratio capability to separate PD patients from non-PD patients with non-parametric test (Mann-Whitney test). Statistical significance was defined as $p < 0.005$. **Results:** 18/51 patients with PD and 33/51 patients with non-PD (4/33 Lewy body dementia, 5/33 multiple system atrophy, 9/33 progressive supranuclear palsy, 2/33 corticobasal degeneration, 2/33 pharmacological parkinsonism, 2/33 vascular parkinsonism, 9/33 others). The optimal e-H/M ratio cutoff was 1.50

(73% sensitivity, 78% specificity, 0.785 area under the ROC curve) and the optimal d-H/M ratio cutoff was 1.49 (70% sensitivity, 83% specificity, 0.756 area under the ROC curve). We found statistical differences between patients with PD and non-PD in both e-H/M ($p=0.001$) and d-H/M ($p=0.003$). **Conclusion:** The e-H/M ratio cutoff was 1.50 and the d-H/M ratio cutoff was 1.49, both of them were able to differentiate PD from non-PD in our population. **References:** None

Significance of epicardial and visceral adipose tissue measurement by 18F-FDG-PET / CT in type 2 diabetes mellitus

D. Dezso¹, K. Zámbo¹, Z. Ritter¹, Z. Bán¹, Z. Szabó¹, E. Várady¹, B. Bódis², O. Nemes², K. Rucz², S. Szujó², E. Mezősi², L. Bajnok², E. Schmidt¹;

¹University of Pécs, Medical School, Department of Diagnostic, Pécs, HUNGARY, ²University of Pécs, Medical School, 1st Department of Medicine, Pécs, HUNGARY.

Aim/Introduction: Type 2 diabetes (T2DM) is a leading risk factor of cardiovascular diseases. There is a strong correlation between coronary artery diseases and the volume of epicardial adipose tissue (EAT) deposits located between myocardium and visceral pericardium. This metabolically active ectopic adipose tissue is in strong relationship with visceral adipose tissue (VAT) developmentally and correlates with its amount. The aim of our study was to investigate the relationship between BMI, calcification of large arteries, VAT and EAT in the diabetic population studied with FDG-PET/CT. **Materials and Methods:** Examinations of 33 T2DM patients' and 62 non-diabetic patients were investigated during our retrospective study. The volume of EAT and VAT was determined with FDG-PET/CT scans using Slicer 4.10.0 software (free and open source software package). SUVmax (Standardized Uptake Value calculated with Interview Fusion software, Mediso), the volume of calcified arterial plaque (density above 130 Hounsfield Units), EAT and VAT were measured and the results were evaluated using SPSS software. The mean SUVmax of the mediastinal blood-pool was measured to correct the SUVmax value of the adipose tissue. **Results:** Results of our ongoing research showed significant correlation between EAT volume ($r=0.242$, $p<0.05$), mediastinal blood-pool corrected EAT SUVmax ($r=0.270$, $p<0.05$) and the calcification of the vascular system on the whole examined population. The amount of EAT

($p < 0.001$) and VAT ($p < 0.05$), mediastinal blood-pool corrected SUVmax ($p < 0.001$) and the degree of vascular calcification ($p < 0.001$) in patients with T2DM were significantly higher than in the control group. The amount of EAT and VAT showed significant correlation ($r = 0.495, p < 0.0001$) in both groups. The mediastinal blood-pool corrected EAT SUVmax is significantly higher than VAT SUVmax in both groups ($p < 0.001$), and showed significant correlation ($r = 0.442, p < 0.001$) with each other. There is a significant correlation between the volume of VAT and mediastinal blood-pool corrected VAT SUVmax ($r = 0.221, p = 0.036$), which correlation is significantly stronger in patients with T2DM ($r = 0.455, p = 0.011$). EAT ($r = 0.072, p = 0.491$) and VAT SUVmax ($r = 0.084, p = 0.427$) is independent of pre-examination blood glucose. **Conclusion:** Based on our results, patients with T2DM have significantly higher levels of EAT and VAT, higher FDG uptake, and increased calcification of large arteries too. According to our results, the higher epicardial and visceral fat deposits may contribute to the higher cardiovascular risk in T2DM patients. Our results confirm that EAT is in strong relationship with VAT developmentally and correlates with its amount, and these metabolically active ectopic adipose tissues activity are independent of pre-examination blood glucose. **References:** Under the 20765-3/2018/FEKUTSTRAT research program.

EP-037

The use of gated blood-pool SPECT for evaluation of cardiac dyssynchrony in patients with ventricular tachycardia

V. Saushkin, D. Lebedev, S. Popov, Y. Lishmanov;
Tomsk National Research Medical Center of the
Russian Academy of Sciences, Cardiology Research
Institute, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: The aim of the study was to evaluate the impact of idiopathic ventricular tachycardia and premature ventricular beats on cardiac function and dyssynchrony. **Materials and Methods:** The study included 21 patients with ventricular arrhythmias (VA) (mean age of 43.5 ± 11.7 years). The control group consisted of 15 patients (mean age of 56.3 ± 8.3 years) without cardiac arrhythmias. Electrophysiological study (EPS) and radiofrequency ablation (RFA) procedure for patients with VA were performed according to indications. Phase images were used for calculating the first harmonic Fourier transform. The phase standard deviation (PSD), histogram bandwidth (HBW) and phase entropy (E) were used as an indicator of mechanical dyssynchrony for the both ventricles. **Results:** Patients with VA had local areas of asynchronous myocardial contraction (AMC). Patients with VA had significantly higher values of the end-diastolic and end-systolic volumes, and lower indices of contractility than patients of the control group. More negative changes observed in the

right ventricle. The negative association found between the total number of AMC areas and cardiac contractility indices. Ectopic localization (based on EPS data) associated with topography of AMC areas (based on GBP SPECT). Radiofrequency ablation procedure significantly improved cardiac contractility indices and reduction of intraventricular dyssynchrony. The AMC areas completely disappeared or decreased in a number compared with the preoperative conditions. **Conclusion:** Patients with VA have AMC areas which mostly localized in the right ventricle. The presence of AMC zones is a scintigraphy symptom of arrhythmogenic focus. **References:** None

EP-038

Assessment of vulnerable atherosclerotic plaques in coronary arteries using somatostatin receptor scintigraphy (SRS) and head-to-head comparison with myocardial perfusion scintigraphy (MPI): A paradigm under construction

M. Assadi, A. Amini, E. Jafari, M. Pourbehi, D. Iranpour, R. Nemati;
Bushehr University of Medical Sciences (BUMS),
Bushehr, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Activated macrophages can lead to cardiac events by rupturing the vulnerable atherosclerotic plaques. It has been shown that activated macrophages express somatostatin receptor-2 (SSTR-2), therefore, we aimed first, to detect atherosclerotic plaques by somatostatin receptor scintigraphy (SRS) using ^{99m}Tc -Octreotide SPECT which bind to somatostatin receptor 2, and second, comparison of SRS with myocardial perfusion scintigraphy (MPI) using ^{99m}Tc -MIBI SPECT and angiography in detection of atherosclerotic plaques. **Materials and Methods:** 737 patients with suspicious coronary artery disease who referred to the Nuclear Medicine Department for MPI were participated in this prospective controlled trial, 52 of them representing the final study cohort, performed additional SRS. The SRS analysis was done according to severity of uptakes (mild, moderate, severe) into five cardiac regions (apex, anterior, inferior, septal, lateral). The MPI defects were also reported according the above segments. According to the standard cardiovascular guideline, the angiography was performed during 1 month after SRS. The coronary arteries in all modalities divided into three main arteries inducing LAD, RCA, and LCX. Statistical analysis of all modalities was performed for three main coronary arteries separately and compared. **Results:** In 17 out of 52 patients who underwent coronary angiography, 11 female and 6 male aged from 28 to 84 (54.83 ± 19.7) years old, had been shown remarkable uptake on cardiac SRS. The SRS and angiography in the LAD territory was concordant in 13/17 patients while only 7/17 cases were concordant between MPI and angiography. In RCA territory, the SRS and angiography were concordant in 14/17 cases while MPI and angiography were 11/17 cases.

In LCX territory, SRS and angiography were concordant in 13/17 cases while MPI and angiography were 6/17 cases. In all 35 remaining patients who had not been performed coronary angiography based upon cardiovascular profile, cardiac event was not showed over follow up period of 2-9 months (5.52 ± 2.71), and interestingly they didn't depicted remarkable uptake on SRS. An example of such cases is presented **Conclusion:** ^{99m}Tc -octreotide uptake was more concordant relative to ^{99m}Tc -MIBI SPECT findings with coronary plaques, suggesting a potential role for ^{99m}Tc -octreotide in the evaluation of atherosclerosis. In addition, coronary uptake may provide a molecular guide for the representation of coronary atherosclerotic lesions. Specific regional uptake is warranted to be ascertained by histology.

Prevalence of transthyretin cardiac amyloidosis (ATTR-CA) in a population of patients with hip and knee arthroplasty: could they be early signs?

A. Paccagnella¹, R. Bonfiglioli¹, F. Mattana¹, R. Mei¹, G. Saturi², P. Massa², G. Caponetti², M. Squazzotti², A. Ponziani², C. Gagliardi², S. Longhi², N. Galie², S. Fanti¹;

¹Department of Nuclear Medicine, Policlinico S.Orsola, University of Bologna, Bologna, ITALY, ²Department of Cardiology, Policlinico S.Orsola, University of Bologna, Bologna, ITALY.

Aim/Introduction: ATTR-CA is an under-diagnosed progressive disorder in which excessive extracellular cardiac deposition of mutant (ATTRm) or wild-type ATTR (ATTRwt) causes a restrictive cardiomyopathy. It's well known that ATTR preferentially deposits in ligaments, tendons, articular cartilage and soft tissues (ST), causing carpal tunnel syndrome and lumbar spinal stenosis. We hypothesized that patients with total hip (THA) and/or knee (TKA) arthroplasty would have a significative prevalence of ATTR-CA visualized at whole body scintigraphy (WBS); this may precede and be a red flag of ATTR-CA diagnosis. **Materials and Methods:** we collected all WBS scans performed from March 2010 to March 2020 using technetium-99m (^{99m}Tc)-diphosphonate (DPD). Out of all patients, we selected only those with presence of THA or TKA (group-1) and in this group we investigated the further presence of cardiac uptake with visual score (VS) as well as ST and lung uptake-LU- (group-2). Group-2 was analyzed at cardiologic department, using echocardiography, laboratory test, and/or magnetic resonance in order to define the significance of cardiac uptake. A binary linear regression was used to evaluate correlation between VS and cardiologic diagnosis. **Results:** out of 14858 patients, group-1 was formed by 418 patients (2,8%); 37/418 patients (9%) were included in group-2, of which 8 were excluded for the absence of cardiologic data with a remaining total of 29 (7%)(mean age at WBS: 79 years; male: 65%; female: 35%;

THA: 59%; TKA: 41%; VS 1: 21%, VS 2: 65%, VS 3: 14%). Out of 29, 20 (69%, 4,8% of group-1) received ATTR-CA diagnosis (all ATTRwt) with a mean time of 15 months between scan and diagnosis. WBS detected also ST uptake in 55% and LU in 80%. Positive correlation was found between VS and cardiologic diagnosis (OR 7,064, CI95% 1,173-42,526, $p=0,033$). Date of arthroplasty intervention was only available in 2 patients, in which it occurred on an average of 7,7 years before ATTR-CA diagnosis. 9 patients with no cardiologic diagnosis (VS 1: 45%; VS 2: 55%) showed a low prevalence of ST uptake (22%). **Conclusion:** early recognition of ATTR-CA may be critical for emerging therapeutic options. In our study, all confirmed cardiologic diagnosis were ATTRwt, this is consistent with the hypothesis that ATTRwt disease has a course over a period of decades such as articular degeneration. History of THA and TKA, like carpal tunnel syndrome and lumbar spinal stenosis, may be an important clinical historical marker indicating the presence or future development of ATTR-CA. **References:** None

Intra- and inter-observer repeatability of three myocardial perfusion scintigraphy software packages in quantification of perfusion abnormalities

C. Sachpekidis¹, V. Sachpekidis², A. Kopp-Schneider³, G. Arsos¹, E. Moralidis¹;

¹Department of Nuclear Medicine, Aristotle University of Thessaloniki, Papageorgiou Hospital, Thessaloniki, GREECE,

²Department of Cardiology, Papageorgiou Hospital, Thessaloniki, GREECE, ³Department of Biostatistics, German Cancer Research Center (DKFZ), Heidelberg, GERMANY.

Aim/Introduction: In the quantification of the extent of abnormalities in myocardial perfusion scintigraphy (MPS), the repeatability (agreement between different analyses of a single acquisition of MPS data) of commercially available software packages has not been evaluated, yet. The aim of the present study was to evaluate the intra- and inter-observer repeatability of commonly applied software packages for ischemia quantification. **Materials and Methods:** 182 consecutive patients referred for routine 1-day ^{99m}Tc -sestamibi MPS were prospectively enrolled. Half patients underwent a stress/rest protocol and 91 patients underwent a rest/stress protocol. Automated quantitative analysis was performed with the Cedars Quantitative Perfusion SPECT, Version 4.0, Cedars-Sinai Medical Center (QPS), the Emory Cardiac Toolbox, Version 3.0, Emory

University Medical Center (ECTb), and the 4D-MSPECT, Version 4.0, University of Michigan Medical Center (4DM). From stress images, the parameters summed stress score (SSS) and the total defect extent (TDE), expressed as % percentage of the LV, were automatically calculated with each software tool. Data were analyzed independently by an experienced nuclear cardiologist and a trainee. The Bland-Altman analysis (bias \pm 95% limits of agreement) was used to assess repeatability. **Results:** Based on the Bland-Altman analysis, the intra-observer repeatability results of SSS assessment for the experienced physician and the trainee using the different software programs were 0.0% \pm 4.3% and 0.2% \pm 5.9% (4DM), 0.2% \pm 7.8% and 0.0% \pm 7.5% (ECTb), -0.6% \pm 7.6% and -0.5% \pm 5.4% (QPS), respectively. Further, the intra-observer repeatability results of TDE assessment for the experienced and the trainee were 0.1% \pm 5.2% and 0.3% \pm 6.6% (4DM), 0.1% \pm 7.9% and -0.1% \pm 6.4% (ECTb), 0.1% \pm 2.8% and -0.1% \pm 2.4% (QPS), respectively. Regarding inter-observer repeatability, the results of SSS assessment were 0.2% \pm 5.4% (4DM), 0.1% \pm 9.6% (ECTb), and 0.2% \pm 8.1% (QPS), while the results of TDE assessment were 0.6% \pm 6.4% (4DM), -0.2% \pm 10.3% (ECTb) and -0.1 \pm 4.3 (QPS). **Conclusion:** Those data provide evidence for bothersome limitations in intra-observer repeatability when using commercially available software packages for the assessment of SSS in MPS. Similar were the findings in the assessment of TDE, with only QPS offering a satisfying degree of repeatability. No substantial differences were noted between the experienced and the trainee observer. Concerning inter-observer agreement, 4DM for SSS and QPS for TDE assessment provided the best, yet suboptimal, results, whereas considerable problems were noted with the ECTb package. **References:** None

EP-041

Coronary Flow Reserve (CFR) Obtained with SPECT Discovery NM 530c Camera - Comparison with Coronary Angiography

M. Blaszczyk¹, P. Cichocki², K. Cygulska³, J. Kuśmierk², P. Lipiec³, J. D. Kasprzak³, K. Frynas – Jończyk³, P. Wejner – Mik³, A. Płachcińska¹;

¹Department of Quality Control and Radiological Protection, Medical University of Lodz, Łódź, POLAND, ²Department of Nuclear Medicine, Medical University of Lodz, Łódź, POLAND, ³Chair and Department of Cardiology, Medical University of Lodz, Bieganski Hospital, Łódź, POLAND.

Aim/Introduction: CFR is an important parameter that complements a myocardial perfusion study (MPS), especially in case of a multivessel CAD, due to a frequent underestimation of the disease extent, sometimes resulting even in omission of abnormal perfusion, especially when all 3 vessels are stenosed. CZT cameras are an attractive alternative to PET CFR studies which are more expensive

and less available. The aim of the study was to check whether CFR reflects hemodynamic effects of coronary artery stenoses. **Materials and Methods:** The study involved 34 patients (19 men) with known or suspected CAD, in whom standard MPS (2-day protocol-dipyridamol stress and rest) were preceded by dynamic radiopharmaceutical administration. After injection of 37 MBq of ^{99m}Tc-MIBI (for camera positioning), patients were administered a bolus of 550 MBq, simultaneously with start of dynamic image acquisition lasting 8 min. Scintigraphic list mode data was converted to 15 frames 6s, 4 frames 30s and 4 frames 60s and reconstructed to 3-dimensional SPECT images. Then the study was processed with a Corridor 4M software. Results assess CFR of the entire left ventricular myocardium (CFR_{TOT}) and individual coronary vessel areas (CFR_{LAD}, CFR_{RCA}, CFR_{LCA}). Coronary angiography (CA) was the verification of results in all patients, where artery stenosis was presented as a percentage reduction in its diameter. **Results:** Mean CFR_{TOT} values in patients without critical (\geq 70%) coronary stenoses (n=16) and with stenoses (n=18) differed statistically significantly (p=0.018) and amounted to 2.21 \pm 0.55 and 1.70 \pm 0.65, respectively. In patients without critical stenosis of LAD (n=20), mean value of the CFR_{LAD} was 2.19 \pm 0.60 and was significantly higher (p=0.004) than in patients (n=14) with critical stenosis of this vessel: 1.56 \pm 0.58. In patients with significant stenosis on RCA (n=9), this difference was close to statistical significance: 2.01 \pm 0.52 vs 1.56 \pm 0.82, p=0.07. After a division of patients with significant stenoses into 2 subgroups: without or with one stenosis (n=22) and with at least 2 stenoses (n=12), a significant (p=0.031) difference between mean values of the CFR_{TOT} (2.17 \pm 0.58 vs 1.52 \pm 0.58) was found. In addition, a statistically significant (p=0.00007) correlation (r=-0.63) between CFR_{LAD} and percentages of stenosis of this vessel in CA was demonstrated. **Conclusion:** CFR obtained with CZT camera reflects, in a non-invasive way, hemodynamic effects of coronary artery stenoses, especially on LAD. A significant reduction of the CFR_{TOT} in multivessel patients allows to expect a quantitative criterion for a reliable, non-invasive recognition of multivessel patients, that needs to be worked out on a larger material. **References:** None

EP-042**Optimize the calculation of the left ventricular ejection fraction with myocardial perfusion gated-SPECT in small hearts**

C. Martínez^{1,2}, C. Espinet¹, M. N. Pizzi¹, A. Cardoso¹, S. Aguadé-Bruix¹;

¹Hospital Universitari Vall d'Hebron, Barcelona, SPAIN,

²Complejo Hospitalario Universitario de Vigo, Vigo, SPAIN.

Aim/Introduction: The geometric methods used to calculate the left ventricular ejection fraction (LVEF) with gated-SPECT myocardial perfusion (MP) gives a clear overvaluation when ventricular volumes are small. There are several approaches that can be used to correct the problems related to the effect of partial volume on the LVEF calculation. This study is based on applying the reconstruction zoom correction of a study acquired with a 64x64 matrix, which allows to decrease the pixel size from 6.8mm to 2mm, so we can evaluate the changes obtained in the LVEF and the ventricular volumes applying the reconstruction zoom compared to the normal study. **Materials and Methods:** We analyze 205 patients (139 women, mean age: 72 years±10) with low prevalence of coronary heart disease (up to 10% pretest probability), who have performed a study of myocardial stress perfusion, without clinical, electrical or scintigraphic abnormalities, and with a normal LVEF obtained after post-stress (we did not perform a rest study). LVEF, ventricular volumes, and cardiac output have been assessed with and without reconstruction zoom. **Results:** We obtained global results with the normal processing methods (b) and with reconstruction zoom (z). Also, ventricular function results were grouped according to the following EDV ranges: EDV<40: LVEF: 83,8±7,4(b); 72,2±8,6(z), EDV: 33,3±3,6(b), 56,2±7,1(z), ESV: 5,44±2,5(b), 15,7±5,6(z), Heartbeat volume (HV): 27,9±3,6(b), 40,5±6,9(z), Cardiac output (CO): 2,31±0,53(b), 3,35±0,8(z). EDV 40-54: LVEF: 75,6±9(b); 66,3±8,6(z), EDV: 47,2±4,3(b), 73,1±6,2(z), ESV: 11,5±4,7(b), 24,7±7,2(z), HV: 35,6±4,7(b), 48,4±6,8(z), CO: 2,74±0,54(b), 3,74±0,76(z). EDV 55-69: LVEF: 68,7±6,6(b); 60,5±6,8(z), EDV: 61,4±4,3(b), 89,1±5,2(z), ESV: 19,2±4,3(b), 35,1±6,4(z), HV: 42,1±4,7(b), 54±6,8(z), CO: 3,17±0,55(b), 4,07±0,77(z). EDV 70-84: LVEF: 63,5±7,7(b); 55,9±7,8(z), EDV: 75,7±4,7(b), 103,3±9,2(z), ESV: 27,5±6,6(b), 45,9±10,3(z), HV: 48,3±6,9(b), 57,4±7,7(z), CO: 3,54±0,7(b), 4,23±0,95(z). EDV>84: LVEF: 58,5±4,3(b); 49,8±3,6(z), EDV: 98,7±11,6(b), 126,9±9,2(z), ESV: 40,9±5,8(b), 63,8±10,3(z), HV: 57,8±8,5(b), 63,1±5,8,7(z), CO: 4,24±1,03(b), 4,62±0,97(z). The differences obtained by group respect to the EDV were: EDV<40: Mean EDV: 33,3; HV:12,6; CO:1,03. EDV 40-54: Mean EDV: 47,2; HV:12,8; CO: 1. EDV: 55-69, Mean EDV:61,4; HV:11,9; CO:0,9. EDV: 70-84; Mean EDV: 75,7; HV:9,2; CO: 0,69. EDV>84: Mean EDV: 98,7; HV:5,3; CO:0,38. All calculated LVEF, volumes, and CO show statistically significant differences (p<0.001), overall and by EDV segments. The evaluation of the differences shows a clear decrease between them in HV and

CO from EDV bigger than 69 ml. **Conclusion:** The application of the reconstruction zoom in the calculation of the LVEF, volumes and cardiac output corrects the alterations due to the effect of the partial volume on the gated-SPECT. This reconstruction zoom achieves better performance at EDV values <70 ml. **References:** None

EP-043**Preliminary Comparison of Myocardial Perfusion Study Results on a Standard Dual-head Scintillation Camera and a CZT Semiconductor Camera**

M. Blaszczyk¹, P. Cichocki², J. Kuśmierk², A. Plachcińska¹;

¹Department of Quality Control and Radiological Protection,

Medical University of Lodz, Łódź, POLAND, ²Department of

Nuclear Medicine, Medical University of Lodz, Łódź, POLAND.

Aim/Introduction: Scintillation cameras are reliable diagnostic tools allowing non-invasive assessment of myocardial perfusion. A semiconductor CZT camera is characterized by higher resolution and sensitivity, which should allow obtaining high-quality images in shorter time. Comparison of myocardial perfusion images obtained with scintillation and CZT cameras and assessment of the impact of differences on diagnosis and size of ischemia. **Materials and Methods:** 41 patients (24 men, aged 33 to 83, mean 67 years) were selected randomly from patients referred for myocardial perfusion study (MPS). 2-day protocol was used: rest and stress (exercise/pharmacological). 99mTc-MIBI was administered in activity of 10 MBq / kg. Acquisition, carried out twice, using Discovery NM 530c camera (5 min) and Optima 640 (15 min), was completed with a low-dose CT on Optima camera to correct images for attenuation. Images were assessed according to the semi-quantitative method (17-segment model), assigning each segment values from 0 (normal perfusion) to 4 (no perfusion). First, images reconstructed without attenuation correction (NC) and with correction (AC) were evaluated separately, and then both sets were combined, using a 3-point scale: normal-n, equivocal-e and abnormal-a. First, all images from Optima were assessed, and after a few days - from Discovery. **Results:** Correlation coefficient between SSS values for both cameras, without attenuation correction (NC), was 0.95, for SRS - 0.94. Assuming SSS value≥4 as a criterion for abnormal stress study, results were concordant (normal/abnormal) in 95% (39/41) of studies. SSS lesions detected with both cameras, after division into small (SSS = 4-8) and large (SSS≥9), were concordant in 55% (6/11). With AC, correlations between SSS and SRS obtained with both cameras improved to 0.98 and 0.96, respectively. Accepting SSS≥2 as a criterion for abnormal stress study with AC allowed to achieve agreement between results (normal/abnormal) of 90% (37/41). AC improved agreement of size of defects (small/large) to 100% (10/10). After combined assessment of NC and AC studies on Optima, 21n, 9e and

11a results were obtained, and on Discovery - 25, only 5 and 11, respectively. **Conclusion:** Satisfactory agreement was obtained between results of MPS on Discovery NM530c (3 times shorter acquisition) and Optima 640 camera. AC based on a CT scan performed on Optima applied to images obtained with both cameras fulfilled its role properly. The study needs to be continued on a larger group of patients.

Evaluation of the dyssynchrony difference between pharmacological stress and rest of gated myocardial perfusion single photon emission computed tomography in patients after acute myocardial infarction

M. Ota¹, T. Kato¹, S. Matsuo²;

¹Gifu prefectural general medical center, Gifu, JAPAN,

²Matsuo Medical Clinic, Hirakata, JAPAN.

Aim/Introduction: Quantification of left ventricular (LV) dyssynchrony has been developed by using gated myocardial perfusion single photon emission computed tomography (GMPS). Heart Function View (HFV) software activated on GMPS was introduced which can investigate clinical usefulness for LV phase analysis. Hence, we reported that the results of calculating phase analysis were changed by the accumulated counts of myocardium at baseline of GMPS¹. Presumably, the high-count GMPS data can provide better quantification of LV dyssynchrony. The aim of this study is evaluation of comparison post pharmacological stress dyssynchrony with rest dyssynchrony on the same level accumulated counts of myocardium at baseline of using 2days protocol GMPS in acute myocardial infarction (AMI) patients after successful percutaneous coronary intervention (PCI). **Materials and Methods:** We retrospectively examined 53 consecutive AMI patients (39 men and 14 women; mean age 68.5±11.5 years old) who underwent successful PCI on admission were enrolled in this study. All patients were referred for routine rest and post pharmacological stress ^{99m}Tc-GMPS imaging on the two days protocol. Rest ^{99m}Tc-GMPS was performed within 12 days after the PCI of achieving successful coronary reflow. After within 9 days from rest imaging, post pharmacological stress GMPS imaging was performed. Rest ^{99m}Tc-MIBI GMPS images were obtained at 1 hour after the injection of ^{99m}Tc-MIBI at a dose of 740 MBq. Post stress ^{99m}Tc-MIBI GMPS images were obtained at 1 hour after adenosine stress (120µg/kg/min, infusion) and the injection of ^{99m}Tc-MIBI at a dose of 740 MBq. Phase standard deviation (SD) and Bandwidth was analyzed using HFV of ^{99m}Tc-GMPS stress and rest. Data from the perfusion defect score of each GMPS were used to divide patients into 3 groups: patients with SDS≥7 group, patients with SDS<7 and SSS≥9 group, patients with SDS<7 and SSS<9. (SSS: summed stress score, SRS: summed rest score, SDS: summed difference score)

In 3 groups, Phase SD and Bandwidth were compared between pharmacological stress and rest of GMPS. **Results:** In the patients after successful PCI on AMI, the dyssynchrony was no significant difference between rest and post pharmacological stress GMPS on the same level accumulated counts of myocardium. Hence, in stress-induced severe ischemia group (patients with SDS≥7 group, patients with SDS<7 and SSS≥9 group), it was significant difference between rest EF with post pharmacological stress EF. **Conclusion:** We suggested myocardial dyssynchrony is not changed between rest GMPS with post pharmacological GMPS in the patients after successful PCI on AMI. **References:** None

EP-045

Relevance Of Myocardial Perfusion Gated-SPECT(gMPS) As A Pre-Transplant Screening Method To Detect Ischemia

B. Pérez López, F. Sebastián Palacid, N. Álvarez Mena, P.J. Turbay Eljach, C. Gamazo Laherrán, M. Alonso Rodríguez, M. J. González Soto, A. Sainz Esteban, M. A. Ruiz Gómez, R. Ruano Pérez; Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To assess the importance of myocardial perfusion gated-SPECT (gMPS) as a screening method to detect ischemia in patients with cardiovascular risk factors (CVRF) before kidney transplantation. **Materials and Methods:** We analysed all patients with cardiovascular risk factors (CVRF) considered eligible to be included in kidney transplantation list referred to our Nuclear Medicine Department from January-2017 to December-2019. Pharmacologic vasodilator stress test with dipyridamole and gMPS with ^{99m}Tc- MIBI (1 day protocol, stress-rest) was performed in all patients. Variables such as demographic data, CVRF, stress test result, gMPS result and clinical course were studied. **Results:** 62 patients were studied (42 males and 20 females) with average age of 63.3 years old (range 31-83). The 30.6% of patients had a personal history of ischemic cardiopathy, being stable angina pectoris the most frequent pathology (58.9%) followed by myocardial infarction (42.1%). Regarding pharmacologic vasodilator stress test, the majority of patients (74.2%) showed a negative result (both clinical and electrographic), the 3.2% showed a positive result (both clinical and electrographic), the 12.9% clinically positive without EKG changes and the 9.7% showed EKG changes without symptoms due to ischemia. gMPS result was reported as normal in 38.8% of cases, ischemia in 53.2% (mainly slight), transmural myocardial infarction in 3.2%, ischemia+ non-transmural myocardial infarction in 1.6% and ischemia+ transmural myocardial infarction in 3.2%. In the cases with pathological gMPS result, a subsequent cardiac catheterization was performed in the 52.7% of cases, being normal in the 7.9% of them, revealed non-significant lesions in coronary arteries in the 13.2%, and significant lesions with stent placement in the 31.6%. Furthermore,

a bypass surgery (internal mammary artery to left anterior descending artery) was carried out in 1 patient. Finally, the 24.2% of patients were transplanted and the 22.6% are included in the waiting list for kidney transplantation. The 8% are still pending of being reassessed and kidney transplantation was dismissed in the 45.2% **Conclusion:** The inclusion of gMPS in clinical practice as a screening method to detect ischemia in patients considered eligible to kidney transplantation with cardiovascular risk factors is justified given the high prevalence of ischemic cardiopathy that revealed. **References:** None

EP-046

Locating The Latest Site Of Left Ventricular Mechanical Contraction Through Gated-SPECT Phase Analysis In Subjects With Normal Perfusion And Functional Parameters

F. Ferrando-Castagnetto¹, C. Real², M. Pedrera Canal³, I. Vilacosta², M. Ollarves Carrero³, L. García Belaustegui³, P. Pascual³, R. Ricca-Mallada¹, M. Pérez Castejón³, J. Carreras Delgado³;
¹Departamento de Cardiología - CCVU, Hospital de Clínicas, FM, UdelaR, Montevideo, URUGUAY, ²Instituto Cardiovascular, Hospital Clínico San Carlos, Madrid, SPAIN, ³Servicio de Medicina Nuclear, Hospital Clínico San Carlos, Madrid, SPAIN.

Aim/Introduction: Detecting the site of latest mechanical contraction in the left ventricle (LV) acquires special therapeutic relevance in patients with symptomatic systolic dysfunction and prolonged QRS complex. However, the normal location of this site has been characterized only by some non-invasive techniques. The objective of this experience was to locate the final site of mechanical LV contraction in subjects with normal myocardial perfusion, as reference values for next researches. **Materials and Methods:** Phase histograms at rest were obtained in 20 consecutive non-diabetic patients derived to 99mTc-MIBI gated-SPECT, without coronary artery disease, in sinus rhythm, with narrow QRS, no renal dysfunction, and normal perfusion images and quantified functional parameters. Phase standard deviation (PSD) and phase bandwidth (PBW) were obtained at rest applying SyncTool (Emory Cardiac Toolbox®), comparing them with a control sample already reported (1) using multiple “t” tests. The latest mechanical contraction region was obtained by freezing the digital video of ventricular contraction on the polar map during the last 10-40 degrees of phase. **Results:** PSD and PBW of the sample were higher than controls, both in men (PSD = 26.6 + 13.3 vs. 14.2 + 5.1, PBW = 72.3 + 35.6 vs. 38.7 + 11.8 degrees, $p < 0.05$ for all comparisons) as in women (PSD = 17.5 + 7.7 vs. 11.8 + 5.2, PBW = 48.2 + 21.5 vs. 30.6 ± 9.6 degrees, $p < 0.05$). The latest site of mechanical contraction was located predominantly at the anteroseptal (45%) and inferior (40%) regions. The mechanical contraction ended in two simultaneous regions (antero-septal and antero-

lateral) in two patients. **Conclusion:** Subjects with normal myocardial perfusion derived to gated-SPECT exhibit some degree of LV mechanical dyssynchrony. The region of the latest mechanical contraction obtained by gated-SPECT phase analysis agrees with previous findings obtained through other imaging modalities. It is required to validate these results in a head-to-head design with other imaging techniques and to expand the series in candidates for resynchronization therapy. **References:** 1) Chen J, Garcia EV, Folks RD, et al. The Effect Of Respiration Motion Correction On Myocardial Perfusion Quality

E. Popov, A. Mochula;

FSBSI «Tomsk National Research Medical Center, Russian Academy of Sciences», Cardiology Research Ins, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Breathing is a source of motion artifacts during myocardial perfusion scintigraphy. Currently, there are methods for correcting of the motion of the heart [1] and heart motion during breathing [2], but they were originally developed for radiation therapy [4]. The use of these methods in cardiology imaging will also eliminate artifacts from heart motion during breathing and will improve the diagnostic value of the images. **Materials and Methods:** . 15 healthy male volunteers (age 28 ± 2 years) underwent two-day stress-rest myocardial perfusion scintigraphy with 99mTc-MIBI (370 MBq). All data was acquired in List-mode. There were used two methods for respiratory correction. The first technique was to acquire SPECT data on the background of a breath holding. Respiratory arrest was carried out for 15 seconds. The study time increased from five to ten minutes. The second method was to process the native SPECT data using software - Motion Detection and Correction for Alcyone. This software allows the exclusion of offset scintigraphic images from common scintigram pool. Correction was carried out along three perpendicular axes of heart movement. Subsequent analysis of the processed data was performed using 4DM SPECT software. **Results:** A comparative analysis of myocardial perfusion data showed that the SSS obtained with breath-holding test was significantly less than software method correction motion detection or standard technique processing MPS: 2 (1.5; 3); 3 (1.5; 4.5); 4.5 (3.5; 5), respectively ($p < 0.05$). SRS and SDS were not significant different for three methods. **Conclusion:** Using the breath-holding test allows to identify the size of the perfusion defect with more accuracy. The correction of respiratory movements of the heart for SPECT is promising

and requires further study. **References:** 1. Zavadovsky K.V, Mishkina A.I., Mochula A.V., Lishmanov Yu.B. The method for correction of motion artefacts to improve myocardial perfusion imaging. EP-048

Safety of Regadenoson MPI in STEMI Patients Treated with Ticagrelor

A. Jimenez-Heffernan, C. Salgado-Garcia, A. Amr-Rey, T. Aroui-Luquin, J. Lopez-Martin, E. Sanchez de Mora; Hospital Juan Ramon Jimenez, Huelva, SPAIN.

Aim/Introduction: Ticagrelor, a direct-acting P2Y₁₂-adenosine diphosphate receptor blocker, is associated with a significant increase in adenosine plasma concentration through inhibition of cellular reuptake. More frequent and severe side effects, especially bradycardia and dyspnea, may be anticipated in patients undergoing adenosine and dipyridamole stress testing. However, the interaction with regadenoson has not yet been studied. We aim to assess the safety profile of MPI with regadenoson combined with low-level exercise in STEMI patients receiving ticagrelor. **Materials and Methods:** We studied 12 STEMI patients (83.3% male, age 64.2±14.3 years) treated with ticagrelor who underwent MPI for ischemia guided PCI of nonculprit vessel. Stress was 4 minutes of low-level exercise with a 15-s bolus injection of regadenoson (0.4 mg) at 1.5 minutes, followed by a saline flush, ^{99m}Tc-tetrofosmin, and a new saline flush. Medical history, adverse events, changes in systolic blood pressure (SBP), heart rate (HR), and oxygen saturation (SatO₂) were registered. **Results:** Cardiovascular risk factors were dyslipidemia (66.7%), hypertension (41.7%), obesity/overweight (20.0% and 50.0%, respectively), smokers/exsmokers (41.7% and 50.0%, respectively), and diabetes mellitus (8.3%). Clinical symptoms were self-limiting and well tolerated: fatigue (75%), dyspnea (25%), gastrointestinal discomfort (25%), dizziness (16.7%), headache (16.7%), dry mouth (8.3%), feeling hot (8.3%), and chest pain (8.3%). We observed significant increases in SBP and HR from baseline (127 mmHg ± 20 vs 137 mmHg ± 19, and 74 bpm ± 14 vs 106 bpm ± 13, respectively, p<0.05). No ECG or SatO₂ changes were observed following regadenoson administration (97.1% vs 97.5%, p=0.4). **Conclusion:** MPI with regadenoson in combination with low-level exercise is safe and well tolerated in STEMI patients treated with ticagrelor.

Could music positively influence cardiac perfusion studies?

M. Guiote Moreno¹, B. Luque Espejo¹, F.R. Maza Muret¹, J.F. Labraca¹, R. Zureta Pareja², J.A. Vallejo Casas¹;

¹Hospital Universitario Reina Sofia, Cordoba, SPAIN, ²Instituto Maimonides de Investigación Biomédica, Cordoba, SPAIN.

Aim/Introduction: The aim of the study is to verify if during pharmacological stimulation for a ^{99m}Tc-Tetrofosmin SPECT / CT, music could be a factor that decreased the cardiac stimulation adverse effects and therefore contributed to the well-being of the patient. **Materials and Methods:** 63 patients were recruited, 2 of whom were excluded due to Alzheimer's disease and the other due to hearing loss. The mean age was 69.13 years (S = 10.15 years), 27 were men and 34 women. The study was requested for the diagnosis of inducible myocardial ischemia in 45 of the patients, and for the prognostic purpose of evaluating their known ischemic heart disease in 16 of them. 35 of these patients were stimulated with Atepodin, and 25 with Regadenoson for obesity or respiratory pathology. The patients were randomly selected to make two groups, one listen to "Clair de Lune" of Debussy during the administration of the medication, and another control without music. All of them subsequently underwent a survey with the following variables, tolerability, presence of palpitations, sweating / heat, nausea, headache, central thoracic pain, gastralgia, dyspnea, cough, tingling sensation. At the end of the survey we asked if the music had positively influenced in them. These variables were included, since most of them are possible adverse effects of both drugs. Blood pressure constants (BP) were taken before and after pharmacological stimulation, heart rate (HR), saturation of O₂ (SatO₂), as well as the electrocardiogram. **Results:** 29 patients were placed with music, of which 25 of them had a positive influence according to the survey. 85% of all the patients tolerated well. Dyspnea and sweating were the predominant adverse effects in 27 patients respectively. Of the patients that underwent music stimulation 14 presented dyspnea and only 9 presented sweating. Given the small sample, we did not obtain statistically significant differences between the adverse effects and the different drugs. We will later conduct the study with a larger group. **Conclusion:** Music could be a useful tool for patients to better tolerate the administration of Atepodin and Regadenoson during cardiac stimulation for subsequent acquisition of studies with ^{99m}Tc-tetrofosmin. **References:** None

EP-051**Spleen uptake of sestamibi as an unexpected witness of sympathetic response to exercise in myocardial perfusion imaging**

S. Raffa¹, M. Pennone², M. Bauckneht², A. Borra¹, A. Miceli¹, I.

Donegani¹, S. Marra¹, S. Morbelli¹, C. Marini³, G. Sambucetti¹;

¹Dept. of Health Sciences (DISSAL), University of

Genoa, Genoa, ITALY, ²IRCCS Ospedale Policlinico

San Martino, Genoa, ITALY, ³Istituto di Bioimmagini e

Fisiologia Molecolare (IBFM), CNR, Milan, ITALY.

Aim/Introduction: Spleen volume decreases around 40% during vigorous exercise due to an increased drive of alpha-adrenergic fibers in the splenic nerves. Defining this autonomic response in humans might help verify the competence of the ortho-sympathetic nervous system in a variety of clinical conditions. In the present study, we aimed to verify whether myocardial perfusion imaging can provide information about spleen perfusion response to the sympathetic drive induced by exercise. **Materials and Methods:** We re-evaluated the images of 120 patients consecutively submitted to myocardial ^{99m}Tc-Sestamibi gated single-photon emission computed tomography (G-SPECT) because of known or suspected coronary artery disease (CAD) in the last three months. Images reconstruction was performed by filtered back projection using the Volumetrix software (Xeleris, GE). Regions of interest (ROI) were manually drawn to estimate average counts of spleen and liver as well maximal counting rate of left ventricular myocardium. Clinical and follow-up data of enrolled patients were also collected. **Results:** Stress was induced by physical exercise or by dipyridamole infusion (0.56 mg/Kg over 4 minutes) in 99 and 21 subjects, respectively. Exercise stress test significantly increased the spleen to liver radioactivity ratio (SLR) compared to dipyridamole (123±37% vs. 76±32%, respectively, p<0.05). This difference was not observed in the corresponding rest images (88±41% vs. 89±38%, p=ns, respectively). Similarly, spleen to myocardial radioactivity ratio (SMR) was remarkably similar in the two subgroups at rest G-SPECT (9±3% vs. 9±7%, respectively, p=ns). By contrast, SMR significantly increased during exercise (to 21±10%, p<0.001 vs. baseline), while it remained stable after dipyridamole infusion (10±8%, p=ns vs. baseline). Moreover, SMR was higher in the 53 patients performing a maximal exercise (maximal heart rate ≥85% of age-predicted maximum) than in the remaining 46 ones (15±3% vs. 11±2%, p<0.01, respectively). This difference was obviously reproduced when absence or presence of active betablocker treatment was considered. By contrast, SMR was not virtually independent of reversible ischemia (SDS >3) or contractile dysfunction (rest LV ejection fraction ≤45%). **Conclusion:** Physical exercise increases splenic Sestamibi uptake. This effect is not reproduced by dipyridamole and is not related to the occurrence of ischemia or left

ventricular dysfunction. Accordingly, it seems to reflect the increased splenic perfusion caused by the alpha-mediated contraction of splenic smooth muscle cells. **References:** None

EP-052**Effect of Ischemia Percentage in MPS on Patient Management and Revascularization Decision in CAD with Solid-State Cardiac Gamma Camera**

N. Talay^{1,2}, E. Özdemir^{1,2}, N. Coşkun^{1,2};

¹Nuclear medicine, Ankara, TURKEY, ²Ankara

şehir hastanesi, Ankara, TURKEY.

Aim/Introduction: Myocardial Perfusion Scintigraphy (MPS) is a highly sensitive noninvasive diagnostic method used in coronary artery disease (CAD). With this method, visual, quantitative / semi-quantitative evaluation is made. In this study, we aimed to evaluate the effect and results of the percent of ischemic area calculated on a semiquantitative basis on the revascularization decision in follow-up. **Materials and Methods:** : 611 patients who were sent to our clinic for MPS and taken with Cardiac Spect NM 530 GE device were scanned retrospectively. 93 patients (C: 36, M: 57, mean age: 60.11 ± 9.07) who underwent coronary angiography (CAG) were included in the study. Percentages of ischemic area were calculated by semiquantitative evaluation (average 6.16 ± 5.85%, median: 4%, minimum: 0%, maximum: 40%). In the follow-up of patients, the relationship between the choice of medical treatment or revascularization treatments (PTCA / Stent and CABG) and the percentage of ischemic area was evaluated statistically. **Results:** When the frequency of risk factors for CAD was examined, DM: 52% (n: 48), HT: 62% (n: 58), HPL: 17% (n: 16), smoking: 18% (n: 17) detected. 24 of the patients (25.8%) had known CAD. The number of patients with ischemia on MPS images was 85 (91%). In patients with ischemic area above 5%, stenosis detection rate in CAG was 85.4% (p: 0.002), and the rate of application of revascularization treatments (Stent, CABG) was found as 56.1% (p: 0.000).% Of ischemic area < % It was found to be statistically significantly higher than 5 patients. In patients with an ischemic area below 5%, the rate of patients who were decided to undergo medical treatment as a result of CAG was found to be 65.4% (p: 0.001). In addition, multivascular stenosis was detected in 68.3% of patients with ischemic area percentage of 5% and above, and the percentage of ischemic area was found to be significantly higher than patients below 5% (p: 0.000). In our study, the percentage of ischemic area above 5% was found to be 89% sensitivity and 69% specificity in determining patients to undergo revascularization, and it was found to be an important marker in clinical patient management. **Conclusion:** The percentage of ischemic area calculated by semi-quantitatively calculated MPS imaging with solid-state cardiac gamma cameras was observed to play an

important role in post-scintigraphic KAG planning and revascularization decision. **References:** None

EP-053

The results of myocardial perfusion SPECT and coronary angiography in Russian patients with different pretest CAD probability

A. Ansheles¹, E. Denisenko-Kankiya², I. Sergienko¹, V. Sergienko¹;

¹National Medical Research Center of Cardiology, Ministry of Healthcare, Moscow, RUSSIAN FEDERATION,

²City Hospital №4, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: To study the relationship between pretest probability (PTP) of coronary artery disease (CAD), calculated according to 2013/2019 European Society of Cardiology (ESC) guidelines, LV myocardial perfusion according to single-photon emission tomography (SPECT), and the results of invasive coronary angiography (CAG). **Materials and Methods:** The study included data from 220 patients with suspected CAD assigned to invasive CAG. All patients underwent rest-stress perfusion SPECT within 1 month before or after CAG with the assessment of standard quantitative parameters of left ventricle (LV) perfusion. Clinical data was retrospectively analyzed and CAD PTP was calculated according to 2013 and 2019 ESC guidelines. **Results:** Invasive CAG revealed obstructive lesion of one or more coronary arteries (CA) in 204 out of 220 patients (92.7%). In a retrospective analysis, taking into account gender, age and nature of symptoms, according to the 2013 ESC guidelines PTP was rated as low (<15%) in 13 patients (5.9%), as intermediate (15–85%) in 207 patients (94.1%). Based on the results of comprehensive examination, including SPECT and CAG, 8 patients with low PTP (61.5%) underwent CA revascularization. Among patients with intermediate PTP, significant (>10%) transient ischemia according to SPECT was revealed in 31 (15.0%), initial (5–10%) - in 107 patients (51.7%). According to CAG data, among 207 patients with intermediate PTP, obstructive CA lesion was detected in 192 (92.7%), of which 113 patients (58.8%) underwent CA revascularization. According to 2019 ESC guidelines, corrected PTP (clinical likelihood) was rated as low (<15%) in 117 patients (53.2%), including 98 (44.5%) with PTP 5–14%. After complete examination, 68 of them (58.1%) underwent CA revascularization. **Conclusion:** The principles of corrected CAD PTP evaluation proposed by 2019 ESC guidelines cannot be applied without significant amendments to the patients of Russian population with suspected CAD. 2013 ESC guidelines with higher CAD PTP values for all categories reflected Russian population better, while the 2019 guidelines mistakenly attributed patients with obstructive CAD and proved significant ischemia to a low clinical likelihood in at least 58% of cases. We suggest that underestimation of the symptoms by the patients and physicians may play a role. These results are preliminary and

will be expanded in subsequent studies in a larger group. **References:** None

Rubidium Myocardial Perfusion PET/CT: Initial Experience In First 200 Patients

L. Price, C. Copland, B. Ade-Ojo, M. Burnistion, M. Costa, S. Ferreira, R. Gregory, T. Hussain, B. Ribeiro, A. Simeonova, G. Testanera, L. Menezes;

Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Positron Emission Tomography/Computed Tomography (PET/CT) has many advantages over Single Photon Emission Computed Tomography in Myocardial Perfusion Scintigraphy (MPS) (1). However, UK availability, has been limited (2). We describe a new Rubidium (Rb) PET MPS service; the third in the National Health Service in England. **Materials and Methods:** Audit of the first 200 patients from November 2019 to February 2020. 131 men, 69 women, mean age 65 ±11, mean Body Mass Index 29.7±6.8. Imaging comprised CT for attenuation correction, CT for Agatston scoring (CAC) if no known Coronary Artery Disease (CAD) or prior intervention, and PET with and without adenosine vasodilation, in List mode. **Results:** The commonest indication was symptoms post-revascularization (29%). 29% had had previous percutaneous intervention, 16% had had previous coronary surgery. 21% had had prior cardiac CT. 96% received 140 mcg/kg/min adenosine, 4% received 210 mcg/kg/min. Two patients did not show adequate vasodilation. 1 scan was not of diagnostic quality. 47% had Agatston scoring. The mean total Agatston score was 564 ±1040. 14% had no coronary calcium, 24% had CAC <100, 31% had CAC <400, and 17% CAC >400. The normalcy rate for PET MPS was 63%. The prevalence of myocardial infarction was 19%. The mean global stress myocardial blood flow was 2.32 ±0.8 mL/g/min, and global Myocardial Flow Reserve was 2.36 ±0.9. The mean wait from request to scan was 32 days, and to report 33 days. **Conclusion:** Rb PET MPI is feasible and high quality in a new service. It provides detailed coronary assessment, with plaque burden, relative perfusion and absolute myocardial blood flow quantification (3). It will be an essential contributor to patient diagnosis, treatment response and risk stratification. **References:** (1) Chatal J-F, Rouzet F, Haddad F, et al. EP-055**Myocardial Perfusion Imaging SPECT May Reveal Silent Myocardial Ischemia In Patients With Epilepsy**

C. Sioka, A. Tsoumani, C. Votti, M. Beltsiou, L. Lakkas, K. Pappas, D. Kiortsis, A. Fotopoulos, A. Kyritsis, S. Markoula;
University Hospital of Ioannina, Ioannina, GREECE.

Aim/Introduction: The aim of the study was to assess whether asymptomatic myocardial ischemia can be diagnosed in patients with epilepsy employing myocardial perfusion imaging (MPI) with ^{99m}Tc tetrofosmin stress - rest single photon emission computer tomography (^{99m}Tc - SPECT). **Materials and Methods:** Twenty-nine adult epileptic patients were compared to 32 age and gender matched individuals, all with atypical cardiac symptoms and negative ECG and cardiologic examination. MPIs SPECT were performed and summed stress scores (SSS), summed rest scores (SRS) and summed difference scores (SDS) images were acquired. MPIs were designated as pathological with $\text{SSS} \geq 4$. In addition, lower SDS score denoted more irreversible ischemia at rest. **Results:** In the patient group, 20 of 29 (69%) patients had abnormal MPI; in the control group, 14 of 32 (43.8%) had abnormal MPI ($p=0.04$). The difference was significant in males, since 18/23 (78.2%) male patients and 11/25 (44%) male controls had abnormal MPI ($p=0.01$). However, male patients demonstrated more reversible myocardial ischemic abnormalities in their MPI than the control group, assessed by SDS. In addition, differences in the reversibility at rest of their myocardial ischemia was also detected in patients treated with inducers and patients treated with VPA. **Conclusion:** Patients with epilepsy with atypical cardiac symptoms are at high risk for cardiovascular disease. MPI SPECT may represent a non-invasive tool to detect early myocardial ischemia, in order to treat and possibly reduce sudden cardiac death in patients with epilepsy. **References:** None

EP-056**Increased Hypotensive Response With Regadenoson In Elderly Patients**

J. Villena-Salinas, J. Alors Ruiz, S. Ortega Lozano, E. Ramos Moreno;
Hospital Universitario Virgen de la Victoria, Malaga, SPAIN.

Aim/Introduction: Analyze the variability of arterial pressure (AP) and cardiac frequency (CF) in a series of patients that were exposed to regadenoson stimuli according to the age of each. **Materials and Methods:** Demographic data (age, gender) and clinical data (basal and maximum CF, basal AP and AP after 3 minutes) were gathered for an observational, prospective study, from 170 patients to which Regadenoson 400mcg was administered before performing a Myocardial Perfusion SPECT with ^{99m}Tc -Tetrofosmin (25mCi). Side effects and their treatment were registered. All the variables

showed a normal distribution, according to Kolmogorov-Smirnov test. A bivariate logistic regression was used, dividing the sample in age groups and establishing the cut off point at 71 years of age. The variability in the 10% AP decrease and the variability $>20\%$ of the CF were analyzed in both groups. **Results:** 170 patients were analyzed: 79 male and 91 female, mean age being 72.4 ± 9.1 years. The basal CF was 142.2 ± 20 mmHg and mean basal DAP was 76.3 ± 11.7 mmHg. SAP after 3 minutes was 90.8 ± 8.3 mmHg and DAP after 3 minutes 51 ± 8.2 mmHg. 78.82% of the patients showed $>20\%$ increase in basal CF. The variability was $<10\%$ in 64.71% of the patients, with $>10\%$ increase in 8.82%, and $>10\%$ decrease in 26.47%. In patients older than 71 years of age, a lower variability of the CF was obtained (OR:0.78, $p>0.05$), having the tendency to remain constant. In the group of patients older than 71 years of age, an OR of 2.68 ($p<0.05$) was obtained for a decrease in the SAP of $>10\%$. **Conclusion:** The results fit our experience in administering Regadenoson, by obtaining a higher risk of decrease in SAP in patients older than 71 years of age, with more constant values of the CF in this group. **References:** None

EP-057**Repeatability of Coronary Flow Reserve Values Determined with SPECT Technique Using a CZT Semiconductor Camera**

P. Cichocki¹, M. Błaszczak², K. Cygulska³, K. Filipczak², J. Kuśmierek¹, P. Lipiec³, J. D. Kasprzak³, A. Plachcińska²;

¹Department of Nuclear Medicine, Medical University of Lodz, Lodz, POLAND, ²Department of Quality Control and Radiological Protection, Medical University of Lodz, Lodz, POLAND, ³Chair and Department of Cardiology, Medical University of Lodz, Bieganski Hospital, Lodz, POLAND.

Aim/Introduction: Scintigraphic coronary flow reserve (CFR) examination is one of the most recent diagnostic methods in nuclear cardiology. It allows, in contrast to FFR determination in coronary angiography, to assess CFR of the whole myocardium of the left ventricle and of selected vascular territories. This expands the diagnostic potential of myocardial perfusion scintigraphy, especially in diagnosis of multivessel coronary artery disease, where standard study is characterized by lower sensitivity. CFR assessment with CZT semiconductor cameras is an alternative to analogous PET study using ^{82}Rb , ^{15}O or ^{13}N isotopes that is expensive and less available. The methodology of processing scintigraphic data obtained in this study (both in SPECT and PET techniques) is not free from subjective factors and must be performed with utmost care. Therefore, it is reasonable to evaluate reliability of this method, by assessing intra- and interobserver repeatability of values obtained by one and two independent operators. **Materials and Methods:** 33 patients were included in the study. CFR was assessed using CZT camera Discovery NM530c in a two-day protocol - at rest

and after stress test with dipyridamole. Each time patients were given 37MBq ^{99m}Tc -MIBI (for positioning on the camera) followed by 550MBq bolus injected simultaneously with the start of image acquisition lasting 8 minutes. Scintigraphic data in list-mode format was converted to 23 frames (15x6s, 4x30s, 4x60s) and reconstructed into SPECT images, that were processed using the Corridor 4DM program 3 times by one operator (twice on the same day and once after 2 weeks) and once by another independent operator. **Results:** Repeatability of CFR values was assessed in the myocardium of the whole left ventricle (Total) and in vascular territories of main coronary arteries (LAD, LCX and RCA). Pearson's correlation coefficients were as follows: 1) One operator, the same day: Total: 0,92; LAD: 0,91; LCX: 0,94; RCA: 0,92 2) One operator, 2 weeks apart: Total: 0,90; LAD: 0,89; LCX: 0,93; RCA: 0,86 3) Two independent operators: Total: 0,87; LAD: 0,91; LCX: 0,92; RCA: 0,73 **Conclusion:** CFR values obtained by the same and two independent operators displayed high repeatability in the whole myocardium and territories of LAD and LCX. In RCA territory, results obtained by different operators were less reproducible. This may be explained by the so-called "cardiac creep" phenomenon - motion of the heart, especially its inferior wall, probably caused by faster and deeper breathing in response to dipyridamole.

EP-058

The evaluation of myocardial blood flow and coronary flow reserve in MINOCA patients: comparison with cardiac magnetic resonance

A. Mochula, O. Mochula, A. Maltseva, D. Vorobyeva, V. Ryabov, K. Zavadovsky;

Cardiology Research Institute, Tomsk NPMC,
Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Aim. To assess the global and regional myocardial blood flow and coronary flow reserve impairment in MINOCA patients compared to CMR. **Materials and Methods:** The study group comprised 28 patients with acute coronary syndrome. Based on ICA results all patients were divided into two groups: 1) MINOCA (n=11); 2) patients with MI and obstructive CAD (MICAD) (n=17). Within 7-10 days after admission to the hospital all patients underwent SPECT MPS with the assessment of standard indices and quantitative parameters: stress /rest MBF and CFR (on CZT gamma-camera)[1]. Also, all patients underwent CMR with evaluation of infarct size (IF), microvascular obstruction (MVO), size of myocardial edema (ME) and transmural extent of myocardial infarction (TE)[2]. **Results:** According to the quantitative MPS data analysis, global sMBF and CFR values were significantly higher in MINOCA than in MICAD patients group: 1.2 (0.82;1.69) ml/min/g vs 0.62 (0.52;0.9) ml/min/g; 1.96 (1.23;2.42) vs 1.16 (0.98;1.64), respectively. CMR indices such as IS, ME and TE were significantly lower in MINOCA

compared to MICAD patients: 1.6 (0;7.8) vs 14.8 (6.3;22.6)%; 8(0;14) vs 18.5 (10;23)%; 0 (0;5) vs 18 (10;25), respectively. Seven(40%) MICAD group patients showed MVO, whereas there were no such patients in MINOCA group. The regional analysis revealed that sMBF and CFR were significantly lower in LV regions characterized by myocardial injury compared to non-injured regions (based on CMR data): 0.78 (0.51;0.94) ml/min/g vs 1.11 (0.82;1.4) and 1.22 (0.91;1.74) vs 1.52 (1.14;2.42), respectively. Also, we found out significant correlation between regional quantitative SPECT indices and TE evaluated by CMR: r=-0.4 for sMBF; r=-0.35 for CFR (p<0.05). **Conclusion:** The analysis of quantitative MPS SPECT parameters showed that such approach allows identifying MBF and CFR disturbances both on global and regional level. These results showed that MINOCA patients characterized by mild reduction of MBF and perfusion assessed visually and quantitatively. It means that despite the absence of obstructive coronary artery lesion this group of patients has more pronounced risk of cardiac events and need more aggressive observation and treatment. The study was supported by a grant of President Russia (MK-1347.2020.7). **References:** 1. Zavadovsky K.V., Mochula A.V., Boshchenko A.A., et al. Association of electrocardiographic changes during adenosine stress with perfusion defect on myocardial perfusion SPECT

O. Ben Hamida, W. El ajmi, A. Sellem, H. Hammami;
Military hospital of instruction of tunis, Tunis, TUNISIA.

Aim/Introduction: Myocardial perfusion single-photon emission computed tomography (SPECT) is a valuable and noninvasive imaging modality in the evaluation of patients with coronary artery disease(CAD). Adenosine stress may occasionally be associated with electrocardiographic (ECG) changes, but significance of ECG changes is controversial. The aim of this study is to evaluate the strength of association between adenosine stress-related ECG changes and perfusion defects on scintigraphy. **Materials and Methods:** One hundred and fifty (mean age: 63,69 years; sex: men 67, women 83) patients with known/suspected CAD underwent adenosine stress myocardial perfusion SPECT. Patients with baseline ECG abnormalities, previous history of coronary artery bypass graft surgery or myocardial infarction (MI) were excluded. ECG was monitored continuously during adenosine stress for ST-

depression. On the basis of the summed difference score, reversible perfusion defects were categorized as follows: normal: less than 4, mild: 4-8, moderate: 9-13, and severe: more than 13. **Results:** ST-depression was observed in 43/150 (28.6%) and reversible perfusion defects were observed in 22/43 (51.16%) patients. 12/27, 6/27, and 4/27 patients had mild, moderate, and severe ischemia, respectively. 21/43 patients had normal perfusion. ECG changes and perfusion defects showed a moderate strength of association. The sensitivity, specificity, positive predictive value, and negative predictive value of ECG findings for prediction of ischemia were 27.8, 69.44, 51.16, and 42.72%, respectively. **Conclusion:** ECG changes during adenosine stress are not uncommon. It shows a moderate strength of association with reversible perfusion defects. Studies showed that patients with ischemic ECG response to adenosine administration and normal perfusion on SPECT are at low risk of cardiovascular events. Nevertheless, ECG changes during adenosine merit critical evaluation of myocardial perfusion SPECT findings. **References:** 1. Comparison of different simplified methods to determinate Glomerular Filtration Rate with ^{99m}Tc -DTPA

M. A. Hernandez Fructuoso¹, J. E. Romero Herrera², B. Santos Montero¹, C. G. Franco Monterroso², S. Ruiz Llama², J. Castell Conesa²;

¹Hospital Universitario Vall d'Hebron. Institut de Diagnòstic per la Imatge, Barcelona, SPAIN, ²Hospital Universitario Vall d'Hebron., Barcelona, SPAIN.

Aim/Introduction: Due to [^{51}Cr]Cr-EDTA withdrawal in January 2019, centers had to adapt the technique to calculate glomerular filtration rate (GFR) using [^{99m}Tc]Tc-DTPA. The aim of this study was to validate different simplified method

of determining GFR with [^{99m}Tc]Tc-DTPA by analyzing the radioactive concentration of three and two plasma samples, compared to the validated reference method with 10 extractions. **Materials and Methods:** GFR of 30 patients was analyzed after intravenous administration of 18.5MBq of [^{99m}Tc]Tc-DTPA. Blood samples were withdrawn from the contralateral arm post-injection at different times: t=5', t=10', t=20', t=30', t=60', t=90', t=120', t=150', t=180' and t=240'. Blood samples were centrifuged at 1500g for 5 min to isolate the plasma. 1 ml of plasma samples in duplicate and standards in triplicate were counted 10 minutes in a gamma-counter (Wallac 1470, Wizard), correcting the values obtained by decay at time zero (dose administration). The GFR of the reference method, (RM), calculated by two-compartment bi-exponential kinetic analysis using 10 samples, was compared against the values obtained from 4 simplified methods (SM), calculated by "slope-intercept", one compartment mono-exponential analysis: 1)SM1: using 3 extractions at 120', 180' and 240' and Bröchner-Mortensen correction; 2)SM2: using 3 extractions at 120', 180' and 240' and Chandler's correction; 3)SM3': using 2 extractions at 120' and 240' and Bröchner-Mortensen correction; 4)SM4: using 2 extractions at 120' and 240' and Chandler correction (SM4). The GFR was normalized with respect to the body surface and the absolute errors (EA, EA=reference GFR-simplified GFR) and relative errors (ER, ER=GFR reference/EA x100) of each method were determined. **Results:** The mean values of GFR obtained by the MS1, MS2, MS3 and MS4 was 90.16±29.35ml/min/1.73m², 93.12±33.82ml/min/1.73m², 90.10±29.32ml/min/1.73m², 92.96±33.37 ml/min/1.73m² respectively and that of the MR was 92.79±30.55ml/min/1.73m². All the simplified evaluate method showed a significant correlation with respect to the reference method (MS1:r=0.994, MS2: r=0.992; MS3: r=0.993 and MS4: r = 0.995). The average AE for MS1, MS2,MS3 and MS4 were of 2.62±3.36 ml/min/1.73m², -0.33±5.25ml/min/1.73m², 2.69±3.17 ml/min/1.73m²; 0.17±4.96 ml/min/1.73m² respectively and the mean ER were 2.75±3.15%, 1.21±6.17%, 2.84±2.95%, 1.41±6.07% respectively. **Conclusion:** All this methods simplify the GFR measurement test and all show good correlation with the reference methods. Small differences without clinical relevance were found. In our series, one compartment mono-exponential analysis with 2 samples and Chandler correction was the most accurate test (least relative and absolute errors). **References:** None

EP-061

Correlation between the findings in the first post-transplantation Renogram and the allograft renal function twelve months after surgery

G. Guzmán Prudencio, S. Álvarez Ruiz, L. M. Del Barco Diez Canseco, M. Calderón Calvente, L. Nieto Morcillo, L. De la Cueva Barroa, M. Falgás Lacueva, M. Sangrós Sahún, P. Navarro Beltrán, D. Abós Olivares;

Hospital Universitario Miguel Servet, Zaragoza, SPAIN.

Aim/Introduction: To study the correlation between findings in the first renogram post-transplantation, and the evolution of the renal function of the graft twelve months after surgery. **Materials and Methods:** 20-minute duration renogram with ^{99m}Tc -MAG3, performed in the first 72 hours post-kidney transplantation, of patients attended at the Nuclear Medicine Service between January-December of 2018 are reviewed, extracting: a) the concentration angle (CA) that measures the inclination of the ascent section of the concentration phase with respect to the vertical axis (cutoff threshold $<40^\circ$ vs $\geq 40^\circ$); b) the time, in minutes (Tmax), at which the maximum concentration occurs (<10 vs ≥ 10 min); and c) the percentage of cortical retention (CR) at the end of the study ($<80\%$ vs $\geq 80\%$). These 3 parameters are correlated with renal function at 12 months post-transplantation, through the need or not of dialysis. **Results:** A total of 62 renograms were obtained, excluding 7 due to death as a result of intercurrent diseases and 2 due to vascular complications and graft loss, before the first year after surgery. 53 patients, 15 female and 38 male, aged between 20-80 years, were included in the analysis. Functional failure (dialysis) of the graft one year after the transplantation occurred in 15% (8/53). In patients with CA $\geq 40^\circ$ the probability of failure was 28% (5/18) and in CA $<40^\circ$ 8.6% (3/35), with relative risk (RR) of 3.2. 7/34 (20,6%) patients included in the group with Tmax ≥ 10 min were on dialysis one-year after, unlike just 1/19 (5,3%) if Tmax <10 min (RR 3,8). Among the 37 patients with CR $\geq 80\%$, 8/37 (22%) were dialyzed one year after, while none of the 16 in the group of patients with CR $<80\%$ (0% probability if CR $<80\%$). The matching of parameteres CA $\geq 40^\circ$, Tmax ≥ 10 min and CR $\geq 80\%$ together do not improve the prediction of dialysis one year after (27%, 5/18). **Conclusion:** 1. Renogram parameters 72 hours post-transplantation, such as concentration phase angle $\geq 40^\circ$, time at maximum concentration ≥ 10 min and percentage of cortical retention $\geq 80\%$, allow recognize a group of patients with greater probability of needing dialysis in the first year after surgery, but they do not are capable of indentify in which specific patients it will occur. 2. The parameter that best predicts the viability of the graft is cortical retention $<80\%$. **References:** None

EP-062

Usefulness of Additional Quantitative Parameters of Dynamic Renal Scintigraphy (DSN) in the Diagnosis of Obstructive Uro- and Nephropathy

P. Cichocki¹, K. Filipczak², A. Płachcińska², J. Kuśmierk¹;

¹Department of Nuclear Medicine, Medical University of Lodz, Lodz, POLAND, ²Department of Quality Control and Radiological Protection, Medical University of Lodz, Lodz, POLAND.

Aim/Introduction: One of the main indications for DSN is

diagnosis of obstructive uro-/nephropathy. In standard practice, this study includes assessment of sequential scintigraphic images, renographic curves and such quantitative parameters as: T_{MAX} , $T_{1/2}$ and split function of each kidney (SF). Due to the relative nature of SF and limitations of diagnostic capabilities of T_{MAX} and $T_{1/2}$, DSN was expanded to include new quantitative parameters describing kidney function in absolute values. This study aims to evaluate usefulness of kidney efficiency index (KEi) - new, in-house developed parameter proportional to clearance function of the kidney, as well as mean and parenchymal transit times (MTT and PTT). **Materials and Methods:** Study included 226 people aged 18-84 (average 53). First group, from which normative values of new parameters were determined, consisted of 20 healthy volunteers. Second group consisted of 206 patients selected retrospectively, based on archived scintigraphic data. Values of KEi were determined twice, by two independent operators, to assess their repeatability. In addition, "normalcy rate" (percentage of normal results among selected 62 patients with low likelihood of obstructive uro-/nephropathy) was used to evaluate reliability of all new parameters. Reliability of KEi and PTT was also assessed by their correlation with each kidney's eGFR calculated using CKD-EPI formula (in 92 patients who had current serum creatinine levels in archived medical records). A comparative differential analysis of obstructive uro-/nephropathy, based on standard and new DSN parameters, was performed on selected 74 patients (92 kidneys) with single functioning kidney or bilateral obstructive uropathy, where SF is unreliable. **Results:** Normative values: KEi ≥ 8 , MTT ≤ 250 s, PTT ≤ 225 s. Inter-observer reproducibility of KEi results: 0.987 Normalcy rate: 95% for KEi, 91% for PTT, 81% for MTT. KEi vs eGFR correlation was 0.84 ($p < 0.0001$) and was significantly higher than SF vs eGFR (0.66) and PTT vs eGFR (-0.53). In comparison with standard DSN evaluation, application of KEi changed the diagnosis in 34% of assessed kidneys (from uropathy to nephropathy in 27/92 kidneys and vice versa in 4 kidneys). **Conclusion:** KEi enables repeatable, quantitative assessment of absolute kidney function without any modifications of the standard DSN protocol. Its values can be compared between independent studies (e.g. follow-up examinations). KEi corrected the diagnosis of obstructive uro-/nephropathy in 1/3 cases of single functioning kidney or bilateral obstructive uropathy. MTT and PTT displayed limited utility in diagnosis of obstructive uro-/nephropathy. **References:** None

EP-063**Who Can We Trust More? A Comparison of Three Methods for GFR Determination**

I. Grierosu^{1,2}, M. Starcea^{3,2}, R. Tibu¹, A. Tarca¹, C. Gavrilovici^{3,2}, C. Stolniceanu^{1,2}, W. Jallou^{1,2}, T. Ionescu^{1,2}, A. Statescu¹, R. Iacob², C. Stefanescu^{1,2};

¹Hospital Sf. Spiridon, Nuclear Medicine Laboratory, Iasi, ROMANIA, ²University of Medicine and Pharmacy Grigore T. Popa, Iasi, ROMANIA, ³Hospital Sf. Maria, Paediatric Nephrology Department, Iasi, ROMANIA.

Aim/Introduction: We would like to share our experience, in consequence of more than a decade of fruitful collaboration between the Paediatric Nephrology Clinic and the Nuclear Medicine Department. The glomerular filtration rate (GFR) remains a subject of multiple controversies, especially in children. We found studies in literature data, for instance Garcia-Covarrubias L. et al. who demonstrated the strong correlation between estimated GFR by cystatin C equations and measurement by 99mTc-DTPA nephrogram. **Materials and Methods:** From the total of 974 nephrograms in children we considered only 539 cases diagnosed with congenital hydronephrosis. Granting a maximum of 2 days interval between scintigraphy and mandatory creatinine dosage, we finally selected 485 pediatric cases, with an age range between 1 month and 17 years. 99mTc-DTPA images were acquired with a Siemens Diacam double headed gamma camera. **Results:** We compared the GFR by three methods: one scintigraphical and two creatinine based mathematical equations, Schwartz and bedside Schwartz. The patients were devised in four groups: group I = 87 cases (under 1 year), group II = 198 cases (between 1 and 6 years), group III = 124 cases (6 - 12 years) and finally, group IV = 76 cases (12-17 years old). For each group we correlated the GFR using statistic Pearson correlation factor (R): A. Schwartz and scintigraphy, B = bedside Schwartz and scintigraphy, C = Schwartz and bedside Schwartz. We found: no correlation between scintigraphy and mathematical formulas in any group: RIA = 0.0157, RIB = 0.0408, RIIA = 0.2193, RIIB = 0.2256, RIIEA = 0.3298, RIIBB = 0.3321, RIVA = 0.4994, RIVB = 0.5445. Oppositely, the correlation between the two mathematical equations is very high: RIC = 0.9985, RIIC = 0.9959, RIICC = 0.9998, RIVC = 0.8811. **Conclusion:** It is obvious that the smaller the age, the less does mathematical GFR correlate with scintigraphic GFR. Even if the 99mTc-DTPA scintigraphical GFR may not be perfect, we acknowledge its tremendous usefulness when other techniques such as serum cystatin C dosage or Gates' method with plasma sample measuring are not available. To conclude, we do not recommend the use of a mathematical formula for GFR alone, but in comparison with an alternative method to serum cystatin C dosage, such as scintigraphical GFR. **References:** Garcia-Covarrubias L et al. Correlation of the Glomerular Filtration Rate Measured With the Use of DTPA-

Tc99m in Live Kidney Donors With Equations Based on Creatinine and Cystatin C. *Transplant Proc.* 2018; 50(2): 423-427.

EP-064**The Diagnostic Contribution of 18F-FDG PET/CT SCAN in Cancer of BMUO**

Y. Liu;

The First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: The purpose of this study was to investigate the value of 18F-FDG PET / CT in finding primary tumors in patients with bone metastasis of unknown primary origin (BMUO). **Materials and Methods:** A total of 223 patients were enrolled from November, 2017 to April, 2018 in the Department of Nuclear Medicine of the First Affiliated Hospital of Zhengzhou University to find the primary tumor for 18F-FDG PET/CT examination due to the discovery of bone metastases. The patients who found bone metastasis by routine examination were performed 18F-FDG PET/CT examination to find the primary tumor within 3 days after routine examination. All patients were finally diagnosed by histopathology. The diagnostic efficacy of 18F-FDG PET/CT to find the primary lesion was calculated by comparing the histopathological results with the 18F-FDG PET/CT imaging results. **Results:** A total of 223 patients were enrolled in this study, including 122 males and 101 females, with a median age of 62 years. Among 223 cases, the primary tumor was found in 205 cases, but 18 cases were not found. 18F-FDG PET/CT imaging was positive in 203 cases, including 199 true positives and 4 false positives. 18F-FDG PET/CT imaging was negative in 20 cases, including 14 true negatives and 6 false negatives. The sensitivity, specificity, accuracy, positive predictive value and negative predictive value of 18F-FDG PET/CT in detecting primary tumors in patients with BUMO were 97.1% (199/205), 77.8% (14/18), 91.9% (205/223), 98.0% (199/203), and 17% (14/20) respectively. 18F-FDG PET/CT detected all previously known metastases and found new metastases in 173 patients. **Conclusion:** 18F-FDG PET/CT, as a non-invasive examination method, is of great value in finding primary tumors in patients with unknown primary tumor bone metastasis. It can be used as the first choice for finding primary lesions. **References:** [1] Anqin, Han, Jie, Xue, Man, Hu, Jinsong, Zheng, Xiaohui, Wang. Role of ¹⁸F-FDG PET/CT in assessment of treatment response in transitional cell carcinoma

P. Kaushik, S. Shamim, J. Hussain, G. Arora, S. Datta Gupta, R. Kumar, C. Bal;

All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Role of ¹⁸F-FDG PET/CT in transitional cell carcinoma (TCC) has been mostly limited to detection of metastatic disease. There are very few studies evaluating the application of this modality in response assessment. This retrospective study aims to determine utility of FDG PET/CT in assessing response to chemotherapy in TCC. **Materials and Methods:** Patients with newly diagnosed as well as recurrent metastatic TCC who underwent chemotherapy and were referred to our department for assessing response with FDG PET/CT were retrospectively included in the study. Whole body (vertex to mid thigh) PET/CT scans were acquired on dedicated PET/CT scanner (Biograph mCT, Siemens, Germany and 710 Discovery, GE, USA) 45- 60 minutes after injection of 10 mCi of FDG intravenously. A delayed abdomen spot image was acquired at 120 minutes post-injection of FDG. FDG PET/CT done at baseline and at 4-6 weeks after starting chemotherapy were analyzed by an experienced nuclear medicine physician. Response was assessed as per PERCIST criteria. Clinical follow-up was used as reference standard. **Results:** A total of 9 patients (7 male and 2 female) were retrospectively analyzed in this study. Mean age of the patients was 58.1±5.4 years. The site of primary disease was kidney in 7 and urinary bladder in two. Lymph node metastases were present in all 9 patients with additional extra-nodal disease in 4 patients including bone (n=2), lung (n=1) and peritoneum (n=2). On response assessment four patients had stable disease, 4 had disease progression, 3 patients had complete metabolic response and 2 patients had partial metabolic response on FDG scan. **Conclusion:** FDG PET/CT may be a useful modality to assess chemotherapy response in patients with TCC. With its increasing use in metastatic workup and detecting recurrence, it may be a 'one stop shop' modality for staging, response assessment and detecting recurrence in TCC. **References:** None

EP-066

Performance of digital PET/CT in the assessment of liver metastases

F. Fuentes-Ocampo, A. Flotats, D. López-Mora, M. Sizova, S. Abouzian, V. Camacho, A. Fernández, M. Estorch, J. Duch, A. Domènech, I. Carrió;

Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.

Aim/Introduction: Recent studies have established a superior lesion detectability of digital PET/CT over analog PET/CT in cancer patients. In this study we evaluated the performance of digital PET/CT in the assessment of liver involvement in patients with known or suspected liver metastases. **Materials and Methods:** We prospectively included 83 oncological patients with various primary tumors (24 colorectal cancer, 16 lung cancer, 11 breast cancer, 3 sarcomas, 2 urothelial, 2 cancer of unknown primary origin and 9 others) from February 2018 to October 2019. All patients had previous history or liver metastases or were considered at risk of liver metastases because of type of primary, blood biomarkers and clinical presentation. All patients underwent a 18F-FDG PET/CT with a conventional digital scanner (Philips VEREOS). To compose a reference standard, the findings on digital PET/CT were compared with other imaging modalities (including magnetic resonance, contrast CT and echography), with biopsy when available, and with subsequent follow-up including PET/CT and other imaging modalities. Three nuclear medicine physicians evaluated the liver parenchyma to determine the presence or absence of liver metastases. Results on digital PET were compared with the composite reference standard. **Results:** Fourteen patients were excluded because confirmation of the results was not possible (death or follow up not appropriately performed). Finally, a total of 67 patients were considered evaluable, with a mean age of 69±12 years, 36 women and 31 men. A total of 54 patients had a true positive result and only 2 patients were considered false positive. Eleven patients were considered true negative, and none had a false negative result. This analysis based on our composite reference standard indicates a sensitivity of Digital PET/CT of 100%, with a specificity of 85% with a diagnostic accuracy of 97%. In addition, the false negative rate was 0 and the false positive rate was 0.15. Finally, the positive predictive value was 0.98 and the negative predictive value of 1. **Conclusion:** Digital PET/CT offers high sensitivity and diagnostic accuracy in the assessment of liver involvement in patients with known or suspected liver metastases, and may be considered the instrument of choice when available. **References:** None

EP-067**Diagnosis of Immunotherapy Adverse Effects with 18Fdg Pet-Ct. Our Experience:**

M. Agolti, L. Solari;

Centro de Medicina Nuclear Clinica Modelo, Parana, ARGENTINA.

Aim/Introduction: Immunotherapy is an increased useful therapy in oncology. Adverse effects can be diagnosed through 18 PET CT, and this is very important in life-threatening effects to start treatments. We describe our incidence and findings during one year. **Materials and Methods:** We have made 46 18FDG PET CT since 31st March 2019 to 31st March 2020 to patients treated with Immunotherapy: the treatments were ordered for Lung Cancer in 15 patients, renal cancer in 11 patients, melanoma in 15 patients, pancreatic cancer in 3 patients, 2 head and neck cancer. **Results:** We found possible IrAE in 7 patients: 1 increased uptake in Hypophysitis, without clear symptoms, 3 patients with findings possibly related to Colitis, however one of them was discharged for he was under oral treatment for Type II Diabetes, 2 Patients with increased uptake in Thyroid, without clear Hyperthyroid symptoms 2 findings compatible with pneumonitis. **Conclusion:** The incidence of our findings was 15,21%. When reporting 18 FDG PET CT in immunotherapy evaluation, to look after IrAE is very important for findings, and every nuclear medicine physician should have a check list for some of these undesirable effects maybe life-threatening and once diagnosed they can be correctly treated. **References:** None

EP-068**Dual time point PET/CT adds little to standard PET/CT in patients with renal cell carcinoma**L. Geertsen¹, J. A. Simonsen², S. Hvidsten², P. Højlund-Carlson^{2,3}, L. Lund^{1,3};

¹Department of Urology, Odense University Hospital, Odense, DENMARK, ²Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, ³Department of Clinical Research, University of Southern Denmark, Odense, DENMARK.

Aim/Introduction: FDG PET/CT is a well-established method of diagnosing and staging several types of cancer. In renal cell carcinoma (RCC) the use of FDG PET/CT is hampered by low tumour FDG uptake and high urine excretion. Dual time point (DTP) PET/CT has been proposed for better distinction between malignant and benign processes. The aim in this prospective pilot study was to investigate the potential advantages of DTP PET/CT in patients with RCC. **Materials and Methods:** Seven patients with primary or recurrent RCC had DTP FDG PET/CT (4 MBq ¹⁸F-FDG per kg bodyweight) performed 1 and 3 hours p.i. Images were interpreted by visual assessment with supplementary measurements of standardized uptake values (SUVs). The tumour or metastases were delineated manually based on

CT scans. Both early and delayed PET scans were aligned with the early, contrast-enhanced CT scan. SUVmax and SUVmean in volumes of interest were read automatically. **Results:** Five patients had primary RCC with no known metastases. Two patients had recurrent disease after nephrectomy; one had a lymph node metastasis in the renal hilus, the other multiple lung metastases. Judged by visual evaluation primary tumours showed varying FDG uptake, while the FDG uptake of all metastases was low. Quantitative results showed varying FDG uptake in tumours and metastases with SUVmax 1.60–17.70 g/mL and SUVmean 0.61–9.70 g/mL in scans performed at 1 h p.i. There was no significant or consequent change in SUVs from early (1h) to delayed (3h) images; some increased while others decreased. Average SUVmax was 7.4 g/mL vs. 6.9 g/mL, $p=0.85$, and average SUVmean was 3.7 g/mL vs. 3.2 g/mL, $p=0.72$, at the two time points. Delineation of tumours turned out to be quite difficult and prone to intra-observer variation, since tumours were not well-defined. SUVmean was influenced by a generally heterogeneous structure with varying degrees of central necrosis or cystic components. SUVmax was affected by the partial volume effect to different degrees in early and delayed PET images, since calices contained different amounts of urine at the two time points. Hence, delayed imaging did not facilitate delineation or quantification. **Conclusion:** Quantitative DTP FDG PET/CT appears to be of limited value in RCC, even when supplied by delayed imaging. **References:** None

EP-069**⁶⁴CuCl₂: New Radiopharmaceutical PET for Urological Cancers**M. Mascia¹, C. Villano¹, V. De Francesco¹, M. Marchioni², L. Schips², L. Cindolo³;

¹SS.Spirito Hospital, Dept. of Nuclear Medicine, Pescara, ITALY, ²G. D'Annunzio University, Dept. of Urology, Chieti, ITALY, ³CDC Villa Stuart, Dept. of Urology, Rome, ITALY.

Aim/Introduction: This study was designed to evaluate safety and efficacy of ⁶⁴Copper(II)dichloride (⁶⁴Cu(II)Cl₂) as a new positron emission tomography radiopharmaceutical PET for urological malignancies (UM). **Materials and Methods:** Patients diagnosed with UM were enrolled in a prospective single-center study. All Patients were staged with preoperative computed tomography (CT) and ⁶⁴Cu(II)Cl₂ PET/CT. Patient characteristics, anatomical and functional imaging, final histopathology were recorded. Surgical specimens for histopathological examination were collected after biopsy or surgery. To determine time-activity curves for ⁶⁴Cu(II)Cl₂ uptake in UM and normal tissues, standardized uptake values (SUVs) were calculated in tumors and corresponding normal tissue in healthy subjects, in liver and gluteus muscle. The safety of ⁶⁴Cu(II)Cl₂ was assessed and based on subjective symptoms and objective findings.

All the patients involved in this study have expressed their written informed consent including the use of their data for scientific purpose. The EudraCTnumber 2017-000940-17 has been issued for Sponsor's Protocol Code Number 64Cu in date 27/02/2017. The study was registered at ISRCTN as 11735211 on 21/11/2017 and it obtained the approval of the Ethical Committee of Chieti/Pescara on 12/03/2018 and the authorization of the OsSC-AIFA on 07/05/2018. **Results:** Twenty-three patients were included (mean age:69.6) and 82.6% were men. As dosimetry, an administered dose of 174.75 MegaBequerel for $^{64}\text{Cu}(\text{II})\text{Cl}_2$ was equal to 9.80milliSievert of the effective dose. The median SUVmax were 5.7, 0.9, 1.8 and 9.8 for the prostate, bladder, penis and kidney, respectively. All patients had histopathological report: 26.1%(6/23) with prostate cancer, 21.7%(5/23) with renal cancer, 21.7%(5/23) with bladder cancer, 22.7%(5/23) with penile cancer; 8.7%(2/23) patients had no cancer at the final pathological report. Median SUVmax were higher in organs with a malignancy in comparison with healthy tissue [prostate (11.5vs5.3, $p<0.001$), bladder (6.2vs0.9, $p=0.007$) and penis (3.9vs1.3, $p=0.027$)], but not in the kidneys (5.0vs10.4, $p=0.998$). the highest area under curve (AUC) was reported for prostate cancer (AUC=0.978), the lowest for penile cancer (AUC=0.775). The detection rates based on the best suggested cut-off according to the SUVmax were 85.7%(6/7) for prostate and bladder, 83.3%(5/6) for penile cancer. Neither drug-related effects or physiologic responses occurred, not adverse reactions observed. **Conclusion:** $^{64}\text{Cu}(\text{II})\text{Cl}_2$ is an effective and well tolerated tracer in patients with UM. Our results show higher SUVmax in cancer patients than in healthy subjects. Although large prospective trials are needed in order to extend the indication of this PET tracer, our findings suggest that $^{64}\text{Cu}(\text{II})\text{Cl}_2$ PET/CT is useful in patients affected by prostate, bladder and penis cancer. **References:** None

EP-070

The Role Of 18F-FDG PET/CT In The Management Of Merkel Cell Carcinoma: The Experience Of 51 Studies In Our Institution

V. Lopez Prior, B. LLombart Cussac, R. Diaz Expósito, F. Manchón Adsuar;
Valencian Oncologic Institution (IVO), Valencia, SPAIN.

Aim/Introduction: Merkel cell carcinoma (MCC) is a rare and aggressive neuroendocrine tumor with limited evidence on the role of 18F-FDG PET/CT. The aim of this study was to assess the impact of the 18F-FDG PET/CT in the management of MCC. **Materials and Methods:** Fifty-one studies of 18F-FDG PET/CT of 35 patients (19 men (54,30%); 72,17+-14,63 years) with histologic diagnosis of MCC were retrospectively evaluated. The change in tumor staging and the impact on the treatment were analysed. **Results:** There were 23 PET/CT positive studies (45,10%) and 28 (54,90%)

negative. Thirty four (66,7%) studies were performed for assessment of stage at initial presentation and 17(33,3%) were performed during the follow up: 6(35,29%) for suspected recurrence; 7(41,18%) for restaging; 4(23,53%) as a part of ongoing surveillance. On the basis of PET/CT results, there was a change in disease stage (SC) in 20 studies (39,20%) and impact in the management (MI) in 28 (54,90%): 11 (32,40%) SC and 12 (35,30%) MI in the initial staging; 5(71,43%) SC and 7(100%) MI in the restaging; 3 (50,00%) SC and 6 (100%) MI in suspected recurrence; 1 (25,00%) SC and 3 (75,00%) MI in the surveillance. 18F-FDG PET/CT incidentally detected 1 additional histologically confirmed cancer. The presence of nodal involvement in the beginning (0,0098; HR 3,82; IC95% 1,38-10,6), chemotherapy treatment (6e-04; HR 7,06; IC95% 2,30-21,60), size of primary tumor >2 cm (6e-04; HR 7,06; IC95% 2,30-21,60) and positive resection margin (0,00069; HR 4,01; IC95% 1,46-11,00) were statistically significant prognostic factors for overall survival. There was a trend towards significance for worse overall survival with initial positive 18F-FDG PET/CT but the trend did not reach statistical significance. **Conclusion:** 18F-FDG PET/CT altered the stage in 2 out of 5 studies and changed the treatment in more than half of the studies performed. The study confirms the important impact of 18F-FDG PET/CT on the management of MCC patients. **References:** None

EP-071

Quantification of 18F-FDG accumulation in the intact testes of oncological patients

G. Arsos, D. Katsampoukas, P. Exadaktylou, A. Kalaitzoglou, V. Mpalaris, S. Georga, E. Moraliadis;
3rd Dept. of Nuclear Medicine, Aristotle University of Thessaloniki School of Medicine, Papageorgiou Gen. Hospital, Thessaloniki, GREECE.

Aim/Introduction: From childhood to adulthood, testicular function first matures and then declines. Accordingly, testicular metabolic activity and 18F-FDG accumulation varies with age. Despite the existence of the blood-testis barrier, testis can be nevertheless affected by both neoplastic disease and antineoplastic agents, resulting in 18F-FDG uptake alterations. Considering symmetry, right and left testis have differing venous vasculature and also show subtle size and position differences. We aim to assess the levels of 18F-FDG uptake in the intact testes in relation to age and in comparison to other established reference sites, as well as their symmetry in the setting of the ordinary oncological 18F-FDG PET/CT scan. **Materials and Methods:** M A selected age-balanced sample of male patients admitted for oncological 18F-FDG-PET/CT scan from October 2018 to December 2019 was retrospectively analyzed. Patients with pediatric genitourinary operation, nephrourological malignancies or detectable testicular lesions were excluded. The 18F-FDG skull-base to mid-thigh

PET/CT scan was performed in all according to recognized guidelines. Properly sized spherical volumes of interest were drawn over each of both testes, mediastinum, right lobe of the liver and left thigh musculature, omitting any lesions and maximum standardized uptake value (SUVmax) was obtained. **Results:** Eighty-three patients with an age range 6–89 years (mean 46.3), were included. SUVmax (mean \pm standard deviation) was: left testis (L) 3.4 ± 0.9 , right testis (R) 3.5 ± 0.9 , mediastinum (MD) 2.3 ± 0.4 , liver (LIV) 3.2 ± 0.5 , left thigh (TH) 0.9 ± 0.1 . There was no significant difference between either L and R or between their ratios to mediastinum (L/MD and R/MD), liver (L/LIV and R/LIV) and thigh (L/TH and R/TH). Both L and R were significantly higher than MD, LIV and TH ($p < 0.001$ in every case). L and R were strongly linearly correlated each other ($r = 0.936$, p less than 0.005). The correlation of R with age was positive until the age of 23 years ($r = 0.842$, p less than 0.0001) and slightly negative ($r = -0.251$, $p = 0.04$) thereafter. Interestingly, in the younger group (18 patients), the ratios R/MD, R/LIV and R/TH were also significantly increased with age ($r = 0.610$, 0.666 and 0.713 respectively, p less than 0.05 for all) up to 23 years. **Conclusion:** 18F-FDG uptake in the intact testis of oncological patients shows considerable inter-testes parity. The correlation of 18F-FDG uptake with age is biphasic with fast increase of the former from childhood to early adulthood; this must be kept in mind considering uptake normality at this period. **References:** None

18-F-fluorodeoxyglucose positron emission tomography (18FDG PET) as an attractive oncology imaging modality in patients with brain metastasis of unknown origin - initial experience

P. Nikolova¹, V. Hadzhiyska¹, K. Mladenov¹, M. Ilcheva¹, V. Grudeva²;

¹University Hospital Alexandrovska, Sofia, BULGARIA,

²Department of Imaging Diagnostics, University Hospital „Sv.Ekaterina“, Sofia, BULGARIA.

Aim/Introduction: The aim of the study is to evaluate the role of positron emission tomography/computed tomography (PET/CT) in detecting primary site in patients with brain metastasis of unknown primary as well as the extent of the disease. **Materials and Methods:** Thirty-nine patients (23 men; 16 women; aged from 26 to 85 years, mean: 62 years old) with a diagnosis of brain metastasis according to histopathology and/or MRI were included in this retrospective study. Almost half of them had solitary metastases (49%), followed by those with several (33%) and multiple (18%) metastatic foci. Twenty-eight out of 39 patients were proved to have metastases histopathologically and 11 patients had highly suspicious metastases by conventional imaging. The most common histology types were adenocarcinoma, poorly- and undifferentiated carcinoma and other rarer variants

as melanoma, anaplastic blastoma, NHL and etc. Half of the patients had available baseline examinations and previous imaging studies prior to PET/CT, with only 9 of them (23%) having a whole-body CT. **Results:** 18FDG PET/CT suggested primary site in 31 cases (79%), 27 of which were subsequently proved to be correct either by direct histological verification or indirectly by the observation of lesion appearance or lesion growth on structural imaging as the standard of reference (true positive rate; 69%), mainly in the following locations: lung (21), testis (2), colorectal (1), prostate (1), uterus(1) and primary brain tumor(1). Findings for the other 4 cases were categorized as false positive since another primary location was confirmed by further investigations. Of 8 PET/CT-negative patients, no primary lesion was identified by other diagnostic procedures and formal clinical follow-up results in a false-negative rate of 0 and a true negative rate of 21%. Sensitivity, specificity, and accuracy were calculated as 100%, 67%, and 90%, respectively. PET/CT revealed additional metastasis in 77% (30/39) with most frequent sites being: lymph nodes(59%), lung(31%), bones(28%) and liver(18%). The calculated average survival rate, based on the date of PET/CT examination was around 9 months and in 8/39(21%) patients it was under 40 days, respectively. **Conclusion:** Our results demonstrate positive PET/CT findings in almost three-quarters of the patients with the lung being the most common primary location. Therefore, we believe that CUP patients may benefit from PET/CT assessment because of its highly sensitive and noninvasive nature - detection of possible primary site, determining the best location for biopsy as well as the extent of the metastatic disease. **References:** None

EP-073

Tonsils are the Most Frequent Primary Source of Cancer of Unknown Primary by FDG-PET/CT

G. Al-Obthani¹, J. Hatazawa²;

¹Hadramout University, Mukalla, YEMEN,

²Osaka University, Osaka, JAPAN.

Aim/Introduction: Cancer of unknown primary (CUP) refers to metastatic malignancy without an identified primary source. Carcinoembryonic antigen (CEA) is a glycoprotein, present at very low levels in the blood normally, but may elevate in many cancers. To check the detection rate (DR) for the primary lesions of CUP by FDG PET/CT and its correlation with the CEA level. **Materials and Methods:** 287 cases of CUP that were referred for FDG PET/CT during the period 2007–2017 at Osaka University Hospital, Japan. The cases had biopsy-proven malignancy whose primary origin remains unidentified. **Results:** DR of the primary lesions of CUP by FDG PET/CT was 18% (52/287). The primary sources in 40% (21/52) were located in the cervical area, and extra cervical in 60% (31/52). Neck lymph nodes metastases were

the initial presentation in 23% (67/287) of the CUP cases, while 77 % (220/287) with extra cervical metastases. DR for the primary lesion of the CUP cases that presented with neck LN metastases was 39% (26/67). The location of the primary tumor was also in the neck area in 80% (21/26) of the detected primary cancer with cervical metastases presentation. Tonsils were the most frequent primary lesion of CUP in the neck; 52% (11/21), followed the base of the tongue, and larynx, each of them 14% (3/21). While the primary source of 20% (5/26) of the detected primaries that presented with neck LN metastases, were located in extra cervical areas; 3 cases in the thoracic esophagus and one case in each of the stomach and sigmoid colon. 77% (220/287) of the CUP cases presented by extra cervical metastases, DR was 12% (26/220). The common primary sources were: lung 27% (7/26), the stomach 15% (4/26). 32 cases of the CUP cases had high carcinoembryonic antigen (CEA). Of them, the primary cancers were detected in 34% (11/32), While 66% (21/32), their primary cancers were not detected. **Conclusion:** DR was higher for the primary cancers of the CUP with cervical lymph nodes metastases than non-cervical. Tonsils should be checked carefully in cases with cervical metastases. The efficacy of FDG PET/CT in the detection of the CUP was not correlated with the level of CEA. **References:** None

EP-074

Utility ¹⁸F-FDG PET/CT of the detection of unknown primary tumors (UPT)

A. Baena-Garcia, M. Cruz-Montijano, S. Garcia-Martinez, M. De Bonilla-Candau, J. Rodriguez-Rubio Corona, Y. Santaella-Guardiola, M. Pajares-Vinardell;
Hospital Universitario Puerta del Mar, Cadiz, SPAIN.

Aim/Introduction: The aim of this study is to evaluate the utility ¹⁸F-FDG PET/CT of the detection of unknown primary tumors (UPT). **Materials and Methods:** We analysed all the ¹⁸F-FDG PET/CT studies with an indication of UPT addressed to our department from the start of PET/CT from March 2016 to December 2019. We defined as pathological all studies with positive metabolic malignancy findings. We differentiated studies with primary localized tumour (PLT), studies with positive metabolic without primary located tumour (P), and studies without pathological findings (WP). Final diagnosis criteria were histological confirmation by guided PET/CT or other techniques biopsy and/or clinical/radiological follow-up for at least six months. **Results:** Under the established criteria, 66 patients (43 males, 25 females) with an average age of 62 years old were identified. 59 of all the cases showed correctly tumor etiology. Positive metabolic lesions were identified in 57/66 patients, 96% of them were diagnosed as pathological (55/57. PLT+P). 4 patients were diagnosed as false positive by PET-CT. The primary tumor was identified in 36 patients, 41% of those

were diagnosed by guided PET-CT biopsy. The PET-CT was decisive in the final diagnosis of 37% (22/59) of the patients with UPT. **Conclusion:** The primary tumor was correctly diagnosed by PET-CT in 41% of the patients where a malignant origin was found. PET-CT contributed to establish the final diagnosis in 37% of all cases. **References:** 1. Talavera-Rubio, M. D. P., García-Vicente, A. M. (2013). EP-075

It Takes Two to Tango: Detection Efficiency of ¹⁸F-FDG PET-CT and High Resolution Contrast Enhanced CT in the evaluation of Hidden Primary Malignancy

M. Siddique¹, A. Iqbal², A. B. Rai³, M. K. Nawaz¹;

¹Pakistan Kidney and Liver Institute & Research Centre, Lahore, PAKISTAN, ²LINCS Diagnostic & IR Services, Lahore, PAKISTAN, ³Oxford University, Oxford, UNITED KINGDOM.

Aim/Introduction: ¹⁸F-FDG PET-CT is an astute detective in unraveling unknown primaries in cases presenting either with metastatic disease or constitutional symptoms that remains unspecified despite thorough diagnostic evaluation. We took a slingshot by adding anatomical probe high resolution contrast enhanced (HR CECT) in diagnostic regimen. **Materials and Methods:** Retrospectively, 92 patients [52 males, 40 females; age 8 - 73 y, mean: 49.8 y] with unknown primaries or negative nodal or extra-nodal diseases who underwent multimodal imaging (combined ¹⁸F-FDG PET-CT and HR CECT) from June 2019 till March 2020 were evaluated. We assessed combined work of both as compared with them working alone. Tissue diagnosis and follow up particularly in negative cases was considered reference standard. Statistical analysis included detection rate, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and area under curve (AUC) for FDG PET alone and combined molecular-diagnostic imaging. Linear regression was calculated to interpret PET-CT outcome based on background corrected target nodal / extra-nodal SUVmax values. **Results:** Of 92 cases, pre-scan biopsy was suggestive of metastases in 29.5% (n=27), inconclusive in 14% (n=13) and rest of 56.5% (n=52) had only constitutional symptoms. Of 66 patients with hypermetabolic disease, 52.2% (n=48) turned out to be true positive for primary tumor on biopsy and false positive in rest of 19.6% (n=18) cases due to underlying granulomatous disease. Of 26 (28%) FDG non-avid cases, three were false negative while rest of 23 (25%) were true negative. The

primary tumor was detected in gastrointestinal (n=8), pancreaticobiliary (n=10), genitourinary (n=2) and respiratory (n=6) systems. Two cases had breast carcinoma, 17 lymphoproliferative origin, three of malignant melanoma and miscellaneous sites in 3 cases. Putting all the pieces of jigsaw puzzle revealed that combined molecular - high resolution anatomical imaging was more precise in picking the true positives. Receiver operating character curve (ROC) revealed that the working model of two was accurate in detecting unknown primary with statistically significant (P-value < 0.01) difference. **Conclusion:** High resolution CECT when added to ¹⁸F-FDG PET-CT works much better providing higher detection quotients and reducing the number of false positives. In unison, both work as an effective tool for identifying occult primary pathology. **References:** None

Diagnostic Yield of F-18 FDG PET-CT in Staging and Restaging of Breast Cancer: Where Do We Need the Addition of Metabolic over Conventional Radiological Imaging?

M. Siddique¹, A. Iqbal², M. K. Nawaz¹, A. B. Rai³;

¹Pakistan Kidney and Liver Institute & Research Centre, Lahore, PAKISTAN, ²LINCS Diagnostic & IR Services, Lahore, PAKISTAN, ³Oxford University, Oxford, UNITED KINGDOM.

Aim/Introduction: Over the years, addition of metabolic over anatomical imaging is being investigated in intermediate to high risk breast cancer. In current study, we will evaluate the potential role of FDG PET-CT in different clinical settings by comparing its precision with conventional radiological imaging. **Materials and Methods:** 43 female breast cancer patients (age range:21-79 years, mean:52.6 years) with histological diagnosis of invasive ductal carcinoma/IDCA between June 2019 and March 2020 were evaluated retrospectively. Patients were stratified into cases with preoperative staging, post chemo and/or radiotherapy (CRT) or recurrence? Initial staging was performed based on clinico-pathological results, according to the American Joint Committee on Cancer(AJCC) classification. Following PET-CT imaging, modification in the staging was executed in patients with metastatic findings. Pearson's correlation coefficient was implicated to evaluate the impact of various factors. **Results:** Of 43 cases, PET-CT was performed preoperatively in 26%(n=11), post-treatment in 48%(n=21) and 26%(n=11) patients with suspicion of recurrence.

61%(n=27) had IDCA grade II while 39%(n=17) had grade III histology. Immunohistochemistry revealed 7(16%) ER/PR+ HER/2+, 15(35%) ER/PR+ HER/2-, 10(23%) ER/PR+ HER/2 equivocal and 6(14%) ER/PR- HER/2- cases, missing data in 5(12%) cases. By AJCC staging system; stage I, 7(16%); stage II, 12(28%); stage III, 13(30%) and stage IV 11(26%). 13 cases underwent CRT following mastectomy and axillary nodal dissection, while 21 had neo-adjuvant chemotherapy alone. Of total, 9(21%) were upstaged, 11 (25.6%) down-staged, two (4.6%) cases were equivocal, required MR correlation. Of baseline(n=11) cases, apart from primary tumor(mean size: 2.8 cm), hypermetabolic nodal, visceral and osseous metastases were seen in five, three and one case respectively. Cases with suspicious recurrence(n=11), local recurrence was identified in three, axillary and distant nodal metastases in three and extra-nodal metastases in five. Of post treatment cases (n=21), 10 cases had progressive disease, four had partial response and seven were unremarkable. No statistically significant difference seen in maximum standardized uptake value (SUV_{max}) of primary tumor with grade II versus III. Addition of PET-CT showed statistically significant impact on modification of tumor staging in intermediate, IIB[T₂N₁/T₃N0] disease, or higher clinical stage, tumor size > 2 cm and axillary nodal metastases. **Conclusion:** F-18 FDG PET-CT has been shown to be of utmost importance in recognizing the site of relapse in breast cancer cases where traditional imaging features are equivocal or conflicting. For baseline staging, PET has imperative role in high grade tumors with suspicious axillary and/or non-axillary metastases. **References:** None

EP-077

¹⁸F-FDG digital PET/CT performances for initial axillary lymph node status in breast cancer

C. Provost^{1,2}, A. Belly-Poinsignon³, O. Madar¹, L. Champion²;

¹Radiopharmacology department, Institut Curie, Saint Cloud, FRANCE, ²Nuclear Medicine department, Institut Curie, Saint Cloud, FRANCE, ³Medical Physics department, Institut Curie, Saint Cloud, FRANCE.

Aim/Introduction: Breast cancer represents 11.6% of new tumors in 2018 in the world. Axillary lymph node status is one of the most important prognostic factors at diagnosis. PET/CT is an efficient imaging tool in oncology. Evolution of PET technology (Time-of-Flight TOF and then digital detectors) permits to improve small lesions detectability. In literature, sensitivity of analog and analog TOF PET/CT in the assessment of axillary lymph node status is between 24 and 85%. In this study, we analyzed ¹⁸F-FDG digital PET/CT results for the detection of axillary lymph nodes in initial breast cancer staging. **Materials and Methods:** Eighty-eight women with breast cancer (mean age 51; range 24-79 years) underwent ¹⁸F-FDG digital PET/CT before surgery, between September 2018 and February 2019. Mid-thigh

acquisition (1min/bed position) was performed 60 min after injection of the radiotracer (3MBq/Kg). Images were reconstructed to a target image voxel size of 2×2×2 mm. Digital PET performances were compared with surgical pathology and analog PET results. **Results:** Sixty-six patients with T2 or higher breast carcinoma and 22 patients with T1 carcinoma were included. Axillary lymph node metastases were histologically confirmed in 37 of 88 patients (42%). For axillary lymph node evaluation, ¹⁸F-FDG digital PET/CT accuracy, sensitivity, specificity, positive and negative predictive values were 89, 86, 90, 86 and 90 %, respectively. Mean SUVmax value was 6.6 ± 3.8 (range 2.5–18.2) and mean size was 10.5 ± 3.6 (range 5–22 mm). In comparison with ¹⁸F-FDG analog PET/CT sensitivity, digital PET/CT results are significantly better (p=0.002). In comparison with analog TOF PET/CT, there is no significant difference between the both PET technologies (p=0.7). Even if specificity seems better with digital PET than TOF PET (90% vs 78%), no significant difference was found (p=0.1). **Conclusion:** Accurate evaluation of axillary lymph nodes status is crucial for treatment choice and prognosis prediction. In this study, axillary lymph node detection by ¹⁸F-FDG digital PET/CT is promising with high index performances. **References:** Cooper KL, et al. EP-078

Metabolic activity by 18F-FDG-PET/CT is predictive of early response after ribociclib combination therapy in previously treated hormone positive advanced carcinoma breast : a hope of future

H. Rathore, N. Thaker, I. Talwar, B. Smruti, R. Pai, M. Ansari, R. Jaiswar;

Bombay Hospital and Medical Research Centre, Mumbai, INDIA.

Aim/Introduction: Therapy with Ribociclib and aromatase inhibitor (Letrozole) is a novel combination for hormone positive metastatic carcinoma breast. To assess the efficacy of Ribociclib combination therapy by clinical, radiological and metabolic responses, and toxicity. **Materials and Methods:** Ribociclib combination therapy was given to two patients (A and B) with HR+/HER2-CABreast and kept under observation for 8 months. 18F-FDG-PET/CT was performed prior to initiation and after 8 months of treatment and evaluated for radiological and metabolic response assessment by size of lesions and SULpeak by using RECISTv1.1 and PERSIST1.0 criteria respectively, metabolic

tumour volume (MTV) and total lesion glycolysis (TLG) were also calculated. FISH study was negative for HER2. In addition, early response and toxicity of ribociclib was also evaluated by ECOG performance scale and CBC, liver and renal function tests (LFT and RFT), serum electrolytes, LDH and alkaline phosphate (ALP) prior to therapy and followed by 4 weekly as per ECOG-CTC criteria. **Results:** A complete to partial metabolic response as SULpeak to ribociclib combination therapy was observed in both patients which were further categorised to individual organs. All lesions detected by 18F-FDG-PET/CT scan exhibited significant reduction in metabolic activity (MA). First patient (A) showed a reduction in MA of 48.71% in lung nodules, 28.23% in mediastinal nodes, 22.89% in liver lesions, 30% in skeletal lesions with increased sclerosis, 100% in subcutaneous deposits and 68.04% in muscle deposits. Another patient (B) showed reduction in MA of 100% in mediastinal nodes, 52.63% in right axillary nodes, 6.09 % in liver lesions and 48.18 % in skeletal lesions suggestive of CMR and PMR according to PERSIST1.0, however increase in size of liver lesions seen in both patient as increase in extent of necrosis (24.48% and 15.08 %) suggestive of PD and SD respectively according to RESIST1.1 criteria. There are no new lesions seen in any of the patients with no significant haematological, lung, liver, kidney toxicity. ALP and LDH remains constant (grade) from the baseline values. **Conclusion:** Metabolic responses by 18F-FDG uptake (especially TLG) are closely associated with therapeutic response and survival at 8 month after Ribociclib and endocrine therapy. Even if morphological changes on CT-scans it is difficult to distinguish between responders and non-responders. Thus, the 18F-FDG uptake on PET/CT appears to be a promising biomarker for predicting the therapeutic efficacy of ribociclib and should be implemented in clinical practice. **References:** Gabriel N. EP-079

PET-CT And Breast Cancer: Indications And Interest

A. Hind, H. Maha;

Faculty of Medicine, Casablanca, MOROCCO.

Aim/Introduction: Positron emission tomography is an expensive examination with reduced availability in our country from where the interest to limit its indications and to approach them in a spirit of evaluation and rationalization of the requests. Our study aims to describe the place that PET currently occupies in our context in the staging of the disease, in the evaluation of the response to treatment as well as its role in the therapeutic decision-making in patients with breast cancer. **Materials and Methods:** This is

a retrospective observational study of patients with breast cancer treated in the Mohammed VI cancer center in Casablanca and having performed a PET-CT scan between January 2016 and December 2018. **Results:** 46 patients were included in the study. Their mean age at diagnosis was 47.91 (SD=10.61). The PET in the initial extension assessment allowed upstaging and downstaging at the lymph node stage in respectively 21.43% and 7.14% of the patients. It made it possible to classify 50% of patients as metastatic. In the recurrence assessment, PET allowed upstaging in 27.27% of cases and downstaging in 3.03% of Lymph node level 19.23% of patients underwent upstaging and 7.69% had downstaging. In the evaluation of the therapeutic response, PET showed a favorable response to treatment in 35% of the cases at the lymph node level and 30% of the cases at the metastatic level. It made it possible to detect a progression of the disease in 5% and 10% of the cases respectively at the lymph node and metastatic level. **Conclusion:** It remains essential to target its indications as well as possible to avoid duplication of examinations and to offer patients the best therapy, taking into account cost-effectiveness. **References:** 1. EP-080

Prospective comparison of early interim 18F-FDG PET/CT and 18F-FLT PET/CT for predicting treatment response and survival in metastatic breast cancer

S. Chan¹, T. Su², P. Chang²;

¹Hualien Tzu Chi Hospital, Hualien, TAIWAN, ²Keelung Chang Gung Memorial Hospital, Keelung, TAIWAN.

Aim/Introduction: Our purpose was to compare the value of 3'-deoxy-3'-18F-fluorothymidine (18F-FLT) and 18F-fluorodeoxyglucose (18F-FDG) positron emission tomography/computed tomography (PET/CT) for early prediction of treatment response and survival in patients with metastatic breast cancer after salvage therapy. **Materials and Methods:** Twenty-five patients with metastatic breast cancer were prospectively enrolled and received PET/CT using 18F-FLT and 18F-FDG at baseline, after 1st cycle, and after 2nd cycle of systemic chemotherapy. The

standard reference for treatment response was classified according to Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 criteria for contrast-enhanced CT (CE-CT) after 3 months of systemic chemotherapy. The metabolic response on PET was assessed according to PET response criteria in solid tumors (PERCIST) criteria. The metabolic response on PET was correlated to the treatment response, progression-free survival (PFS), and overall survival (OS). **Results:** Complete response was observed in 4% (n=1), partial response in 44% (n = 11), stable disease in 24% (n = 6), and progressive disease in 28% (n = 7) of the study patients. The median follow-up time was 38 months. The responders had a significant greater reduction of maximal SUV of the tumor on 18F-FDG-PET after 2 cycles of chemotherapy than non-responders (P=0.03). Metabolic response on 18F-FDG-PET after 2 cycles of chemotherapy showed a higher area under the receiver operating characteristics curve (AUC) of 0.801 in predicting treatment response compared with AUCs of 18F-FLT PET after 1 cycle or 2 cycles (AUC=0.593 and 0.587, respectively; P = 0.09 and 0.08, respectively) and 18F-FDG uptake after 1 cycle (AUC=0.679; P = 0.17). Patients who were responders at 18F-FDG-PET after 2 cycles of chemotherapy had significantly longer PFS (53.8% vs. 16.7%, P = 0.014) and OS (100% vs. 47.6%, P = 0.046) than non-responders. Survival differences between responders and non-responders in 18F-FLT PET were not significant. **Conclusion:** Early-interim 18F-FDG-PET is more accurate than 18F-FLT PET in predicting treatment response and survivals in metastatic breast cancer patients. **References:** None

EP-081

Prediction of recurrence in locally advanced breast cancer using deep learning analysis

I. Jo¹, J. Kim², S. Jeong¹, Y. Chae³, S. Lee¹;

¹Department of Nuclear Medicine, School of Medicine and Chilgok Hospital, Kyungpook National University, Daegu, KOREA, REPUBLIC OF, ²School of Computer Science and Engineering, Kyungpook National University, Daegu, KOREA, REPUBLIC OF, ³Department of Hematology/Oncology, Kyungpook National University Hospital, Kyungpook National University School of Medicine, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: The purpose of this study was to identify whether convolutional neural network (CNN)-based features can predict recurrence in locally advanced breast cancer. **Materials and Methods:** This retrospective study included 265 breast cancer patients who diagnosed from Jun 2007 to Dec 2015. Pre-treatment PET/CT images, clinicopathologic data such as age, clinical T and N stages, histologic grade, estrogen and progesterone receptors, HER2 status were given for the prediction of the recurrence. Regions of interest (ROIs) were manually drawn to place primary tumors in the individual PET/CT images. Then, we

cropped ROIs using 3D cuboids with standard size (130 x 114 x 60) for all subjects. We implemented a 3D residual neural network following the architecture of ResNet-34 with 34 convolutional layers with skip connections. The individual clinicopathologic data were transformed into one-hot vectors and were concatenated with convolutional feature vectors through a fully-connected layer. The concatenated features were passed through two fully-connected layers followed by sigmoid activation function for the binary prediction of recurrence. The network was trained using binary cross-entropy loss. **Results:** Sixty-one patients had recurrence (23%). To validate the prediction accuracy, we performed 5-fold cross-validation. Without clinical variables, the model achieved a prediction accuracy of 0.804 (sensitivity 0.358 and specificity 0.946) on the validation sets. When clinicopathologic data were incorporated, the accuracy for the validation sets showed no significant change (accuracy 0.804, sensitivity 0.359, and specificity 0.939). We also observed large variations of sensitivity from 0.231 to 0.5 according to the validation sets, which are thought to include outliers. **Conclusion:** It was able to predict recurrence of breast cancer with a model from pre-treatment PET/CT images regardless of additional clinicopathologic data. We suggest that these data will be leveraged to improve patient management. **References:** None

EP-082

NaF-PET/CT has very limited clinical impact as a routine adjunct to FDG-PET/CT in breast cancer staging

S. Hess^{1,2}, R. Horvat¹, E. H. Jakobsen³, P. C. Holdgaard⁴;

¹Dept. of Radiology and Nuclear Medicine, Hospital South West Jutland, University Hospital of Southern Denmark, Esbjerg, DENMARK, ²Department of Regional Health Research, University of Southern Denmark, Odense, DENMARK, ³Dept. of Oncology, Lillebælt Hospital, University Hospital of Southern Denmark, Vejle, DENMARK, ⁴Dept. of Nuclear Medicine, Lillebælt Hospital, University Hospital of Southern Denmark, Vejle, DENMARK.

Aim/Introduction: Correct staging of breast cancer is essential. Previous strategies included CT and bone scintigraphy, but FDG-PET/CT has replaced CT. Sclerotic metastases may be less FDG-avid than lytic ones, but it remains controversial whether routine supplemental bone imaging is warranted. We retrospectively assessed the added clinical value of NaF as an adjunct to FDG in staging breast cancer patients. **Materials and Methods:** All breast cancer patients referred to Hospital South West Jutland for staging with both NaF and FDG within 2 weeks during a one-year period were retrospectively divided into group A (novel diagnosis with intended neoadjuvant treatment) and group B (confirmed local recurrence). Medical records were reviewed for results of PET/CT scans and clinical course on a per-patient basis. Scans were classified as FDG(+/-), CT(+/-) or NaF(+/-) with

regards to bone metastases and concordance. Clinical impact was based on composite MDT decisions. **Results:** 66 consecutive patients were eligible for group A (n=45) or group B (n=21). In group A, most patients were without any metastases (n=17), or with loco-regional lymph node metastases on FDG and CT only (n=20). The remaining eight patients were NaF+, i.e. multiple bone metastases and concordant with FDG and CT (n=2), or solitary bone lesions with discordance, i.e. FDG-/CT+/NaF+ (n=3), FDG+/CT-/NaF+ (n=1), and FDG-/CT-/NaF+ (n=2). In the case with concordant PET scans (FDG+/CT-/NaF+), and the two NaF-only positive cases (FDG-/CT-/NaF+), PET results were considered false positive and treatment strategy remained unchanged. Of the three cases with discordant PET scans (FDG-/CT+/NaF+), two were considered false positive, and in one patient suspicion was maintained but treatment strategy remained unchanged. In group B, most patients were also without any metastases (n=9), or with soft tissue metastases only (n=4). The remaining seven patients were NaF+, i.e. multiple bone metastases concordant with FDG and CT (n=4), or solitary bone lesions with discordance, i.e. FDG-/CT+/NaF+ (n=1) and FDG-/CT-/NaF+ (n=1). Both cases with solitary NaF+ findings were considered false positive. One patient was considered true positive for bone metastases based in CT only and discordant with PET (FDG-/CT+/NaF-). **Conclusion:** The clinical impact of NaF-PET/CT as an adjunct to FDG-PET/CT is very limited; Of 66 patients, only seven displayed solitary NaF-positive findings discordant with FDG, and only one was considered suspicious, but with no consequence for treatment strategy. Thus, NaF-PET/CT does not seem warranted as a routine supplement to FDG-PET/CT for staging of breast cancer, but prospective confirmation is needed. **References:** None

EP-083

Bone Scan Index as Overall Survival predictor in Breast cancer patients with bone metastases at diagnosis

V. Frantellizzi, A. Matto, M. Conte, G. Brunotti, L. Cosma, J. Lazri, M. S. De Feo, G. De Vincentis;
Sapienza University of Rome, Rome, ITALY.

Aim/Introduction: Bone metastases represent a leading cause of death in patients with advanced breast cancer. It is not clear whether the bone metastatic load might have an impact on Overall Survival (OS) in patients with bone metastatic breast cancer at diagnosis. For this purpose we used Bone Scane Index (BSI) which is a reproducible and quantitative expression of the tumor load observed at bone scintigraphy. The aim of this analysis was to correlate BSI with OS in bone metastatic breast cancer patients. **Materials and Methods:** In this retrospective study breast cancer patients with bone metastases at the first bone scan and no visceral metastatic involvement (from the beginning of 2000 until 2015) were enrolled. All patients underwent

scintigraphic bone scan for staging purposes in our centre, after administration of 740 (550–800) MBq of ^{99m}Tc labelled with HDP (hydrodiphosphonates); images were acquired approximately 2 hours after injection. The BSI was then calculated using the DASciS software and a statistical analysis of the obtained results was carried out. Other clinical variables relevant for OS analysis such as age, any treatments (radiotherapy, hormonal therapy, diphosphonate therapy and chemotherapy) and post-treatment response were taken into account. **Results:** 94 patients were studied and scintigraphic bone scans were analyzed to correlate the BSI with OS in breast cancer patients using DASciS program. On a total of 94 patients 30 (32%) died. In 90% of cases the histotype was ductal infiltrating carcinoma. The median OS from diagnosis was 72 months (CI 95%: 62–NA). The univariate analysis with COX regression showed that only hormone therapy is significantly correlated with OS (HR 0.417, CI 95%: 0.174–0.997, $p < 0.049$), resulting as protective factor. Regarding the BSI value, our statistical analysis showed that it does not represent a significant predictor of OS in breast cancer patients (HR 0.960, 95% CI: 0.416–2.216, $p < 0.924$). The other variables included in the statistical analysis specifically age, radiotherapy, treatment with diphosphonates, chemotherapy and post-treatment response, resulted not significantly correlated with OS. **Conclusion:** Although the BSI showed to be useful as OS predictor in several tumours (such as prostate cancer), in this study we observed that the metastatic load of bone disease has no key role in prognostic stratification in this setting of patients. **References:** None

EP-084

Comparison of 1 day protocol and 2 day protocol of lymphoscintigraphy by subareolar injection in the detection of sentinel lymph nodes in breast cancer patients

J. Seok;

Chung-Ang University, College of Medicine,
Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Lymphoscintigraphy and sentinel node biopsy were used for the detection of axillary lymph node metastasis in breast cancer patients. We compared the results of subareolar injections on the day of surgery (1 day protocol) with injections the day before surgery (2 day protocol). **Materials and Methods:** This study included 1,266 breast cancer patients who underwent surgery between 2001 and 2020. For the 1 day protocol 0.8 ml of ^{99m}Tc -Colloid (37MBq) was injected in 887 patients in the subareolar region on the morning of the surgery. For the 2 day protocol 0.8 ml of ^{99m}Tc -Colloid (185MBq) was injected in 379 patients on the afternoon before surgery. Lymphoscintigraphy was performed in the supine position and sentinel node identification was performed by hand-

held gamma probe during surgery. **Results:** Among 887 patients with the 1 day protocol, 855 cases (96.4%) were identified by sentinel node lymphoscintigraphy, and 860 cases (97.0%) were identified by gamma probe. Among the 379 patients, in the 2 day protocol, 356 cases (93.9%) had the sentinel node identified by lymphoscintigraphy, and 346 cases (91.3%) had the sentinel node identified by the gamma probe. There was no significant difference in the identification rate of the sentinel node between the 1 day and 2 day protocol by lymphoscintigraphy and the gamma probe. **Conclusion:** The results of the identification of the sentinel node according to 1 day or 2 day protocols showed no significant differences. Because the 2 day protocol allows for an adequate amount of time to perform the lymphoscintigraphy, it is a more useful protocol for the identification of sentinel nodes in patients with breast cancer. **References:** 1. Seok JW, Kim IJ, Heo YJ, Yang YJ, Choi YS, Kim BG, Park SJ. Comparison of subareolar injection lymphoscintigraphy with the 1-day and the 2-day protocols for the detection of sentinel lymph nodes in patients with breast cancer. *Ann Nucl Med.* 2009 Jul;23(5):465–9.

EP-085

Negative Predictive Value Of ^{18}F -FDG PET/CT In The Axillary Response to Neoadjuvant Chemotherapy In Patients Diagnosed Of Locally Advanced Breast Cancer

M. Lara Martínez¹, M. López Acosta², A. Díaz Silván², O. Vilahomat Hernández², D. Cabello García², J. Uña Gorospe², A. Allende Riera²;
¹Hospital Universitario de Canarias, Santa Cruz de Tenerife, SPAIN, ²Hospital Universitario Nuestra Señora de La Candelaria, Santa Cruz de Tenerife, SPAIN.

Aim/Introduction: To determine the negative predictive value of ^{18}F -FDG PET/CT (PET/CT) in the detection of axillary metastatic disease response after neoadjuvant chemotherapy (NACT) in patients with complete structural response. **Materials and Methods:** Retrospective descriptive study of 45 patients diagnosed of locally advanced breast cancer who had undergone studies of conventional image (MRI, axillary ultrasound and mammography) with the result of axillary complete structural response after NACT. PET/CT was performed on this group of patients and those who presented complete metabolic response at the axillary level that underwent sentinel lymph node biopsy (SLNB). We have analyzed the pathological results of the sentinel nodes. **Results:** In the period from January 2019 to January 2020 a total of 45 patients with T1–T3 cN1 breast cancer received QTN with clinical and morphological response assessment using conventional imaging tests (MRI, ultrasound and mammography), who afterwards underwent a PET/CT. Twenty-six of them presented a complete axillary metabolic response result by PET/CT. The SLNB performed to this group showed metastatic axillary lymph node in 10 patients, so the negative predictive value of PET/CT in

this type of patients is 61.5%, similar to the referenced in the literature found at values of 65%. The mean age of the patients attended was 53 years, of which 73% presented infiltrating breast tumor, being predominantly affected the right breast in 54% of the patients. **Conclusion:** PET/CT together with SLNB after NACT along with conventional morphological imaging that detects complete structural response are a complementary diagnosis tool to rule out disease and avoids lymphadenectomy to be done in this group of patients. **References:** None

EP-086

Positron Emission Mammography In The Evaluation Of Interim Response To Neoadjuvant Chemotherapy In Patients With Locally Advanced Breast Cancer

S. Medina-Ornelas¹, I. Soldevilla-Gallardo¹, F. García-Perez¹, C. Villarreal-Garza¹, E. Bargallo-Rocha¹, E. Estrada-Lobato²;

¹Instituto Nacional de Cancerología, Mexico City, MEXICO, ²IAEA, Vienna, AUSTRIA.

Aim/Introduction: Neoadjuvant chemotherapy (NAC) has an important role in patients with locally advanced cancers, treating distant micrometastases, downstaging tumors, improving operability, and sometimes allowing breast-conserving surgery to take place. We studied the association between two Positron Emission Mammography with ¹⁸F-FDG (¹⁸F-FDG-PEM) semi-quantitative parameters in 108 patients and correlated with pathologic response in each of the following breast cancer subtype: **Triple negative breast cancer (TPN), HER2-positive, and ER-positive/HER2-negative cancers, our objective is** Examine the association between two Positron Emission Mammography (PEM) semi-quantitative parameters: PUVmax (maximum uptake value) and LTB (lesion to background) baseline and the end of NAC with pathologic response in each breast cancer subtype. **Materials and Methods:** 108 patients, 71 with invasive ductal carcinoma and 37 with infiltrating lobular carcinoma were evaluate with ¹⁸F-FDG-PEM scans baseline and after end of NAC. We assessed the impact of 2 PEM semi-quantitative parameters for molecular subtype correlated with pathologic response according Miller-Payne grade (MPG) **Results:** After NAC, an overall reduction of 2 PEM semi-quantitative parameters was found. Neither breast cancer subtypes nor Ki67 modified chemotherapy responses. Compared to PUVmax, an overall increase of LTB was found in baseline condition, independent of the expressed immunophenotype. Post-treatment values of PUVmax revealed a significant reduction compared to baseline values (4.8±0.26 vs. 1.9±0.18; p<0.001) and LTB exhibited a significant decay after the first course of NACT (15.8±1.36 vs. 5.5±0.49; p<0.001). Using the Kruskal-Wallis H test which showed no correlation between the different molecular subtypes and the MPG and PUVmax and LTB (p=0.52), but if a correlation was found between

the response rate by MPG and both semiquantitative parameters (p=0.05). **Conclusion:** 2 PEM semi-quantitative parameters demonstrated a statically significant correlation and equivalence across the different breast cancer subtypes correlated with pathologic response according to MPG. PEM did not allow for prediction of NAC response in terms of breast cancer biomarkers, it is not discarded that this technology might be helpful for individual treatment stratification in breast cancer. **References:** None

EP-088

Is there a correlation between PET and histopathology findings of the invasive ductal carcinoma of breast with the histopathological features of coexisting DCIS?

I. Sarikaya¹, A. Sarikaya², A. N. Albatineh¹, E. Tastekin², Y. A. Sezer²;

¹Kuwait University Faculty of Medicine, Kuwait, KUWAIT,

²Trakya University Faculty of Medicine, Edirne, TURKEY.

Aim/Introduction: Ductal carcinoma in-situ (DCIS) often coexists with invasive ductal carcinoma (IDC) of the breast. DCIS is recognized as non-obligate precursor of IDC when it coexists with IDC. ¹⁸F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) is commonly used in the staging and follow-up assessment of high risk and inflammatory breast cancers. In this study, we aimed to determine if there is any correlation in primary tumor's PET and histopathology findings with the histopathological features of the coexisting DCIS. In other words, we wanted to determine if PET findings can support the hypothesis of DCIS to be the precursor of IDC in cases with IDC-DCIS. **Materials and Methods:** FDG PET/CT images and histopathology results of the patients with newly diagnosed IDC-DCIS were selected for further analysis. Primary tumor's grade and the largest dimension, pathological staging, nuclear grade of DCIS, and architectural subtype of DCIS were noted from the post-operative histopathology results. Weight and lean body mass corrected maximum standardized uptake values (SUV_{max} and SUL_{max}) of the primary tumor were measured. Statistical analysis was conducted to determine if there is any correlation between PET and histopathological findings of the primary tumor with the nuclear grade and architectural subtype of the coexisting DCIS. **Results:** Forty six (46) female patients with IDC-DCIS of the breast were included in this study. Grade of the primary tumor was significantly correlated and associated with the nuclear grade of the coexisting DCIS (r=0.616, Polychoric correlation and P-value=0.001). Size of the primary tumor was mildly correlated with the nuclear grade of the coexisting DCIS (0.285, Polyserial correlation). There was no significant difference in median primary tumor SUV in cases with nuclear grade-3, -2 and -1 DCIS (p >0.05). There was no significant difference in median primary tumor SUV in cases with comedo and non-comedo

DCIS ($p > 0.05$). There was a weak correlation between the primary tumor's SUV with the nuclear grade and no correlation with the architectural subtype of the coexisting DCIS ($r=0.185$, Polyserial correlation, and $r=-0.033$, Point biserial correlation). **Conclusion:** Primary tumor's grade is significantly and positively correlated with the nuclear grade of the coexisting DCIS but the metabolic activity of the primary tumor does not seem to be correlated with the nuclear grade and architectural subtype of the coexisting DCIS. **References:** Sarikaya I, et al. Is there a difference in FDG PET findings of invasive ductal carcinoma of the breast with and without coexisting DCIS? *AOJNMB* 2020;8:27-35.

The comparative study of the validation for Tc-99m Tin-colloid and Tc-99m Phytate in sentinel node detection in breast cancer patients

J. Seok;

Chung-Ang University, College of Medicine,
Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Lymphoscintigraphy and sentinel node biopsy has become a standard method for detection of axillary lymph node metastasis in breast cancer patients, but the standard radiopharmaceutical was not prepared. About detection of axillary lymph node metastasis by lymphoscintigraphy and sentinel node biopsy in breast cancer patient, we compared the results of Tc-99m Tin-colloid and Tc-99m Phytate by subareolar injection. **Materials and Methods:** This study included 1,266 breast cancer patients who were performed operation during 2001-2020. Four hundred twelve patients were injected 0.8 ml of Tc-99m Tin-colloid (37-185 MBq) by subareolar injection. Eight hundred thirty-eight patients were injected 0.8 ml of Tc-99m Phytate (37-185 MBq). Lymphoscintigraphy was performed in supine position and sentinel node localization was performed by hand-held gamma probe in operation. **Results:** Among 412 patients by Tc-99m Tin-colloid, 374 cases (90.8%) were localized the sentinel node by lymphoscintigraphy and 367 cases (89.1%) were localized by gamma probe. Among 838 patients by Tc-99m Phytate, 821 cases (98.0%) were localized by lymphoscintigraphy and 823 cases (98.2%) were localized by gamma probe. The detection rate by lymphoscintigraphy and gamma probe was superior for Tc-99m Phytate compared to that for Tc-99m Tin-colloid, with a statistically significant difference. ($p < 0.05$, $p < 0.05$) **Conclusion:** Tc-99m Phytate is a better choice for localization of sentinel node than Tc-99m Tin-colloid in breast cancer patients. **References:** 1. Evaluation of low glucose uptake of lymph nodes in patients with advanced breast cancer

C. Romagnolo¹, G. Biscontini¹, C. Cottignoli¹, D. Morichetti², A. Savini³, F. Fringuelli¹, A. Palucci¹, L. Burroni¹;

¹Nuclear Medicine, Ancona, ITALY, ²Pathological
Anatomy department, Ancona, ITALY,

³Oncology Department, Ancona, ITALY.

Aim/Introduction: Breast cancer is frequently characterized by expression of the glucose transporter protein Glut-1 and elevated glucose consumption. ¹⁸F-FDG PET / CT is the suitable examination to detect lesions with these characteristics and therefore particularly useful for staging and restaging of cancer. Unfortunately, recent studies have shown that distant metastases of breast cancer are capable of changing their immuno-phenotype compared to primary tumor because of reduced expression of the glucose transporter protein Glut-1. The aim of our study was to evaluate the reduced or absent glucose metabolic activity of the thoracic lymph nodes in breast cancer operated patients and to compare these findings with the morphological positive ones obtained by high resolution CT (HRCT). **Materials and Methods:** 14 patients (14 F; mean age 51.6 yrs) underwent a ¹⁸F-FDG PET/CT scan and HRCT survey 3 months after breast cancer surgery. The patients presented infiltrating ductal carcinoma (6/14), lobular carcinoma (4/14) and mixed carcinoma (4/14). All of them had tumor grade G3 and pT2N3a disease stage. HRCT images were evaluated by two expert radiologists who described all positive or suspected lymph node lesions of the chest. The reconstructed PET/CT images were assessed separately by two nuclear medicine physicians who also provided for the semi-quantitative calculation of glucose uptake (SUV_{max}) of the lesions. Because of mismatched findings in the two methods used, all the patients underwent Fine Needle Aspiration Cytology (FNAC) and cytological evaluation of chest pathological lymph nodes. **Results:** The lymphadenopathies reported with contrast-enhanced HRCT were compared with ¹⁸F-FDG PET/CT scan. All lymph nodes detected as positive at HRCT exams showed glucose metabolism and SUV_{max} values slightly modified compared to normal limits ($SUV_{max}=2.1-3.1$). Of the 14 patients studied with FNAC, three tested positive for lymph node metastasis ($SUV_{max}=3.07$) **Conclusion:** In patients with breast cancer (pT2N3a stage) with lymph node morphology suspected for contrast-enhanced HRCT disease and low glucose metabolism detected at PET ¹⁸F-FDG, FNAC is recommended for the diagnosis of metastatic lesions. The lymph nodes with low-grade activity of ¹⁸F-FDG are characterized by reduced expression of the glucose transporter protein Glut-1, normally expressed in the primary tumor. However, this reduced expression is probably present also in the primary tumor, especially

when increasing in size. *References:* None

EP-091

Usefulness of PET/CT scan in Breast Cancer Patient

A. Guensi, I. Essongue, A. Sallak, H. Benider, S. S. Zouine; Hassan II University, Casablanca, MOROCCO.

Aim/Introduction: Breast cancer is the leading cause of death from cancer in women, with an incidence of 6,650 new cases / year in 2014 in Morocco. The prognosis for breast cancer patients improved by the new treatments available in addition to radiotherapy, hormone therapy and chemotherapy. The objective of this work is to show the usefulness of 18-FDG PET / CT in the assessment of the initial staging, in the assessment of the reclassification of patients with breast cancer. **Materials and Methods:** This is a retrospective work carried out in the nuclear medicine department of the Ibn Rochd University Hospital from January 2019 to December 2019. The study carried out based on data from the PET-CT files. The 18-FDG PET / CT was investigated in first assessment and also for restaging if recurrence is suspected. **Results:** Among the 1412 scans carried out, 36 were for breast cancer patients. The average age was 52 years. Six scans carried out for the initial extension assessment and 30 scans for the relapse suspicion. On the 18 FDG PET/CT scan, the 9 scans done for initial extension assessment were positive and found in 5 cases a hypermetabolic breast mass associated with hypermetabolic axillary lymphadenopathy and in 1 case a hypermetabolic breast mass associated with a hypermetabolic lung mass. Of the 30 exams done for relapse suspicion, 9 were negative. The 21 positive PET / CT distributed as follows: contralateral breast recurrence associated with a bone extension (1 case). A local recurrence associated with axillary lymphadenopathy (4 cases). a local recurrence with lymph node and bone extensions (5 cases), local recurrence with bone extension (1 case), local recurrence with pulmonary extension (2 cases), lymph node and pulmonary extension (2 cases). Only mediastinal lymph node recurrence (3 cases), lymph node and bone extension (1 case), lymph nodes, bone and pulmonary extension (1 case), one only hepatic extension (1 case). **Conclusion:** The indication of 18 FDG PET-CT at during the initial assessment remains limited to triple negative patients and advanced tumors. In the event of suspected recurrence, the PET / CT scan at 18FDG is very useful for carrying out an extension assessment and allows precise reclassification which allows the continuation of treatment to be adapted to the actual stage of the disease. *References:* None

EP-092

Paraneoplastic Cerebellar Degeneration: Initial Presentation of Occult Breast Cancer

N. Filizoglu, S. Kesim, C. O. Engur, T. Ones, S. Ozguven, T. Y. Erdil; Marmara University Pendik Training and Research Hospital, Istanbul, TURKEY.

Aim/Introduction: Paraneoplastic cerebellar degeneration (PCD) is a rare type of paraneoplastic syndrome characterized by the progressive onset of cerebellar dysfunction as a result of immune-mediated response against neoplasm rather than metastasis. We present a case of occult breast cancer who had PCD at initial presentation with diffuse cerebellar uptake depicted on the FDG PET/CT scan. Six months after the treatment, a follow-up FDG PET/CT scan revealed complete resolution of the cerebellar hypermetabolism. **Materials and Methods:** FDG PET/CT was performed to A 64-year-old female patient presented with complaints of progressive dysarthria, ataxia, nystagmus, headache and gait disturbance. **Results:** FDG PET/CT showed diffuse and intensely increased uptake in both cerebellar hemispheres and vermis (A). FDG PET/CT images also depicted moderate hypermetabolic lymph node in the right axillary region; however, no hypermetabolic foci was detected in breast tissues (A). Histopathology of the right axillary lymph node revealed metastasis of breast cancer. Based on these findings, the diagnosis of paraneoplastic cerebellar degeneration associated with occult breast cancer was made and treatment with doxorubicin-docetaxel-trastuzumab-pertuzumab was initiated. After four cycles of chemotherapy, follow-up FDG PET/CT showed complete regression of cerebellar hypermetabolism (B). **Conclusion:** PCD is a rare central nervous system disorder that is triggered by an immune system response to a neoplasm. PCD affects 1-3 % of all cancer patients, and it occurs typically in patients with cancer of the ovary, uterus, breast cancer, small-cell carcinoma of the lung and Hodgkin lymphoma. Patients typically develop subacute cerebellar ataxia, dysarthria, diplopia, and vertigo, which often precede the detection of the primary tumor. PCD is characterized by extensive loss of Purkinje cells and the presence of highly specific antineuronal antibodies in the serum and cerebrospinal fluid. Proteins expressed by tumors induce the production of onconeural antibodies leading to a T-cell mediated destruction of Purkinje cells in the cerebellum. The treatment of the underlying malignancy is considered the optimal treatment for PCD. FDG PET/CT is crucial in the early detection of the unknown primary tumors. Most of the recently published studies emphasizing the potential of FDG PET/CT in the assessment of the functional neurologic consequences of the disease in the brain as well as changes that follow after therapeutic interventions. To the best of our knowledge, this is the first case in the literature that uses FDG PET / CT to assess the current state of occult

breast cancer with PCD and subsequently following up the disease. **References:** None

Value of Volumetric and Textural Analysis in Predicting the Treatment Response in Patients with Locally Advanced Rectal Cancer

*N. Karahan Sen, A. Aksu, G. Capa Kaya;
Dokuz Eylül University, Izmir, TURKEY.*

Aim/Introduction: The aim of this study was to assess the value of 18F-FDG PET/CT in predicting the response to neoadjuvant chemo-radiotherapy (NCRT) in patients with locally advanced rectal cancer (LARC) via the volumetric and texture data obtained from 18F-FDG PET/CT images. **Materials and Methods:** Patients with staging FDG PET/CT and who had diagnosed LARC were evaluated retrospectively. In total, 110 patients who had undergone NCRT after PET/CT and followed by surgical resection were included in this study. Patients were divided into two groups randomly as train set (n:88) and test set (n:22). Pathological response using three-point tumor regression grade (TRG) and metastatic lymph nodes (increased size, changes in shape and high FDG uptake visually detectable from background were considered as metastatic) in PET/CT images were determined. TRG1 were accepted as responders and TRG2-3 as non-responders. Region of interest for the primary tumors was drawn and texture features were calculated. In train set, the relationship between these features and TRG was investigated with Mann Whitney U test. Receiver operating curve analysis was performed for features with $p < 0.05$. Correlation between features were evaluated with Spearman correlation test, features with correlation coefficient $< 0,8$ were evaluated with the logistic regression analysis for creating a model. The model obtained was tested with a test set that has not been used in modeling before. **Results:** In train set 32 (36.4%) patients were responders. The rate of visually detected metastatic lymph node at baseline PET/CT was higher in non-responders than responders (71.4% and 46.9% respectively= 0.022). There was a statistically significant difference between TLG, MTV, SHAPE_compacity, NGLDMcoarseness, GLRLM_GLNU, GLRLM_RLNU, GLZLM_LZHGE and GLZLM_GLNU between responders and non-responders. (All of these parameters were at higher values in non-responders except NGLDMcoarseness). MTV and NGLDMcoarseness demonstrated the most significance ($p=0.011$). However,

conventional SUV parameters did not demonstrate any significant difference ($p > 0.05$). A multivariate logistic regression analysis that included MTV, coarseness, GLZLM_LZHGE and lymph node metastasis was performed. Multivariate analysis demonstrated MTV and lymph node metastasis were the most meaningful parameters. The model's AUC was calculated as 0.714 ($p=0.001, 0.606-0.822, 95\%CI$). In test set, AUC was determined 0.838 ($p=0.008, 0.671-1.000, 95\%CI$) in discriminating non-responders. **Conclusion:** In this study, it was thought higher MTV value and metastatic lymph nodes in PET/CT images could be a predictor of low treatment response in patients with LARC. The combine evaluation of MTV and lymph node metastasis in pre-treatment PET/CT images should be considered to predict pathologic response to NCRT. **References:** None

EP-094

¹⁸F-FDG PET/CT Metabolic Tumor Burden in Primary Staging of Colorectal Cancers

*E. Etchebehere, J. S. Fonseca, A. O. Santos, M. C. L. Lima, M. S. Mendes, M. N. Silveira, B. J. Amorim, C. R. Martinez, L. P. Cunha, P. Fanti, J. B. Carvalheira;
The University of Campinas, Campinas, BRAZIL.*

Aim/Introduction: FDG PET/CT metabolic tumor burden (whole-body and primary tumor MTV (wbMTV; tuMTV) and TLG (wbTLG; tuTLG) parameters) has shown a direct correlation with prognosis in several solid tumors. However, the impact of these parameters in staging colorectal cancer (CRC) has not been studied. The purpose of this study was to determine if metabolic tumor burden plays a prognostic role in the primary staging of CRC. **Materials and Methods:** A retrospective analysis of 115 CRC patients submitted to a staging FDG PET/CT were studied. Semi-automatic calculation of metabolic tumor burden (hSUVmax, tuMTV, wbMTV, tuTLG, wbTLG) was performed. Cox proportional hazards regression was used to analyze predictors of survival. **Results:** The wbMTV ($p < 0.0001$; HR= 1.082), tumor histology ($p= 0.0024$; HR= 32.258) and clinical stage (IV vs I+II+III; $p= 0.0116$; HR= 7.407) were independent predictors of overall survival (OS). Only the presence of neural invasion was an independent predictor of progression-free survival (PFS) ($p= 0.0479$; HR= 4.902). **Conclusion:** wbMTV should be considered as a tool to make the fine adjustments in the treatment choice since it is a good predictor of survival. The evaluation of the primary tumor alone (tuMTV, tuTLG) are not able to predict OS and PFS. A higher number of patients and a longer period of observation should better demonstrate the reliability of these markers, cutoff values and the precise cases in which they are helpful. **References:** None

EP-095**The role of ¹⁸F- FDG PET-CT in the decision making of radiotherapy treatment in patients with anal cancer**

A. Palucci¹, M. di Benedetto², C. Cottignoli¹, L. Vicenzi², C. Romagnolo¹, F. Fringuelli¹, G. Biscontini¹, F. Fenu², S. Costantini², L. Burroni¹, G. Mantello²;

¹Nuclear Medicine, Ancona, ITALY, ²Radiotherapy Department, Ancona, ITALY.

Aim/Introduction: Chemo-radiotherapy represents the standard treatment in patients with anal cancer. Intensity Modulated Radiotherapy (IMRT) leads to a precise treatment of the tumor, with dose escalation on Gross Tumor Volume (GTV), saving the surrounding healthy tissues. ¹⁸F-FDG PET-CT and MRI of the pelvis are both used to for the definition of radiotherapy treatment plans. Our study assessed the impact of FDG PET-CT on the radiotherapy contouring process and its contribution to the assessment of the lymphatic spread allowing a personalization of Clinical Target Volume (CTV) and dose prescription. **Materials and Methods:** We carried out a retrospective study on 31 patients (25 females and 6 males) affected by anal cancer, treated with concomitant chemo-radiotherapy. Initial staging was based on MRI of the pelvis and ¹⁸F-FDG PET-CT performed in radiation treatment position. The whole pelvis, plus bilateral inguinal lymph node stations were include in the Radiotherapy Target volume. A total dose of 54 Gy (up to 59 Gy) was delivered to the primary tumor and 45 Gy to the elective lymph node areas; a simultaneous integrated boost of 50-54Gy was planned on involved lymph nodes. **Results:** 25 out of 31 patients presented lymph nodes involvement, in one or more areas detected on PET-CT and/or MRI. In 9 patients, PET-CT showed positive lymph nodes not detected on MRI: the lymph node stations involved were pre-sacrum-coccygeal (in 2 patients), external iliac (in 3 patients) and inguinal (in 6 patients). In 8 patients, MRI reported lymph nodes involvement not described on PET-CT: the lymph node stations reported were mesorectal (in 6 patients), pre-sacral (in 1 patient) and obturator (in 3 patients). Radiotherapy Clinical Target Volume (CTV) was modified including common iliac region only in 1 patient. Both diagnostics (PET-CT and MRI) had reported the presence of disease. Simultaneous integrated boost was performed in the 25 patients with lymph nodes involvement. **Conclusion:** PET-CT and MRI are both useful to define the Clinical Target Volume (CTV). An accurate definition of lymph nodes involvement allows dose escalation and CTV personalization. In our experience, MRI seems to be more accurate in defining perivisceral lymph node involvement, like mesorectal stations. PET-CT may be more useful in defining lymph node disease spread in the remaining pelvic and inguinal stations. **References:** None

EP-096**Metabolic parameters of primary tumor in preoperative ¹⁸F-FDG PET/CT do not accurately predict occult regional lymph node metastasis in patients with clinically N0 colorectal cancer**

M. Zhou^{1,2}, X. Wang^{1,2}, Y. Wang^{1,2};

¹Department of Nuclear Medicine, the Third Affiliated Hospital of Soochow University, Changzhou, CHINA, ²Changzhou Key Laboratory of Molecular Imaging, Changzhou, CHINA.

Aim/Introduction: To investigate whether metabolic parameters of primary tumor in preoperative ¹⁸F-FDG PET/CT could predict occult regional lymph node metastasis in patients with clinically N0 colorectal cancer. **Materials and Methods:** The present study consecutively enrolled a total of 60 patients (male: female = 2:1, age 64.5 ± 10.5 years) from January 2012 to June 2019 with clinically N0 colorectal cancer based on preoperative ¹⁸F-FDG PET/CT and contrast-enhanced CT. The SUVmax, tumor metabolic volume (MTV) and total glycolysis (TLG) of the primary tumor were measured on the dedicated PET/CT workstation. Using a logistic regression model, the relationships between clinicopathologic characteristics including PET/CT parameters and regional lymph node metastasis were analyzed. **Results:** 15 out of 60 patients were pathologically confirmed to have regional lymph node metastasis. No significant difference was found in SUVmax of regional lymph nodes between LNM(+) and LNM(-) groups (1.6 ± 0.8 vs 1.4 ± 0.8, t = 0.730, P = 0.472). There were also no significant differences in SUVmax, MTV and TLG of the primary tumor between two groups [20.4 ± 9.6 vs 23.4 ± 11.2, t = 0.907, P = 0.368; 32.5 (20.4, 43.2) vs 24.2 (14.7, 40.0), u = 0.810, P = 0.417; 200.7 (117.2, 432.1) vs 174.3 (86.3, 376.0), u = 0.248, P = 0.804]. The ROC curve analysis showed the area under the curve of SUVmax, MTV and TLG for predicting occult regional lymph node metastasis was 0.430, 0.570 and 0.521, respectively (all P > 0.05). Univariate and multivariate analysis showed that PET/CT metabolic parameters, age, gender, preoperative serum CEA and clinical T stage were not risk factors associated with occult regional lymph node metastasis (all P > 0.05). **Conclusion:** Metabolic parameters of primary tumor in preoperative ¹⁸F-FDG PET/CT have no ability to accurately predict occult regional lymph node metastasis in patients with clinically N0 colorectal cancer. **References:** None

Dual-Time Point Imaging (DTPI) in Gastrointestinal Stromal Tumors (GIST)

M. Aly^{1,2}, E. Kotheke¹, T. Seierstad³, C. Rojulpote¹, Ø. Bruland⁴, T. J. Werner¹, A. Alavi¹, M. E. Revheim^{1,5,6};

¹Department of Radiology, University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA, ²Department of Radiology, Asyut University Hospital, Asyut, EGYPT, ³Department of Research and Development, Oslo University Hospital, Oslo, NORWAY, ⁴Department of Oncology, Oslo University Hospital, Oslo, NORWAY, ⁵Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, ⁶Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, NORWAY.

Aim/Introduction: Increased activity between dual time point imaging (DTPI) was shown to be correlated with more malignant behavior in different cancers. With the introduction of tyrosin kinase inhibitors (TKI), the overall survival increased tremendously but some patients did not respond to first line treatment with imatinib or developed drug-resistant tumor clones. Approximately 20% of GISTs do not show sufficient FDG uptake or are too small to be detected by PET. We aim to evaluate the clinical value of DTPI of FDG-PET/CT in patients with metastatic GIST. **Materials and Methods:** 21 patients were included with metastatic GIST imaged after 60 and 90 minutes before treatment (timepoint 0 (Tp0)) and 2 weeks (Tp1) and 3 months after onset of TKI treatment (Tp2). 32 were responders according to RECIST and Choi criteria at Tp2. Examinations were using a Siemens Biograph 64PET/CT scanner. Scans were analyzed using an adaptive thresholding system (ROVER software; ABX GmbH, Radeberg/Germany). ROIs were placed over the active malignant lesions and the adaptive thresholding algorithm delineated the boundaries of active lesions. Quantitative PET parameters as SUVmean and SUVmax were automatically computed in addition to partial volume corrected (PVC). Volumetric measures of global disease burden included: metabolic tumor volume (MTV), total lesion glycolysis (TLG=SUVmean×MTV), and partial volume corrected TLG (pvcTLG=pvcSUVmean×MTV). Liver background was obtained by placing region of interest (ROI) of 3 cm in the right liver lobe. **Results:** 1) Strong correlations between pvcTLG at 60 and 90 minutes: 0.99 for Tp0 and Tp1, and 0.96 for Tp2 ($p < 0.05$). 2) Strong correlation between change based on 60 minutes and change based on 90 minutes between the three time-points. 3) No significant

difference between liver background values at 60 minutes (median;2.2, range;1.2-3.2) and 90 minutes (median;1.9, range;1.1-2.9) ($p < 0.05$) **Conclusion:** Total TLG and liver background activity provided the same result at 60 and 90 minutes after FDG injection in metastatic GIST patients during TKI treatment. Imaging after 90 minutes did not give any additional information. The low SUV results exhibited with GISTs compared with such values in aggressive tumors like lung cancer, indicate the relatively benign nature of these GISTs, and this also applies to the DTP imaging where SUV values may jump by even 30-40, after 30 minutes. And due to this benign-nature of GISTs (32 patients responded to TKI treatment), there was no significant elevation of metabolic activity as imaged between DTPI. **References:** None

EP-098

Comparison of ¹⁸F-FDG PET-CT and ⁶⁸Ga-PSMA PET-CT in Hepatocellular Carcinoma

S. Shamim, G. Arora, J. Hussain, S. Gupta, Shalimar, S. Gamanagatti, C. Bal; AIIMS, New Delhi, INDIA.

Aim/Introduction: Hepatocellular carcinoma (HCC) is the sixth most common malignancy globally with a rising trend owing to increase in chronic liver disease. FDG PET is known to have low sensitivity in HCC due to variable FDG avidity and physiological uptake in liver. Few studies have demonstrated PSMA expression in HCC. Although, there is paucity in data available comparing FDG and PSMA avidity in HCC. Our objective was to assess the feasibility of HCC evaluation using ⁶⁸Ga-PSMA PET-CT in HCC and compare it with the established ¹⁸F-FDG PET-CT. **Materials and Methods:** This prospective study recruited treatment naive radiological proven HCC patients from liver cancer clinic, in whom ¹⁸F-FDG PET-CT and ⁶⁸Ga-PSMA PET-CT were performed within 2 weeks of one another. Institutional ethical clearance was sought and written informed consent was taken from each participant. ¹⁸F-FDG PET/CT images were acquired at 45-60 minutes after intravenous administration of 8-10mCi of ¹⁸F-FDG. ⁶⁸Ga-PSMA PET/CT images were acquired at 30-40 minutes after intravenous administration of 2-4mCi of ⁶⁸Ga-PSMA. Images were visually analysed by two expert nuclear physicians independently. Semi-quantitative image analysis was done by drawing region of interests and estimating standardized uptake values (SUVmax) of positive lesions, liver background & mediastinum; and calculating ratios between the same. **Results:** Five patients (4 male; 1 female) of HCC were prospectively recruited, who underwent FDG PET/CT and PSMA PET-CT. Mean age of patients was 67±8.7 years. Mean imaging interval between two scans was 5.2±3.3 days. On qualitative assessment PSMA showed better liver lesion to background contrast as compared to FDG in three cases (mean tumor to liver ratio: 3.28 vs 2.33)

and inferior to FDG in 2 cases (mean tumor to liver ratio: 5.62 vs 2.28). FDG detected more liver lesions than PSMA in one case and FDG missed additional liver lesions that were detected on PSMA in another case. Overall mean tumor to liver ratios in FDG PET/CT was 3.64 (range: 1.29–9.87) and PSMA PET/CT was 2.87 (0.69–5.01), with no significant difference ($p=0.893$). Overall mean tumor to mediastinum ratios of FDG vs PSMA was 5.70 (1.84–12.95) and 9.56 (6.42–15.86), also comparable ($p=0.080$). **Conclusion:** PSMA PET/CT may be a promising imaging modality for HCC, which can be complimentary to existing FDG PET/CT in staging and detection of multifocal liver disease. This opens up a theranostic avenue with PSMA targeted radionuclide therapy in patients of HCC. **References:** None

EP-099

Asphericity as a measure of spatial heterogeneity predicts therapy outcome in FDG-PET of patients with esophageal carcinoma

F. Hofheinz¹, Y. Li², J. Maus¹, P. Nikulin¹, J. Rogasch³, J. van den Hoff¹, S. Zschaek⁴;

¹Helmholtz-Zentrum Dresden-Rossendorf, Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY,

²Department of Radiation Oncology, Xiamen Cancer Hospital, The First Affiliated Hospital of Xiamen University, Xiamen, CHINA,

³Department of Nuclear Medicine, Charite – Universitätsmedizin Berlin, Berlin, GERMANY, ⁴Department of Radiation Oncology, Charite – Universitätsmedizin Berlin, Berlin, GERMANY.

Aim/Introduction: It has been previously demonstrated that the quantifying the primary tumor asphericity (ASP) adds prognostic information to what is provided by standard parameters (SUV, MTV, TLG) in FDG-PET of patients with head and neck cancer. In the present study we address the question if ASP is also able to predict therapy outcome in patients with esophageal carcinoma. **Materials and Methods:** FDG-PET/CT was performed in 143 consecutive patients ((62+/-10)y, 112 males) with newly diagnosed esophageal squamous cell carcinoma prior to definitive radiochemotherapy. In the PET images, the metabolic active volume (MTV) of the primary tumor was delineated with an adaptive threshold method. For the resulting ROIs, SUVmax and ASP were computed. Kaplan-Meier analysis and univariate Cox regression were performed with respect to overall survival (OS) and event-free survival (EFS) for the PET parameters and clinically relevant parameters. Additionally, a multivariate Cox regression including clinical parameters as confounding factors was performed. **Results:** Survival analysis revealed MTV and ASP as prognostic factors for OS and EFS ($p<0.001$). SUVmax was not prognostic for any of the clinical endpoints ($p>0.15$). Among the clinical parameters, T-stage, N-stage, and UICC-stage were prognostic for OS and EFS ($p=0.001-0.02$). In multivariate analysis, MTV remained a significant factor indicating its

independent prognostic value. ASP was independent of clinical parameters ($p=0.024-0.049$) but not independent of MTV ($p=0.12-0.23$). **Conclusion:** In the investigated group of patients with esophageal carcinoma, ASP of the pretherapeutic FDG uptake pattern in the primary tumor adds prognostic information to clinical parameters but not to MTV. **References:** None

EP-100

DNA synthesis PET imaging with 4DST: A radiomics approach for predicting prognosis in patients with esophageal cancer

M. Hotta, R. Minamimoto, K. Yamada;

National Center for Global Health and Medicine, Tokyo, JAPAN.

Aim/Introduction: 4'-[methyl-11C] thiothymidine (4DST) has been developed as a cell proliferation imaging positron emission tomography (PET) tracer that directly incorporates into DNA. The aim of this study was to investigate whether a radiomics approach using 4DST PET/computed tomography (CT) is helpful for predicting prognosis in patients with esophageal cancer compared to fluorodeoxyglucose (FDG) PET/CT. **Materials and Methods:** This prospective study was approved by the Institutional Ethics Review Board. Between August 2015 and October 2018, 74 patients with pathologically proven esophageal cancer underwent 4DST PET/CT. Among them, 49 patients (44 men and 5 women; mean age, 67.9 ± 10.0 years) who underwent pretreatment 4DST and FDG PET/CT were used for the analysis. To obtain the volume of interest of the primary tumor, a three-dimensional sphere was set to encompass the lesion; the area showing a threshold of 40% of the maximum standardized uptake value was contoured; and PET features including conventional features and global, local, and regional textural features were measured. The study endpoint was overall survival (OS). Important PET features for predicting cancer-related death were selected using a machine-learning method: the Boruta algorithm. The selected features were evaluated based on Kaplan-Meier analysis and Cox proportional hazards regression analysis after determining the optimal cut-off value based on receiver-operating characteristic curve analysis. **Results:** Twenty patients died during the follow-up period [median 19.4 (interquartile range: 10.1–30.7) months]. Among all 4DST PET features, kurtosis and skewness were selected as statistically significant prognostic factors, and kurtosis was the most important feature, whereas none of the FDG PET features showed statistical significance in the feature selection. Patients with high 4DST kurtosis (>3.37) showed significantly short OS (log-rank p -value = 0.008; hazard ratio = 1.61). 4DST kurtosis was an independent statistically significant prognostic factor in multivariate analysis of clinical features including clinical stage, treatment method, and histological type. **Conclusion:** Radiomics features of

4DST PET are helpful for predicting prognosis in patients with esophageal cancer. Higher 4DST kurtosis, which potentially represents intratumoral heterogeneity, can lead to poor prognosis. **References:** None

EP-101

Digital vs Analog PET/CT in the detection of liver metastases

F. Fuentes-Ocampo, D. López-Mora, A. Flotats, M. Sizova, S. Abouzian, V. Camacho, A. Fernández, M. Estorch, J. Duch, A. Domènech, I. Carrió;
Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.

Aim/Introduction: To determine if digital PET/CT improves liver lesion detectability in patients with known or suspected liver metastases. **Materials and Methods:** Eighty-three oncological patients were prospectively included from February 2018 - October 2019 (42 women, mean age 69 ± 11 years) with one of the following criteria: previous history or liver metastases, risk of presenting liver metastases and/or presence of at least one liver lesion in the first scan performed (digital or analog). All patients underwent a dual imaging protocol (digital and analog PET/CT) during the same day. The order of acquisition was aleatory: the digital PET/CT was performed first in 43 patients (group 1) and the analog PET/CT first in 40 patients (group 2). Three nuclear medicine physicians assessed and counted liver lesions suspicious of malignancy. **Results:** The mean number of liver lesions detected per patient by the digital PET/CT was significantly higher than the analog PET/CT (digital: 3.25 ± 4.03 vs. analog: 2.49 ± 3.20 ; $P < 0.001$). We found no statistically significant difference in the time delay between scans of groups 1 and 2. Sixty-seven patients were considered positive for liver lesions by any PET/CT. The digital PET/CT detected more liver lesions than the analog PET/CT in 30/67 patients (45%), of whom 11/30 patients (16%) only had lesions detected by the digital system. The analog PET/CT detected more liver lesions in only 2/67 patients (3%). Thirty-five patients had the same number of liver lesions detected by both systems and 16 patients were considered negative for liver lesions. A total of 32 patients had different number of liver lesions detected between both PET/CT. In 7/32 patients (22%) their oncological disease upstaged due to the increased detectability by the digital system. In the remaining 25/32 patients (78%) their disease staging was not modified. **Conclusion:** Digital PET/CT offers higher liver lesion detectability in patients with known or suspected liver metastases. **References:** None

EP-102

Usefulness of regionally different cut-off SUVmax of the lymph nodes for the N staging of esophageal cancer

K. Takahashi¹, K. Takanami², K. Takase², T. Kamei¹;
¹Department of surgery, Tohoku University, Sendai, JAPAN, ²Department of Diagnostic Radiology, Tohoku University Hospital, Sendai, JAPAN.

Aim/Introduction: Although F-18 Fluorodeoxy-glucose (FDG) PET/CT is useful for the diagnosis of lymph node (LN) metastasis of esophageal cancer, it is often difficult to differentiate the FDG avid LNs as a reaction to inflammation from metastatic LNs and the inflammation might be different at each region. The aim of this study was to determine the usefulness of regionally different cut-off SUVmax of the lymph nodes (LNs) for N staging of esophageal cancer. **Materials and Methods:** We retrospectively reviewed a clinical data in our institution. This study included the patients with thoracic esophageal cancer who had undergone F-18 FDG PET/CT and contrast-enhanced CT (CE-CT) before radical esophagectomy with two- or three-field node dissection. We measured a nodal short-axis diameter on CE-CT image and a SUVmax of the LNs on PET/CT image. The LN regions were divided to "upper thoracic", "middle to lower thoracic" and "abdominal" regions. The common cut-off SUVmax and the regionally different cut-off SUVmax at each region of the LNs for detecting LN metastases were determined using receiver operating characteristic (ROC) analysis. Diagnostic accuracy in the metastatic LNs using the common cut-off SUVmax was compared with that using the regionally different cut-off SUVmax. **Results:** In this study, we included 216 LNs in 75 patients and identified 42 metastatic LNs in 27 patients. The short axis diameter and SUVmax were 8.65 ± 3.31 mm and 5.41 ± 3.96 for the metastatic LNs and 5.53 ± 1.71 mm and 1.94 ± 1.44 for the non-metastatic ones, respectively. The numbers of the metastatic LNs and non-metastatic ones were 15 and 91 at the upper thoracic region, 7 and 40 at the middle to lower thoracic region and 20 and 43 at the abdominal region, respectively. The SUVmax did not differ significantly among the three groups (Kruskal-Wallis test). Based on the ROC analysis, the common cut-off SUVmax was 2.61, and the regional cut-off SUVmax at upper thoracic, middle to lower thoracic and lower thoracic region, were 4.33, 3.36 and 2.40, respectively. The overall accuracy for detecting LN metastases was improved from 0.80 to 0.87 by using the regionally different cut-off SUVmax. **Conclusion:** Regionally different cut-off SUVmax of the lymph nodes may be useful for the N staging of esophageal cancer. **References:** None

EP-103**The Relationship Between Microsatellite Instability and ¹⁸F-FDG PET / CT Parameters in Colorectal Cancer Patients**

Z. Hasbek¹, N. Demir², M. Yılmaz¹, H. Özer¹, S. A. Ertürk¹, Ö. Ulaş Babacan¹, F. Arslan¹;

¹Sivas Cumhuriyet University School of Medicine, Sivas, TURKEY, ²Sivas Medicana Hospital, Sivas, TURKEY.

Aim/Introduction: Microsatellite Instability (MSI) is due to incompatibilities in the DNA repair mechanism (mismatch repair) caused by DNA replication errors resulting from the accumulation of somatic changes in nucleotide repeat sequences which are called microsatellites and some of these changes occur in gene promoter regions. MSI is considered stable (MSS) when patients without unstable marker. The effectiveness of immunotherapy is lower in patients with MSS colorectal cancer. Our aim in this study was to evaluate the relationship between MSI status and ¹⁸F-FDG PET / CT parameters in patients with colorectal cancer. **Materials and Methods:** There were 58 patients (39M / 19F, mean age: 63; range: 41-89) with colorectal adenocarcinoma in this study. In the immunohistochemical examination, nuclear staining was considered positive for all antibodies. Normal colon mucosa and lymphocytes in tissue were used as an internal positive control group. The absence of nuclear staining in tumor cells was considered “loss” in “Mismatch Repair Gen” proteins. MSI status of the patients was divided into 3 groups according to the number of MSI genes. The first group was determined as patients without MSI (MSS), the second group as MSI with only 1 gene (MSI-L), and the third group with MSI with 2 or more genes (MSI-H). The relationship between MSI status and both PET parameters and clinicopathological data were evaluated. **Results:** MSI was not observed in 46 (79.3%) of 58 patients in the study. The incidence of MSI was low (MSH-L) in 4 patients (6.9%) and high in 8 patients (13.8%) (MSH-H). There was a statistically significant relationship between MSI status and SUVmax value ($p = 0.02$). In patients with MSI-H, the median SUVmax value was higher than MSS and MSI-L patients (18, 14.75, 14, respectively). In addition, although not statistically significant, the rate of distant metastasis in PET / CT was higher in patients without MSI ($p = 0.082$) (Table 1). 17.2% of our patients had a family history of colorectal cancer. There was no statistically significant relationship between family history and MSI ($p = 0.141$). **Conclusion:** In our study, although it was not statistically significant the rate of distant metastasis in PET / CT was found lower in patients with high MSI. In addition, SUVmax values were found to be higher in patients with high MSI. In our literature review, although a positive correlation was reported between MSI and SUVmax values in gastric cancers, we think that the results of our study are valuable since no studies evaluating MSI and PET / CT data in colorectal cancers were found. **References:** None

EP-104**PET and cervical cancer: staging and therapeutic impact**

A. Hind, H. Hajar;

Faculty of Medicine, Casablanca, MOROCCO.

Aim/Introduction: Cervical cancer is the second most common cancer in the world after breast cancer. The most disadvantaged countries are the most affected by this disease. The aim of our work is to study, in our context, the role of PET in staging the disease and its impact on therapeutic decision in patients with cervical cancer. **Materials and Methods:** We conducted a descriptive study including patients with cervical cancer referred for treatment to Mohammed VI cancer center at university hospital IBN ROCHD in Casablanca, between January 2017 and December 2018 and explored with PET-CT. **Results:** We included 39 women (among 284 referred during this period). The mean age was 52 years +/- 11.5 years. PET has shown its superiority by making a contribution to other explorations (CT and MRI) in the assessment of lymph node invasion. (77% vs 48% respectively) in the pelvic region, and (20% vs 14% respectively) in the lumbo-aortic region. A secondary localization was revealed by PET in 26% of cases (lymph nodes, bone and parietal), with a change in the stage of the disease (Up staging to IVB) and therefore an impact on the therapeutic management. Moreover, PET revealed intercurrent pathologies in 20% of cases. **Conclusion:** If MRI remains essential in the assessment of local extension of cervical cancer, PET is very effective in the evaluation of pelvic and lumbo-aortic lymph node involvement, as well as in the distant metastasis detection. **References:** 1. EP-105

Role of early FDG PET/CT at 6 weeks for the prediction of response in cervical cancer treated with chemoradiotherapy

I. Zerizer¹, A. Divoli¹, S. Chua¹, A. Parsai²;

¹Royal Marsden Hospital, London, UNITED KINGDOM,

²Barts Healthcare, London, UNITED KINGDOM.

Aim/Introduction: We have evaluated the role of early FDG PET/CT performed at 6 weeks following chemotherapy and external beam radiotherapy in predicting final response in patients with advanced cervical cancer (CC). **Materials and Methods:** 43 female patients had a PET/CT(1) for staging, PET/CT(2) 6 weeks after platinum-based chemotherapy and external beam radiotherapy (prior to brachytherapy) and an end of treatment PET/CT(3) 3 months after completion of chemoradiotherapy. Maximal and peak standardized uptake values (SUV_{max} , SUV_p), size and volumes were measured on each PET/CT and percentage differences in ΔSUV_{max} , ΔSUV_p , size and metabolic volumes between responders (R) and non-responders (NR) were calculated between the baseline PET/CT(1) and early PET/CT(2) as well as PET/CT(1) and end of treatment PET/CT(3). **Results:** Final treatment response as determined by the end of treatment response PET/CT(3) at 3 months revealed 32 patients as responders (R) having reached a complete metabolic response, 11 patients as non-responders (NR) with 10 having had a partial metabolic response and 1 progressing with new disease outside the pelvis. On the early PET/CT (2), the ΔSUV_{max} % and ΔSUV_p % were significantly higher in the R (65-97%) compared with the NR (22-64%) and correlated with the ΔSUV_{max} % and ΔSUV_p % on the end of treatment PET/CT(3) ($P < 0.001$, $P < 0.002$ respectively). Similarly the percentage difference in metabolic volume was highly predictive of an early response with a marked decrease in volume of the primary tumour on the early PET/CT(2) in R (56-100%) compared with NR (15-55%), which also correlated with the end of treatment response ($P < 0.001$). However difference in tumour size did not correlate with a response on the early PET/CT(2) or end of treatment PET/CT (3). **Conclusion:** An early PET/CT performed at 6 weeks following induction chemotherapy and external beam radiotherapy for CC is predictive of a final response on the end of treatment PET/CT. This provides valuable information on early tumour response in CC and can identify NR early with the possibility of treatment intensification and escalation. **References:** None

EP-106

Correlation between tumor biological parameters at diagnosis and response to chemo-radiation therapy in cervical cancer patients

O. Kagna, R. Abdah-Bortnyak, Z. Keidar;

Rambam Health Care Campus, Haifa, ISRAEL.

Aim/Introduction: Cervical cancer is the fourth most common cancer among women both in incidence and in mortality. The treatment of choice in locally advanced cervical cancer is a combination of radiation with chemotherapy. However, 20-40% of patients do not achieve complete response. FDG PET/CT is a major diagnostic tool in the management of cervical cancer. The aim of this study was to assess the ability of quantitative pre-treatment FDG-PET/CT parameters to predict treatment response in newly diagnosed cervical carcinoma patients. **Materials and Methods:** 93 cervical carcinoma patients (29-85 years), were retrospectively enrolled in the study. All patients underwent FDG PET/CT scan at diagnosis and 3 months after treatment completion. For each patient demographical-biological parameters, treatment regimens (radiation and chemotherapy dosages) and metabolic-radiological parameters of the tumor at diagnosis and after completion of treatment (including tumor SUV max, SUV mean, primary tumor and metastatic lymph nodes size) were recorded. A complete response of the primary tumor was defined as no FDG uptake in the cervix on post treatment PET/CT. Based on this definition, the patients were divided into complete response (CR) and non-complete response (Non-CR) groups. **Results:** Primary tumor SUV max, SUV mean and tumor size measurements were found to be significantly lower in the CR group in comparison to the non-CR group. No statistically significant difference however was observed between these groups regarding the same parameters measured in metastatic lymph nodes. In addition, no satisfactory PET/CT derived parameters threshold in the primary tumor that enables distinguishing responders from non-responders could be established. Histologically, 73 patients had squamous cell carcinoma, 11 had adenocarcinoma and in 9 patients the tumor type record was not available. The complete response rate was 77% in patients with squamous cell carcinoma and 64% in those with adenocarcinoma. A sub-group of 14 (15%) patients had achieved complete response in the primary tumor but had metabolically active metastatic lymph nodes or distant metastases after completion of therapy. In this group patient age, lymph nodes SUVmax/mean, and size at diagnosis were significantly higher in comparison to the same parameters in those patients who achieved complete metastatic response. **Conclusion:** Primary tumor metabolic parameters at diagnosis were found to be associated to complete tumor response rate. Parameters related to lymph nodes involvement however, are not significantly associated to the primary tumor

treatment response. These finding might indicate that the primary tumor and its metastases may response differently.

FDG-PET/CT Leads A Better Target Volume Definition In Radiotherapy Of Locally Advanced Cervical Cancer

A. Palucci¹, L. Vicenz², C. Romagnolo¹, M. di Benedetto², G. Biscontini¹, F. Fringuelli¹, C. Cottignoli¹, F. Cucciarelli², G. Mantello², L. Burroni¹;

¹Nuclear Medicine, Ancona, ITALY, ²Radiotherapy Department, Ancona, ITALY.

Aim/Introduction: Concurrent chemo-radiotherapy is the elective therapeutic strategy in locally advanced cervical cancer. CT and MRI are routinely performed at diagnosis to evaluate disease extension. In our study, we assessed the impact of ¹⁸F-FDG-PET/CT acquired before radiotherapy in optimizing dose and volume prescription. **Materials and Methods:** 43 patients (pts) with locally advanced cervical carcinoma, treated between December 2015 and April 2020, were retrospectively analyzed. All patients underwent definitive Intensity Modulated Radiotherapy (IMRT) of pelvis +/- para-aortic region, followed by brachytherapy. All patients received Platinum based concomitant chemotherapy. CT was assessed in 35 patients and MRI in 41 patients. All the 43 patients underwent planning ¹⁸F-FDG-PET/CT. The total delivered dose was 45-50.4 Gy, 1.8 Gy/fr on the pelvis +/- paraaortic region and 54 Gy (50-56 Gy, 2-2.16 Gy/fr) with simultaneous integrated boost (SIB) on ¹⁸F-FDG-PET/CT positive nodes. **Results:** Local lymph nodal involvement was identified in 29 patients (67%). In 11 patients (26%), ¹⁸F-FDG-PET/CT showed pelvic positive lymph nodes in one or more areas, not detected in the other imaging techniques (PET+, CT SCAN-, MRI-): common iliac lymph nodes (LN) were shown in 3 pts, internal iliac LN in 4 pts, obturator LN in 4 pts, external iliac LN in 3 pts and perirectal LN in 2 patients. Radiotherapy Clinical Target Volume (CTV) was modified including para-aortic region in 8 patients with metabolically active nodes not evidenced in CT and MRI reports. **Conclusion:** In our experience, ¹⁸F-FDG-PET/CT leads to a better definition of the target volume, playing a crucial role in dose escalation and organ at risk sparing. **References:** None

EP-108

PET/CT in calcified metastatic ovarian serous papillary cystadenocarcinoma, mimicking a benign lesion on CT: two case reports

Z. Dancheva¹, A. Konsulova², P. Bochev³, B. Chaushev¹, M. Dyankova¹, T. Yordanova¹, A. Klisarova¹;

¹St Marina University Hospital, Varna, BULGARIA, ²Department of Oncology, Complex Oncological Centre, Burgas, BULGARIA, ³Acibadem Cityclinic Oncology center Sofia, Sofia, BULGARIA.

Aim/Introduction: Calcification is detected in 8% of all ovarian carcinomas and ~12% of serous ovarian tumours on computer tomography (CT) but is nonspecific as it may also be seen in benign serous tumours, following chemotherapy or in granulomatous diseases. The ability of PET/CT for metabolic activity assessment and the knowledge to expect a disease progression in calcified lesions could guide the biopsy, prompting initiation of treatment in patients with progressive ovarian carcinoma. **Materials and Methods:** We present two cases of patients with serous papillary ovarian carcinoma with calcified lesions. **Results:** During follow-up, both patients had progressive elevation of their tumor marker (Ca-125), and no other suggestion of progression, detected by clinical or conventional radiological imaging. CT findings included generalized lymphadenopathy, presented with small to medium size lymph nodes with calcifications and pleural masses with calcifications, initially falsely interpreted by CT as benign. Subsequently, patients were followed up by CT scans and no progression by RECIST criteria was registered. In view of the progressive CA 125 dynamics, a PET/CT was organized and it was helpful to identify disease progression in both patients. PET/CT also identified a biopsy site for histological confirmation of the disease progression. In both cases we observed similar findings -calcified lymph nodes and pleural masses presented with increased metabolic activity up to SUVmax 10.4. In general, serous ovarian cancer metastases rarely present with calcifications in contrast to metastatic lymph nodes in osteosarcoma, tuberculosis, silicosis, treated lymphoma, medullary thyroid carcinoma or colorectal mucinous adenocarcinoma. Large calcified pleural masses could be seen in tuberculosis, osteosarcoma, chondrosarcoma, mucinous adenocarcinoma types, etc. Although in ovarian carcinoma with progressively rising tumor marker, calcified lymph nodes and soft tissue masses might be taken into account and further examined. **Conclusion:** Calcified metastatic ovarian carcinoma may become a pitfall in CT imaging and RECIST criteria are unreliable in follow up of this kind of metastatic tumors as they only rely on dynamics of size. PET/CT lead to diagnosis of disease progression and identified the site for biopsy, thus prompting subsequent treatment in patients with progressive disease. It is an important diagnostic modality in elevated tumor marker and negative CT studies in ovarian carcinoma. **References:** Burkill G, Allen S, A'hern R, Gore M, Significance of tumour calcification in ovarian carcinoma., Br J Radiol. 2009 Aug;82(980):640-4. Detection of Second Primary Tumors in patients with head and neck cancers using FDG PET/CT as a screening imaging tool

T. Yordanova¹, A. Klisarova¹, B. Chaushev¹, T. Stoewa¹, Z. Dancheva¹, S. Chausheva¹, M. Dyankova¹, N. Sapundzhiev²;

¹Medical University Prof. dr P. Stoyanov, Department of nuclear medicine, Varna, BULGARIA, ²Medical University Prof. dr P. Stoyanov, Department of neurosurgery and ENT diseases, Varna, BULGARIA.

Aim/Introduction: The purpose of this study was to assess the efficacy of 18F fluorodeoxyglucose positron emission tomography and computed tomography (PET/CT) in detecting second primary tumors in patients with head and neck cancers (HNC). **Materials and Methods:** Retrospectively we analyzed 120 patients with initial HNC diagnosed between 2015-2017. The selected patients were with previous untreated HNC referred for FDG-PET/CT for staging and detection of unexpected second primary malignant neoplasms. The diagnoses of malignancy were confirmed with histopathology and imaging. **Results:** Nine second primary malignancy were identified from 120 patients. FDG-PET/CT correctly identified unexpected second primary cancers in 8 of these 9 patients, there was 1 false positive result. Most common localisation of the second primary malignancy were colorectal region 50%, thyroid gland 12.5%, lung 12.5%, head and neck 12.5% and renal 12.5%. FDG-PET/CT showed a sensitivity of 100%, a specificity of 99%, a positive predictive value 88.9%, a negative predictive value 100% and accuracy 99% identifying additional primary malignant neoplasms. **Conclusion:** The non-invasive whole body FDG-PET/CT is a useful as a screening imaging tool for detecting unexpected second primary malignancy in patients with Head and neck tumors. **References:** None

EP-110

Usefulness of MTV, TLG and SUVmax as predictive values of the response to definitive chemo-radiotherapy treatment in head and neck tumors

A. Santos Bueno^{1,2}, M. Guite Moreno^{1,2}, L. Rodriguez Perez¹, A. Herrero Muñoz³, J. Gutierrez Jodas¹, M. Albala Gonzalez^{1,2};

¹Hospital Universitario Reina Sofia, Córdoba, SPAIN, ²IMIBIC, Córdoba, SPAIN, ³Facultad de Medicina, Universidad de Córdoba, Córdoba, SPAIN.

Aim/Introduction: To assess the usefulness of tumor

metabolic volume (MTV), total lesion glycolysis (TLG) and SUV maximum (SUVmax) as predictors of the response to treatment in patients with head and neck tumors and the threshold value in which they present the highest diagnostic value. **Materials and Methods:** Retrospective study that includes 30 patients (27 males and 3 females) with a mean of age of 59.6 years old (range 42-72) who were diagnosed with head and neck cancer and underwent treatment with definitive chemo-radiotherapy. The response to the treatment was assessed in all cases by PET-CT 12 weeks after the end of treatment. Patients were labelled in two categories: whether they presented a complete response (responder group) or did not present it (non-responder group) (22 and 8 respectively). The SUVmax value and the MTV and TLG values, were measured in pre-treatment PET-CT by a VOI sphere with a threshold value of 40%, 45% and 50% of the SUVmax in the primary lesion. We performed hypothesis testing using the Mann-Whitney U test between each threshold value of MTV, TLG and SUVmax and the responder /non-responder groups, with a statistical significance value of $p < 0.05$. Receiver operating characteristic (ROC) curve analysis was accomplished to obtain optimal predictive cut-off values. **Results:** We found statistically significant differences ($p < 0.05$) of the MTV and TLG values in all the threshold values (40, 45 and 50%) between the responder group and the non-responder group, while the SUVmax value was not significant ($p = 0.056$). Analyzing the ROC curves of each of the threshold values of MTV and TLG, we found that all of them have an AUC (area under the curve) value greater than 0.79; being the highest one the MTV45 (AUC = 0.84; sensitivity 0.77, specificity 0.76, for a cut-off point value of 8.27). SUVmax AUC is 0.7 (sensitivity 0.66, specificity 0.8, for a cut-off point value of 18.85). **Conclusion:** Both MTV and TLG are good predictors of the response to treatment with definitive chemo-radiotherapy in patients with head and neck tumors, with the value of MTV45 showing the highest AUC value. **References:** None

EP-111

Comparison between the efficacy of physical examination/endoscopy with the efficacy of FDG-PET/CT for the identification of recurrence in head and neck squamous cell carcinoma after curative treatment

T. Yordanova¹, A. Klisarova¹, B. Chaushev¹, T. Stoewa¹, Z. Dancheva¹, S. Chausheva¹, M. Dyankova¹, N. Sapundzhiev²;

¹Medical University Prof. dr. P. Stoyanov, Department of nuclear medicine, Varna, BULGARIA, ²Medical University Prof. dr P. Stoyanov, Department of neurosurgery and ENT diseases, Varna, BULGARIA.

Aim/Introduction: The aim of our study was to compare the efficacy of physical examination/endoscopy (PE/E) with the efficacy of fluorodeoxyglucose (FDG)-positron

emission tomography/computer tomography (PET)/CT) for the detection of recurrence in head and neck squamous cell carcinoma (HNSCC) after curative treatment. **Materials and Methods:** We retrospectively reviewed total 21 curatively treated patients with primary head and neck squamous cell carcinoma. They were referred to Medical University Department of nuclear medicine Varna Bulgaria in the period 2015- 2017. All patients underwent physical examination/endoscopy and FDG-PET/CT scan during their follow-up period. The final diagnosis of local recurrence were confirmed by histopathology report. **Results:** PET/CT correctly identified local recurrence of the head and neck squamous cell carcinoma in 16 cases, 1 false positive and 4 true negative findings, there were no false negative results. Physical examination/endoscopy demonstrated 13 true-positive, 5 false positive, 3 false negative and 0 true-negative findings in a patient-basis. The sensitivity, specificity, accuracy, positive and negative predictive values for detecting local recurrence were 100%, 80%, 95%, 94% and 100%, respectively, for PET/CT versus 81%, 0%, 62%, 72%, and 0%, respectively, for PE/E. FDG- PET/CT scan identified sites suggestive local recurrence of HNSCC in 17 patients. The malignancy was located in the following localizations: larynx (n=6), nasopharynx (n=2), oropharynx (n=3) and oral cavity (n=6). **Conclusion:** FDG PET/CT has a high sensitivity and negative predictive value in the identification of the local recurrence in patients with head and neck squamous cell carcinoma and it is effective non-invasive method even if there is a diagnostic doubt after physical examination/endoscopy. **References:** None

Study on the Relationship Between SUVmax in F-18-FDG PET/CT and Expression of Ki-67 in Patients with Non-small Cell Lung Cancer

R. Wang^{1,2}, X. Liao¹, M. Liu¹, Y. Cui¹, Y. Fan¹, J. Zhang¹, X. Zhang¹, L. Di¹, Q. Jiang¹;

¹Peking University First Hospital, Beijing, CHINA, ²Peking University International Hospital, Beijing, CHINA.

Aim/Introduction: To investigate the association between the preoperative maximum standardized uptake value (SUVmax) of primary lesions measured on 18F-fluorodeoxyglucose positron emission tomography/computed tomography (F-18-FDG PET/CT) and expression of Ki-67 labeling index (Ki-67) in patients with non-small cell

lung cancer (NSCLC). **Materials and Methods:** One hundred and eleven patients with NSCLC received surgical treatment and the F-18-FDG PET/CT examination was performed preoperatively. The SUVmax values of F-18-FDG PET/CT were estimated, and the expression of Ki-67 in cancer tissue was detected with histoimmunochemistry SP method. The association between SUVmax and Ki-67 expression, and the association of dichotomized SUVmax (2.5), mean SUVmax and median SUVmax with Ki-67 was analyzed with multivariate Logistic regression, respectively. **Results:** Multiple linear regression showed regardless of pathological subtypes, TNM stage and maximum diameter of primary lesion, Ki-67 and SUVmax displayed a moderate correlation ($r=0.66$). In acinar predominant adenocarcinoma, N0 or N1-3, SUVmax was significantly correlated with Ki-67. Dichotomous SUVmax (cutoff point:2.5) was significantly associated with Ki-67 ($P=0.01$). **Conclusion:** A moderate relationship exists between the SUVmax values and Ki-67 expression. SUVmax ≥ 2.5 of primary lesion may suggest active tumor proliferation and poor prognosis of patients with NSCLC. **References:** None

Evaluation of Different Registration Landmarks for Thoracic MR-PET/CT Fusion Using High-Frequency Non-Invasive Ventilation (HF-NIV) for Lung Nodule Assessment

M. Jreige, M. Neury, M. Nicod Lalonde, N. Schaefer, E. Darçot, C. Beigelman, J. O. Prior;
Lausanne University Hospital, Lausanne, SWITZERLAND.

Aim/Introduction: To evaluate the co-registration of thoracic MR and PET/CT images acquired under HF-NIV and assess the effect of this ventilation technique in providing reproducible lung volume that would optimize sequential image fusion and thus allow the feasibility of low-cost, virtual thoracic PET/MR imaging. **Materials and Methods:** Four patients known for a suspicious lung nodule underwent both PET/CT and MR under HF-NIV. On both HF-NIV axial MR and CT images, eleven thoracic anatomical landmarks were manually located, including the lesion center, using landmark co-registration application (AW workstation, GEMS). For each pair of landmarks, mean and maximum co-registration errors were calculated for fusion of HF-NIV-MR with either HF-NIV-CT or free-breathing-(FB)-CT of PET/CT. Co-registration of HF-NIV-CT and an undersampled-HF-NIV-MR reconstruction using only movement-free raw data were tested in cases of significant respiratory motion (n=3). **Results:** For the 11-thoracic landmarks, the mean and maximum co-registration errors were 20.6 ± 7.3 and 32.8 ± 13.9 mm in HF-NIV-MR/FB-CT; 8.0 ± 2.9 and 15.6 ± 7.1 mm in HF-NIV-MR/HF-NIV-CT; 6.4 ± 3.1 and 12.3 ± 7.8 mm in undersampled-HF-NIV-MR/HF-NIV-CT. Mean lesion co-registration error was 16.3 ± 6.0 mm, 5.3 ± 3.2

mm and 5.0 ± 4.2 mm in HF-NIV-MR/FB-CT, HF-NIV-MR/HF-NIV/CT and resampled-HF-NIV-MR/HF-NIV-CT, respectively. HF-NIV allowed to reduce co-registration error by 61%, 52%, 68% for mean, maximum and pulmonary lesion errors, reaching 69%, 62% and 70% with HF-NIV-MR motion-free-sampling. **Conclusion:** We showed a notable error reduction of sequential thoracic PET/CT and MR co-registration using HF-NIV. This optimization of thoracic HF-NIV-PET/MRI fusion for assessing lung nodules has the advantage of creating a low-cost hybrid "PET/MR" from sequential, separate PET-MR acquisitions, which allows for easier accessibility and better hybrid fusion results. **References:** None

EP-114

Diagnostic effect of benign lung changes in initial cancer staging with F-18 FDG PET/CT. The Kwa-Zulu Natal experience

N. Nyakale^{1,2}, J. Kabunda², C. Kalinda^{3,2}, L. Harry^{1,2}, P. Ramdass², T. Ebrahim²;

¹Sefako Makgatho Health Sciences University, Pretoria, SOUTH AFRICA, ²University of Kwa-Zulu Natal, Durban, SOUTH AFRICA, ³University of Namibia, Namibia, SOUTH AFRICA.

Aim/Introduction: The incidence of lung pathology in sub-Saharan Africa is high due to the high prevalence of pulmonary infections and inflammatory disorders including granulomatous diseases such as tuberculosis or sarcoidosis. This is known to compromise evaluation of metastatic lung involvement when staging patients with malignancy. The aim of this study was to determine the ability of a single phase PET to characterize lung disease involvement during the staging of treatment naïve cancer patients in our patient population in Kwa-Zulu Natal. **Materials and Methods:** A retrospective analysis of patients referred for initial staging of cancer with F-18 FDG PET/CT scan in the period between 2014 and 2017. The PET and CT lung findings, reported by an experienced Nuclear Physician and Radiologist respectively, were recorded and confirmatory findings were assessed based on pathological results and /or follow-up imaging. Lung findings were classified as benign, metastases or equivocal. Patients with lung cancer, no confirmed primary or no histological confirmation of malignancy were excluded. Data obtained was analysed by comparing the level of agreement between the PET and CT lung findings using the variance-ratio test and concordance correlation tests. **Results:** A total of 326 patients (180 females, 146 males) with a mean age (\pm SD) of 50.9 ± 16.5 were included. The cancer types were variable with the most common being lymphoma, oesophagus and breast cancer. There was no FDG uptake noted in the lungs in 55% of patients, no CT changes were noted in 32%. The PET scan reported lung metastases in 28% (n=91), benign changes in 12% (n=40) and equivocal in 4.6% (n=15) of patients. The CT reported the lung metastases in 29% (n=96), benign

changes in 23% (n=74) and equivocal in 15% (n=49) of patients. The mean SUV_{max} in metastases was 7.5 ± 0.598 while reported benign disease was 3.88 ± 0.615 . Using the variance ratio test, statistical differences were observed in the PET and CT lung findings ($F_{325, 325} = 0.6672$, $P = 0.003$). There was no concordance achieved in the PET with the CT lung findings ($\rho = 0.348$, 95% CI: 0.266-0.430, $p \leq 0.001$) nor with the final diagnosis ($\rho = 0.341$, 95% CI: 0.245-0.437, $p \leq 0.001$). **Conclusion:** PET findings are not able to successfully characterize the changes in the lungs at initial staging of cancer patients due to the high prevalence of pulmonary infection and inflammation in the Kwa-Zulu Natal population and require anatomical description as well as histological confirmation to increase specificity. **References:** To be provided during the presentation

Semi-quantitative analysis of ¹⁸F-FDG PET/CT in single pulmonary lesion: the role of blood glucose level and body mass index normalization

A. Capozza¹, C. Dolci¹, A. Scarale¹, A. Franchini², I. Gotuzzo², E. Gay¹, G. Cabrini¹, M. Milella¹, C. Rossetti¹;

¹Nuclear Medicine Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY, ²Nuclear Medicine, University of Milano-Bicocca, Milan, ITALY.

Aim/Introduction: ¹⁸F-FDG PET/CT is widely applied for metabolic characterization of pulmonary nodules. In clinical practice, FDG uptake is commonly evaluated with a standard parameter normalized by body weight, SUV_{MAX}. Nevertheless, this value is burdened by several factors that limit its reliability. Few correction factors have been proposed to overcome this limitation, such as blood glucose level (SUV_{BGL}) and body mass area (SUV_{BMI}). Aim of this study is to evaluate the accuracy of different normalization of FDG uptake, in detecting malignancy in single lung lesions, both in general population and in a subgroup of diabetic subjects. **Materials and Methods:** ¹⁸F-FDG PET/CT scans performed, between 04/2014 and 02/2020, were retrospectively reviewed. Patients, referred to our Unit for metabolic characterization of single pulmonary lesions, were selected. Semi-quantitative analysis was performed to assess FDG uptake in pulmonary lesions; the uptake value, SUV_{MAX} was then normalized by blood glucose level (BGL) and body mass index (BMI). Histological analysis reports, performed on bioptical or surgical samples on each patient, were collected. Student's t-test was performed to evaluate the association between malignancy of pulmonary single lesion and tracer uptake entity, normalized by body weight, BMI and glycemia. **Results:** Seventy-nine patients (55male/24female) were enrolled. Population had median age of 70 years (range 51-89) and mean BMI 26.2 (16.66-41.80); 11/79 (14%) patients were treated for diabetes and presented mean BGL= 131 ng/mL (90-155) pre-FDG

injection. The population was divided in two groups: benign abnormalities (n=22) vs malignant lesions (n=57), according to histopathological findings. FDG-PET/CT semi-quantitative analysis showed an overall mean $SUV_{MAX}=7.76$ (0.45-29.21); SUV_{MAX} 3.69 (0.45-24.97) and 9.59 (0.54-29.21) in benign and malignant group of patients, respectively. A statistically significant correlation was found between histopathological findings and all three uptake parameters evaluated, SUV_{BML} showing a slightly less significant correlation: SUV_{MAX} $p < 0.01$, SUV_{BGL} $p < 0.01$ and SUV_{BML} $p = 0.03$. Selecting diabetic patients, the sub-population presented mean BMI = 27.31 (28.13-29.14), with 55% (6/11) patients overweight and the remaining 5/11 in healthy BMI-range. In diabetic patients' subgroup, no significant correlation was seen between malignancy and SUV_{MAX} , nor with SUV_{BML} : p value = 0.17 and 0.33 respectively. The only statistically significant correlation (p value = 0.01) was found between malignancy and SUV_{BGL} . **Conclusion:** Overall, SUV_{MAX} measured on FDG-PET shows good accuracy in differentiating benign alterations from malignancy, in pulmonary lesions. However, in diabetic population, normalizing the uptake value according to glycemia might be a more reliable method to properly identify lesions with higher malignant likelihood. **References:** None

Value Of [¹⁸F]FDG PET/CT In The Diagnosis Of Thoracic Lymph Node Metastasis In Non-Small Cell Lung Cancer

M. Calderón Calvente¹, S. Álvarez Ruiz¹, M. Sangrós Sahún¹, L. Nieto Morcillo¹, G. Guzmán Prudencio¹, L. Del Barco Díez Canseco¹, P. Navarro Beltrán², M. Falgás Lacueva¹, L. De la Cueva Barroa¹, D. Abós Olivares¹;

¹Hospital Universitario Miguel Servet, Zaragoza, SPAIN,

²hospital universitario miguel servet, Zaragoza, SPAIN.

Aim/Introduction: To assess the diagnostic effectivity of [¹⁸F]FDG PET/CT in thoracic nodal characterization of recently diagnosed patients with non-small cell lung cancer in our hospital, relating it to nodal histopathological results.

Materials and Methods: Patients with non-small cell lung cancer who had PET/CT scan during initial staging (May to December 2019) were selected. Data was collected of nodal SUV_{max} , considering positive nodes those with $SUV_{max} \geq 2.5$. When available, citohistopathological results from lymphadenectomy were used as Gold Standard, using those of US guided bronchoscopy otherwise. To evaluate the results, contingency tables were constructed for each node station, assigning values for TP, TN, FP and FN. Secondly, an analysis "per station" was performed, in two groups, bronchopulmonary and mediastinal, calculating sensitivity (SE), Specificity (SP), Positive Predictive Value (PPV) Negative Predictive Value (NPV) and its 95% confidence intervals (95% CI). Finally an analysis "per patient" was performed with imaging findings that involve N2-N3 staging (any

positive node in PET/CT in mediastinal or contralateral bronchopulmonary stations) according to the 8th edition of the TNM classification. **Results:** 43 patients were collected (mean age 68 years old, 88% men, 12% women) with non-small cell lung cancer (adenocarcinoma 53%, squamous 37%, big-cell 5%, undifferentiated 5%). When evaluating all lymph node stations, prevalence of metastasis in our sample is 25%, obtaining SE 0'81 (95%IC(0'64-0'93)), SP 0'84 (95%IC(0'77-0'92)), PPV 0'64 (95%IC(0'5-0'78)) and NPV 0'93 (95%IC(0'88-0'98)) in PET/CT's identification of nodal metastasis. When comparing bronchopulmonary and mediastinal territories, we find SE 0.75 (95%IC(0'35-0'97)), SP 0.81 (95%IC(0'64-0'93)), PPV 0.5 (95%IC(0'21-0'79)) and NPV 0.93 (95%IC(0'77-0'99)) for the former and SE 0.84 (95%IC(0'64-0'95)), SP 0.86 (95%IC(0'75-0'93)), PPV 0.7 (95%IC(0'51-0'85)) and NPV 0.93 (95%IC(0'83-0'98)) for the latter. The prevalence for positive nodes was 19'5% and 28% respectively. When analyzing "per patient", the results for the identification of patients with N2-N3 stage were SE 0'9 (95%IC(0'68-0'98)), SP 0'78(95%IC(0'56-0'92)), PPV 0'78 (95%IC(0'56-0'92)) and VPV 0'93 (95%IC(0'68-0'99)) (prevalence 46'5%). **Conclusion:** 1 SE and SP results of PET/CT for diagnosis of thoracic lymph node metastasis is in line with the published evidence. 2. In view of the low PPV, PET/CT positive results which establish N2-N3 staging must be citohistologically confirmed so as not to deprive FP patients of an appropriate curative treatment. However, we must bear in mind that some FP in our study may be due to EBUS low sensitivity. 3. Negative results allow to generally rule out node metastasis, as long as clinical suspicion (prevalence) is not high. **References:** None

EP-117

Lymphonodular anthracosis in patients undergoing FDG PET/CT for initial lung cancer diagnostics and/or staging is a mayor pitfall: a comparison to the histological gold standard

H. Hautzel¹, T. Plönes², K. Darwiche³, W. P. Fendler¹, C. Rischpler¹, D. Theegarten⁴, C. Aigner², K. Herrmann¹;

¹University Hospital Essen, Department of Nuclear Medicine, Essen, GERMANY, ²University Medicine Essen - Ruhrlandklinik, Department of Thoracic Surgery and Thoracic Endoscopy, Essen, GERMANY, ³University Medicine Essen - Ruhrlandklinik, Department of Pneumology, Division of Interventional Bronchology, Essen, GERMANY, ⁴University Hospital Essen, Department of Pathology, Essen, GERMANY.

Aim/Introduction: Coal miners demonstrate an increased incidence of various pneumoconioses, especially coal dust induced anthracosis. Case reports indicate that anthracosis might lead to false positive findings in FDG PET/CT for diagnosing or staging of lung cancer with regards to lymph node involvement. However, no larger series of patients with lung cancer and anthracosis undergoing FDG

PET/CT have been investigated so far. Nonetheless, the concurrent appearance of these diseases is of particular relevance in areas with coal mining industries. Aim of this study was to elucidate the diagnostic performance of FDG PET/CT in n-staging of patients synchronously suffering from lung cancer and anthracosis with respect to the histopathological gold standard. **Materials and Methods:** 23 patients were retrospectively identified in the period from 01/2018 to 03/2020 who were referred for FDG PET/CT imaging of previously untreated lung cancer or pleural mesothelioma, subsequently underwent either surgery (n=14), mediastinoscopy (n=4) or systematic ultrasound-guided bronchoscopic (EBUS-TBNA) lymph node sampling (n=5), and finally were diagnosed with lymph node anthracosis with or without lymph node metastasis. Per patient 12+/-6 lymph nodes were investigated. Sensitivity, specificity, accuracy, positive predictive value (PPV) and negative predictive value (NPV) of FDG PET/CT for thoracic n-staging were calculated taking the lymph node histology as gold standard. **Results:** In 15 of 23 patients the final diagnosis was lung cancer, in 2 of 23 pleural mesothelioma and 6 of 23 had a benign lesion. In the context of concurrent anthracosis FDG PET/CT identified lymph node malignancy with a sensitivity of 100% and NPV of 100% but with severely impaired specificity (23%), accuracy (32%) and PPV (6%). **Conclusion:** Due to an increased glucose consumption in thoracic lymph nodes with anthracotic changes FDG PET/CT yields a high rate of false positive results when used for n-staging of lung cancer or pleural mesothelioma. Therefore, its diagnostic accuracy is limited in patients with pulmonary malignancies and potentially coexisting anthracosis. In this specific setting only a negative FDG PET/CT is reliable in terms of an appropriate n-staging. **References:** None

EP-118

The relationship between the standard uptake value and the BMI in the patients with lung cancer: A study of PET-CT scans

Z. Zhao¹, S. Jia¹, J. Zhang², H. Yang³;

¹Shenzhen Yunshan Yinghe medical imaging diagnosis center, Shenzhen, CHINA, ²Shenzhen shajing people's hospital, Shenzhen, CHINA, ³Peking University Shenzhen Hospital, Shenzhen, CHINA.

Aim/Introduction: The standard uptake value (SUV) was widely used in the positron emission tomography (PET) examination in the patients with cancer. In general, the focal zone of the malignant tumor often has a higher SUV. As a measure of overweight, BMI was also used to evaluate the patients' physical condition. For patients with cancer, physical condition was also important. While, the relationship between the SUV and BMI in the patients with lung cancer is not clear. In this study, we intended to explore this relationship using 18F-FDG PET. **Materials and Methods:** 31 patients with lung cancer were enrolled in this

study. 15 of them had the BMI less than 22.4 (group 1) and 16 matched controls had the BMI more than 22.4 (group 2). All of these patients received the 18F-FDG PET/CT scanning. The SUVmax was used only in this study and it was got by the hand-painted measurement. The student's t test was used to estimate the differences between groups. Nominal P values of less than 0.05 were considered to demonstrate statistically significant differences. **Results:** The media SUVmax was 10.57±6.86 in group 1 and 11.91±5.86 in group 2. The highest SUVmax was 25.4 in group 1 and 24.6 in group 2. The lowest SUVmax was 1.4 in group 1 and 4.9 in group 2. There was no significant difference between the two groups (P = 0.565). **Conclusion:** This study demonstrated there was no significant difference of SUVmax between the high BMI patients and the low BMI patients with the lung cancer. As the diagnosis of these patients were same, the characteristic of PET/CT scanning were also same in spite of the difference of the BMI. That means for the patients with the same cancer, different BMI of the patients indicate the same characteristic of the cancer. This can give us more information about this disease and help us to know better about the lung cancer. **References:** None

EP-119

Comparison of the image quality and precision of fused lung images acquired by FDG PET/MRI with ZTE and PET/CT

J. Inukai¹, M. Nogami¹, F. Zeng¹, T. Kurimoto², T. Murakami¹;

¹Department of Radiology, Kobe University Graduate School of Medicine, Kobe, JAPAN, ²GE Healthcare, Hino, JAPAN.

Aim/Introduction: Although lung imaging by magnetic resonance imaging (MRI) remains challenging, advent of newer technologies such as pulse sequences, including zero echo-time imaging (ZTE), yields better image quality than conventional sequences. This study examined images acquired by positron emission tomography (PET)/MRI using ZTE and PET/computed tomography (CT). The image quality of normal lung structures and the precision for identifying lung lesions in fused images acquired by hybrid scanners were compared statistically. **Materials and Methods:** For image quality assessment, one hundred age-, sex-, and body-mass index- matched patients who underwent FDG PET/MRI (n=50) or PET/CT (n=50) were retrospectively evaluated. Normal lung structures were separately evaluated for subjective image quality in the upper and lower lung fields on two-point-Dixon T1-weighted (Dixon), ZTE, and CT images by two radiologists using a 5-point visual scoring system, followed by statistical comparison using Kruskal-Wallis test. Inter-reader agreement was tested by Cohen's kappa coefficient. To evaluate precision from the fused images, the FDG-avid lung nodules (diameter, ≤ 1 cm) of 118 matched patients were assessed on FDG PET/MRI (n=59) and PET/

CT (n=59) images for both lung fields. The distances of the lung lesions between PET and MRI (dist-PET/ZTE and dist-PET/Dixon) images and that between PET and CT (dist-PET/CT) images were semi-automatically calculated by measuring the distance between the coordinates of the centre of the regions of interest placed on respective lung lesions. The degree of misregistration of the lung lesions were statistically compared between dist-PET/ZTE, dist-PET/Dixon and dist-PET/CT images by Kruskal-Wallis test. **Results:** Image quality of normal lung structures by PET/MRI with ZTE was significantly superior to that by Dixon between both readers and in both lung fields ($p < 0.000001$), but significantly inferior to CT ($p < 0.000001$). A substantial agreement (weighted kappa=0.68) was firmed in the inter-rater assessments for image quality. The degrees of lung lesion misregistration with PET/Dixon (3.574 ± 1.520 mm) and PET/ZTE (2.832 ± 1.432 mm) were significantly smaller than that with PET/CT images (6.806 ± 4.457 mm) ($p < 0.0001$ and $p = 0.0006$, respectively) in lower lung fields. The upper lung fields showed no significant differences in misregistration when compared between dist-PET/ZTE and dist-PET/Dixon with dist-PET/CT ($p = 0.6346$ and $p = 0.5774$, respectively). **Conclusion:** PET/MRI with ZTE provides superior image quality of the normal lung structures than conventional Dixon sequences, but inferior to the CT component of PET/CT. Fused images of lung lesions with PET/MRI provides significantly better precision than PET/CT images. Therefore, PET/MRI could be used to acquire spatially-matched, precise, hybrid images of lung lesions. **References:** None

EP-120

Establishment and Verification of an ^{18}F -fluorodeoxyglucose (FDG) PET/CT Based Prediction Model for Identifying Malignant from Benign Ground-Glass Nodules

R. Niu, X. Shao, X. Shao, J. Wang, Y. Wang;
The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: In recent years, with the popularity of low-dose CT in lung cancer screening, the detection rate of ground-glass nodule (GGN) has gradually increased. GGN is common in early-stage lung adenocarcinoma but can also be a result of inflammation, interstitial fibrosis, or local bleeding. But, any single CT morphological feature or quantitative parameter is ideal for the differential diagnosis of GGN, and a multivariate prediction model is likely to improve the diagnostic performance for GGN. Currently, few prediction models are dedicated to GGN prediction. In this study, we aim to build a prediction model based on ^{18}F -FDG PET/CT imaging, and take both functional metabolism and CT image characteristics into account, in order to improve the efficacy of identifying malignant from benign GGNs.

Materials and Methods: We retrospectively analyzed 170 patients with GGN (197 GGNs in total) who underwent PET/CT examination in our hospital from November 2011 to December 2019. The clinical and imaging data of all patients were collected, and the nodules were evenly and randomly divided into derivation set and validation set. For the derivation set, we used multivariate logistic regression to develop a prediction model for distinguishing benign and malignant GGNs. The receiver operating characteristic (ROC) curve was used to evaluate the diagnostic efficacy of the model, and the data in the validation set was used to verify the prediction model. **Results:** The 197 GGNs were classified into benign group (27) and adenocarcinoma group (170). A total of 5 parameters, including the patient's gender, nodule location, margin, pleural depression, and SUV index (the ratio of nodule SUVmax to liver SUVmean), were selected to develop a prediction model for distinguishing benign and malignant GGNs. The AUC of the model was 0.875 in the derivation set, with a sensitivity of 0.702 and specificity of 0.923. The positive likelihood ratio was 9.131, and the negative likelihood ratio was 0.322. In the validation set, the AUC of the model was 0.874, which was not significantly different from the derivation set ($P = 0.989$). **Conclusion:** The prediction model based on PET/CT imaging has good diagnostic efficacy and high specificity. It can be used to distinguish benign and malignant GGNs. **References:** None

Value of total metabolic tumor burden as predictor of overall survival in NSCLC patients treated with pembrolizumab

D. Calabro¹, F. G. Dall'Olio², F. Formica², G. Argalia¹, S. Fantì¹, A. Ardizzoni², V. Ambrosini¹;
¹Nuclear Medicine, S.Orsola-Malpighi Hospital, DIMES University of Bologna, Bologna, ITALY, ²Sant'Orsola-Malpighi Teaching Hospital, University of Bologna, Medical Oncology Unit, Bologna, ITALY.

Aim/Introduction: Pembrolizumab has improved the outcome of patients with advanced NSCLC and $\geq 50\%$ PDL1 expression. Predictive factor of benefit from immunotherapy alone are lacking. Total metabolic tumour volume (TMTV) $\geq 75\text{cm}^3$ has been shown to be a predictor of shorter overall survival (OS) in non-small cell lung cancer (NSCLC) patients (pts) treated with immunotherapy in advanced setting (DOI:10.1007/s00259-019-04615-x). Our aim is to confirm this finding in first line pembrolizumab. **Materials and Methods:** We retrospectively enrolled pts with advanced NSCLC (stage IV) and PD-L1 expression $\geq 50\%$ (Ethical Committee approval no. 2381/2019). Only those with a positive [^{18}F]18F-FDG PET/CT performed at our center within 60 days of treatment initiation were included in the study. MTV was calculated for each lesion by a

dedicated software (PETVCAR, GE Healthcare) on transaxial PET images, that semi-automatically delineates the tumour contours with a SUVmax threshold of 42% within the lesion. The results were checked by comparison with the fused CT images to determine if percentage threshold adjustment was needed and therefore was performed until a satisfactory outcome was achieved. TMTV was obtained summing each single lesion's MTV. Potential prognostic parameters for OS were analysed (TMTV, SUVmax, presence of bone/live metastasis, neutrophil/lymphocyte ratio \geq 4, ECOG Performance Status \geq 2, LDH>ULN). **Results:** Overall, 32 pts (squamous=5; non-squamous=27) were included (median follow up= 13.5 months, 95% CI [10.1 - 17.0]). Pts with a TMTV \geq 75cm³ (18/32 pts) showed a worse outcome (median OS= 4.7 mo, 95% CI [1 - 8.4] vs not reached). Parameters associated with worse outcome both in univariate and multivariate analysis were TMTV \geq 75cm³ (HR=11.3; 95% CI [2.3 - 55.2], p=0,01), neutrophils/lymphocyte ratio \geq 4 (HR=13.3; 95% CI [2.8- 64], p=0,002), ECOG PS \geq 2 (HR=9.1; 95% CI [1.8-46.2], p=0,006). **Conclusion:** Our data showed that TMTV \geq 75cm³ can be used as predictor of outcome in pts candidate to first line pembrolizumab, suggesting that this parameter could be useful for the early identification of pts needing the association of chemo-immunotherapy. **References:** DOI:10.1007/s00259-019-04615-x

EP-122

Molecular imaging as a predictive biomarker response to Ceritinib in ALK-Rearranged Non-Small-Cell Lung Cancer

S. Medina-Ornelas, F. Garcia-Perez, O. Arrieta-Rodriguez, F. Barron-Barron;

Instituto Nacional de Cancerologia, Mexico City, MEXICO.

Aim/Introduction: Demonstrate the usefulness of ¹⁸F-FDG-PET/CT as a predictive tool for response to treatment of patients with non-small-cell lung cancer with ALK-rearrangement (NSCLC-ALKr) treated with ceritinib. **Materials and Methods:** We studied 20 patients with NSCLC-ALKr with ¹⁸F-FDG-PET/CT as a baseline study from two institutions between April 2017 to February 2020. All patients were treated with ceritinib at dose of 750mg/day. An evaluation was made by ¹⁸F-FDG-PET/CT after 1 month of treatment (28 \pm 7 days) and one month after 6-10 cycles (mean 6 cycles). Obtaining SUVmax, SUVmean, VTMA (metabolically active tumor volume) and TLG (total lesion glycolysis) values, RECIST 1.1 and PERCIST 1.0 criteria was performed. The best cut discriminative values for SUVmax, VTMA and TLG were identified by ROC curves. The analysis of semiquantitative values was made with Fisher's exact test and Cox regression. A significant value of p was considered when this was \leq 0.05. **Results:** The mean values of the initial SUVmean was 8.2 \pm 3.9 SD, after the first cycle (interim) SUVmean was 6.3 \pm 3.8 SD in target lesions; and 3.7 \pm 4.1 SD after the last cycle. The mean values of the initial SUVmax were 13.4 \pm 7.6 SD, 6.2 \pm 5.8 SD

interim; and 4.6 \pm 4.3 SD after the last cycle. The mean values of the initial VTMA were 34.9 \pm 65.8 SD, 23.0 \pm 49.8 SD interim, and 21.0 \pm 39.5 SD after the last cycle. The mean values of the initial TLG were 269.4 \pm 1028.1 SD, 231.8 \pm 667.2 SD interim, and of 208.0 \pm 395.9 SD after the last cycle. In the analysis after the first cycle, no patient presented disease progression assessed. In the analysis after the last cycle, 15 patients presented a partial metabolic response, of which 12 had a statistically significant decrease in TLG after the first cycle; while those with stable disease did not show a statistically significant decrease after the first cycle. At the end of the last cycle through the RECIST criteria, 5 patients had stable disease. The measurement of the TLG was the most significant parameter for the prediction of response to treatment in the univariate analyzes (p=0.001). In the multivariate analysis with the Cox regression method, a low TLG, and the clinical stage before therapy were significant prognostic factors to present good response to treatment (p=0.001). **Conclusion:** The TLG is an excellent response prediction parameter superior to values of SUVmax, SUVmean or VTMA. Low TLG values after first cycle associated with a clinical stage IIIC or IVa can predict a good response to treatment. **References:** None

EP-123

Clinical role of F-18 FDG PET/CT in thymic epithelial tumors

K. Hayasaka, T. Saitoh, H. Inoue, Y. Shiraishi, J. Atsumi, T. Tohgoh, M. Hiramatsu, K. Shimoda, H. Yoshimori, K. Ohta; Fukujuji Hospital, Anti-Tuberculosis Association, Tokyo, JAPAN.

Aim/Introduction: We aimed to determine whether ¹⁸F-FDG PET/CT is useful for the 8th UICC staging and WHO classification of thymic epithelial tumors. **Materials and Methods:** We retrospectively reviewed the medical records, PET and other findings of 36 patients (male, n = 16; mean age [SD], 64.8 [10.9] y) with thymic epithelial tumors who underwent ¹⁸F-FDG PET/CT. The maximum standardized uptake (SUVmax) of ¹⁸F-FDG within one hour was determined and the findings of thymic epithelial tumors, lymph nodes and distant metastases were reviewed. According to the WHO classification, thymic epithelial tumors were grouped as low risk (types A, AB, B1), high risk (types B2, B3) and carcinoma. All data were statistically analyzed using SPSS version 11.0 software (SPSS Inc., Chicago, IL, USA). Statistical significance was set at p < 0.05. **Results:** Thymic epithelial tumors were confirmed in 32 surgical and four surgical biopsy specimens. The histological classifications were thymoma (n = 23; A, n = 3; AB, n = 7; B1, n = 4; B2 and B3, n = 9), carcinoma (n = 13, squamous cell carcinoma (n = 10), adenocarcinoma (n = 1) and well-differentiated neuroendocrine carcinoma (n = 2). The thymomas were staged as I (n = 14), II, (n = 1), III (n = 5), and IV (n = 1). The mean (SD) tumor size (mm) and SUVmax

were respectively 57.1 (25.6) and 3.24 (1.04) in low risk, 67.4 (21.6) and 6.57 (2.50) in high risk, 64.6 (30.0) and 9.53 (4.86) in carcinoma, 55.1 (23.0) and 3.81 (2.07) in stage I/II, and 72.8 (16.1) and 3.81 (2.07) in stage III/IV thymomas. Pearson correlation analysis revealed a statistically significant association between tumor size and SUVmax in stage III/IV thymomas ($r = -0.855$, $p = 0.030$). Analysis of variance showed that differences were statistically significant for low vs. high risk ($p = 0.008$), low risk vs. carcinoma ($p = 0.001$), and stage I/II vs. III/IV thymoma ($p = 0.007$). **Conclusion:** We found that 18-F FDG PET/CT was useful for differentiating histological types and staging the extent of thymic epithelial tumors. **References:** Park SY et al. Value of F18-FDG PET/CT for predicting the World Health Organization malignant grade of thymic epithelial tumors. Clin Nucl Med 2016;20: 15-20

EP-124

Prediction of overall and free progression survival by means of post-induction chemo/chemoradiotherapy ¹⁸F-FDG PET/CT in non-small cell lung cancer patients

P. García-Talavera San Miguel, F. Gómez-Caminero, J. G. Villanueva, B. Lucas, C. Riola, A. C. Peñaherrera, J. C. Cañadas, E. Martín, P. Tamayo;
Nuclear Medicine. University Hospital of Salamanca, Salamanca, SPAIN.

Aim/Introduction: To demonstrate the value of post-induction ¹⁸F-FDG PET-CT as a predictive factor of the progression free survival (PFS) and overall survival (OS), in locally advanced non-small cell lung cancer patients (LA-NSCLC), treated with neoadjuvant Chemotherapy (CH), or Chemoradiotherapy (CH-RT) **Materials and Methods:** Thirty patients with LA-NSCLC were included (20 males; mean age: $62,3 \pm 9,2$ years old; histology: 13 adenocarcinomas and 17 squamous cell carcinomas; Staging (8th ed. AJCC): IIB (3), IIIA (13), IIIB (10), IIIC (4). Two ¹⁸F-FDG PET-CT studies were acquired to all patients. One of staging (PET1), and the other post-neoadjuvant CH (28 patients) or CH-RT (2 patients) (PET2), acquired 3 weeks after the end of treatment. SUVmax, SUVmean, MTV (metabolic tumor volume) and TLG (total lesion glycolysis) were analyzed in PET2, as well as Δ TLG and Δ SUVmax. Patients were monitored by means of clinical and radiological follow up (CT or PET-CT). PFS and OS were collected from the moment of PET2 acquisition. PFS and OS Curves were performed, by means of Kaplan Meir analysis and Log Rank test, after calculation of cut off values of the variables, based on ROC curves. SPSS 22.0 version was used for the statistical analysis (statistical significance: $p < 0.01$) **Results:** Regarding to the ROC curves for PFS, only Δ SUVmax reached established statistical significance, getting 45.4% as the best cut off ($p=0.004$), with a sensitivity of 92% and specificity of 71%. In survival curves, a PFS of 25 months for a decrease $> 45.4\%$ vs 7.6 months for a decrease $< 45.4\%$ were

obtained ($p=0.003$). For ROC curves of OS, SUVmean and SUVmax achieved statistical significance. We obtained as optimal cut off 7.9 ($p=0.007$) for SUVmean and 14.1 ($p=0.01$) for SUVmax. Sensitivity of 71% and 100% of specificity, for both parameters, were found. In Kaplan Meier curves, a OS of 15.8 months vs 34.6 months were obtained, for a SUVmax >14.1 and SUVmax <14.1 ($p=0.000$), respectively. With regard to SUVmed, 12.4 months vs 34.6 months, for a SUVmean >7.9 and <7.9 ($p=0.000$), respectively. **Conclusion:** Some parameters, SUVmean and SUVmax, from post-induction ¹⁸F-FDG PET-CT, and Δ SUVmax (from PET1 and PET2), have demonstrated to be predictive factors for PFS and OS, in patients with LA-NSCLC, treated with neoadjuvant CH or CH-RT. **References:** None

Evaluation of regional lymph node involvement in the staging of non-small cell lung cancer with 18F FDG PET/CT

M. Keskin;
Mersin City Training and Research Hospital, Mersin, TURKEY.

Aim/Introduction: To evaluate the diagnostic performance of mediastinal blood pool activity (MBP) threshold for lymph node staging of non-small cell lung cancer (NSCLC) in PET / CT and examining other variables that may improve the diagnostic performance of 18F FDG PET / CT in evaluating regional lymph node involvement by taking advantage of mediastinal blood pool activity. **Materials and Methods:** Patients diagnosed with NSCLC who underwent endobronchial ultrasound guided transbronchial needle aspiration (EBUS-TBNA) and 18F-FDG-PET / CT were included in the study. Analysis of lymph node station and lymph node staging, MBP threshold value and five other PET / CT parameters (lymph node SUVmax value, lymph node short diameter, lymph node / MBP SUVmax ratio, lymph node / tumor SUVmax ratio, and lymph node SUVmax / lymph node short diameter ratio) compared with histopathological results. Optimal threshold values were determined using receiver operating characteristic curve analysis to compare the diagnostic value of all parameters examined in PET / CT. **Results:** Eighty eight patients were included in the study and pathological samples were performed from 250 lymph node stations. The higher lymph node activity in PET / CT than MBP showed a sensitivity of 95.3%, a specificity of 36.1%, a positive prediction value of 33.1% and a negative prediction value of 96.2%. From the other five PET / CT parameters examined, lymph node SUVmax value and lymph node / MBP SUVmax ratio were the most diagnostic parameters. The 3.8 threshold value for lymph node SUVmax showed a sensitivity of 90.2% and a specificity of 61.7%, and the 1.8 threshold for lymph node/MBP SUVmax ratio showed a sensitivity of 90.1% and a specificity of 60.5%. **Conclusion:** Compared to the MBP

threshold value in the nodal staging of the NSCLC, the use of higher lymph node / MBP SUVmax ratio threshold value and other PET / CT variables may increase the diagnostic value of PET / CT. **References:** None

Role of 18F-FDG PET/CT in the evaluation of response to therapy in non-small-cell lung cancer (NSCLC) patients treated with immunotherapy (preliminary results)

M. Suarez-Piñera¹, A. Taus², D. Rama³, L. Pijuan⁴, A. Mestre-Fusco⁵, E. Arriola²;

¹Nuclear Medicine Department, Hospital del Mar, Barcelona, SPAIN, ²Medical Oncology Department, Hospital del Mar, Barcelona, SPAIN, ³Radiology Department, Hospital del Mar, Barcelona, SPAIN, ⁴Pathology Department, Hospital del Mar, Barcelona, SPAIN, ⁵Nuclear Medicine Department, Hospital del Mar, Barcelona, SPAIN.

Aim/Introduction: The main issue to evaluate response to immunotherapy with FDG PET/CT in NSCLC patients, are the inflammatory infiltration secondary to this treatment that might also show FDG uptake, hamper reliability of PET signal. We aimed to analyze response to immunotherapy (anti-PD-1/PD-L1) in a sample of NSCLC patients. **Materials and Methods:** Retrospective study of 14 NSCLC stages III-IV in immunotherapy treatment. All underwent a baseline 18F-FDG PET/CT (PET1), prior to the start of immunotherapy and another (PET2) during / at the end of it, due to clinical / radiological suspicion of progression. PET analysis was visual and quantitative: SUVmax, SUVlbmy ratio SUVmax / SUVfund. The results of PET1 and PET2 were compared. Patients were classified into local progression and non-local progression. PET findings will correlate with clinical, CT, and histology when available. **Results:** Time between the start of treatment and PET2 was 15.4 ± 8.8 months. PET identified 8 patients in local progression (7 true positive/1 false positive) in 6 patients PET was negative (6 true negative). A reduction in SUVmax of $75.5\% \pm 12$ and a ratio in PET2 SUVmax / SUV background of 1.8 were established as quantitative response criteria. The PET showed a sensitivity 100%, specificity 83%, positive predictive value 87% and negative predictive value 100% in the assessment of the local response. **Conclusion:** FDG PET/CT let to evaluate response to immunotherapy in NSCLC patients. Quantitative analyze might give support when visual analysis show doubts. Prospective long-series studies are needed that can assess the actual role of PET in these patients. **References:** None

Added Value of SPECT/CT in the Monitoring and Long-Term Follow-up of Malignant Lymphomas

L. Chavdarova, E. Piperkova;

University Specialized Hospital for Active Treatment in Oncology, Sofia, BULGARIA.

Aim/Introduction: Modern hybrid imaging assists monitoring and treatment individualization with PET/CT undoubtedly being the “gold imaging standard” in FDG-avid lymphomas. SPECT/CT evolved later but could offer a lot in oncology, using different tumor-seeking radiopharmaceuticals (TSRP). Compared to PET/CT, there is still much less evidence about the place of improved SPECT/CT imaging in lymphoma. Our aim was to study the added value of SPECT/CT with TSRP 99mTc-MIBI or TF in Hodgkin and Non-Hodgkin lymphomas: diagnostic and staging capacity, predictive role for multi-drug resistance, assessment of cardiotoxicity and as a probable alternative for 18F-FDG-PET/CT. **Materials and Methods:** We studied 42 adult (22-77y) patients with proven or suspected lymphoma (16 HL, 23 NHL, 3 undefined) with clinical indication for: primary diagnosis/staging (5 pts), restaging after first-line therapy (33 pts); relapse-restaging (3 pts). Using previous “non-hybrid” experience, we introduced a new one-day protocol including whole-body (WB: base of skull-upper thigh) SPECT/CT tumor-seeking scan followed by myocardial perfusion imaging MPI-Gated-SPECT/CT with only one application of the RP. Overall 71 scans were performed on a Symbia-T16-SPECT/(low-dose) CT in our Clinic of Nuclear medicine during 3 year-period: 45 for tumor imaging and 26 MPI. We checked all nodal and extranodal/organ regions for lymphoma engagement, assessed concordant and discordant SPECT vs CT findings and looked for multidrug resistance and myocardial toxicity. In 2 patients SPECT/CT was compared to a previously done PET/CT without intermittent therapy. **Results:** SPECT was concordant to CT in 36 pts. In 9 pts SPECT showed non-viable tumor residues after therapy. Comparing SPECT/CT and PET/CT, one patient was diagnosed with MDR and the other showed totally concordant PET and SPECT viable lymphoma lesions. 9/26 MPI showed pathologic myocardial perfusion and/or kinetics, 8 patients were diagnosed with post-therapeutic cardiotoxicity. **Conclusion:** Tumor-seeking SPECT/CT shows significant added value for primary diagnosis and staging in lymphoma patients with very high SPECT vs CT concordance. During restaging/follow up SPECT/CT could confirm clinical remission or relapse

and differentiate between viable tumor and post-therapy fibrosis with up to 100% accuracy. ^{99m}Tc -MIBI/TF-SPECT/CT allows non-invasive pre-therapeutic assessment of chemo-sensitivity and can predict multidrug resistance. The introduced protocol for subsequent tumor-seeking and myocardial perfusion hybrid imaging gives simultaneous multifunctional assessment and supports individualized treatment design. In the case of non-sufficient PET/CT equipment, the more readily available ^{99m}Tc -MIBI/TF-SPECT/CT might serve as an alternative in lymphoma monitoring at a lower cost and reduced radiation burden. Additional studies could give further evidence. **References:** None

EP-128

Inter reader agreement and variability of FDG PET volumetric parameters in a cohort of patients with Diffuse Large B-Cell Lymphoma (DLBCL)

M. Simó¹, A. Hernandez Martinez², M. Cortes Romera³, M. Sarandeses Fernández⁴, A. Rotger Regí⁵, X. Setoain Perego⁶, M. Coronado Poggio⁷;

¹Hospital Universitari Vall De Hebron, Barcelona, SPAIN,

²Hospital Santa Lucia, Cartagena, Murcia, SPAIN, ³Hospital Universitario de Bellvitge. Idibell, Barcelona, SPAIN, ⁴Hospital Universitario 12 de octubre, Madrid, SPAIN, ⁵Hospital Universitario Gregorio Marañón, Madrid, SPAIN, ⁶Hospital Universitari Clinic, Barcelona, SPAIN, ⁷Hospital Universitari La Paz. On Behalf on the imaging subcommittee of GELTAMO, Madrid, SPAIN.

Aim/Introduction: Measurement of metabolic tumor volume (MTV) and tumor lesion glycolysis (TLG) in patients with advanced (DLBCL) is challenging due to large amount of nodal and extranodal lymphomatous involvement. The purpose of this study was to evaluate the inter reader agreement and variability of these two parameters in our group of patients. **Materials and Methods:** Fifty patients with unfavourable DLBCL and baseline staging FDG PET/CT scans from a clinical trial (NCT01848132) were included. Three observers in-dependently read the scans and segmented metabolic tumor volume and total lesion glycolysis using a custom semi-automated workflow in the MIM Encore™ software (MIM Software Inc., Cleveland, OH, USA). Lesions were identified by visual assessment with PET images scaled to a fixed SUV of 2.5 and by Positron Emission Tomography Response Criteria in Solid Tumors (PERCIST) value. Contours of all hypermetabolic lesions were automatically created by fixed threshold method at 41% of SUVmax. Bland-Altman plots were used to compare volume parameters between observers. Inter-observer reproducibility was assessed using an intraclass correlation test. Based on Landis and Koch scale, agreement between operators was considered excellent if the intraclass correlation coefficient (ICC) was superior to 0.8. **Results:** The average MTV and TLG values measured by SUV max: 2.5 and

PERCIST in all patients were 1634cc and 1542cc respectively. No significant differences were documented between two methods. (t student 0.8). Using the SUV max:2.5 criteria, a greater dispersion of measures were found between the observers at a higher disease volume. This effect was not found when the PERCIST criteria was used. In 24 of 50 patients (48%) at least one VOI had to be manually modified, since it included some physiological uptake, as kidney or bladder. In this subgroup of patients there were also no differences between the observers, although there was also a greater dispersion at higher volumen. From a time consuming point of view, RECIST Criteria was better than fix SUV max method since fewer VOIS had to be removed. An excellent inter-observer reproducibility (higher than 0.90, $p < 0.05$) between the 3 observers were found considering TLG (SUVmax:2.5), MTV (SUVmax:2.5), $\text{TLG}_{41\%}$ (SUVmax:2.5), $\text{MTV}_{41\%}$ (SUVmax:2.5), MTV (percist), $\text{MTV}_{41\%}$ (percist), $\text{TLG}_{41\%}$ (percist) analysis **Conclusion:** There was good interreader agreement for measurement of metabolic tumor volume and total lesion glycolysis in our patients with DLBCL. A major dispersion had been observed at a greater volume of disease. **References:** None

EP-129

End of therapy ^{18}F -FDG PET/CT for assessment of persistent bone involvement in B-cell lymphoma

L. Michaud, R. Nakajima, E. Joffe, P. Ghione, S. Ahsanuddin, A. Navitski, H. Schöder; MSKCC, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: Bone involvement in B-cell lymphoma is often perceived by oncologists to indicate a more aggressive disease. Radiographic resolution of the lesions post-treatment is crucial for prognosis. ^{18}F -FDG PET/CT has become the standard for response assessment in most lymphomas. However, there are many reasons for residual FDG uptake in bone, other than persistent disease. To assess this hypothesis, we evaluated and characterized PET response patterns in patients with B-cell lymphoma with initial bone involvement. **Materials and Methods:** Lymphoma patients with reported initial bone involvement and end of therapy ^{18}F -FDG PET/CT (=EoT-PET) evaluation between 2001 and 2018 were identified from our institutional data base (n=413). We selected all cases with FDG uptake in bone higher than reference liver in EoT-PET report (n=54). In addition, we randomly selected 55 cases without EOT bone uptake. Thus, 109 patients were evaluated (74 DLBCL, 19 FL, 16 HL). Two independent nuclear medicine physicians, blinded to original PET report and patient clinical outcome, retrospectively reviewed baseline (n=101) and EoT-PETs (n=109). Response on EoT-PET was evaluated using Deauville/Lugano criteria to which three criteria for FDG bone uptake were added: M=diffuse reactive medullar uptake, S=uptake around surgery site,

F=uptake around a fracture site. In case of discordant results between the two readers, a third independent expert reader (HS) established the final classification. **Results:** Discordant results between the two readers occurred in 26 patients (24%): Deauville ≤ 3 versus ≥ 4 (n=7); fracture or surgery overlooked by one reader (n=6); disagreement regarding M status: Deauville ≤ 3 versus M (n=12); and classification as X vs 5 (n=1). After consensus, 60 patients were classified as D ≤ 3 for bone involvement (including n=6 with extra-osseous status D ≥ 4). The 49 other patients showed the following bone uptake: D ≥ 4 (n=21), S (n=11), F (n=5), M (n=8), X (n=2) and indeterminate (n=2). The latter two patients had a paravertebral/vertebral lesion impossible to characterize without biopsy and unchanged mild femoral uptake. Among these 49 patients, only 8 had confirmed persistent/progressive disease in bone (n=5 with D ≥ 4 , n=1 with S and n=2 indeterminate). The EoT response was evaluated by the clinician (complete response=negative biopsy, follow up imaging with resolved uptake, or no treatment despite persistent stable uptake and unremarkable clinical course). Particularly, among the 21 patients D ≥ 4 , 15 (71%) had a complete response. **Conclusion:** Non-tumoral residual FDG uptake in bone with intensity higher than reference liver background (e.g., due to surgery, fractures, or diffuse reactive marrow), is common on EoT PET, whereas true residual bone disease is rare. Of note, 71% of patients with residual bone uptake on EoT PET achieve a complete response, particularly when there is no residual extra-osseous uptake. **References:** None

PET/CT for Detecting Bone Marrow Involvement in Diffuse Large B-cell Lymphoma Compared with Bone Marrow Biopsy

C. Soldevila¹, M. Cortés-Romera¹, A. Sabaté-Llobera¹, S. Mercadal-Vilchez², A. Palomar-Muñoz¹, F. Climent-Esteller³, E. Llinares-Tello¹, M. Pudiš¹, E. González-Barca²;

¹PET/CT Unit (IDI)- Department of Nuclear Medicine. Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat (Barcelona), SPAIN, ²Department of Hematology. ICO. Hospital Duran i Reynals-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN, ³Department of Pathology. Hospital U. de Bellvitge-IDIBELL, L'Hospitalet de Llobregat (Barcelona), SPAIN.

Aim/Introduction: Diffuse large B-cell lymphoma (DLBCL) is the most commonly occurring lymphoma subtype. Detection of bone marrow involvement (BMI) is important in these patients because it may have prognostic and therapeutic implications. Focal bone or bone marrow FDG uptake in PET/CT is highly sensitive to detect bone marrow involvement (BMI) in Hodgkin lymphoma and in aggressive non-Hodgkin lymphoma (NHL). However, diffuse FDG uptake in PET/CT is more controversial in aggressive NHL. The aim of this study was to compare PET/CT with BMB for

detecting BMI in patients with newly diagnosed DLBCL. **Materials and Methods:** One hundred fifty-two patients (73 women; mean age 57 years) newly diagnosed with DLBCL underwent a pretreatment FDG PET/CT and BMB. PET/CT was considered positive for BMI at the visual assessment when there was a focal, heterogeneous or diffuse bone marrow uptake (BMU) higher than liver uptake. Focal pattern was subclassified as unifocal, bifocal and multifocal. Morphological changes on CT were studied in patients with BMI and they were subclassified as diffuse increased bone density, lytic and/or sclerotic lesions. Concordance between PET/CT and BMB was analyzed. **Results:** BMI was detected in 25 patients (16%) by BMB and in 48 (31%) by PET/CT. Of all positive PET/CT, diffuse uptake was observed in 10 cases, heterogeneous in 8 and focal pattern in 30 (20 multifocal, 4 bifocal and 6 unifocal). Morphological changes on CT were observed in 24 patients (8 with diffuse increased bone density, 10 with lytic lesions and 6 with mixed sclerotic and lytic lesions). Concordant results between PET/CT and BMB were obtained in 119 cases (78%): 20 of them with positive PET/CT (6 diffuse, 3 heterogeneous and 11 focal pattern) and BMB results (16%), and 99 patients with negative PET/CT and BMB results (83%). Discordant results were obtained in 33 cases (22%): 28 of them with positive PET/CT (4 diffuse, 5 heterogeneous and 19 focal pattern) and negative BMB (85%), and 5 with negative PET/CT and positive BMB (15%). **Conclusion:** PET/CT detects more BMI compared with BMB in DLBCL, though there is a good concordance between both techniques. Around 60% of patients with a focal and/or heterogeneous pattern at the PET/CT had a negative BMB, so the omission of BMB in these cases should be considered. However, 60% of patients with a diffuse pattern had a positive BMB, so in these cases we recommend the BMB. **References:** None

EP-131

Disease Free Survival on Follow-up ¹⁸FDG PET/CT in NHL Patients with Complete Metabolic Response on Interim scans

N. Fatima¹, M.U. Zaman¹, A. Zaman², U. Zaman³, S. Zaman⁴, R. Tahseen¹;

¹Aga Khan University, Karachi, PAKISTAN, ²Department of Medicine, Dr Ruth Hospital, Karachi, PAKISTAN, ³Dept of Medicine Suny Downstate, Hospital, New York, NY, UNITED STATES OF AMERICA, ⁴Dow Medical College, Dow University of Health Sciences (DUHS), Karachi, PAKISTAN.

Aim/Introduction: Aim of this retrospective study was to determine disease free survival (DFS) in patients with non-Hodgkin's lymphoma (NHL) on follow-up ¹⁸FDG PET/CT who had complete metabolic response (CMR) on interim scan (iPET). **Materials and Methods:** This retrospective study was conducted at PET/CT Section of a JCI A accredited healthcare facility from December 2015 till February 2020.

NHL patients with CMR on iPET were selected and followed for a median period of 11 months (4–144 months). End point response on follow- PET/CT (either end of treatment or surveillance) was categorized as sustained CMR (sCMR) and disease recurrence using Deauville 5-point scoring. Kaplan Meier survival curve was used to measure DFS and receiver operating characteristics (ROC) was plotted for age, largest lesion size, highest standardized uptake value (SUVmax), disease stage and body mass index (BMI) on baseline scan to find their impact on disease recurrence on follow-up ^{18}F FDG PET/CT **Results:** During study period, 185 NHL patients achieved CMR on iPET with a median age 55 years (19 - 88 yr.) with male predominance (63% male). On follow-up, 123 (66%) patients were found to have sCMR while recurrence was found in 34% ($p < 0.05$). No significant difference in demographics was found between two groups. Median DFS time was 34 months (22.8 - 45.1 months). On ROC analysis, baseline highest SUVmax was found to be a significant independent predictor of disease recurrence at a cut off > 22.6 (highest area under curve: 0.595; SE 0.046; $p < 0.05$). **Conclusion:** We conclude that significant higher proportion of NHL patients with CMR had a DFS of median 34 months (range: 22.8 - 45.1 months) and highest baseline SUVmax (> 22.6) was found to be an independent predictor of disease recurrence. **Key words:** Interim PET/CT; Non-Hodgkin's Lymphoma; Responder; Disease free survival; predictor. **References:** None

EP-132

Can Metabolic Parameters Obtained From PET/CT Images Be Used As A Prognostic Factor For Hodgkin Lymphoma?

C. Sezzin, G. Mutevelizade, E. Sayit, I. Aydogdu, G. Gumuser; Celal Bayar University, Manisa, TURKEY.

Aim/Introduction: F-18-fluorodeoxyglucose (F-18 FDG)PET/CT is currently used as the gold standard method in patients with Hodgkin lymphoma for staging, evaluation of response to therapy, detecting residual tumor tissue and recurrence. In this study, we investigated PET/CT metabolic parameters' value for predicting the treatment response. In addition, the relationship between Ann Arbor staging and international prognostic score 3 (IPS3) with metabolic parameters and treatment response was evaluated. **Materials and Methods:** Seventy-two patients with histopathologically proven Hodgkin lymphoma underwent F-18 FDG PET/CT (Philips, True Flight Select, USA) imaging for staging and response to therapy evaluation. 35 patients (20 men, 15 women; mean age 38.3 ± 16 years) with available laboratory, pathology and treatment data were evaluated retrospectively. Metabolic tumor parameters [(SUVmax, SUVmean, lesion/liver SUVmax ratio, metabolic tumor volume (MTV) and metabolic index max (Mlmax)] achieved from PET/CT images taken for initial staging. After 4 cycles of Adriamycin, Bleomycin, Vinblastin, Dakarbazin (ABVD) treatment patients underwent PET/

CT for evaluation of response to therapy and Deauville response scale were identified. Metabolic tumor parameters and Deauville response scale were compared. Ann Arbor stages and IPS3 scores (age ≥ 45 , stage IV disease, Hgb < 10.5 ; each were given 1 point) were determined. Deauville score 1–3 was considered as response to treatment, score 4–5 as treatment failure. The relationship between Ann Arbor stages and IPS3 scores with metabolic tumor parameters and Deauville response scores were examined. **Results:** Nineteen of 35 patients were nodular sclerosing, 7 were mixed cellular, 4 were in lymphocyte predominant subtype, whereas 5 patients subtypes could not be determined pathologically. There was a significant relationship between response to 4 cycles of ABVD treatment with SUVmax, SUVmean, lesion / liver SUV max ratio and Mlmax ($p = 0.016, p = 0.020, p = 0.033, p = 0.013$, respectively). There was no significant relationship between total tumor volume and treatment response. Patients' IPS3 scores and SUVmax; Ann Arbor stages and tumor volumes were found to be related ($p = 0.039, p = 0.014$, respectively); whereas there was no significant relationship between IPS3 scores and Ann Arbor stage with treatment response. There was a statistical relationship between MTV and Mlmax values with serum LDH levels ($p = 0.002, p = 0.038$, respectively). **Conclusion:** We conclude that SUVmax, SUVmean, lesion/liver SUV max ratio and Mlmax values achieved from PET/CT images taken for initial staging of patients with Hodgkin's lymphoma are promising in terms of creating a new prognostic scoring system and treatment guidance. **References:** Barrington SF. Time to prepare for risk adaptation in lymphoma by standardising measurement of metabolic tumour burden. J Nucl Med. 2019; jnumed.119. 227249. doi:10.2967/ jnumed.119.227249

EP-133

Impact of Gender on Metabolic Response in Patients with Non-Hodgkin's Lymphoma using Interim ^{18}F FDG PET/CT

N. Fatima¹, M. U. Zaman¹, A. Zaman², U. Zaman³, S. Zaman⁴, R. Tahseen¹;

¹Aga Khan University, Karachi, PAKISTAN, ²Department of Medicine, Dr Ruth Hospital, Karachi, PAKISTAN, ³Dept of Medicine Suny Downstate, Hospital, New York, NY, UNITED STATES OF AMERICA, ⁴Dow Medical College, Dow University of Health Sciences (DUHS), Karachi, PAKISTAN.

Aim/Introduction: The purpose of this study was to determine the impact of gender on response in patients with non-Hodgkin's lymphoma (NHL) based on interim ^{18}F -fluorodeoxyglucose (FDG) positron-emission tomography/computed tomography (PET/CT). **Materials and Methods:** This retrospective study was conducted at PET/CT section of a JCI-accredited healthcare facility from January 2019 to February 2020. Patients with baseline and interim ^{18}F FDG PET/CT scans were selected. Interim

scans were performed not earlier than 2nd or later than 4th chemotherapy. The study population was divided on the basis of gender and various demographic factors were compared among them. Furthermore, predictors for responders between two groups were analysed using receiver operating characteristics (ROC) and logistic regression analysis (LRA). **Results:** Total 330 patients with NHL were categorized on the basis of gender into male (211/330) and female (119/330) cohorts. Female group was significantly obese (Body Mass Index ≥ 30 kg/m²). Rest of the demographic factors (age, fasting blood level, FDG dose, uptake time, mean liver uptake, baseline highest SUVmax and the largest lesion size) were statistically similar. Male group was found to have significantly higher Stage III disease while rest of disease burden was found to have similar distribution in both groups. Significantly higher proportion of female was found as responders (with Deauville Score: 1-3) than males (82% vs. 66%; p value <0.05). Among responders, obesity was found significantly higher in female responders (32% vs. 19%; p-value <0.05). Rest of the factors were found non-significant in both groups. Using ROC, baseline BMI (>26.8 Kg/m²) was found to be an independent predictor of response in female responders. While stage IV disease, was found to be a predictor of non-responders in male. Using LRA, a negative correlation was found for baseline highest SUVmax for BMI >26.8 Kg/m² in female responders. **Conclusion:** We conclude that prevalence of NHL is higher in males but females are good responders and baseline BMI >26.8 Kg/m² is an independent predictor in female responders. Furthermore, baseline SUVmax has inverse correlation with baseline BMI in female responders. **References:** None

EP-134

Melanoma patients: is it really necessary a whole-body PET/CT scan?

D. Calabro¹, L. Vetrone¹, A. Farina¹, F. Serani¹, P. Castellucci², S. Fanti¹;

¹Nuclear Medicine, DIMES University of Bologna, S.Orsola-Malpighi Hospital, Bologna, ITALY, ²Nuclear Medicine, S.Orsola-Malpighi Hospital, Bologna, ITALY.

Aim/Introduction: The aim of the study is to assess the utility of performing a whole body 18F-FDG PET/CT scan (head to toe) in patients (pts) with uveal, mucosal and cutaneous melanoma. **Materials and Methods:** Inclusion criteria were: i) pts with histologically proven diagnosis of

uveal, mucosal and cutaneous melanoma of the head and neck, trunk and proximal extremities, ii) at least one whole body PET/CT scan (head to toe) performed for post-surgical restaging of melanoma. Exclusion criteria were: i) pts with melanoma unknown primary tumour ii) primary lesion in the upper/lower limbs. Each scan was reviewed by two experienced nuclear medicine physicians, in order to assess the presence of secondary lesions that would have been excluded by a shorter field of view (FOV) from the vertex to the thighs. PET findings were considered positive when the uptake was more than two times the surrounding tissues. Data analysis was performed both per patient and per examination. **Results:** Among 506 scans performed from January 2016 and March 2020, 148 scans in 82 pts matched the inclusion criteria. PET/CT was positive in 29/82 pts (35%) and negative in 53/82pts (65%). PET/CT was positive in 48/148 scans (32.4%) and negative in 100/148 scans (67.6%). Among the 48 positive PET scans, only in two cases (4.2 %; 2 pts) secondary lesions outside the shorter FOV were found: in the tibia in one patient and in the distal arm and distal femoral diaphysis in the other. It is important to note that these two patients had already a known widespread disease, for which they were under immunotherapy, so the detection of lesions outside the standard field of view had no clinical impact in these two patients. Main limitation of the study is that most PET positive findings (although reported by two experienced nuclear medicine physicians) were not validated by biopsies or other imaging. **Conclusion:** This analysis shows that it is not strictly necessary to routinely extend FOV to the toes, in pts with uveal, mucosal and cutaneous melanoma of the head and neck, trunk and proximal extremities, sparing dose to the patient and shortening the acquisition time. **References:** None

Interim¹⁸F-FDG PET/CT in survival prediction of anti-PD-1 immunotherapy in metastatic melanoma

C. Sachpekidis¹, J. C. Hasse², A. Dimitrakopoulou-Strauss¹;

¹Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, ²Department of Dermatology and National Center for Tumor Diseases, University Hospital Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: A growing amount of literature has highlighted the potential role of ¹⁸F-FDG PET/CT in the prediction of treatment response to immunotherapeutic agents in metastatic melanoma. In quest of identifying reliable biomarkers for the prediction of long-term outcomes to immunotherapy, we aim in the present prospective study to assess the value of interim ¹⁸F-FDG PET/CT performed after the first two cycles of anti-PD-1 treatment. **Materials and Methods:** 29 patients with metastatic melanoma underwent immunotherapy with pembrolizumab (n=9), nivolumab (n=4) or a combination

of nivolumab/ipilimumab (n=16). All patients were examined with dynamic PET/CT (dPET/CT) of the thorax and upper abdomen as well as static, whole body PET/CT with ^{18}F -FDG before the start (baseline) and after two cycles (interim) of treatment. PET-based patient response evaluation to treatment was based on the European Organization for Research and Treatment of Cancer (EORTC) criteria and the recently proposed PET Response Evaluation Criteria for Immunotherapy (PERCIMP). The evaluation of dPET/CT studies was based on semi-quantitative (SUV) and quantitative analysis, based on two-tissue compartment modeling and a fractal approach. Progression-free survival (PFS) from the beginning of treatment was calculated. **Results:** According to the EORTC criteria, interim PET/CT demonstrated progressive metabolic disease (PMD) in 14 patients, stable metabolic disease (SMD) in 7 patients, partial metabolic response (PMR) in 7 patients, and complete metabolic response (CMR) in 1 patient. According to the PERCIMP, interim PET/CT demonstrated PMD in 8 patients, SMD in 13 patients, PMR in 7 patients and CMR in 1 patient. The results of semi-quantitative and quantitative PET analysis as well as PFS analysis data will be presented. **Conclusion:** Interim ^{18}F -FDG PET/CT performed after the first two cycles of immunotherapy provides significant prognostic information in metastatic melanoma patients treated with PD-1 inhibitors, which, in turn, may affect therapeutic decisions. **References:** None

EP-136

The application of 18F-FDG PET/CT for the assessment of tumor response to immunotherapy with PD-1/PD-L1 blockage in patients with advanced melanoma

I. Kostadinova;

Clinic of nuclear medicine, University Hospital
Acibadem City Clinic, Mladost, Sofia, BULGARIA.

Aim/Introduction: The advent of immune checkpoint inhibitors has revolutionized metastatic melanoma treatment, as they have led to longer progression free survival and overall survival rates. However their introduction in the clinics has raised the issue of appropriate treatment response evaluation since the tumor responses are typically longer than in conventional treatment and they are partially associated with immune related adverse events. The aim of the study was to evaluate the treatment response of patients with metastatic malignant melanoma to check point inhibitors, using 18F-FDG PET-CT. **Materials and Methods:** We have studied retrospectively 21 patients (12 women and 9 men), treated with pembrolizumab (18 patients) and with nivolumab (3 patients) for the period 2016-2019, performing 89 PET-CT investigations (on the average 4.2 per patients), before and after beginning of the immunotherapy (the first follow up scan was performed on 3 month in order to escape visualization of eventual

early pseudoprogression). We have used metabolic criteria PERCIST and morphological criteria- RECIST 1.1 and irRC for treatment response evaluation. **Results:** Progression was registered in 7/21 patients with 43.5% metabolic increase of activity of the target lesions on average (including new lesions) and the treatment was discontinued; complete response in 5/21 patients (without active lesions); partial response in 5/21 patients with 40.8% metabolic decrease of activity of the target lesions on average and stable disease was registered in 4/21 patients. In 6 of the patients the therapeutic answer was visualized earlier on PET than on CT (in some lymph nodes, bone marrow, peritoneum and muscles). Three of the patients with negative PET findings and residual lesions on CT had no signs of the progression in the following 2 years. Five of the patients showed adverse effects of the treatment such as sarcoidosis, pneumonitis, hypophysitis, colitis, skin changes. From these, three were successfully early visualized with PET but not with CT and were treated later on. **Conclusion:** We consider PET-CT a promising tool for evaluating patients with metastatic melanoma under PD-1/PD-L1 blockage in order to optimize treatment. It could show earlier therapeutic answer and visualization of the adverse effects on the basis of the changed metabolism, compared to usage of CT only.

^{18}F FDG PET/CT role in a case of Pembrolizumab associated sarcoidosis mimicking progression in metastatic melanoma patient

Z. Dancheva¹, A. Konsulova², B. Chaushev¹, P. Bochev³, M. Dyankova¹, T. Yordanova¹, A. Klisarova¹;

¹St Marina University Hospital, Varna, BULGARIA, ²Department of Oncology, Complex Oncological Centre, Burgas, BULGARIA, ³Acibadem Cityclinic Oncology center Sofia, Sofia, BULGARIA.

Aim/Introduction: Pembrolizumab is a widely used cancer immunotherapy humanized antibody. It is an IgG4 isotype antibody that blocks a protective mechanism of cancer cells and thereby, allows the immune system to destroy them. It is used in the treatment of metastatic melanoma, and recently for many other malignant diseases as lung cancer, head and neck cancer, urothelial cancer, lymphoma and many others. Most adverse effects of Pembrolizumab are immune-related and may affect any organ in the human body. Sarcoidosis is a rarely described in the literature adverse reaction. **Materials and Methods:** We report a case of a female patient with a diagnosis of metastatic skin melanoma of the left leg, treated with first line immunotherapy with pembrolizumab, who developed a granulomatous sarcoidosis-like reaction. **Results:** While on treatment, the patient had a PET/CT as a procedure for response assessment 3 and 5 months after initiation of pembrolizumab. She developed at first mediastinal lymph nodes (Stage 1 sarcoidosis), which were

interpreted as pseudoprogression and the treatment was continued as the condition of the patient was unchanged and very good. To exclude rapid disease progression, a second re-assessment by PET/CT 2 months later was organized and granulomatous sarcoidosis-like reaction in lungs (stage 2) was observed. It was misinterpreted as progressive disease by another institution and treatment with pembrolizumab was interrupted. **Conclusion:** This case enriches the literature, enlarging the knowledge of immune-related adverse events spectrum and mimicking condition. As PET/CT is largely used for treatment response assessment, it is important to remain vigilant and not to interpret the immunotherapy-associated imaging changes, e.g. sarcoidosis as disease progression. **References:** 1. Significance of FDG PET/CT in the Evaluation of Melanoma Patients

J. Stojanovic, I. Grozdic Milojevic;

Centre for Nuclear medicine, Clinical Center of Serbia, Faculty of Medicine University of Belgrade, Belgrade, SERBIA.

Aim/Introduction: The aim of this study was to determine the usefulness of FDG PET / CT in the evaluation of patients with advanced malignant melanoma. **Materials and Methods:** The retrospective analysis of data from 102 patients with a confirmed pathohistological diagnosis of advanced malignant melanoma who underwent FDG PET/CT scanning was performed. The FDG acquisition was quantitatively analyzed in the form of maximum standardized value (SUVmax). PET/CT was interpreted as positive or negative depending on the SUVmax value, with values ≥ 2.5 considered pathological. The examination was done with PET/CT scan, 60 minutes after ^{18}F -FDG injection in standard whole body mode including orbits. **Results:** Based on the results the disease was present in 71% patients on FDG PET/CT, average SUVmax value was 12.9 ± 11.06 . The evaluation of distant areas identified the disease predominantly located in the retroperitoneal lymph nodes in 48% ($\text{SUVmax } 10.12 \pm 8.51$) and in the liver in 39%

patients ($\text{SUVmax } 9.18 \pm 6.24$). The disease was present in lymph nodes of the neck in 28% ($\text{SUVmax } 7.71 \pm 7.49$), in the axillary lymph nodes in 15% ($\text{SUVmax } 12.3 \pm 19.43$), in the mediastinal lymph nodes in 35% ($\text{SUVmax } 10.65 \pm 14.09$), in the lymph nodes of the pelvis in 35% ($\text{SUVmax } 11.3 \pm 8.07$) and in the inguinal lymph nodes in 35% ($\text{SUVmax } 6.96 \pm 4.85$), in the bones in 34% ($\text{SUVmax } 10.65 \pm 10.55$), in the lungs in 21% ($\text{SUVmax } 7.4 \pm 4.78$) and in the brain in 4% ($\text{SUVmax } 10.67 \pm 5.85$) patients. **Conclusion:** Due to its ability in detecting functional and anatomical changes, FDG PET/CT has become a powerful tool in identification of distant metastases, assessment of response to therapy, and selecting candidates for surgical treatment. **References:** None

^{18}F -FDG PET/CT in Primary and Recurrent Adrenocortical Carcinoma

S. Shamim, G. Arora, J. Hussain, S. Datta Gupta, R. Kumar, C. Bal; AIIMS, New Delhi, INDIA.

Aim/Introduction: Adrenocortical Carcinoma (ACC) that originates from the cortex of adrenal gland is a rare but aggressive tumor. The prognosis is generally poor with 5-year survival of <35%. Surgery is the only curative option, which makes early diagnosis of operable disease imperative. We assess the role of ^{18}F -FDG PET/CT in diagnosis of primary and recurrent ACC. **Materials and Methods:** FDG PET/CT scans of 15 patients (3 female; 12 male) with primary/recurrent ACC were retrospectively analyzed. Patients who were referred to our department for evaluation of ACC underwent whole body (vertex to mid thigh) FDG PET/CT scan on dedicated PET/CT scanners (Biograph mCT, Siemens and 710 Discovery, GE) 60 minutes post-injection of 10 mCi ^{18}F -FDG. First, low dose CT scan was acquired followed by PET scan with 1.5-2 min per bed position. Images were reconstructed with iterative reconstruction technique. Scans were visually evaluated by an experienced nuclear medicine physician. Semi-quantitative analysis was done by estimating SUVmax and tumor to background ratio (TBR) of primary lesion using normal liver as background. **Results:** Mean age of the patients was 41.2 ± 13.7 year. Of the 15 patients, 4 underwent FDG scan for baseline disease evaluation for metastatic work up prior to surgery, while 11 were follow up (F/U) cases to assess recurrent or residual disease. Two of the 11 follow up cases, were inoperable and

hence were only treated with chemotherapy. In all the cases referred for baseline staging (n=4), FDG PET/CT detected primary lesion (mean SUVmax=11.2; mean TBR=4.99) as well as metastatic sites (lung =3; liver=2; nodes=3). In the 2 inoperable F/U cases, FDG PET/CT detected residual primary (mean SUVmax=4.95; mean TBR=3.22) as well as metastatic sites (lung =2; nodes=1; bone=1). Of the remaining 9 post-operative F/U cases, 5 patients had recurrent disease at primary site and metastasis was present in 8 patients (lung =7; bone=3; nodes=5). **Conclusion:** ¹⁸F-FDG PET/CT appears to be of diagnostic utility in primary, metastatic as well as recurrent ACC and may assist in guiding its management. **References:** None

EP-140

Results of a sequential strategy ⁶⁸Ga (DOTATOC) - ¹⁸F-FDG PET/CT in real-life diagnosis and staging of neuroendocrine tumors

M. Ollarves Carrero¹, J. Rodriguez Gomez¹, M. Cabrera Martin¹, F. Ferrando-Castagnetto², C. Wakfie Corieh¹, A. Blanes Garcia¹, R. Couto Caro¹, J. L. Carreras Delgado¹;

¹Hospital Clinico San Carlos, Madrid, SPAIN, ²Universidad de la República Montevideo, Montevideo, URUGUAY.

Aim/Introduction: Neuroendocrine tumors (NETs) are a rare family of malignancies characterized by overexpression of somatostatin receptors (STTRs) in tumor cells. This molecular hallmark has established the basis for pharmacological treatment with analogues and diagnostic imaging. Following investigation was aimed to characterize our clinical experience by applying a sequential diagnostic algorithm with ⁶⁸Ga PET/CT (DOTATOC) followed by ¹⁸F-FDG PET/CT in selected patients with NET **Materials and Methods:** This is an observational, analytical, and retrospective real-life experience developed in a single reference center. All patients with confirmed/highly suspicious diagnosis of NET who underwent ⁶⁸Ga PET-CT (DOTATOC) between April 2019 and March 2020 were included. Patients with a negative result of ⁶⁸Ga PET/CT (DOTATOC) and/or high clinical suspicion of NET or with high-grade tumors (histological G3 according to the Ki67 criteria) were sequentially referred to ¹⁸F-FDG PET/CT. Clinical and anatomical data, histological grade (G1-G2 or G3), diagnostic accuracy, and changes in therapy after PET results are reported **Results:** Thirty-two patients with ⁶⁸Ga PET/CT (DOTATOC) results were included, 50% women, aged 40-81 years, 48% with metastatic NET. Fourteen patients (44%) had gastrointestinal and pancreatic primary tumors. The technique aimed at control/staging (confirmed NET) in 23 patients, diagnosing NET (highly suspicious NET) in 5 patients and locating the primary tumor (NET with unknown primary) in 4 cases. SSTR overexpression was detected in 22/32 patients (69%). Histopathological confirmation was obtained in 19 patients exhibiting a high tracer affinity for the SSTR; 88% of available histological

grading were classified as low-grade (G1-G2) and 12% as high-grade (G3). The sequential PET strategy yielded better sensitivity than isolated ⁶⁸Ga PET/CT (DOTATOC); 91% vs. 95% and optimal PPV; 100% vs. 100% in diagnostic indications. Based on PET results, oncology therapy was modified in 63% and continued as previously defined in 37% of patients **Conclusion:** ⁶⁸Ga PET/CT (DOTATOC) allows the diagnosis and staging of NETs in the real-life care of patients and provides clinically useful information to improve treatment individually. In our experience, a complementary sequential ⁶⁸Ga PET/CT (DOTATOC) strategy followed by ¹⁸F-FDG PET/CT in selected patients is associated with better sensitivity over ⁶⁸Ga PET/CT (DOTATOC) alone **References:** None

EP-141

Evaluating Neuroblastoma - Role of 18F-DOPA PET/CT Compared with 131I-MIBG Scintigraphy

A. Hemrom, A. Tupalli, K. S. Reddy, S. Agarwala, R. Seth, S. Bakhshi, M. Prabhu, A. Kumar, N. A. Damle, C. Bal;

All India Institute Of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: 131I-MIBG scintigraphy and 18F-DOPA PET/CT are established imaging modalities in evaluation of neuroblastoma. This study intends to compare 131I-MIBG scintigraphy and 18F-DOPA PET/CT in picking up the lesions and to evaluate extent of the disease in children with neuroblastoma using standardised scoring methods i.e SIOOPEN and Curie Scoring systems. **Materials and Methods:** Biopsy proven consecutive neuroblastoma patients underwent 131I-MIBG (planar and SPECT/CT) scan and 18F-DOPA PET/CT scan (± 1 month). 131I-MIBG scan (whole body Planar and SPECT/CT) and whole body 18F-DOPA PET/CT were acquired according to standard guidelines. Curie and SIOOPEN system scoring of both the modalities were compared and correlation between the same were assessed. Number of lesions detected in planar 131I-MIBG vs MIP image of 18F-DOPA and SPECT/CT vs fused regional PET/CT images were correlated. **Results:** In total 42 patients were included, (27 males, 15 females). Age ranged from 3 months to 84 months (Mean age was 34.4 ± 23 months). Out of 42 patients, 27 patients were indicated for initial staging and 15 patients for restaging. They were staged according to INRGSS staging. In 17 patients urinary catecholamines were elevated. Bone marrow biopsy was performed in 28 patients (12 positive, 14 negative and 2 inadequate). 131I-MIBG was positive in 38 and negative in 4 patients and 18F-DOPA PET/CT scan was positive in 39 patients and negative in 3 patients. Curie score in 131I-MIBG scan ranged from 0-28 (Mean - 5.9 ± 8.2) and in 18F-DOPA PET/CT ranged from 0-30 (Mean - 7.6 ± 9.5) with statistically significant difference ($p=0.0147$). SIOOPEN score in 131I-MIBG ranged from 0-44 (Mean - 7.3 ± 13.8) and in 18F-DOPA PET/CT ranged from 0-51 (Mean - 9.0 ± 15.3). Strong correlation in describing the disease extent was

noted between 131I-MIBG and 18F-DOPA in both Curie (Spearman correlation, $\rho = 0.83$) and SIOPEN scoring ($\rho = 0.82$). Total no. of lesions detected in planar 131I-MIBG v/s MIP 18F-DOPA were 205 v/s 305 ($\rho = 0.84$) and SPECT/CT 131I-MIBG v/s fused PET/CT 18F-DOPA were 194 v/s 329 ($\rho = 0.8$). Higher number of bone/bone marrow lesions were picked up on 18F-DOPA PET/CT. **Conclusion:** Total number of lesions picked up were more in 18F-DOPA MIP and corresponding PET/CT images in comparison to 131I-MIBG planar and SPECT/CT images, respectively. When curie scoring is considered in staging, F-DOPA PET/CT performs better compared to 131I-MIBG scan. **References:** None

EP-142

Are we enough for insulinoma?

P. Soeiro, L. Fadiga, R. Silva, J. Saraiva, A. Moreira, G. Costa, J. Pedroso de Lima;
Centro Hospitalar e Universitário de
Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Neuroendocrine Neoplasms of the pancreas account for less than 2% of all pancreatic tumors, and insulinomas are the most frequent. Even though mostly benign, insulinomas cause significant morbidity due to hypoglycemia. The aim of this study was to assess the accuracy of all available nuclear medicine imaging techniques in a tertiary center, without GLP-1R molecular-based imaging, for the diagnosis and identification of insulinoma. **Materials and Methods:** Data from all insulinoma patients diagnosed at our center was thoroughly reviewed, including clinical information, imaging studies, and genetic profiling. **Results:** Between 1986 and 2020 twenty four patients were found to have histology proven insulinomas (54% women). Four of these tumors were malignant. The average age at diagnosis was 60 ± 4.3 (25-89) years. In 87.5% of cases, the initial symptom was hypoglycemia; and in 1 case, secondary hepatic lesions. Three patients had previously been diagnosed with MEN1, and insulinoma was detected in follow-up. Out of 11 insulinoma patients who performed nuclear medicine techniques, including [^{68}Ga]Ga-DOTA-NOC, 2- ^{18}F]FDOPA and 2- ^{18}F]FDG PET/CT and Octreoscan, only 4 tumors were detected, and only 2 not detected by morphologic techniques. [^{68}Ga]Ga-DOTA-NOC PET/CT detected 1 in 5 patients scanned, 2- ^{18}F]FDG PET/CT 1/1 and octreoscan 2/4. 2- ^{18}F]FDOPA PET/CT was performed in only 1 patient, and was not able to detect the tumour. In contrast, CT was able to detect 13/24, echoendoscopy 9/13 and MRI 4/8. In the remaining 4 patients, tumor localization was achieved only by angiography with intra-arterial calcium stimulation. The average size of the tumors detected by nuclear medicine techniques was 2.0 ± 1.5 , in contrast to 1.8 ± 0.5 cm for the undetected tumors. One tumor was located in the head, 2 in the tail and 1 in the body of the pancreas. **Conclusion:**

Nuclear medicine techniques, including [^{68}Ga]Ga-DOTA-NOC, 2- ^{18}F]FDOPA and 2- ^{18}F]FDG PET/CT and Octreoscan are not sensitive for insulinoma detection, and should play a minor role in these tumors. New nuclear medicine techniques, with improved accuracy, such as GLP-1R based imaging, are eagerly awaited. **References:** None

EP-143

Are post-therapeutic SPECT/CT acquisitions useful to predict response to PRRT in patients with gastroenteropancreatic neuroendocrine tumors ? Preliminary results

T. Godefroy, C. Ansquer, Y. Touchefeu, M. Barbaud, T. Matysiak-Budnik, F. Kraeber-Bodéré, T. Carlier;
CHU de Nantes, Nantes, FRANCE.

Aim/Introduction: PRRT is a well-established therapeutic option in advanced gastroenteropancreatic neuroendocrine tumors (GEP-NET). This study analyzed some parameters extracted from post-therapeutic SPECT-CT for the prediction of PET response at 12 months. **Materials and Methods:** Five patients (3 males, median age: 68 years), diagnosed with metastatic Grade 1 and 2 GEP-NETs were treated with a total of 4 cycles of 7.4 GBq of ^{177}Lu -DOTATATE every 2 months. Two of them had pancreatic NETs, two others midgut NETs and one a rectal NET. A thoracic-abdominal-pelvic SPECT/CT was performed 24h after ^{177}Lu -DOTATATE injections. Data were reconstructed with attenuation, scatter and point spread function correction using 64 MLEM-equivalent iterations (voxel size: $2.4 \times 2.4 \times 2.4$ mm 3). Normalized peak count (NPC) of the focus with the highest uptake at cycle 1 was considered. Its variation between cycle 1 and 4 (DeltaNPC) was calculated. The same computation was derived between the most intense lesion of cycle 1 and cycle 4 (PERCIST-like). Each patient had a ^{68}Ga -DOTATOC PET/CT before and one year after PRRT1. DeltaNPC was compared with the PET-based SUVpeak variation of this same lesion (DeltaSUVpeak). Outcome defined with PERCIST criteria using the two ^{68}Ga -DOTATOC PET/CT was then compared with parameters derived from SPECT/CT (DeltaNPC, PERCIST-like) and DeltaSUVPeak from ^{68}Ga -DOTATOC PET/CT. **Results:** At one year, one patient (patient 1) had complete metabolic response (CMR), three patients (patients 2, 3 and 4) had partial metabolic response (PMR), and one patient (patient 5) had stable metabolic disease (SMD) according to PERCIST criteria. A decrease was observed in DeltaNPC (-73%), as well as in the DeltaSUVPeak (-57%) for the patient who had CMR after one year. Among patients who achieved PMR, two showed decreased DeltaNPC and DeltaSUVpeak (respectively -91% and -79% for patient 2 and -17% and -58% for patient 3). Patient 4 showed heterogeneous results with rising DeltaNPC (33%) but decreased DeltaSUVpeak (-52%). Finally, patient 5, who had SMD, showed stable DeltaNPC (-3%) and DeltaSUVpeak

(-7%). PERCIST-like using SPECT/CT exhibited the same trend as results obtained with DeltaNPC. **Conclusion:** These preliminary results obtained using parameters extracted from post-therapeutic SPECT/CT, seem to be predictive of the 12-month metabolic response after PRRT. These results need to be confirmed on a larger cohort of patients.

Post Lu-177 PRRT Scintigraphy; Value of SPECT-CT

M. Numair Younis, I. U. Khan, M. Masood, A. Shahid;
Institute of Nuclear Medicine and Oncology-
INMOL, Lahore, PAKISTAN.

Aim/Introduction: Theranostic application for detection and treatment of gastroenteropancreatic neuroendocrine tumors (GEP-NETs) using Ga-68 Dotatate (Ga-tate) and Lutetium-177 Dotatate (Lu-tate) is being widely applied as clinical trials have shown survival benefit with Lu-tate based Peptide Receptor Radionuclide Therapy (PRRT). Guidelines suggest multiple doses of Lu-tate PRRT each of maximum 200 mCi to NET patient. Lu-tate PRRT is available and being applied in Pakistan for over 2 years (1). Post therapy imaging using gamma camera is routinely performed between day 1-7 post therapy. There is no consensus on routine use of SPECT-CT in these patients. We conducted study to determine if there is any additional value of performing SPECT-CT imaging post Lu-tate PRRT. **Materials and Methods:** 10 patients of biopsy proven NET with metastatic disease documented on Ga-tate PET scan underwent Lu-tate PRRT. In a previous institutional study performed earlier, 10 patients underwent whole body scans on days 1, 3 and 5 post therapy. It was established that there was no difference between day 3 and 5 scans as far imaging characteristics, tumor to background ratio and detection of disease sites is concerned. Day 1 scan showed higher soft tissue background, relatively lower tumor to background and less number of disease sites as compared to days 3 and 5 scans. So in this study SPECT-CT was performed on day 3 following whole body imaging. Scans were compared with immediate pre therapy Ga-tate PET scans. **Results:** In our study a total of 72 disease sites were detected on Ga-tate PET scans performed in 10 patients. Whole body Lu-tate scans showed 64 disease sites, with successfully showing 8 of 8 in neck, 14 of 16 in thorax, 32 of 38 in abdominopelvic region and 10 of 10 in bones or bone marrow when compared with Ga-tate PET scans. SPECT-CT imaging identified all 16 of 16 in thorax and 38 of 38 in abdominopelvis region showing 100% concordance with Ga-tate PET scans. **Conclusion:** Our study concludes that there is no statistically significant benefit of using SPECT-CT scans post Lu-tate PRRT as far lesion detection rate is concerned. We suggest that SPECT-CT in post PRRT setting may be used judiciously in selected patients only after reviewing

whole body scans in combination with Ga-tate PET scans for detection of obscured lesions only, keeping radiation concerns in mind. **References:** 1. Bashir H, et al. Nuclear Medicine Theranostics: Perspective from Pakistan. Nucl Med Mol Imaging. 2019;53(1):38-41.

EP-145

18F-FDG PET/CT diagnosis of adrenal tumors

J. Liu, X. Han, Henan Medical Key Laboratory of Molecular Imaging;
Hospital, Zhengzhou, CHINA.

Aim/Introduction: To investigate the diagnostic criteria and differential diagnosis of 18F-FDG PET/CT in the diagnosis of adrenal tumors by summarizing the characteristics of adrenal tumors on 18F-FDG PET/CT imaging. **Materials and Methods:** A total of 134 patients with adrenal tumors underwent 18F-FDG PET/CT scans in our department were analyzed for tumor size, morphology, density, and tumor FDG uptake. Plotted ROC curves of tumor SUVmax for diagnosis of benign and malignant adrenal tumors, and compared different tumor sizes and tumor SUVmax difference. **Results:** Of the 134 patients, 6 cases of myelolipoma, 17 cases of adenoma, 4 cases of Adenocarcinoma, 3 cases of malignant pheochromocytoma, 9 cases of neuroblastoma, 34 cases of lymphoma and 61 cases of adrenal metastases. The threshold value of SUVmax for the diagnosis of benign and malignant adrenal tumors was 4.85. The sensitivity and specificity were 88.5% and 88.9%, respectively. There were differences between different adrenal tumor sizes and tumor SUVmax. **Conclusion:** Different types of adrenal tumors generally have certain characteristics in ¹⁸F-FDG PET/CT. It was easy to make a diagnosis in combination with laboratory tests and clinical symptoms. **References:** None

⁹⁰Y- or ¹⁷⁷Lu-DOTATOC therapy improves symptoms control and impacts on clinical management of metastatic insulinoma

M. Freitag¹, M. Braun², E. Christ¹, B. Goichot³, T. O'Dorisio⁴, D. Bushnell⁴, M. Walter¹, D. Wild¹, N. Guillaume¹;
¹University Hospital of Basel, Basel, SWITZERLAND,
²Claraspital, Basel, SWITZERLAND, ³Hôpitaux Universitaires de Strasbourg, Strasbourg, FRANCE, ⁴University of Iowa, Iowa City, IA, UNITED STATES OF AMERICA.

Aim/Introduction: Metastatic insulinoma is an extremely rare neuroendocrine neoplasia with estimated incidence of 1-4/10'000'000. Uncontrolled hypoglycaemia is a major cause of acute morbidity and mortality in this disease. Here, we retrospectively evaluate the hitherto largest patient series on this topic assessing the value of radiolabelled somatostatin analogue (DOTATOC) for the clinical control of progressive, metastatic insulinoma. **Materials**

and Methods: All Patients with diagnosis of malignant insulinoma were enrolled between 2001–2018. Patients were treated with repeated cycles of Yttrium-90-DOTATOC, with consecutive cycles of Yttrium-90-DOTATOC and Lutetium-177-DOTATOC, or with Lutetium-177-DOTATOC alone. Symptomatic response was assessed using a score of hypoglycaemia between 0 (no hypoglycaemic events), 1 (some hypoglycaemic events, treatment conservative with optimization of nutrition) and 2 (severe hypoglycaemic requiring medication, history of coma). Standard of reference of a successful therapy was defined as reduction of medication necessary to maintain stable blood glucose level during the observation time. **Results:** Within 18 years, 23 patients were included and observed for a median time of 205 days (102.1 - 526.7). 7 patients received Yttrium-90-DOTATOC only (2.7 ± 1.0 cycles, 165 - 200 mCi), 12 patients received Yttrium-90-DOTATOC and Lutetium-177-DOTATOC (4.2 ± 2.3 cycles, 150 - 220 mCi) and 4 patients received Lutetium-177-DOTATOC only (3.5 ± 0.6 cycles, 150 mCi - 200 mCi). 16 of 23 patients experienced grade 1/2 hematotoxicity (88%), no higher grade occurred. 17 patients of 23 patients (73.9%) demonstrated improvement of hypoglycemia during the observation period. In 10 of 17 responders, anti-hypoglycemic medication could be reduced after DOTATOC therapy. **Conclusion:** Yttrium-90/Lutetium-177 DOTATOC therapy is able to reduce anti-hypoglycaemic medication in a significant proportion of patients with progressive malignant insulinoma and therefore helps to control hypoglycaemic events. In conclusion, radiolabelled DOTATOC therapy is a promising therapeutic option in this rare disease. **References:** None

Role of [68Ga]68Ga-DOTANOC PET/CT in presurgical staging of small intestine neuroendocrine tumour

D. Calabro^{1,2}, *S. Telo*^{1,2}, *G. Argalia*^{1,2}, *E. Fortunati*^{1,2}, *E. Tabacchi*^{1,2}, *L. Zanon*^{1,2}, *C. Ricci*^{2,3}, *R. Casadei*^{2,3}, *D. Campana*^{2,3}, *S. Fanti*^{1,2}, *V. Ambrosini*^{1,2};

¹Nuclear Medicine, S.Orsola-Malpighi Hospital, DIMES University of Bologna, Bologna, ITALY, ²NET team Bologna, ENETS Center Of Excellence, Bologna, ITALY, ³DIMEC University of Bologna, Bologna, ITALY.

Aim/Introduction: Although recommended by current guidelines, [68Ga]68Ga-DOTANOC PET/CT (SSA-PET) is not often performed in the pre-surgical staging of small intestine (si) neuroendocrine tumour (NET), due to the frequent presentation as intestinal obstruction needing urgent surgery. The aim of this study is to retrospectively evaluate the usefulness of pre-surgical PET staging in patients (pts) with not occlusive siNET, comparing it with conventional imaging (CI). **Materials and Methods:** Inclusion criteria were: i) si lesion detected on CI (entero-CT, CT, EUS, MRI); ii) SSA-PET performed before surgery, within 60

days from CI. SSA-PET/CT was performed and interpreted following standard EANM procedure. All images were reviewed by two experienced nuclear medicine physicians. CI and SSA-PET were compared by lesions' site and number. **Results:** Twenty-two pts were included in the final analysis. SSA-PET was positive in all cases. SSA-PET and CI were concordant in 10/22 pts (45.5%) while in the remaining 12/22 pts (54.5%) SSA-PET and CI were discordant. Among discordant cases, in 4/12 pts (33%) CI detected more lesions than SSA-PET: 2/4 a higher number of hepatic lesions, 1/4 peritoneal carcinosis, 1/4 a necrotic lympho-adenopathy. In the remaining 8/12 pts (67%), SSA-PET showed more lesions than CI: 4/8 (50%) multiple ileal localizations, 1/8 multiple hepatic lesions (missed by EUS but later confirmed by CT performed after SSA-PET), in 2/8 sub-centimetric nodal findings (in 1/2 PET also showed bilateral lesions in normalized ovaries, confirmed as additional NET secondary metastasis after surgery). **Conclusion:** Despite the small population: in more than half of the cases pre-surgical SSA-PET showed more lesions than CI and, in particular, for the detection of multiple sub-centimetric primary ileal lesions. Additionally, PET/CT proved to be useful to identify small pathologic nodes not reaching the dimensional criteria for CT positivity. **References:** None

Early post-surgical 68Ga-DOTANOC PET/CT imaging in GEP NET patients

S. Telo^{1,2}, *E. Fortunati*^{1,2}, *G. Argalia*^{1,2}, *D. Calabrò*^{1,2}, *E. Tabacchi*¹, *L. Zanon*¹, *D. Campana*³, *S. Fanti*^{1,2}, *V. Ambrosini*^{1,2};

¹Nuclear Medicine, Policlinico S.Orsola-Malpighi, Bologna, ITALY, ²DIMES University of Bologna, Bologna, ITALY, ³DIMEC University of Bologna, Bologna, ITALY.

Aim/Introduction: To evaluate the value of early-post-surgery-68Ga-DOTANOC-PET/CT in patients (pts) with gastro-entero-pancreatic-neuroendocrine-tumours (GEP-NET). **Materials and Methods:** Inclusion criteria: 1) Pts with GEP-NET enrolled in a prospective electronic archive from September 2017 to April 2019 2) first 68Ga-DOTANOC-PET/CT performed within 3-months from surgery 3) not receiving any treatment prior to PET/CT-imaging 4) diagnostic CT performed before surgery. **Results:** 102/822 pts were included: in most cases (77/102) early-post-surgery-68Ga-DOTANOC-PET/CT was negative. In 25/102 pts detected the presence of active-disease confirmed at follow-up (grade 1: 11/25 pts; grade 2: 14/25 pts). Among grade-1 pts, 5/11 underwent radical-surgery and early-post-surgery-68Ga-DOTANOC-PET/CT showed additional lesions not detected by pre-surgical-CT. A subcentimetric mesenteric lymph-node (SUVmax=7), a second concordant primary ileal-lesion (SUVmax=13.9) and 2 liver metastases (SUVmax=10.8) were detected in 3 pts with ileal-primary-NET. A mesenteric lymph-node (SUVmax=11) was detected

in 1 pt with jejunum-primary-NET. A pelvic lymph-node (SUVmax=17.5) was detected in 1 pt with rectum-primary-NET. Non-radical surgery was performed in 6/11 pts with ileum-primary-NET and known metastatic lesions reported at pre-surgery-CT. Early-post-surgery-68Ga-DOTANOC-PET/CT was concordant with pre-surgical CT in 4/6: liver metastases (SUVmax-range=6-27) were detected in 3 pts, peritoneal carcinomatosis (SUVmax=12.5) in 1 pt. Lung-metastases (SUVmax=23), undetected by pre-surgical-CT with a field of view not including the thorax, were observed at early-post-surgery-PET/CT in 1 pt. Finally, an additional subcentimetric primary-ileal-lesion (SUVmax=16.3) was detected by PET/CT in 1 pt in which both CT and PET/CT showed nodal spread. Among grade 2 pts, 5/14 underwent radical-surgery: early-post-surgery-68Ga-DOTANOC-PET/CT detected additional lesions not detected by pre-surgical-CT: a local sub-centimetric lymph-node (SUVmax=8.5) and a mesenteric lymph-node (SUVmax=18.2) in 2 pancreatic-primary-NET pts, an iliac lymph-node (SUVmax=9.6) in an ileum-primary-NET pt, and multiple unknown liver lesions (SUVmax=10.1;15.2) in 2 caecum-primary-NET pts. 9/14 underwent non-radical-surgery: early-post-surgery-68Ga-DOTANOC-PET/CT was concordant with pre-surgery-CT in all cases, confirming liver metastases in 3 pancreatic-primary pts and in 2 ileum-primary pts (SUVmax range=9.3-38.6); multiple (mesenteric and pelvic) lymph-nodes in 1 pancreatic, 1 caecum and 2 ileum-primary-NET pts (SUVmax range=6.6-29.4). Overall, early-post-surgery-68Ga-DOTANOC-PET/CT was positive in 25/102 pts. In particular, PET/CT showed lesions undetected by pre-surgical CT in 10/10 cases after radical surgery and in 2/15 cases after non radical surgery. **Conclusion:** Our data, though limited by the small sample, show that early-post-surgery-68Ga-DOTANOC-PET/CT is positive in approximately one fourth of cases. PET/CT detected additional lesions in half of the cases when performed after radical surgery. On the contrary, in the non-radical setting, PET/CT detected additional lesions in a small minority of cases. **References:** None

EP-149

G1/G2 discrimination of pNET with [68Ga]Ga-DOTANOC PET/CT quantitative parameters: is it feasible?

D. Calabro^{1,2}, S. Malavasi³, A. Bevilacqua³, C. Ricci^{4,2}, S. Telo^{1,2}, G. Argalia^{1,2}, E. Fortunati^{1,2}, E. Tabacchi^{1,2}, L. Zanoni^{1,2}, R. Casadei^{4,2}, D. Campana^{4,2}, S. Fanti¹, V. Ambrosini^{1,2};

¹Nuclear Medicine, S.Orsola-Malpighi Hospital, DIMES University of Bologna, Bologna, ITALY, ²NET team Bologna, ENETS Center Of Excellence, Bologna, ITALY, ³Advanced Research Center for Electronic Systems (ARCES), University of Bologna, Bologna, ITALY, ⁴DIMEC University of Bologna, Bologna, ITALY.

Aim/Introduction: To evaluate if [68Ga]Ga-DOTANOC PET/CT derived TLRE (tumour lesion receptor expression) and

SUVmax/SUVmean ratio of the primary lesion, can be used to discriminate G1 from G2 pancreatic neuroendocrine tumours (pNET). **Materials and Methods:** Among the patients (pts) with pancreatic tumour eligible for primary tumour surgery and included in a prospective electronic archive, only those with a neuroendocrine primary and a positive 68Ga-DOTANOC PET/CT performed before surgery were included in the study. 68Ga-DOTANOC PET/CT was performed and interpreted following standard EANM procedure. TLRE, defined as the product of receptor tumour volume and the SUVmean of the lesion, was calculated by a dedicated software (PET VCAR, GE Healthcare) that semi-automatically delineates the tumour contours by using a threshold of 42% of the maximal SUV within the lesion. The results were checked by comparison with the fused CT images to determine if percentage threshold adjustment was needed and therefore was performed until a satisfactory outcome was achieved. The mean and maximum SUV of each primary lesion were assessed by expert nuclear medicine physicians. TLRE and SUVmax/mean ratio results were correlated with tumour grade G1/G2 as assessed on the primary tumour mass after surgical excision. **Results:** In the final analysis, 25 pts with pNET and a positive [68Ga]Ga-DOTANOC PET/CT were included (G1= 13 pts; G2=12pts). TLRE (G1: 132.7±187.0 [5.8-587.4]; G2=696.9±1098.9 [8.8-3988.5]) showed a good correlation with pathological grade (p=0,0276; AUC= 0.76) and sensitivity, specificity, accuracy, positive predictive, negative predictive value were respectively 75%, 77%, 76% 75% and 77%. SUVmax/mean ratio (G1: 2.1±0.4 [1.5-2.7]; G2: 1.8±0.3, 1.2-2.4) showed a weaker correlation (p=0.0414, AUC= 0.74) with sensitivity, specificity, accuracy, positive predictive and negative predictive value of 92%, 54%, 72%, 65%, 88%. **Conclusion:** Considering the clinical implications derived from accurate evaluation of tumour heterogeneity, the definition of easily accessible and measurable PET-derived parameters is mandatory. Although preliminary, our data show potential utility of using the TLRE and the SUVmax/mean ratio to discriminate G1 from G2 tumours. If confirmed in larger population, these results may prove valuable especially in patients not amenable to biopsy of the primary lesion. **References:** None

Role of [¹⁸F] FDG-PET/CT in assessment of effectiveness of paraganglioma embolization

J. Maczewska¹, K. Kulesza², M. Kobylecka¹, K. Fronczewska¹, L. Królicki¹;

¹Nuclear Medicine Department Warsaw Medical University, Warsaw, POLAND, ²Department of General, Endocrine and Vascular Surgery Warsaw Medical University, Warsaw, POLAND.

Aim/Introduction: Preoperative embolization of carotid paragangliomas is a common procedure in interventional

neuroradiology. It appears to decrease estimated blood loss and operative time when compared with that without preoperative embolization. However, the effect depends on the effectiveness of embolization. Aim of the study was to assess the effectiveness of paraganglioma embolization using [^{18}F]FDG-PET/CT. **Materials and Methods:** 10 patients (5 women and 5 men) with neck paraganglioma were analyzed. One week before embolization CECT and [^{18}F]FDG-PET/CT were performed to assess morphology, size and location of tumors. All patients had paraganglioma embolization according to standard procedure. Angiography performed after procedure was used to assess early effectiveness of embolization. Follow-up [^{18}F]FDG was repeated minimum 3 months after embolization. **Results:** All patients had single neck tumor. Average size of the tumor was $32 \pm 18,5\text{mm}$ (range 8 - 60mm), average SUVmax in initial examination was $12,2 \pm 11,6$ (range 3-34,1). Angiography after embolization confirmed good result of procedure. In the control PET study, lack of [^{18}F]FDG accumulation was found only in one patient, decrease of tumor diameter as well decrease of tracer accumulation was observed in 5 patients and no changes was described in 4 patients. **Conclusion:** [^{18}F]FDG PET/CT can be useful method in assessment of effectiveness of paraganglioma embolization. In our study 40% of patients had stable image of tumor in [^{18}F]FDG-PET/CT examination, despite angiography showing successful embolization. **References:** None

EP-151

[^{68}Ga]-DOTA-TOC PET-TC prospective comparison with [$^{99\text{mTc}}$]-HYNIC-TOC SPECT-CT and [^{18}F]-FDG PET-CT in patients with low grade gastroenteropancreatic neuroendocrine tumors (GEPNETs)

M. Simó¹, A. García², J. Hernando³, D. Villasboas², F. Dellepiane², I. Navales², M. Barios², M. Boronat², J. Capdevila³, J. Castell²;
¹Hospital Universitari Vall De Hebron, Barcelona, SPAIN, ²Hospital Universitari Vall de Hebron, Barcelona, SPAIN, ³Vhio, Barcelona, SPAIN.

Aim/Introduction: Initial workup in GEPNETs is usually challenging due to their heterogeneity, and accurate staging is important for selecting the appropriate treatment. [^{68}Ga]-DOTATOC imaging is a promising approach and could help in selecting optimal therapeutic strategies, but it is not yet available in all centers. The aim of this study was to prospectively determine the impact of [^{68}Ga]-DOTATOC-PET/CT versus [$^{99\text{mTc}}$]-HYNIC-TOC SPECT-CT, and the role of [^{18}F]-FDG PET-CT in low grade tumors. **Materials and Methods:** Patients underwent [^{68}Ga]-DOTATOC-PET/CT, [^{18}F]-FDG PET/CT and [$^{99\text{mTc}}$]-EDDA/HYNIC-TOC whole body planar imaging and thoracic-abdominal SPECT/CT, with less than four-week interval. Primary objective was accuracy assessment in diagnosis of [^{68}Ga]-DOTATOC-PET/CT compared with [$^{99\text{mTc}}$]-EDDA/HYNIC-TOC, determine

the different binding patterns of [^{18}F]-FDG and [^{68}Ga]-DOTA peptides in this group of patients and assess the therapeutic impact on treatment decision. **Results:** 29 and 27 patients were positive for [^{68}Ga]-DOTATOC-PET/CT and for [$^{99\text{mTc}}$]-EDDA/HYNIC-TOC, respectively. [^{68}Ga]-DOTATOC-PET/CT found the primary tumor in 14/16 non resected patients, whereas [$^{99\text{mTc}}$]-EDDA/HYNIC-TOC found it in 8/14 patients. Neither could detect the primary in two patients with primary unknown origin. In liver, [^{68}Ga]-DOTATOC-PET/CT was positive in 25 patients (all histological confirmation) and negative in 5. The only patient with false negative result had both lung carcinoid and pancreatic TNE. [$^{99\text{mTc}}$]-EDDA/HYNIC-TOC could not detect liver metastases in two [^{68}Ga]-DOTATOC-PET/CT positive patients. In one patient, with potentially resectable hepatic disease by [$^{99\text{mTc}}$]-EDDA/HYNIC-TOC, [^{68}Ga]-DOTATOC-PET/CT detected multiple unresectable liver disease. [^{68}Ga]-DOTATOC-PET/CT was superior to [$^{99\text{mTc}}$]-EDDA/HYNIC-TOC in detecting the number and localization of liver metastases, bone metastasis and peritoneal carcinomatosis detection. Only [^{68}Ga]-DOTATOC-PET/CT could detect extrahepatic disease in 43% of patients, with a major impact on therapeutic management 3 out of 26 patients potentially candidates for peptide receptor radionuclide therapy using [^{68}Ga]-DOTATOC-PET/CT were not by [$^{99\text{mTc}}$]-EDDA/HYNIC-TOC. [^{18}F]-FDG PET/CT added clinical information in only one of all cohort patients. **Conclusion:** [^{68}Ga]-DOTATOC-PET/CT provides important information for accurate workup of GEPNETs and selection of appropriate treatment decisions, compared to [$^{99\text{mTc}}$]-EDDA/HYNIC-TOC. [^{18}F]-FDG PET/CT provides residual information in this group of G1/G2 patients and it is not recommended in daily routine. **References:** None

EP-152

Utility of SUVmax values of PET / TC ^{68}Ga -DOTATOC in the diagnosis and monitoring of patients with pulmonary neuroendocrine tumors (NPT)

T. Moreno-Monsalve, T. Rodríguez-Locarno, D. Cáceres-Silva, M. Castellón-Sánchez, J. Navarro-Fernández, L. Frutos-Esteban, L. Mohamed-Salem, J. Contreras-Gutiérrez, M. Claver Valderas; Hospital Universitario Virgen De La Arrixaca, Murcia, SPAIN.

Aim/Introduction: TNPs express somatostatin receptors according to the degree of differentiation and the histological type. Our objective is to study the correlation between the SUVmax values of the ^{68}Ga -DOTATOC PET / CT and the different histological subtypes of the TNP. **Materials and Methods:** We conducted a retrospective study in 32 patients with suspected or previous diagnosis of TNP between December 2018 and 2019, who had histological confirmation and PET / CT ^{68}Ga -DOTATOC. Subjects were 13 women (40.6%) and 19 men (59.4%) with a mean age of 60.84. Diagnostics comprised 16 typical carcinoids

(CT) (50%), 6 atypical carcinoids (CA) (18.75%), 1 diffuse idiopathic neuroendocrine cell hyperplasia (3.12%), 1 large cell neuroendocrine carcinoma (CNCG) (3, 12%), 2 with undetermined pathological diagnosis, and finally 6 subjects with negative histology (18.75%). **Results:** We analyzed the SUVmax of 32 patients out of which 6 reported baseline PET / CT 68Ga-DOTATOC and PET / CT 18F-FDG. The CTs had a mean SUVmax for the 68Ga-DOTATOC PET / CT of 16.21, and 6.06 for the PET / CT 18F-FDG. In the CA, the SUVmax for the 68Ga-DOTATOC PET / CT was 3.19, and for the 18F-FDG PET / CT it was 5.2. In the CNCG the mean was 3.06 for the PET / TC 68Ga-DOTATOC, and 5.7 for PET / TC 18F-FDG. Regarding the 68Ga-DOTATOC PET / CT performed after treatment, of 12 CT, only 4 showed pathological uptake with a mean SUVmax of 33.38. And of 6 CA, 5 were pathological with an average SUVmax of 11.4. **Conclusion:** There is a correlation between the SUVmax values and the different histological subtypes of the TNP, where CT shows greater affinity for the PET / CT 68Ga-DOTATOC than the CA, and an inverse relationship with the PET / CT 18F-FDG. Prospective epidemiological studies are necessary to validate this association. **References:** None

EP-153

Characterization and surveillance of cardiac metastasis in well-differentiated gastroenteropancreatic neuroendocrine tumor using Ga68-DOTATATE PET/CT and PET/MR

J. Renfrew, R. Shrestha, M. Yang, T. Halfdanarson, R. Arsanjani, M. Sonbol;
Mayo Clinic - Arizona, Phoenix, AZ, UNITED STATES OF AMERICA.

Aim/Introduction: Gastroenteropancreatic (GEP) neuroendocrine tumor (NET) has gained growing recognition thanks to the clinical utilization of Ga68-labelled somatostatin analogue PET tracers, which target the somatostatin receptor subtype 2 (SSTR2) expressed on the tumor cell membrane. While hepatic and nodal metastases are commonplace at the time of NET diagnosis, cardiac metastases are found much less frequently. In this study, we aim to evaluate the prevalence, distribution pattern, and radiotracer uptake characteristics of cardiac metastasis on Ga68-DOTATATE PET/CT and PET/MR images. **Materials and Methods:** In this IRB approved retrospective study, the diagnostic criterion of cardiac metastasis is focal myocardial tracer uptake on PET with confirmative space-occupying lesion on chest CT or cardiac MR. The SUVmax of the cardiac metastasis and left ventricular chamber (blood pool), the Krenning score of the cardiac metastasis, and the presence of multisystem metastasis were documented and analyzed. **Results:** From Oct. 2017 to Mar. 2020, there were 1,426 Ga68-DOTATATE PET/CT and PET/MR scans performed at our institution. Twenty-one GEP NET patients (mean age of 64 ± 10.17 years old, male

: female ratio of 11:10) were diagnosed with asymptomatic cardiac metastasis, always with coexistence of multisystem metastases on PET, including liver, lymph node, lung and bone marrow, as well as elevated chromogranin A. In this cohort of patients, there were 29 total lesions, including those at the left ventricular free wall (16), septum (8), and right ventricular free wall (5). The average maximal SUV of these lesions was 9.2 (range 2.6-24.1) with the Krenning score of 2 to 4. The average maximal SUV of blood pool was 1.2 (range 0.5-2.4). The average lesion to blood pool SUV ratio was 8.3 (range 2.6-18.2). Seven patients had multiple Ga68-DOTATATE PET/CT scans while on Octreotide therapy. Among them, two (29%) showed initial progression with subsequent lesion stabilization on imaging. **Conclusion:** The prevalence of cardiac metastasis is associated with high tumor burden. Ga68-DOTATATE PET/CT and PET/MR is an established imaging modality in detection and surveillance of this rare clinical entity, and provides further guidance of clinical management. The clinical significance of cardiac metastasis needs to be further investigated. **References:** 1. Bonsen LR, Aslbersberg EA, Tesselaar M, Stokkel MP. Identification and characterization of myocardial metastases in neuroendocrine tumor patients using 68Ga-DOTATATE PET-CT. Cancer Imaging. 2018, 20;18(1):34.

EP-154

Retrospective Analysis of the Indications to 18F-FDG-PET/CT in NET Patients

G. Argalia¹, D. Calabrò¹, S. Telo¹, E. Fortunati¹, E. Tabacchi², L. Zannoni², D. Campana³, S. Fanti¹, V. Ambrosini¹;
¹Nuclear Medicine, S.Orsola-Malpighi Hospital, DIMES University of Bologna, Bologna, ITALY, ²Nuclear Medicine, S.Orsola-Malpighi Hospital, Bologna, ITALY, ³DIMEC University of Bologna, Bologna, ITALY.

Aim/Introduction: To retrospectively analyze the indications to 18F-FDG-PET/CT (FDG) performed before or after biopsy and 68Ga-DOTANOC-PET/CT (SSA) in patients (pts) with Grade-1 (G1) and Grade-2 (G2) neuroendocrine tumours (NET). **Materials and Methods:** Among pts collected in a CE-approved electronic archive between September 2017-June 2019, those with confirmed G1-G2 NET and both SSA and FDG were included. **Results:** 33 pts were included: Group-A (FDG positive=21) and Group-B (FDG negative=12). Group-A: indication to FDG in 9/21 pts was conventional imaging (CI:CT/US/MRI) equivocal (not suggestive for NET) findings characterization before biopsy (performed on average 1 month after FDG) and before SSA. In 2/9 pts biopsy revealed a G1-tumour (lung primary: 1pt, ileum primary: 1pt) but the subsequent SSA showed mismatch lesions in one

case and matched lesions in the other. In the remaining 7/9 pts, biopsy showed a G2-tumour (primary: lung 3pts, ileum 1pt, pancreas 1pt, gallbladder 1pt, 1pt with retroperitoneal paraganglioma with ki67>10%). In the remaining 12/21, FDG was performed after biopsy and SSA. In 4/12 pts FDG was performed to characterize equivocal CT findings: SSA was positive in 2pts (1 ileum primary-G1 with suspected peritoneal lesions; 1 paraganglioma with ki67:5.4% studied for suspected relapse) and negative in 2pts (primary: 1 G1-ileum, 1 G1-lung with lung nodules suspicious for non-NET lesions but later confirmed as NET). In 5/12 FDG was performed for disease progression in pts with an originally well-differentiated lesion (biopsy performed before FDG respectively at 68months in one G1-ileum, at 156months in a G2-ileum, at 15months in two G2-pancreas and at 48months in one G2-pancreas), in 1/12 pt for low uptake at SSA (G2-ileum with suspected lung secondary lesions), in 2/12 pts for pre-surgical staging (G2-pancreas and G2-ileum respectively). Group-B (12pts): in 7/12 pts FDG was performed to characterize equivocal CI findings not suggestive for NET (6 hepatic lesions; 1 abdominal mass) before biopsy and before SSA. Biopsy later revealed ileum primary in 6/7 (G1:4; G2:2) and UPC in 1/7 (G1:1). In 2/12 pts FDG was performed to characterize equivocal CT findings after a NET-positive biopsy and negative SSA: 1/2 hepatic lesions (G2-lung) and 1/2 abdominal nodes (G2-pancreas). Indication to FDG in 3/12 pts was suspected disease progression (1 G1-pancreas, 1 G2-pancreas, 1 MEN1): SSA was respectively positive in the first 2 pts and negative in the latter. **Conclusion:** Indications to FDG in NETG1-G2 pts were CI equivocal findings characterization, disease progression and negative/low-uptake SSA. **References:** None

EP-155

Corticomedullary mixed tumor of the adrenal gland with apparent 18F-FDG activity but no 68Ga-DOTATATE uptake on PET/CT

C. Engur¹, T. Apaydin², T. Ones¹, H. I. Gozu², T. Y. Erdil¹;

¹Marmara University Pendik Training and Research Hospital, Istanbul, TURKEY, ²Marmara University Pendik Training and Research Hospital, Endocrinology Department, Istanbul, TURKEY.

Aim/Introduction: Corticomedullary mixed tumor (CMT) is a single adrenal tumor mass composed histologically by an admixture of adrenal cortical and medullary cells. It is a rare condition with approximately 20 cases reported to date. To our knowledge, the PET imaging findings of this mostly benign tumor have not been reported in the literature. We present a case of CMT who was evaluated with both 18F-FDG and 68Ga-DOTATATE. **Materials and Methods:** A 63-year-old woman referred to endocrinology clinic for a 23x22 millimeter left adrenal adenoma, detected incidentally in abdominal CT which performed for abdominal pain in her left flank. In the laboratory examination; the 1 mg over night

dexamethasone suppression test (DST) was 5.32 µg/dL (normal value(NV):<1.8 µg/dL), 2-day low-dose DST was 3.26 µg/dL (NV: < 1.8 µg/dL). There was no obvious cushingoid features and the patient was diagnosed as subclinical Cushing's syndrome. The patient was evaluated with both 18F-FDG and 68Ga-DOTATATE. **Results:** The hypermetabolic tumor seen on 18F-FDG (SUVmax was 4.4, clearly higher than the background liver SUVmax 2.2, Figure 1A) which was localized on the medial crus of the left adrenal gland, showed no abnormal uptake on 68Ga-DOTATATE (Figure 1B). Laparoscopic left adrenalectomy was performed. The tumor diameter was 2.4x2.3x2 centimeters and histopathologically demonstrated two different cell types composed of cortical and chromaffin cells. The Weiss score was 1, compatible with a definitive pathologic diagnosis of a benign CMT. The patient was followed up at the endocrine outpatient clinic and 1 mg overnight DST was 0.26 µg/dL at postoperative third month. **Conclusion:** In the vast majority of patients with CMT, the symptoms were related to the tumor's hormone hypersecretion. Most of them are benign with a favourable prognosis but some malignant tumors with a poor prognosis have been reported. Due to the lack of specific clinical features, these tumors are discovered accidentally on histological examination. 18F-FDG is a useful imaging technique in characterizing adrenal masses. However false-positive interpretations may result from benign lesions. Our case is the first one to our knowledge to report a case of a benign CMT who was evaluated with PET imaging findings and it should be kept in mind that it may exhibit false-positive results for malignancy with 18F-FDG. Negative 68Ga-DOTATATE findings may be a clue for benignity in this patient group. It may be important to obtain further PET imaging results, especially in patients with pathologic diagnosis of malign CMT. **References:** None

EP-156

Influence of somatostatin analogue type for result of 68Ga-somatostatin analogue PET/CT and its effect on therapeutic decisions in patients with neuroendocrine neoplasm - which result to believe? - case study

M. Opalinska¹, A. Sowa-Staszczak^{2,1}, K. Skórkiewicz¹, M. Buziak-Bereza^{2,1}, A. Stefańska¹, A. Hubalewska-Dydejczyk^{2,1};

¹Nuclear Medicine Unit, Endocrinology Department, University Hospital, Krakow, POLAND, ²Endocrinology Clinic of the Endocrinology Department, Faculty of Medicine, Jagiellonian University Medical College, Krakow, POLAND.

Aim/Introduction: Confirmation of the somatostatin receptors expression in neuroendocrine neoplasm is a basis for choice of diagnostic and therapeutic procedures. Lack of such expression limits treatment options. The somatostatin analogues used for diagnostics may have different affinity for the somatostatin receptors subtypes. The selection of ligand(NOC, DOTA, TATE) often is limited by its availability and

usually is not connected to the real profile of somatostatin receptors expression in the tumor tissues. **Materials and Methods:** Case report: In 03.2009 a 34-years old male was referred to Endocrinology Clinic with suspicion of pancreatic NET. MRI revealed presence of a 54x42mm tumor of the distal part of the pancreas and 2 metastatic changes in the liver. Liver biopsy confirmed neuroendocrine neoplasm. Resection of the pancreatic body and tail with splenectomy was performed on 04.2009 (pathology: neuroendocrine cancer, Ki67 50%, metastases in 17/20 nodes). The tumor had good expression of somatostatin receptors (sstr) in the primary and metastatic lesions. Due to the high expression of sstr, patient received 1 dose of PRRT with the next Gemzar and Erlotinib therapy which was ended in 08.2011. From 2015, the PET/CT scan with 68GaDOTA-TATE show pathological (Krenning score 3 and 4) expression of sstr in the retropharyngeal node. The lesion had slowly progressed in various follow-up studies. In 09.2016, the conglomerate of neck nodes group II and V, the submandibular salivary gland and the node of the mandible angle were removed (metastases to lymph nodes were confirmed, Ki67 3%). The follow-up PET/CT studies with 68GaDOTA-TATE started from 11.2016 showed the persistent pre-vertebral SSTR+ space infiltration extending from the base of the skull to level C1/C2 and involvement of cervical IIa nodes. A follow-up study with 68GaDOTA-TOC showed only slightly elevated (Krenning score 1) expression of sstr in the pre-vertebral space (previously with high pathological expression of sstr seen on 68GaDOTA-TATE PET/CT). The next follow-up study with 68GaDOTA TATE again revealed high, pathological expression of sstr in the neck area. **Results:** Patient with pancreatic NETG3 was found to have incompatible imaging results using both 68Ga-TOC and -TATE ligands. **Conclusion:** The result of PET/CT 68Ga-somatostatin analogue imaging with different ligands may give different results in the same patient and in extreme cases may lead to the suboptimal choice of therapeutic procedures (disqualification from long-acting somatostatin analogue treatment and PRRT in case of dissemination of the disease). **References:** None

Aim/Introduction: The identification of prognostic factors for survival in patients with metastatic gastroenteropancreatic neuroendocrine tumors (GEP-NET) represents a challenge for patient management. This retrospective study investigated the phenotype presentation of these tumors with 18FDG and 68Ga-DOTANOC-PET-CT and analyzed its prognostic impact on survival. **Materials and Methods:** Patients with metastatic histologically proven grade 1 (G1) or 2 (G2) GEP-NET (WHO 2019 classification), who underwent 18FDG-PET-CT and 68Ga-DOTANOC-PET-CT within 2 months between 2013 and 2017, were included. For 18FDG-PET-CT analysis, pathological foci which exceeded in intensity healthy liver were considered significant. Progression was assessed with clinical and radiological criteria. Progression free survival (PFS) and overall survival (OS) were evaluated. Kaplan-Meier method was used (curves being compared with log-rank test). Prognostic factors were evaluated with univariate and multivariate analysis (Cox proportional hazards model), with a p value of less than 0.05 considered significant. **Results:** A total of 39 patients (23 males, 16 females, median age: 59 years), 10 with G1 (26%) and 29 with G2 (74%) tumors were included, mainly pancreatic (n=20; 51%) or midgut (n=13; 33%) origin. Median Ki67 index was 7%, >10% in 11 patients (28%). 68Ga-DOTANOC-PET-CT was positive (at least one lesion) in 100% of patients and 18FDG-PET-CT in 72% of patients (n=28). At least one 18FDG+/68Ga-DOTANOC-lesion was found in 4 patients (10%). After a median follow-up of 39 months, 24 patients had progressive disease (64%) and 11 died (28%). PFS was significantly lower in 18FDG-PET-CT positive patients than in 18FDG-PET-CT negative patients (14vs55.9 months; p=0.0249). Furthermore, the number of 18FDG positive lesions and the presence of at least one 18FDG+/68Ga-DOTANOC-lesion were significantly correlated with PFS in univariate (respectively, p<0.0001 and p=0.007) and multivariate analysis (respectively p=0.0012 and p=0.020). Despite the low number of event, the presence of at least one 18FDG+/68Ga-DOTANOC-lesion was associated with poor OS (p=0.017). The number of previous treatment was associated with PFS in univariate analysis (p=0.0396) but not in multivariate analysis. None of the other clinical, biological (including WHO grade, Ki67 index) or 68Ga-DOTANOC-PET-CT data were significantly associated with PFS or OS. **Conclusion:** Our results showed the high prevalence of 18FDG positive lesions in G1 and G2 metastatic GEP-NET illustrating the heterogeneity of these tumors and confirmed the prognostic impact of 18FDG-PET-CT on PFS. In particular, the number of 18FDG positive lesions and the presence of at least one 18FDG+/68Ga-DOTANOC-lesion were associated with a poorer prognosis in our patients. **References:** None

Prognostic value of ¹⁸F-FDG PET / CT in patients with Multiple Myeloma treated with autologous haematopoietic stem-cell transplantation

L. Brero Sánchez, R. Álvarez Pérez, J. Cuenca Cuenca, E. Carrillo Cruz, J. Tirado Hospital, J. Jiménez-Hoyuela García; Virgen del Rocio University Hospital, Seville, SPAIN.

Aim/Introduction: To assess the prognostic value of ¹⁸F-FDG PET / CT in patients with Multiple Myeloma (MM) treated with autologous haematopoietic stem-cell transplantation (HSCT). **Materials and Methods:** Retrospective study of 17 patients (11 women and 6 men with a mean age of 57.18 years) diagnosed with MM between 2015 and 2019, with available clinical information about disease status before chemotherapy induction treatment, before HCST and a minimum clinical follow-up of 6 months after HCST. All of them underwent a ¹⁸F-FDG PET / CT before HCST (PET0) and at least 3 months after it (PET1). We analyzed the number of lesions and the maximum standardized uptake values (SUVmax) of each study before and after HCST. After literature review, we considered as poor prognosis indicator a SUVmax > 4.2. **Results:** 3/17 patients had negative studies on both PET0 and PET1. 9/17 showed a decrease of SUVmax in PET1 compared to the previous one, with a SUVmax reduction over 25% in 5 of them, all of them had a progression-free survival (PFS) > 12 months. 5/17 patients showed SUVmax increase in PET1 compared to PET0, with PFS < 6 m. 3/5 patients presented a significant increase (25%) in SUVmax between PET0 and PET1 and they were exitus during the follow-up. 2/3 patients showed extramedullary disease and study SUVmax > 4.2 on PET0. We did not observe a correlation between the number of lesions in PET0 and PFS. **Conclusion:** Visual and semiquantitative analysis of ¹⁸F-FDG PET / CT pre and post-HCST in patients with MM, as well as the evaluation of SUVmax value, may predict patient response to HCST. **References:** Multiple myeloma: ESMO Clinical Practice Guidelines for diagnosis, treatment and follow-up. Annals of Oncology 28 (Supplement 4): iv52-iv61, 2017. Interest of Pet Imaging in Multiple Myeloma. Front Med April 9; 6:69. 2019.

PET / CT Imaging in Smoldering Multiple Myeloma Patients F 18-Fluorodeoxyglucose and Ga68-Pentixafor: Preliminary results

U. Korkmaz, E. G. Umit, G. Durmus-Altun; Trakya University, Edirne, TURKEY.

Aim/Introduction: Smoldering multiple myeloma (SMM) is a subgroup of MM, limited to bone marrow, with no other organ involvement. Patients are face the risk of developing active MM over time. The risk increases with bone marrow involvement. Tumor burden is the most important factor for prognosis. FDG PET/CT has proven to be a sensitive technique for the detection of metabolically active MM and has recently been included in the diagnosis of MM by the International Myeloma Study Group (IMSG). Accurate evaluation of bone disease is important in MM, order to be managed clinically correctly. The aim of this study is to evaluate the contribution of Ga68-Pentixafor PET / CT by comparing it with F18-FDG data in the special patient group followed up without tumor after SMM or otolog bone marrow transplantation (OBMT). **Materials and Methods:** In this study, 155 patients (67 years, 46K) who were diagnosed and treated with MM in between 2016-2018 were included. All patients were evaluated with the FDG PET/CT after the initial and remission induction. In patients with suspected SMM, Ga 68-Pentixafor PET / CT was performed. The Ga-68 Pentixafor PET / CT and F-18 FDG PET / CT images taken in the same system with the proposed routine protocol were independently evaluated on the basis of patients and lesions by two experienced nuclear medicine specialists. Data of each patient were obtained from the hematology follow-up files. PET / CT findings were evaluated together with accompanying clinical follow-up data. **Results:** No metabolic active focus was detected in F-18 FDG PET / CT images in 30 of 155 patients at the time of diagnosis. Three patients were accepted as SMM and 3 patients were in complete remission after first line therapy and OBMT according to the IMSG criteria. None of them had evidence that could be associated with bone lesion. **Conclusion:** The findings of this study supported that FDG PET / CT is a sensitive technique for the detection of metabolically active MM. Limited but valuable data has been generated for 68Ga-Pentixafor in six MM patients. It has been possible to show metabolic changes with PET / CT in both SMM patients and MM patients in remission. As a disease that is still considered "incurable", Ga68-Pentixafor PET / CT promises the correct use of newer definitions such as "minimal residual disease" and "limited complete remission" in the clinical approach in MM. **References:** None

EP-160**¹¹C-Methionine and ¹⁸F-FDG PET/CT in multiple myeloma: Comparative study**

O. Cuenca-Vera¹, M. de Arcocha-Torres¹, I. Martínez-Rodríguez¹, R. Quirce¹, J. Jiménez-Bonilla¹, A. Sánchez-Salmón¹, N. Martínez-Amador¹, G. Molina-Mendoza¹, J. Andrés-Pacheco¹, Á. Gutiérrez-González¹, S. Ruiz Llama¹, A. Bermúdez², I. Banzo¹;

¹Nuclear Medicine Service, Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN, ²Hematology Service, Marqués de Valdecilla University Hospital. University of Cantabria, Santander, SPAIN.

Aim/Introduction: Our objective was to evaluate and compare the diagnostic efficacy of ¹¹C-Methionine (MET) and ¹⁸F-FDG (FDG) PET/CT in patients with a diagnosis of multiple myeloma. **Materials and Methods:** We performed a retrospective study involving 12 patients with multiple myeloma (9 men; mean age: 57.5±9.7 years). In all patients both MET and FDG PET/CT were acquired with an interval between examinations ranged from 11.8 to 12.9 days (November-17th to January-20th). In total, 13 sets of PET/CT were evaluated (one patient had two sets of examinations). PET/CT studies were performed prior to treatment in 4 cases (30.8%) and during follow-up in 9 (69.2%). MET and FDG were produced in an in-house cyclotron and using an automated synthesis system. Whole-body PET/CT scans were acquired 20 minutes after iv injection of 555-740 MBq of MET and 90 minutes after iv injection of 7 MBq/kg of FDG. MET and FDG images were blindly visually analysed. Any focal accumulation of the radiotracer higher than the background was considered as positive. The results obtained with MET and FDG were compared, considering both the number and extend of bone uptake foci. **Results:** MET and FDG findings matched in 10 out of 13 studies included (76.9%) and mismatched in 3 (23.1%). Of the 10 matched studies, 6 (46.1%) were MET and FDG positive: in 1 of them both examinations showed the same bone uptake foci, in 4 MET showed more foci than FDG and in 1 the FDG showed more foci than MET. In 3 studies (23.1%) MET and FDG were negative. Finally, in 1 study (7.7%) MET and FDG were inconclusive. Of the 3 mismatched studies, in 1 (7.7%) MET was positive and FDG negative, and in 2 (15.4%) FDG was positive and MET negative. MET detected multiple myeloma involvement in 7/13 studies (53.8%), in 4 of them with greater extent than FDG and in 1 with a negative FDG. FDG detected myeloma involvement in 8/13 studies (61.5%), in 1 of them with greater extent than MET and in 2 with a negative MET. **Conclusion:** MET and FDG PET/CT scans showed a complementary role in the evaluation of patients with multiple myeloma. When both studies, MET and FDG, were positive MET detected a more extensive involvement. These results should be confirmed by a larger population. **References:** None

EP-161**Can ¹⁸F-NaF PET/CT Before Autologous Stem Cell Transplantation Predict Survival In Multiple Myeloma?**

C. Sachpekidis¹, A. Kopp-Schneider², M. Merz³, A. Jauch⁴, M. Raab³, H. Goldschmidt³, A. Dimitrakopoulou-Strauss¹;

¹Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, ²Department of Biostatistics, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, ³Department of Internal Medicine V, University Hospital Heidelberg and National Center for Tumor Diseases (NCT), Heidelberg, GERMANY, ⁴Institute for Human Genetics, University of Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: There is an unmet need for positron emission tomography (PET) radiotracers that can image bone disease in multiple myeloma (MM) in a more sensitive and specific way than the widely used ¹⁸F-fluorodeoxyglucose (¹⁸F-FDG). Sodium fluoride (¹⁸F-NaF) is a highly sensitive tracer of bone reconstruction, evolving as an important imaging agent for the assessment of malignant bone diseases. We attempted to investigate for the first time the prognostic significance of ¹⁸F-NaF PET/CT in newly diagnosed, symptomatic MM patients planned for autologous stem cell transplantation (ASCT). **Materials and Methods:** Forty-seven patients underwent dynamic and static PET/CT with ¹⁸F-NaF before treatment. After correlation with the respective findings on CT and ¹⁸F-FDG PET/CT that served as reference, the ¹⁸F-NaF PET findings were compared with established factors of high-risk disease, like cytogenetic abnormalities as well as bone marrow plasma cell infiltration rate. Furthermore, the impact of ¹⁸F-NaF PET/CT on progression-free survival (PFS) was analyzed. **Results:** Correlation analysis revealed a moderate, significant correlation of the ¹⁸F-NaF parameters SUV_{average} and K₁ in reference tissue with bone marrow plasma cell infiltration rate. However, no other significant correlation was observed regarding all other ¹⁸F-NaF PET parameters. Survival analysis revealed that patients with a pathologic ¹⁸F-NaF PET/CT have a shorter PFS than those with a physiologic scan. Nevertheless, no quantitative ¹⁸F-NaF parameter adversely affected PFS. **Conclusion:** The herein presented findings highlight the rather limited role of ¹⁸F-NaF PET/CT as a single PET approach in MM. **References:** None

EP-162**The role of ¹⁸F-FDG PET/CT and beta-2-microglobulin in diagnostic assessment of patients with multiple myeloma**

K. Mladenov¹, V. Hadzhiyska¹, D. Vasileva², P. Nikolova¹, M. Ilcheva¹;

¹Clinic of Nuclear medicine, University Hospital "Alexandrovka", Sofia, BULGARIA, ²Department of Nuclear Medicine, Specialized Hospital for Active Therapy of Haematological diseases, Sofia, BULGARIA, .

Aim/Introduction: Multiple myeloma (MM) is a malignant haematological disorder characterized by bone marrow infiltration with neoplastic plasma cells, paraproteinemia and osteolytic bone destruction. The detection of extramedullary tissue involvement is important for the treatment planning and prognosis of MM patients (pts). Standard diagnostic imaging methods, such as radiography and bone scan, have certain limitations for early evaluation of bone and bone marrow lesions. FDG-PET/CT has been shown to be able to detect extramedullary lesions and to improve bone lytic lesions detection for appropriate staging of the process. Serum beta-2-microglobulin (β_2M) levels have been used to evaluate tumour burden in MM pts. However data regarding correlations between PET findings with serum β_2M levels in MM pts are limited. The aim of the study was to investigate the clinical usefulness of 18F-FDG-PET/CT imaging and correlations with serum-beta-2-microglobulin in MM pts. **Materials and Methods:** Fifty eight MM patients were evaluated retrospectively (32 males and 26 females) a median age 58.3 years. 18F-FDG-PET/CT scans were performed according to the standard protocol. Serum β_2M levels were measured by radioimmunoassay. **Results:** In 3 pts without bone lesions, disease was detected in the bone marrow with PET/CT scintigraphy (diffuse uptake), before other visual methods. The PET marrow uptake correlated with the percentage of bone marrow plasma cells. The median serum β_2M levels were 4.8mg/l (normal range 1.2–2.4 mg/l). The scintigraphy data showed hypermetabolic bone lesions in 55 pts. The focal and multifocal patterns of FDG-PET/CT were detected in four and 51 pts, respectively. A total of 102 bone lesions were detected in the calvaria, spine, ribs, sternum, pelvis and long bones. The median SUV max was 8,5 mg/l. The extramedullary lesions in the soft tissues were detected in 12.1% (7/58) pts (thyroid gland, mammary gland, lungs, orbita, stomach). The median serum β_2M levels were 9.8 mg/l. 18F-FDG PET revealed 2 previously unknown additional lesions in two patients undetected by conventional visualization methods. The diagnosis was confirmed by bone and bone marrow biopsy. **Conclusion:** The results showed the effectiveness of the 18F-FDG-PET/CT in the detection of skeletal, bone marrow and extramedullary involvement in MM patients. The positive scintigraphy showed a good correlation with the data of serum beta-2-microglobulin in patients with MM. The potential of PET/CT to detect medullary and extramedullary lesions in a single examination is important advantage over other visualization methods. **References:** None

¹⁸F-Fluorocholine in the staging of Multiple Myeloma patients . First impressions

P. Garrastachu Zumaran¹, X. Boulevard¹, M. Albornoz¹, P. Hernández Pérez², F. Cañete Sanchez¹, L. Romero Robles¹, A. Cabrera Villegas¹, M. Hermosilla Fernández², R. Ramirez Lasanta¹;
¹Fundacion Riojasalud. CIBIR, Logroño, Rioja, SPAIN,
²Hospital San Pedro, Logroño, Rioja, SPAIN.

Aim/Introduction: It is well known the negative results obtained when staging some patients diagnosed with MM. The objective of this study is to evaluate the possible role of ¹⁸Fluorocholine -PET/TAC(FCH-PET) in this scenario and compare it with the established imaging work up, the ¹⁸Fluorodesoxiglucose-PET/TAC (FDG-PET). **Materials and Methods:** It is a prospective study that includes patients with diagnosis of MM and candidates for bone marrow autologous transplant (AT). Each patient undergoes PET-CT studies with two tracers: 18-FCH and 18-FDG. For each tracer we evaluate the presence of bone marrow infiltration and its metabolic pattern as well as the presence of focal bone lesions and paramedullary and extramedullary disease according to the proposed IMPeTus criteria (Italian myeloma criteria for PET Use). We compare the findings obtained for both tracers per lesion and per patient. **Results:** We included 9 patients (the study is still opened). The median time between 18FDG-PET and 18FCH-PET scans was 4 days(1-28). 4 out of the 9 patients studied had diffuse bone marrow infiltration in FDG-PET. FCH showed a diffuse pattern in 8 of the 9 patients and a patchy distribution in 1 of them. The FDG-PET visualized 5 focal bone lesions in contrast to the 13 observed in the FCH-PET. 3 of the FDG-PET positive bone lesions were also positive in FCH-PET and 2 of them were negative: one corresponded to a costal fracture and the other to degenerative origin. The 10 bone lesions observed only in the FCH-PET were located in the axial skeleton. 1 patient presented a plasmocitoma, detected by both tracers, although the intensity of the uptake was higher in the FDG-PET. 2 extramedullary foci were detected: one in vagina and the other in the cervical area, both of inflammatory-infectious origin. According to the patient based analysis 3 patients showed more axial foci in the FCH-PET than the FDG-PET. **Conclusion:** FCH-PET could be a useful tool for the staging of MM patients, although, it is still a challenge to determine what patients should benefit from this new tracer. **References:** Nanni C. et al. Image interpretation criteria for FDG PET/CT in multiple myeloma: a new proposal from an Italian expert panel. IMPeTUs (Italian Myeloma criteria for PET Use). EP-164**18F-FDG PET / CT findings of Rosai Dorfman Disease with diffuse extranodal involvement**

N. Filizoglu, S. Kesim, C. O. Engur, K. Oksuzoglu, S. Ozguven, T. Ones, H. T. Turoglu, T. Y. Erdil;
Marmara University Pendik Training and
Research Hospital, Istanbul, TURKEY.

Aim/Introduction: Rosai Dorfman disease (RDD) is a rare benign disease characterized by permanent massive lymphadenopathy mimicking malignant tumors. Extranodal involvement, including the skin, upper respiratory tract, salivary gland, bone, central nervous system and rarely kidneys, may occur in approximately 43% of patients. Although RDD can usually recover spontaneously, it may persist in some patients and mimic lymphoproliferative disorders clinically and visually. We present the 18F-FDG PET / CT findings of the patient with RDD with diffuse extranodal involvement. **Materials and Methods:** An 18F-FDG PET / CT examination was performed to investigate malignancy in a 57-year-old male patient with multiple cervical lymph nodes. **Results:** 18F-FDG PET / CT demonstrated 2.5 cm sized intense hypermetabolic lymph nodes in the bilateral cervical chain. Intense hypermetabolic soft tissue density lesions were observed in the subcutaneous fatty plans of the T12 vertebra left posterolateral section and the right lower quadrant of the abdomen. 12 mm sized mild hypermetabolic soft tissue density nodular lesion was seen in the right adrenal gland medial crust and 3x2.5 cm sized mild hypermetabolic soft tissue density nodular lesion was found in the left adrenal gland corpus. In the skeletal system, intense hypermetabolic lytic lesions compatible with metastasis were observed in the left occipital condyle, the posterior elements of the T6 vertebra, the C1 vertebra transvers process, the posterior part of the right acetabulum and the posterior part of the right iliac bone. Excisional biopsy was performed on the lymph node in the submandibular area and the lesion observed in the subcutaneous fatty plan in the right lower quadrant of the abdomen and the histopathology was found compatible with Rosai Dorfman disease. **Conclusion:** RDD, first described by Rosai and Dorfman in 1969, is a rare benign lymphoproliferative disease. RDD is usually manifested by cervical lymphadenopathy and typically mimics lymphoma. Diseases such as lymphoma, tuberculosis, sarcoidosis, reactive hyperplasia and nasopharyngeal carcinoma can be considered in the differential diagnosis. Extranodal disease is observed in approximately 43% of cases, most commonly in the skin, nasal cavity, eyes and bone. Although Rosai-Dorfman disease is usually self-limited, patients with extranodal involvement may have a more fulminant course and need active treatment. Since lesions show increased FDG uptake, 18F-FDG PET-CT may be useful in determining the extent of the disease, including lymph

node involvement. Therefore, the present case emphasized the importance of 18F-FDG PET-CT scan in the diagnosis, staging and treatment selection of the disease. **References:** None

EP-165**⁶⁸Ga-PSMA PET/CT in prostate cancer patients with biochemical recurrence after primary treatment: diagnostic accuracy and impact on management strategy**

R. Wang, G. Shen, L. Pan, R. Tian;
Sichuan University West China Hospital, Chengdu, CHINA.

Aim/Introduction: ⁶⁸Gallium prostate-specific membrane antigen positron emission tomography/computed tomography (⁶⁸Ga PSMA PET/CT) is a promising imaging modality in assessing prostate cancer. The aims of our study is to evaluate the diagnostic performance of ⁶⁸Ga PSMA PET/CT for detecting relapse or metastasis in prostate cancer patients with biochemical recurrence (BCR) after primary treatment, and to assess the potential impact of ⁶⁸Ga PSMA PET/CT on the management strategy of prostate cancer patients with BCR. **Materials and Methods:** The PubMed, EMBASE and Cochrane Library databases were searched until April 20, 2019. Studies regarding the diagnostic performance of ⁶⁸Ga-PSMA PET/CT in detecting prostate cancer patients with BCR after definitive treatment and/or studies reporting proportion of management changes after ⁶⁸Ga PSMA PET/CT in patients with BCR were included. The quality of each study was assessed using the Quality Assessment of Diagnostic Accuracy Studies-2 (QUADAS-2) tool. The detection rate of ⁶⁸Ga PSMA PET/CT and the proportion of management changes were pooled using random-effects model. The quality of the studies was evaluated using the GRADE system. Subgroup analyses and meta-regression analyses were performed to explore heterogeneity. **Results:** A total of 45 studies were included, and 17 studies of them evaluated the impact of ⁶⁸Ga PSMA PET/CT on management of patients. For prostate cancer patients with BCR, the pooled detection rate of ⁶⁸Ga PSMA PET/CT was 77% (95%CI, 76-78). For PSA categories 0-0.19 ng/ml, 0.2-0.49 ng/ml, 0.5-2.0ng/ml, 2.0-1.9ng/ml and >2ng/ml, the pooled detection rates were 26% (95%CI, 22-29), 48% (95%CI, 45-52), 59%(95%CI, 56-62), 81%(95%CI, 79-84) and 95%(95%CI, 94-96). For the impact of ⁶⁸Ga PSMA PET/CT on the management, the pooled proportion of management changes was 53%(95%CI, 51-55). Among

these management changes, the increasing proportion was seen in the treatments including radiotherapy (42%–49%), surveillance (29%–32%) and surgery (0.4%–3.5%), whereas the proportion of systemic treatment (56%–42%) decreased due to the ^{68}Ga PSMA PET/CT. **Conclusion:** For prostate cancer patients with BCR, the diagnostic accuracy of ^{68}Ga PSMA PET/CT was high, and the detection rate correlated positively with PSA levels. In addition, ^{68}Ga PSMA PET/CT had a significant impact on the management of patients.

Role of ^{68}Ga -PSMA PET/CT in men with biochemical recurrence after definitive treatment of adenocarcinoma prostate

R. Kumar¹, A. Sharma¹, S. Kumar¹, C. Das¹, A. Seth¹, A. Pandey¹, C. Patel¹, E. Estrada-Lobato², J. Cercí³, S. Fantí⁴;

¹AllIMS, New Delhi, INDIA, ²Division of Human Health, IAEA, Vienna, AUSTRIA, ³Diretor do Serviço de PET/CT Quanta - Diagnóstico e Terapia, Curitiba, BRAZIL, ⁴University of Bologna, Bologna, ITALY.

Aim/Introduction: Early localisation of disease recurrence after definitive treatment of prostate cancer is vital to determine suitability for salvage treatment. The aim of present study was to prospectively determine the relationship between prostate specific antigen (PSA) level and detection of suspected cancer recurrence using ^{68}Ga -PSMA PET/CT in patients with biochemical recurrence after radical prostatectomy (RP) or radiotherapy, particularly at low PSA levels. **Materials and Methods:** Sixty patients with histopathologically proven prostate adenocarcinoma who had undergone primary treatment in the form of RP or radiotherapy with rising serum PSA were recruited in the study. Serum PSA levels on which biochemical relapse was diagnosed were assured to be less than or equal to 4 ng/ml. Each patient underwent a whole body PET/CT scan on BiographmCT 64 slice after 30 minutes of injecting 2–5 mCi (74–185 MBq)/kg of ^{68}Ga -PSMA intravenously. PET/CT scans were interpreted independently by two nuclear medicine experts who were blinded to patient information. Data was analysed to determine the relationship of pre-scan PSA level to the probability of a positive scan finding for recurrent prostate cancer. **Results:** Of 60 men, 46 had previous RP and 14 had prior radiotherapy. Median PSA of RP group was 0.346 ng/mL and in radiotherapy group was 0.555 ng/mL. In post RP group, the overall detection rate of ^{68}Ga -PSMA PET/CT was 43.5% (n=20/46). The detection rate was 37.5% (n=6/16) for PSA 0.01 to <0.2 ng/mL, 8.3% (n=1/12) for PSA 0.2 to <0.5 ng/mL, 60% (n=3/5) for PSA 0.5 to <1 ng/mL, 80% (n=4/5) for PSA 1 to <2 ng/mL and 75% (n=6/8) for PSA 2 to 4. Lymph node metastasis post RP was identified in 60% (n=12/20) and bone metastasis in 45% (n=9/20) of men with suspected disease recurrence. In

the post radiotherapy group the overall detection rate was 64.3% (n=9/14). The detection rate was 33% (n=2/6) for PSA 0.01 to <0.5 ng/mL, 80% (n=4/5) for PSA 0.5 to <2 ng/mL, and 100% (n=3/3) for PSA 2 to 4 ng/mL. Out of 9 PET/CT positive patients post radiotherapy, local recurrence was detected in 89% (n=8/9) of men, lymph node metastasis in 66.66% (n=6/9) and bone metastasis in 44% (n=4/9) of men. **Conclusion:** ^{68}Ga -PSMA PET/CT has an important role in detection of suspected recurrence in prostate cancer post definitive treatment. Detection rate for suspected recurrence increases with increase in PSA levels. Detection of suspected recurrent disease outside the pelvis at low PSA levels will influence the decision for salvage treatment options. **References:** None

EP-167

Diagnostic accuracy of ^{68}Ga -PSMA-11 PET/CT in patients with recurrent prostate cancer

V. Fech, C. Sachpkeidís, I. Alberts, C. Mingels, B. Vollnberg, A. Rominger, A. Afshar-Oromieh;

Department of Nuclear Medicine, Bern, SWITZERLAND.

Aim/Introduction: The high sensitivity of ^{68}Ga -PSMA-11-PET/CT has been shown in numerous studies. Recently, many case reports have been published describing various benign and malignant entities exhibiting PSMA-ligand uptake. The present evaluation was performed in order to further analyze the positive predictive value of ^{68}Ga -PSMA-11 PET/CT. **Materials and Methods:** A retrospective analysis was performed for all patients who underwent ^{68}Ga -PSMA-11 PET/CT between January 2017 and March 2019 at our institute in order to detect recurrent PC (n=523). Hitherto, 80 patients were identified who had received radiation therapy, histology or surgical removal of PSMA-positive lesions, enabling a comparison with PSMA-avidity in the previous PET/CT. **Results:** So far, 87 PSMA-positive lesions in the 80 patients have undergone external radiation, were biopsied or surgically removed. 78 of them (89.7%) were true-positive PC lesions (proven by falling PSA following external radiation or by histology). Amongst the mentioned lesions were 42 local relapses, 11 lymph node metastases and 25 distant metastases. **Conclusion:** Our analysis demonstrates the high positive predictive value of ^{68}Ga -PSMA-11 PET/CT. To our conviction, PSMA-positive lesions with a CT-correlate in patients with recurrent PC can be classified as PC lesions with high confidence. Although uptake of PSMA-ligands in various non-prostatic tissues have been described, it must be assumed that their numbers represent only a fraction of the overwhelming numbers of PC lesions detected daily in clinical practice by ^{68}Ga -PSMA-11-PET/CT worldwide. **References:** None

EP-168**⁶⁸Ga-PSMA-11 PET/CT detection rate in very low risk recurrent PCa patients: a single center experience**

S. Telo, A. Farolfi, R. Mei, S. Mattoni, L. Calderoni, P. Castellucci, S. Fanti;

Nuclear Medicine, Policlinico S.Orsola-Malpighi, Bologna, ITALY.

Aim/Introduction: To evaluate ⁶⁸Ga-PSMA-11-PET/CT detection rate in a cohort of very low risk biochemically relapsed (BCR) Prostate Cancer (PCa) patients. **Materials and Methods:** We reviewed all ⁶⁸Ga-PSMA-11 PET/CTs of PCa patients who were referred to our Center, from December 2016 to December 2019. Inclusion criteria were 1) patients with BCR after radical therapy with or without subsequent salvage therapy; 2) ISUP group ≤3; 3) no ongoing androgen-deprivation-therapy (ADT) in the last 6 months; 4) Time to PSA recurrence ≥12 months; 5) PSA doubling time (DT) ≥ 10 months; 6) PSA at time of ⁶⁸Ga-PSMA-11 PET/CT ≤0.5 and ≥0.2 ng/ml. ⁶⁸Ga-PSMA PET/CT findings were categorized as positive and negative by two experienced Nuclear Medicine Physicians. Doubtful findings were re-evaluated and categorized by consensus. Positive findings were categorized as: local relapse in prostate bed, pelvic lymph-nodes, distant lymph-nodes, bone and visceral. Patients with a maximum of 3 lesions were categorized as oligometastatic. **Results:** Out of 1702 patients reviewed, 78 matched the inclusion criteria. ⁶⁸Ga-PSMA-11 PET/CT resulted positive in 9/78 cases (detection rate 11,5%). Characteristics of positive patients were: mean PSA at time of ⁶⁸Ga-PSMA-11 PET/CT= 0,30 ng/ml (range=0,2-0,46); mean PSA DT =14,8 months (range= 10,2-29,9); mean SUVmax of the positive lesions =3,9 (range=3-7,6). Characteristics of negative patients were: mean PSA= 0,31 ng/ml (range=0,2-0,50); mean PSA DT= 20,5 months (range=10-32,8). Single lesions were detected in 5 patients (prostate bed relapse in 2 patients, pelvic lymph-nodes in 2 patients, bone in 1 patient). Oligometastatic disease was detected in 2 patients (bone/pelvic lymph-node and prostate bed relapse in 1 patient; 2 pelvic lymph-nodes in 1 patient). Multimetastatic disease was detected in 2 patients (multiple bone lesions in 1 patient; multiple pelvic lymph-nodes in 1 patient). In our population of very low risk BCR patients ⁶⁸Ga-PSMA-11-PET/CT turned out positive in 11,5% of patients. In patients with low PSA values, long PSA doubling times, low ISUP, no ongoing ADT therapy and time to PSA recurrence longer than 1-year indication to ⁶⁸Ga-PSMA-11-PET/CT should be carefully considered. **Conclusion:** In our population of very low risk BCR patients ⁶⁸Ga-PSMA-11-PET/CT turned out positive in 11,5%. This result needs to be validated in further studies including larger populations. **References:** None

EP-169**Pharmacokinetic PET/CT studies with ⁶⁸Ga-PSMA-11 in patients with biochemical recurrence and progression of a prostatic cancer**

D. Strauss¹, C. Sachpekidis¹, K. Kopka², A. Dimitrakopoulou-Strauss¹, L. Pan¹, U. Haberkorn³;

¹German Cancer Research Center CCU Nuclear Medicine, Heidelberg, GERMANY, ²Institute of Radiopharmaceutical Cancer Research at Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY, ³Department of Nuclear Medicine, University of Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: To investigate the biodistribution and pharmacokinetics of ⁶⁸Ga-PSMA-11 PET in patients with biochemical recurrence or progression of prostate cancer (PC) using multiparametric (dynamic and whole-body) PET/CT. **Materials and Methods:** In total 128 PET/CT scans of 112 patients with PC biochemical relapse or progression were extracted from our database. All patients underwent dynamic PET/CT (dPET/CT) scanning of the pelvis and lower abdomen for 60 minutes as well as whole-body PET/CT with ⁶⁸Ga-PSMA-11. Dynamic and whole-body PET/CT assessment was based on qualitative evaluation and SUV calculation. Moreover, dPET/CT data from the pelvis underwent quantitative analysis based on a two-tissue compartment model and a non-compartmental approach leading to the extraction of fractal dimension (FD). **Results:** Mean plasma PSA in all patients was 8.09 ng/mL (range <0.01-132 ng/mL), and mean Gleason-Score was 7.53 (range 5-10). 100/128 scans of 98/112 patients were PET-positive (detection rate: 87.5%). 11/98 ⁶⁸Ga-PSMA-11 positive patients had a PSA of < 0.5 ng/mL. 24 local recurrence lesions were detected in dPET/CT with following mean values (range): $SUV_{average}$: 14.2 (2.3-62.5), SUV_{max} : 24.7 (3.3-84.6); $k_1 = 0.16$ (0.04 - 0.64), $k_3 = 0.35$ (range <0.01 - 0.99), $FD = 1.25$ (0.94-1.37). 191 lymph node metastases were detected in dPET/CT with the following mean values (range): $SUV_{average}$: 14.9 (range 0.3-171.3), SUV_{max} : 26.4 (range 0.6-250.8), $k_1 = 0.19$ (<0.01-0.83), $k_3 = 0.33$ (<0.01 - 0.99), $FD = 1.25$ (0.85-1.92). Respectively, 49 bone metastases had the following values: $SUV_{average}$: 9.8 (range 1.9-80.5), SUV_{max} : 16.9 (2.8-117.5), $k_1 = 0.19$ (0.02-0.96), $k_3 = 0.25$ (<0.01 - 0.99), $FD = 1.21$ (1.04-1.36). In most lesions time-activity curves revealed an increasing ⁶⁸Ga-PSMA-11 accumulation during dPET acquisition. No statistical significant difference was observed in the pharmacokinetics between metastases and recurrent tissue. **Conclusion:** ⁶⁸Ga-PSMA-11 shows satisfying results in the detection of PC recurrence with a detection rate of 87.5%. A non-negligible number of patients with very low PSA values could benefit from the detection of suspect lesions, though patients with higher PSA have a higher tracer accumulation. **References:** None

EP-170**PET/CT with ⁶⁸Ga-PSMA-11 for detection of rib involvement in a subgroup of prostate cancer patients**

L. Calderoni, A. Farolfi, R. Mei, S. Telo, S. Fanti;

Nuclear Medicine, Sant'Orsola University Hospital, Bologna, ITALY.

Aim/Introduction: In the last years several studies have shown that recommended imaging techniques, including computed tomography (CT) or magnetic resonance imaging (MRI) and bone scintigraphy (BS), have shown a limited detection rate for the detection of lesions in patients with a history of prostate cancer (PCa) in staging, biochemical recurrence (BCR), with particular regard for the detection of costal lesions, which are often misdiagnosed. The objective of this study was to evaluate the performance of ⁶⁸Ga-PSMA-11 PET/CT for the detection of rib involvement with particular attention to oligometastatic patients (defined as having 5 or more lesions), who can benefit considerably from targeted therapy, such as external beam radiotherapy.

Materials and Methods: In our retrospective, single-center study patients were included with the following criteria: histopathological diagnosis of PCa and ⁶⁸Ga-PSMA-11 PET/CT during staging or BCR. We reviewed all the reports of the patients who underwent a ⁶⁸Ga-PSMA-11 PET/CT between March 2016 and February 2018 matching all the inclusion criteria. **Results:** Overall we included 808 ⁶⁸Ga-PSMA-11 PET/CT scans and we found 93/808 scans with reported rib findings at ⁶⁸Ga-PSMA PET/CT (occurrence 11.5%). Out of 93 positive scans, 18 scans (in 18 patients) were PSMA positive at a single rib (occurrence 2.2%); 7 scans (in 7 patients) showed increased ⁶⁸Ga-PSMA-11 uptake in a single rib and in another site (prostate bed 3/7, pelvic lymph nodes 5/7); 10 scans (9 patients) were PSMA positive but could be classified as oligometastatic patients (less than 5 bone lesions); 34 scans (in 30 patients) showed advanced disease (greater than 4 lesions). In 18 cases PET/CT scans showed suspect but inconclusive findings (low PSMA uptake); 6 scans (6 patients) were reported as rib fracture or small high density areas only seen at CT. **Conclusion:** In our study a significant number of PET scans (11.5%) showed one or more lesions with rib involvement, with a significant number of patients (2.2%) with only one rib lesion, who would have been misdiagnosed with standard imaging procedures. Based on PET/CT ⁶⁸Ga-PSMA-11 4.2% of patients could be classified as oligometastatic and be a candidate for targeted therapy, avoiding any hormone therapy and its side effects. **References:** Sarkar S, Das S. A Review of Imaging Methods for Prostate Cancer Detection. Biomed Eng Comput Biol. 2 marzo 2016;7(Suppl 1):1-15.

EP-171**18F-Choline PET/CT in Biochemical Recurrence of Prostate Cancer**

C. Riola-Parada, B. Lucas-Velázquez, F. Gómez-Camínero, J.

Villanueva, P. García-Talavera, L. Díaz, A. Peñaherrera, J. Cañadas Salazar, M. Tamayo;

Nuclear Medicine Department. Hospital Clínico

Universitario de Salamanca, Salamanca, SPAIN.

Aim/Introduction: The aim of this study was to prove the usefulness of 18F-choline PET/CT in the suspicion of prostate cancer recurrence in our patients and to relate 18F-choline PET/CT detection rate with analytical and pathological variables. **Materials and Methods:** We prospectively analyzed 116 consecutive patients with prostate cancer (mean age 68 years, range 47-87 years) who received local therapy as primary treatment and who underwent 18F-choline PET/CT due to suspicion of recurrence (persistently rising serum PSA level). The patients were recruited from the Nuclear Medicine Department of Hospital Clínico Universitario de Salamanca, Spain, from November 2015 to March 2019. 18F-choline PET/CT findings were validated by anatomopathological analysis, other imaging tests or by biochemical response to oncological treatment.

Results: 18F-choline PET/CT detected disease in 81 of 116 patients (detection rate 69.8 %). 20 patients (17.2%) presented exclusively local recurrence, 32 (27.5%) lymph node metastases, 28 (24.1%) bone metastases and 1 (0.8%) splenic metastases. Mean PSA (PSAmed) at study time was 5.55 ng/mL (median 3.8, range 0.017-38 ng/mL). PSAmed in patients with positive PET/CT was 6.33 ng/mL (median 4.03, range 0.7-38 ng/mL), higher than in patients with negative PET/CT: PSAmed 3.71 ng/mL (median 2.89, range 0.017-15.90 ng/mL) ($p < 0.05$). The percent of positive scans was 25% for PSA less than 1 ng/ml, 66.7% for PSA 1-1.9 ng/ml, 60% for PSA 2-2.9 ng/ml and 77% for PSA ≥ 3 ng/ml. PSA level could not differentiate between patients with local recurrence, lymph node metastases or bone disease. Mean total Gleason score at diagnosis was 6.89 (range 4-10). Mean total Gleason score in patients with a positive study was 7.04 (range 4-10) higher than in patients with a negative study: mean total Gleason score 6.56 (range 4-9) ($p < 0.05$). Gleason score could differentiate between patients with local recurrence, lymph node metastases or bone disease ($p < 0.05$). **Conclusion:** 18F-choline PET/CT was able to detect disease in an important number of our patients (69.8%). PSA level could differentiate between positive and negative 18F-choline PET/CT. **References:** None

EP-172**Utility of ⁶⁸Ga-PSMA PET / CT in occult biochemical recurrence of prostate carcinoma with negative 18F-Choline PET / TC. Our experience**P. Plaza López¹, E. Puertas¹, J. Aguiló¹, B. Domenech¹, S. Sanjosé¹, M. Suarez-Piñera², E. Rivera³, J. Casals¹, J. Chicharro⁴;¹Hospital Quironsalud Barcelona, Barcelona, SPAIN,²Hospital del Mar Barcelona, Barcelona, SPAIN, ³HospitalDexeus Barcelona, Barcelona, SPAIN, ⁴Cimes. Fundación

General Universidad de Málaga, Málaga, SPAIN.

Aim/Introduction: To assess the utility of 68Ga-PSMA PET / CT studies in the clinical practice of patients with occult biochemical recurrence of prostate carcinoma, with negative or inconclusive radiological imaging and PET / CT 18F-Choline studies. **Materials and Methods:** Retrospective descriptive study. The first 10 patients with a history of prostate carcinoma, treated with curative intent and who had suspected biochemical recurrence with low PSA values (range: 0.04-2.35 ng / ml) were selected. Imaging, prostate ultrasound, CT, and / or pelvic MRI were negative, and all of them had negative or inconclusive 18F-Choline PET / CT. All patients were referred for a 68Ga-PSMA PET / CT. Protocol: Dose 2.2MBq / Kg. 20mg of furosemide at minute 15. Images from the skull to the proximal third to mid-thigh at 60 min . Late images at 3 hours if needed. **Results:** In 6 of the 10 patients (60%), the 68Ga-PSMA managed to locate the occult biochemical recurrence, and in all of them there were changes in the therapeutic attitude. In 3 of the patients (30%) 68Ga-PSMA was negative, and the vigilant attitude was continued with PSA controls and imaging studies according to the usual protocols. These patients had the lowest PSA values (less than 0.4). One of the 68Ga PSMA studies was inconclusive, reporting the presence of a dubious right iliac adenopathy. **Conclusion:** 68Ga-PSMA PET / CT allows early diagnosis, with low PSA values, of occult biochemical recurrence of prostate carcinoma, even in patients with negative 18F-choline PET / CT. The 68Ga-PSMA findings changed the therapeutic attitude in a significant proportion of patients. **References:** Comparison of PET imaging with a 68Ga-labelled PSMA ligand and 18F-choline-based PET/CT for the diagnosis of recurrent prostate cancer Ali Afshar-Oromieh, Christian M. Predictors Of Positivity Of [¹⁸F]F-Choline PET-CT In Prostate Cancer Recurrence. Preliminary Results

L. Nieto Morcillo, M. Falgás Lacueva, L. de la Cueva Barroa, A. Borque Fernando, A. Méndez Villamón, I. Guerrero Fernández de Alba, M. Calderón Calvente, G. Guzmán Prudencio, L. del Barco Diez Canseco, D. Abós Olivares;

Hospital Universitario Miguel Servet, Zaragoza, SPAIN.

Aim/Introduction: To analyze the validity of [¹⁸F]F-Choline PET-CT results in prostate cancer recurrence in our daily practice, based on theoretical cut-off points of prostate-specific antigen (PSA), its kinetic, and PSA doubling time (PSADT), to identify predictors of positivity and modify the indication criteria. **Materials and Methods:** Prior to the validity analysis, a descriptive, prospective analysis of consecutive patients with prostate cancer treated with curative intent by radical prostatectomy (RP) or radiotherapy (RT), who underwent PET-CT scan with recurrence criteria: PSA ≥ 1 or PSA 0.4-1 with PSADT <6 months after RP; PSA > Nadir + 2 after RT, was performed. **Results:** From April to December 2019, 69 patients were included, 40 were treated with RP (58%) and 29 with RT (42%). In 45 patients (65%) PET-CT was able to identify recurrence of the disease (positive PET) and in 24 it was not (negative PET). Of patients treated with RP, 82,5% (33/40) had PSA >1, and of those, 61% were positive PET. 17,5% (7/40) had PSA <1 and PSADT <6 months (28/69), with positive PET in 43% of patients. 76% of patients had a positive PET after RT. Positive PET results were obtained in 57% of patients with PSADT >6 months (28/69), in 71% if PSADT <6 months (41/69) and in 81% of patients if PSADT <3 months (16/69). After RP and RT, PET was positive in 50% and 62,5% of patients respectively if PSADT >6 months, in 61% and 92% if PSADT <6 months and in 77% and 100% if PSADT <3 months. **Conclusion:** Preliminarily and awaiting validation, it seems that PSA >1 after RP or Nadir +2 after RT is an indicator of PET-CT. There seems to be a tendency that shows that PSA <1 after RP is an indicator of PET-CT if PSADT <3 months. PSADT <3 or <6 months could be the best predictor of positivity of PET-CT with [¹⁸F]F-Choline in recurrent prostate cancer. **References:** None

EP-174

Evaluation Of ¹⁸F-Fluorocoline PET-CT Findings In Patients With Suspicion Of Prostate Cancer Tumor Recurrence And Gleason <7 Or PSA <2ng / mL Prior To PET

S. Garcia Martinez, Á. Baena García, M. De Bonilla Candau, M. Cruz Montijano, J. Rodríguez-Rubio Corona; Puerta del Mar University Hospital, Cadiz, SPAIN.

Aim/Introduction: To analyze the PET CT findings visualized in studies with ¹⁸F-FCH, with tumor recurrence suspicion in patients treated of prostate cancer with Gleason score less than 7 or with a PSA value less than 2ng / mL prior to PET. **Materials and Methods:** Retrospective study was made from March 2016 to October 2019, including 20 patients (22 explorations) treated of prostate cancer (mean age 73 years) with tumor recurrence suspicion and doubtful imaging tests, considering two independent samples: those with Gleason <7 (14 patients) and those with PSA <2ng / mL prior to PET (6 patients). The PET findings, the

subsequent therapeutic management and the evolution of the patients (mean follow-up period 9.06 months) were analyzed. **Results:** In the sample of 15 studies (14 patients) with Gleason score <7 (PSA 2.2-25ng / mL), local or locoregional ^{18}F -FCH uptake was seen in 11 studies (73%) and focal bone uptake was seen in 2/15 (13.3%). In 7 cases (46.6%) there were changes in therapeutic management with a clear decrease in PSA. 2/15 were negative studies (Gleason 5-6). There were no therapeutic changes if the PET findings were doubtful or unconfirmed. In the sample of 7 studies (6 patients) with PSA prior to PET <2ng / mL (Gleason 7-9), only 2/7 (28.5%) showed lymph node uptake: one received radiotherapy (PSA 1.34) and another did not modify further treatment (PSA 1.96). The rest of them were negative studies (3/7) or inconclusive (2/7). None showed progression at follow-up. **Conclusion:** PET-CT with ^{18}F -FCH allows a better therapeutic approach after suspicion of tumor recurrence due to prostate cancer despite Gleason score <7; providing lower therapeutic profitability in cases of PSA <2ng / mL. **References:** None

EP-175

Comparison between $^{99\text{mTc}}$ -MDP bone scintigraphy combined with SPECT/CT and $^{68\text{Ga}}$ -PSMA PET/CT in evaluation of bone involvement in patients with prostate cancer. Preliminary results

G. Mateva, M. Garcheva-Tsacheva;

Acibadem CityClinic Mladost, Sofia, BULGARIA.

Aim/Introduction: The aim of the study was to compare the diagnostic value of whole body bone scintigraphy (WBS) combined with SPECT/CT and $^{68\text{Ga}}$ -PSMA PET/CT in evaluation of bone involvement in patients with prostate cancer. **Materials and Methods:** 151 $^{68\text{Ga}}$ -PSMA PET/CT scans executed in 10 months were retrospectively reviewed. In 14 of the examined patients, a WBS ($^{99\text{mTc}}$ -MDP) was done in the previous 1- 6 months. The used protocols were: WBS combined with SPECT/CT after injection of 555 MBq $^{99\text{mTc}}$ -MDP on GE Discovery NM/CT 670 Pro and head to mid thigh PET scan on GE Discovery IQ, 60 -70 min. after 1-2 mBq/kg $^{68\text{Ga}}$ -PSMA -11. $^{68\text{Ga}}$ -PSMA-11 was produced on site with labeling efficiency > 98%. Three groups were identified according to the indications. Group 1- patients with biochemical recurrence n= 4, all on androgen deprivation therapy (ADT), PSA levels from 1,74 ng/ml to 22 ng/ml with median doubling time of PSA 1-3 months. Group 2 - high risk patients for staging before the start of therapy n=5. Group 3

- patients with bone dissemination confirmed by WBS, n=5 treated with ADT, or radiotherapy, for which the levels of PSA did not correspond with the suspicion for progression. **Results:** All patients in gr. 1 (n=4) had negative WBS, and positive for skeletal involvement $^{68\text{Ga}}$ -PSMA scans, 3 of which bone marrow lesions. Three had additionally local recurrences and/or lymph nodes lesions. In gr. 2 the WBS was positive in 1/5, while $^{68\text{Ga}}$ -PSMA scans were positive in all 5 (2 bone marrow lesions, including lymph node dissemination in 3 of them). In 3 of patients from gr. 3, the WBS positive lesions did not demonstrate increased $^{68\text{Ga}}$ -PSMA uptake, which corresponded to the PSA regression. In 2 other cases - $^{68\text{Ga}}$ -PSMA scan revealed more bone lesions than WBS, including generalized involvement in 1 patient. The bone marrow lesions had higher $^{68\text{Ga}}$ -PSMA SUVmax (mean 43,98) versus lesions with sclerotic substrate (mean value 14,5). **Conclusion:** According to this preliminary study $^{68\text{Ga}}$ -PSMA PET/CT detects skeleton lesions in patients with prostate cancer compared to WBS and SPECT/CT. The interpretation of skeletal involvement was changed in 11/ 14 patients /78%/ in addition to detected local recurrences and/or lymph nodes involvement in 12/14 of the patients /85%/. That makes $^{68\text{Ga}}$ -PSMA PET/CT indispensable not only in patients with biochemical recurrence, but in primary staging of high risk patients and for evaluation of therapy response. **References:** None

EP-176

Detailed advantages of ^{18}F -DCFPyL over ^{18}F -FDG PET imaging in the diagnosis of metastatic and non-metastatic prostate cancers: a comparative study

J. Ning, Y. Liu, C. Li, Y. Chang, G. Wang, P. Yu, J. Gao, B. Xu;
Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: To explore the detailed advantages of ^{18}F -FDG over ^{18}F -PSMA PET targeting the precise assessment of metastatic and non-metastatic prostate cancers (PCa). **Materials and Methods:** We retrospectively analyzed the imaging data of ^{18}F -FDG and ^{18}F -PSMA PET/CT in 20 patients with metastatic and non-metastatic PCa in the Chinese PLA General Hospital, each of whom was confirmed by histopathology. Then a series of parameters including SUV and size of each Volume of Interest (VOI) and lesion distribution were taken into account among the PCa foci and metastases. **Results:** Among the total of 20 patients with PCa, 10 cases were diagnosed as primary PCa without any metastases while multiple metastases were detected on ^{18}F -FDG or ^{18}F -PSMA PET in the other 10 cases. The overall analysis of metastases' number turned out that PSMA imaging did not show proper advantages (P = 0.034) while the subgroup analysis found that PSMA imaging, thanks to high sensitivity and specificity, showed significant advantages in the detection of metastatic lesions' number (P = 0.034), size (P = 0.019) and SUV (P =0.001), and the

primary lesion's size ($P = 0.014$) and SUV ($P < 0.001$). As for the detection potential in lesion distribution, PSMA PET's ability to detect LNs' metastases in the groin region is slightly inferior to FDG PET. But in the metastases' detection of pelvic lymph nodes (LNs), upper abdominal LNs, bones metastases, mediastinal, hilar LNs and clavicle LNs, PSMA modality far outweighed FDG imaging, especially in detection of pelvic LN metastases. **Conclusion:** PSMA PET has more potential to facilitate the identification of PCA primary lesions and metastases, in particular, the LNs in the pelvic cavity and upper abdomen. **References:** None

EP-177

PET/CT with 11C-Choline, 68Ga-PSMA, 18F-FACBC in castration resistant prostate cancer patients: evaluation of MTV and TLA

E. Tabacchi¹, G. Argalia¹, S. Vichi¹, C. Malizia¹, C. Fonti¹, F. Massari², V. Mollica², V. Di Nunno², E. Nobili², C. Nanni¹, S. Fanti¹;
¹Nuclear Medicine, S.Orsola-Malpighi Hospital, DIMES University of Bologna, Bologna, ITALY, ²Division of Oncology, S.Orsola-Malpighi Hospital, Bologna, ITALY.

Aim/Introduction: to investigate, on preliminary data, which radiotracer among 11C-Choline, 68Ga-PSMA, 18F-FACBC provides features better representing the volume of active disease in metastatic castration resistant prostate cancer (mCRPC) patients. This could be useful, on a greater number of patients, to identify the most suitable radiotracer to assess therapy response **Materials and Methods:** in the context of a wider prospective interventional monocentric explorative study (granted project RF-2016-02364809), we evaluated mCRPC pts enrolled from January 2019 to January 2020 that have been assigned randomly to receive 11C-Choline, 68Ga-PSMA or 18F-FACBC PET/CT respectively. Each patient underwent two PET/CT scans: one before therapy onset with abiraterone or enzalutamide and one two months later. No changes in therapy derived from PET/CT results. We evaluated the Metabolic Tumor Volume (MTV) calculated with a fixed threshold set at 40% of SUV max with a licensed software (GE VCAR) and Total Lesion Activity (TLA: MTVxSUVmean) on each scan. Correlation between PSA value and SUVmax, MTV and TLA for the three groups of radiotracers was calculated. For statistical analysis we used a non parametric test (SPEARMAN). **Results:** to date we enrolled 16 mCRPC pts randomized for of 11C-Choline (6pts), 68Ga-PSMA(5 pts)and 18F-FACBC (5 pts). For 11C-Choline group we found a strong significant correlation between PSA value and MTV ($\rho=0.8667$, p -value= $0,0027$), PSA value and TLA ($\rho=0.9125$, p -value= $0,0005$) and no significant correlation between PSA and SUVmax. For 68Ga-PSMA group we found a significant correlation (although weaker than 11C-Choline) between PSA value and MTV ($\rho=0.8167$, p -value= $0,0108$), PSA value and TLA ($\rho=0.85$, p -value= $0,0061$)and no significant correlation between PSA

and SUVmax. No significant correlation has been found for 18F-FACBC group between PSA and SUVmax,MTV,TLA. **Conclusion:** limited to the small number of patients, 11C-Choline seems the tracer providing parameters that better correlate with PSA value, possibly indicating a more accurate representation of the volume of active disease. It is not clear yet whether this suggests a better performance of 11C-Choline for assessing therapy response. Similarly, no conclusion can be drawn about the correlation for 68Ga-PSMA between PSA value and MTV,TLA. A larger number of patients is needed as well as a longer follow up to draw conclusions. **References:** None

EP-178

Assessment of Bone Metastasis Using Deep Learning Software in Prostate Cancer Patients: Correlation with Evaluation by Experts

K. Nomura, M. Nakayama, A. Okizaki;
 Asahikawa Medical University, Asahikawa, JAPAN.

Aim/Introduction: The purpose of this study was to assess the utilization of a deep learning-based software for bone metastases in patients with prostate carcinoma. **Materials and Methods:** 32 patients (52-90 years old) with prostate carcinoma, who had one or more bone metastases, were studied. A deep learning-based software (bone scan index automated calculation software by Tc-99m-HMDP: VSBONE BSI®) was used to evaluate whole body bone scintigraphy. Using the software, bone metastases and nonspecific uptakes were evaluated. A gold standard was determined by two experienced radiologists. When the results of interpretation were not matched, the consensus was used as the gold standard after their discussions. Spearman's rank correlation coefficient was used for evaluation of the correlation between the result with the deep learning-based software and radiologists. **Results:** 632 bone metastases in 32 patients were identified by radiologists. 502 of 632 lesions (79.4%) were also identified by the software. There was a statistically significant correlation ($r=0.976$; $P < 0.01$). **Conclusion:** The deep learning-based software showed significant correlation with the diagnosis by experienced radiologists, and the software may be useful to assess the bone metastases in patients with prostate carcinoma. **References:** None

EP-179

Incidence of lung nodules positive at ⁶⁸Ga-PSMA-11 PET/CT- a single center experience

S. Telo, A. Farolfi, R. Mei, S. Mattoni, L. Calderoni, P. Castellucci, S. Fanti;
 Nuclear Medicine, Policlinico S.Orsola-Malpighi, Bologna, ITALY.

Aim/Introduction: To evaluate incidence of lung nodules showing uptake at ⁶⁸Ga-PSMA-11-PET/CT in prostate-

cancer (PCa) patients. **Materials and Methods:** We consecutively reviewed ^{68}Ga -PSMA-11-PET/CTs of PCa patients referred to our Center from December-2016 to December-2019. Inclusion criteria: 1) positive ^{68}Ga -PSMA-11-PET/CT in one or more lung nodules 2) one of the following clinical settings: PSA-persistence after radical-therapy; biochemical-recurrence after radical-therapy; castration-resistant PCa-patients with PSA progression. **Results:** 36/1702 patients were included. Incidence of ^{68}Ga -PSMA-11-PET/CT-uptaking-lung-nodules in our cohort was 2,1%. Characteristics of included patients were: Mean PSA at time of ^{68}Ga -PSMA-11-PET/CT(PET-PSA):5,8 ng/ml (range:0,21-80); Mean lung-lesions-SUVmax (SUVmax):5,9 (range:faint uptake-43,5); 26 patients had single lung lesions, 10 had several lung lesions; Most of lung lesions studied were small sized (subcentimetric nodules in 28 patients; centimetric nodules in 8 patients with maximum diameters range:1-3,6 cm). Follow-up data were available in 21/36 cases: ^{68}Ga -PSMA-11-PET/CT results were surgically validated in 11 patients (Group 1) and with subsequent imaging/follow-up in 10 (Group 2). Group 1: 7/11 turned out true-positives for PCa-lung-metastases (Mean SUVmax:9,1; range:faint uptake-43,5; Mean PET-PSA:2,3ng/ml; range:0,27-4,5); Localized lung disease was detected in 4 patients, multiple lymph-nodes and a single lung lesion in 1; spread (lung/bone/lymph-node) disease in 2. 4/11 cases turned out consistent with other neoplastic localizations: Small-Cell-Lung-Cancer (SUVmax:faint uptake;PET-PSA:0,30ng/ml) in 1 pt with localized lung-disease, colon adk metastasis (SUVmax:11,7;PET-PSA:4,13ng/ml), primary lung adk (SUVmax:3,3;PET-PSA:2,8ng/ml) and follicular-LNH (SUVmax:3,7;PET-PSA:6,7ng/ml) in 3 cases with concomitant multi-nodal disease. Group 2 (Mean SUVmax:3,9; range:faint uptake-6,6; Mean PET-PSA:3,9ng/ml; range: 0,46-5): 4 were compatible with true-positives, their consecutive ^{68}Ga -PSMA-11-PET/CT showed respectively: no pulmonary nodule uptake after stereotactic radiation-therapy in 1 patient, bone/lung/lymph-nodes disease progression with concomitant increasing of PSA levels in 2 patients, decreased PSA levels after androgen-deprivation-therapy (ADT) in 1 patient. Disease stability at follow-up ^{68}Ga -PSMA-11-PET/CT was detected in 3 patients (2 with multiple lymph-node and lung lesions/1 with a single lung lesion). Multiple bone/lung/lymph-node lesions were detected in 2 patients and, despite starting ADT, a patient deceased and the other had a PSA-increase. Finally, a single pulmonary lesion turned out to be inflammatory after normalization at HRCT follow-up. **Conclusion:** In our population of recurrent, persistent and castration resistant PCa patients ^{68}Ga -PSMA-11-PET/CT was positive in 1 or more lung nodules in about 2% of patients. This result needs to be validated in further studies including larger populations. **References:** None

EP-180

^{11}C -Choline PET/CT Performance in Prostate Cancer Surveillance. Ten Years Evaluation of Effectiveness

F. Gomez-De La Fuente, I. Martínez-Rodríguez, M. de Arcocha-Torres, R. Quirce, J. Jiménez-Bonilla, A. Sánchez-Salmón, N. Martínez-Amador, G. Molina-Mendoza, O. Cuenca-Vera, J. Andrés-Pacheco, Á. Gutiérrez-González, S. Ruiz Llama, I. Banzo; Nuclear Medicine Service, Marqués de Valdecilla University Hospital, Molecular Imaging Group (IDIVAL), University of Cantabria, Santander, SPAIN.

Aim/Introduction: ^{11}C -Choline PET/CT has shown good results in prostate cancer (PCa) surveillance, especially in patients with serum levels of prostate specific antigen (PSA) above 1 ng/ml. Our aim was to analyse the performance of the test in our centre over 10 years and evaluate its effectiveness.

Materials and Methods: Three hundred and twenty-nine ^{11}C -Choline PET/CT examinations from 191 patients with PCa (mean age: 69.2 ± 7.4 years) were retrospectively evaluated. They were randomly selected from a total of 804 tests performed in our centre (from 2009 to 2018) in patients with active surveillance or suspected relapse of PCa. Initial treatment was radical prostatectomy (RP) with or without adjuvant treatment in 81 patients, and other treatments (radiotherapy, chemotherapy, hormonotherapy) in 110 patients. PET/CT scans were acquired 20 minutes after intravenous administration of 555-740 MBq of ^{11}C -Choline. Minimum follow-up time was 12 months. **Results:** From the 329 examinations, 219 (66.6%) were ^{11}C -Choline PET/CT positive and 110 (33.4%) were negative. Of the 219 positive examinations, 130 (59.3%) showed local recurrence, 49 (22.4%) distant recurrence and 40 (18.3%) local plus distant recurrence. One hundred and forty-nine examinations (45.3%) were performed in patients treated initially with RP, with 65 (43.6%) of positive and 84 (56.4%) of negative results, while 180 (54.7%) examinations were performed in patients with other initial forms of treatment, with 154 (85.6%) of positive and 26 (14.4%) negative results. Mean serum PSA level at PET/CT study was 13 ng/ml (range: 0.02-1337.9 ng/ml) and mean Gleason index was 6. In the subgroup of 81 ^{11}C -Choline PET/CT examinations performed with serum PSA levels <1 ng/ml, 23 (28.4%) showed a positive result, and 9 (11.1%) of them prompted a change in the planned therapeutic management. **Conclusion:** ^{11}C -Choline PET/CT demonstrated its effectiveness in PCa surveillance, as two thirds of the examinations showed tumour activity. The diagnostic performance was different depending on the initial treatment. Finally, one third of the ^{11}C -Choline PET/CT examinations performed in patients with serum PSA levels <1 ng/ml showed tumour activity. **References:** None

EP-181**The Relationship Between Four Parameters: 68Ga PSMA PET/CT, Gleason Score, PSA Levels and Metastasis**

C. Sezgin, G. Mutevelizade, Y. Parlak, G. Gumuser, E. Sayit;
Celal Bayar University, Faculty of Medicine, Department
of Nuclear Medicine, Manisa, TURKEY.

Aim/Introduction: 68Ga PSMA PET/CT imaging is a valuable method used for staging prostate cancer, evaluating treatment response, and detecting recurrent disease. We aimed to evaluate the relationship between PSA values and pathological data obtained from 68Ga PSMA PET/CT imaging, which were taken for staging in patients with prostate cancer, and the relationship between pathological data and presence of metastasis. **Materials and Methods:** The data of 55 patients with prostate cancer (mean age 69.8 ± 8.7) underwent 68Ga PSMA PET/CT (Philips, True Flight Select) imaging for initial staging were analyzed retrospectively. None of them had a prostatectomy. We evaluated the relationship between primary tumor parameters [primary lesion PSMA tumor volume (PSMA-TV), SUVmax, SUVmean], serum PSA values and Gleason Score, and also the relationship of all these values with extraprostatic spread and metastases were investigated. **Results:** Fifty-five newly diagnosed patients were included in the study. The extraprostatic spread was not observed in 16 (29%) of them, whereas extraprostatic spread was observed in 39 (71%) patients. Lymph node metastasis was not observed in 23 (42%) of the patients, while 18 (33%) patients had regional and 14 (25%) patients had distant lymph node metastases. Bone metastasis was not observed in 35 (64%) of the patients, 2 (4%) had limited metastases to the pelvic bones, and 18 (33%) had distant bone metastases. Six of the patients (10%) had solid organ metastases. There was a statistically significant relationship between PSA values and primary lesion PSMA-TV ($p < 0.05$), whereas no significant relationship was observed between SUVmax and SUVmean values. There was a statistically significant relationship between Gleason Score and primary lesion PSMA-TV, SUVmax and SUVmean values ($p < 0.05$). There was a significant relationship between primary lesion PSMA-TV values and the presence of extraprostatic spread and lymph node metastasis no significant relationship was found between TV and bone metastasis. There was a significant relationship between primary tumor SUVmax value and the presence of extraprostatic spread and distant bone metastasis ($p < 0.05$). **Conclusion:** Gleason Score and PSA values are the main parameters used in risk classification in patients with prostate cancer. The parameters we obtained from PSMA PET/CT images correlate with both Gleason Score and PSA values. We concluded that PSMA PET/CT parameters of the primary lesion might contribute to the risk classification in prostate cancer patients. Although there is no clear relationship between the presence of metastasis

and PSMA PET/CT parameters, studies with higher patient numbers are promising in this regard. **References:** None

EP-182**Requirements and complexity: interprofessional cooperation within a prospective multicenter clinical trial using [⁶⁸Ga]Ga-PSMA-11 - The German Cancer Consortium (DKTK) experience**

O. Neels^{1,2}, C. Zippel^{3,2}, S. Biedenstein⁴, F. L. Giesel^{4,5,6}, K. Kopka^{1,5,7};
¹Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Institute of Radiopharmaceutical Cancer Research, Dresden, GERMANY,
²Formerly: German Cancer Research Center (dkfz), Heidelberg, GERMANY, ³Witten/Herdecke University, Faculty of Management and Economics, Witten, GERMANY, ⁴University Hospital Heidelberg, Department of Nuclear Medicine, Heidelberg, GERMANY, ⁵German Cancer Consortium (DKTK), Heidelberg, GERMANY, ⁶German Cancer Research Center (dkfz), Clinical Cooperation Unit Nuclear Medicine, Heidelberg, GERMANY, ⁷German Cancer Research Center (dkfz), Heidelberg, GERMANY.

Aim/Introduction: Prospective clinical trials are initiated within the field of nuclear medicine to translate the most promising radioligands into clinical routine [1]. A close cooperation and communication between experts from different fields is necessary for the efficiency and efficacy of the clinical trial which can then have a positive impact on the timely start of recruitment and subsequent patient inclusions [2]. **Materials and Methods:** Given the exemplary phase 1/2 multi-center clinical trial „Ga-68-PSMA-11 in high-risk Prostate Cancer“ (NCT03362359) [3], we demonstrate how professions from clinical research, drug manufacturing and administration can be involved in the planning, preparation and realisation of prospective clinical trials in nuclear medicine. Organisational measures are derived to support the interprofessional cooperation within diagnostic prospective multicenter clinical trials. **Results:** Besides nuclear medicine physicians, urologists and pathologists, other professions like technicians and technologists (nuclear medicine, biology, chemistry), study nurses, radiochemists/-pharmacists and nursing staff are involved in the clinical setting. In addition, radiation safety officers, quality manager, clinical monitors, lawyers, data protection officers, project managers and study coordinators are embedded in the setting of in total eleven study sites in Germany, Austria and Switzerland. **Conclusion:** Interprofessional cooperation is of great importance for high-quality work in health care and re-search in general, as well as the accomplishment of prospective clinical trials in nuclear medicine in particular. Readiness to put oneself in the position of other professions, cooperation under no professional constraints, adequate time for mutual exchange, the ability and skills for interprofessional project management and an integral view on the required expertise by strengthening overall communication skills are required

in particular on senior management level. **References:** 1. Zippel C, Ronski SC, Bohnet-Joschko S, Giesel FL, Kopka K. EP-183

Meningeal carcinomatosis in patients with a diagnosis of prostate carcinoma visualized in [18F]18F-PSMA, report of three cases

M. Acuña Hernandez¹, Q. Pitalua Cortes²;

¹Universidad Autónoma de Bucaramanga, Bucaramanga, Santander, COLOMBIA, ²Instituto Nacional de Cancerología (INCan), Ciudad de México, MEXICO.

Aim/Introduction: Meningeal carcinomatosis is an uncommon pathology that can occur in solid or hematological malignancies present between 1 and 2 years after the initial diagnosis. When its presence is determined, between 60-70% of cases present associated systemic progression. In prostatic cancer, only have in the literature report o series cases. Its origin may be secondary to hematogenous infiltration, by contiguity to parenchymal or bone metastatic lesions or by neural and perivascular route. Patients may report neurological symptoms according to the location of the lesion. The diagnosis is based on cerebrospinal fluid studies, diagnostic images (preferably MRI) and signs and symptoms suggestive of meningeal involvement. **Materials and Methods:** A series of cases of three patients with a diagnosis of castration-resistant prostate adenocarcinoma were staged with [18F]18F-PSMA and incidental meningeal involvement was observed. **Results:** Case 1 is a 61-year-old male patient diagnosed in 2013 with prostate adenocarcinoma Gleason 7 who received initial management with radiotherapy and hormone blockade. In 2017, presented bone progression, treatment with docetaxel was indicated. In 2019, presented an elevated PSA (40.7 ng/ml) and a moderate intensity headache, [18F]18F-PSMA was performed, evidence of compromise in bone structures of the skull with extension in the metabolism over the right frontoparietal region towards the cerebral parenchyma. Subsequently, MRI was performed with contrast that reported pachymeningeal reinforcement of

the right hemisphere and study of cerebrospinal fluid that reported pleocytosis. Case 2 is a 66-year-old male patient diagnosed with prostate adenocarcinoma Gleason unknown, indicating treatment surgical. At follow-up in 2019 elevated PSA (15.0 ng/ml) with no neurological symptoms, indicating [18F]18F-PSMA was performed, evidence of compromise in bone structures of the right skull base with extension in the metabolism on the cerebral parenchyma. Subsequently, MRI was performed with contrast which reported meningeal reinforcement in this area. Case 3 is a 76-year-old male patient diagnosed in 2012 with prostate adenocarcinoma Gleason 7 indicating surgical treatment. At follow-up in 2019 elevated PSA (40.0 ng/ml) and a headache, [18F] 18F-PSMA was performed, evidence of compromise in bone structures of the frontal and parietal right skull with extension in the tracer uptake on the cerebral parenchyma. **Conclusion:** Meningeal carcinomatosis is an infrequent event in patients diagnosed with prostate carcinoma, which should be taken into account, according to our cases, in patients with compromised cranial bone structures that may be affected by contiguity. **References:** None

Ga 68 PSMA PET/CT at the initial staging of high risk patients with prostate cancer

V. Prassopoulos, T. Pipikos, D. Kechagias, V. Filippi, F. Vlachou, J. Andreou, K. Dalianis, R. Efthymiadou;
PET/CT department, Hygeia Hospital, Athens, GREECE.

Aim/Introduction: Ga68 PSMA is a specific PET agent for the investigation of prostate cancer patients. Although it is not routinely used at initial staging, in selected cases it can be of great value. Aim of this study is to evaluate the results of Ga68 PSMA PET/CT study in high risk prostate cancer patients at initial staging. **Materials and Methods:** The data of 38 patients who underwent a Ga68 PET/CT study between 1/2019 and 12/2019 were retrospectively evaluated. They were categorized as high risk based on their Gleason score (8 or higher). The area from the base of the skull to the mid-thigh was covered in the scan. SUVmax values in the prostate gland as well as in possible other sites of abnormal uptake were calculated. **Results:** Twenty-two patients (22/38-58%), had abnormal extra prostatic uptake, with twelve of them showing only lymph node lesions (12/22,54%), eight (8/22, 36%) mixed lymph node and bone foci, while two (2/22, 9%) patients had only bone lesions. Usual sites of abnormal lymph node uptake were the inner inguinal lymph nodes,

lymph nodes in the anatomic space by the prostatic bed, the outer inguinal lymph nodes, the pre-sacral area and less frequently the para-aortic lymph nodes. Mean SUVmax of the lymph nodes foci was 22,17 (4,6 to 42). In the majority of the cases the lymph nodes were not abnormal using CT criteria alone (16/20, 80%). Mean SUVmax of the bone lesions was 20,25 (5,7 to 31), with most usual sites of pathology the spine and the pelvis. Sixteen patients had only uptake in the prostatic gland lesions, with mean SUVmax of 14,6, while the mean SUVmax in the prostate lesions in the group of patients with also extra-prostatic abnormal uptake was 25,65. There was no significant statistical difference of the SUVmax between the two groups ($p=0,36$). On the contrary when comparing the mean PSA values, the extra-prostatic group showed significantly higher PSA values compared to the prostate limited only group (59,2 to 10,95 respectively, $p=0,006$). **Conclusion:** Ga68 PSMA PET/CT study can be of great value in the initial staging of patients with high risk prostate cancer. In the majority of patients extra prostate pathology can be identified, with a great impact in the therapy planning. **References:** Silver DA, Pellicer I, Fair WR, Heston WD, Cordon-Cardo C. Prostate-specific membrane antigen expression in normal and malignant human tissues. *Clin Cancer Res.* 1997;3:81-5

EP-185

Primary staging of untreated prostate cancer in two-phase Ga-68-PSMA-11 PET/CT: The clinical impact of semi-quantitative parameters

F. Weitzer¹, B. Pernthaler², R. Riedl³, R. M. Aigner²;

¹Medical University of Graz, Graz, AUSTRIA, ²Medical University of Graz, Department of Radiology, Division of Nuclear Medicine, Graz, AUSTRIA, ³Medical University of Graz, Institute for Medical Informatics, Statics and Documentation, Graz, AUSTRIA.

Aim/Introduction: The value of Ga-68-PSMA-11 in diagnosing both nodal and bone metastases in recurrent prostate cancer is undoubted. The aim of this retrospective study was to evaluate the value of semi-quantitative PET parameters in a two-phase imaging protocol in patients with untreated prostate cancer (PC). **Materials and Methods:** We retrospectively evaluated 128 patients with newly diagnosed histopathologically confirmed untreated PC who underwent Ga-68-PSMA-11 PET/CT at our division from January 2017 to October 2019. 28 patients did not meet our inclusion criteria. Static Ga-68-PSMA-11 PET/CT scan of the pelvis was performed 6 min p.i. (early image) and a total-body PET/CT scan was performed 60 min p.i. (late image). Regions of interest for calculating SUVmax and SUVmean were drawn manually around the prostate gland, avoiding the bladder activity in both early and late images. Associations of SUVmax and SUVmean with Gleason score and PSA levels were investigated. **Results:** In 94 patients (94%) the primary tumor in the prostate gland could be

detected in both early and late phase. In 29 (29%) patients metastases could be detected at a median PSA level of 32.2 (range 0.4 - 503.0) ng/ml vs 10.1 (range 0.6 - 102.9) ng/ml in patients without metastasis ($p<0.001$). PC associated lesions demonstrated in the early vs late images a median SUVmax value of 8.2 (range 3.1 - 45.3) vs. 12.2 (range 3.1 - 73.4) and a median SUVmean of 4.2 (range 1.6 - 4.1) vs 5.8 (range 1.6 - 39.9) statistically significantly increase over the time. ($p<0.001$). Higher SUVmax and SUVmean were observed for higher Gleason grading ($p=0.004$ and $p=0.003$, respectively) and PSA levels positively correlate with SUVmax (Spearman's rank correlation coefficient: $r=0.40$, $p<0.001$) and SUVmean ($r=0.35$, $p<0.001$). **Conclusion:** Two-phase Ga-68-PSMA-11 PET/CT demonstrated a high overall detection rate of untreated PC of 94% and improves the diagnostic accuracy in primary staging as metastases could be detected in 29 (29%) patients. In primary PC SUVmax and SUVmean values are significantly increasing over the acquisition time points. Higher PSA levels and higher Gleason grading were associated with higher SUVmax and SUVmean levels in the primary lesion. **References:** Demirci E, Kabasakal L, Şahin OE, Akgün E, Gültekin MH, Doğanca T, et al. Can SUVmax values of Ga-68-PSMA PET/CT scan predict the clinically significant prostate cancer? *Nucl Med Commun.* 2019;40(1):86-91.

EP-186

The Role Of Fluciclovine 18F-FACBC-PET/CT In The Characterization Of High Risk Primary Prostate Cancer: Comparison With 11C-Choline-PET/CT And Histopathological Analysis

R. Mei^{1,2}, L. Maltoni², L. Zannoni¹, C. Pultrone³, F. Giunchi⁴, C. Nanni¹, I. Bossert⁵, A. Matti², R. Schiavina³, M. Fiorentino⁴, L. Bianchi³, C. Fonti¹, F. Lodi¹, E. Brunocilla³, S. Fanti^{1,2};

¹Nuclear Medicine Policlinico S.Orsola-Malpighi, Bologna, ITALY, ²DIMES, University of Bologna, Bologna, ITALY, ³Urology, AOU di Bologna Policlinico S.Orsola-Malpighi, Bologna, ITALY, ⁴Pathology, AOU di Bologna Policlinico S.Orsola-Malpighi, Bologna, ITALY, ⁵Nuclear Medicine, Istituti Clinici Scientifici Maugeri, Padua, ITALY.

Aim/Introduction: To explore the potential role of ¹⁸F-fluciclovine PET/CT in the differentiation of malignant from benign intraprostatic lesions in patients with high-risk primary prostate cancer (PCa) eligible for radical surgery, compared with ¹¹C-choline PET/CT and confirmed by prostatectomy histopathological examination. **Materials and Methods:** Among patients ($n=94$) who underwent additional ¹⁸F-fluciclovine PET/CT for staging high-risk PCa as part of a prospective monocentric investigational study (139/2014/O/Sper), the following inclusion criteria were considered for this subgroup analysis: histologically confirmed high-risk Pca, staging PET/CT performed both with standard ¹¹C-choline and ¹⁸F-fluciclovine (within max 1 month), radical surgery within 3 months, availability of

all pre-operative investigations in our hospital and of an accurate histopathological analysis of each intraprostatic malignant/benign lesion. A 6 sextants prostate template was created and used independently by PET readers and pathologists for data comparison and validation. PET visual and semiquantitative analyses (SUVmax; SUVmean; target-to-background ratios [TBR], using abdominal aorta, bone marrow, liver and healthy prostate as backgrounds) were performed on both ^{11}C -choline and ^{18}F -fluciclovine scans: at first patient-based, blinded to histopathology (imaging only) and subsequently lesion-based, unblinded, according to pathology reference template. All staging clinical data were collected. **Results:** Overall 19 out of 94 patients were included. Main clinical characteristics were mean age 63 (range 51–72) years, 89% high and 11% very-high-risk [D'Amico], mean PSA 9.15 (range 4.2–25 ng/mL), whereas pathological ones were pT3a 53%, R1 47%, extracapsular/seminal vesicle/perineural involvement respectively 74%, 21% and 84%; pGS 4+3 42%, 4+5 37%. Overall, 45 malignant and 31 benign lesions were found. For both tracers, the location of the “blinded” prostate SUVmax matched with the lobe of the index lesion (highest pGS) in 17/19 cases (89%). A significant positive correlation was found between SUVmax and pGS with ^{18}F -fluciclovine ($p=0.0082$), but not with ^{11}C -choline ($p=0.30$). SUV max was not significantly higher in malignant than benign lesions ($p=0.12$ and $p=0.10$) but was significantly higher in malignant than healthy tissue (Mann Whitney, $p=0.0012$ and $p=0.0004$ for ^{18}F -fluciclovine and ^{11}C -choline, respectively). Overall TBRs differed significantly between malignant and benign groups. Diagnostic performance of SUVmax resulted significant with both tracer (AUC=0.662, $p=0.004$ for ^{18}F -fluciclovine; AUC=0.675, $p=0.001$ for ^{11}C -choline). **Conclusion:** In our setting, ^{18}F -fluciclovine SUVmax demonstrated a significant performance in identifying PCa lesions, not different from standard ^{11}C -choline, however still inadequate to accurately differentiate malignant from benign intraprostatic lesions. A significant correlation was found between SUVmax and pGS, with ^{18}F -fluciclovine only. TBRs should be further investigated as more promising parameters. **References:** None

EP-187

The Value of the Gleason Score and the Initial PSA (Prostate Specific Antigen) Level in Predicting the Results of Bone Scan in Patients with Newly Diagnosed Prostate Cancer

M. Habbache, Q. Naili, M. Abdi, B. Said;

Nuclear medicine Center or Blida, Algier, ALGERIA.

Aim/Introduction: The factors that can predict a higher risk of bone metastasis (BMets) from prostate cancer (PC) are still a subject of debate. The aim of this work is to assess the value

of the GLEASON score, and the PSA level, in the prediction of BMets from newly diagnosed PC, and thus determine the indications for basic bone scan (BS) **Materials and Methods:** From 2017 to 2019, 256 patients have been enrolled in this retrospective study, with an average age of 71.45 (44 to 88 years). The following informations were collected for each patient: initial PSA level, GLEASON score, and the result of bone scan. We analyze the correlation of the results of the BS, with the PSA level, then with the Gleason score according to whether this score is ≤ 7 , or > 7 , and finally with the association of the PSA level and the GLEASON score. **Results:** The frequency of BMets increased as the PSA level increased ($p < 0.01$). 5 groups were distinguished. Group 1 (PSA ≤ 10 ng/ml): 28 patients, all having a negative BS. Group 2 (PSA: 10–20 ng/ml): 3/80 patients (3.7%), have BMets, two of which had a Gleason score > 7 , and one was classified T4N1. Group 3 (PSA: 20–50 ng/ml): 10/58 patients are metastatic (17%). Group 4 (PSA: 50–100 ng/ml): 25/52 patients, are metastatic (48%). Group 5 (PSA > 100 ng/ml): 29/38 patients are metastatic (76%). The number of metastatic patients also increased according to the Gleason score, ranging from 19% (37/194 patients) for a Gleason ≤ 7 , to 48% (30/62 patients) if the Gleason score is > 7 ($p < 0.01$). In patients with a PSA level > 20 ng/ml, the number of metastatic patients increased from 35% (36/104) if the Gleason score is ≤ 7 , to 63% (28/44) if the GLEASON score is > 7 ($p < 0.01$). The frequency of BMets in patients with PSA ≤ 20 , increased from 1% (1/90) if the Gleason score is ≤ 7 , to 11% (2/18) if the GLEASON score is > 7 ($p < 0.01$). **Conclusion:** Bone scan is not indicated if the PSA level is ≤ 10 ng/ml. It doesn't seem necessary if the PSA level is between 10–20 ng/ml, unless the GLEASON score > 7 , There is a lymph node involvement, or a large tumor. The risk of the existence of BMets increases from a PSA level > 20 ng/ml, especially if the GLEASON score is > 7 . Thus it can be considered that a PSA level > 20 ng/ml, or a Gleason score > 7 , would be predictors of BMets in newly diagnosed prostate cancer, which may therefore indicate to perform an initial bone scan **References:** None

EP-188

The Relationship Between The SUVmax Value Obtained in Ga-68 PSMA PET / CT Examination and LDH and ALP in Prostate Cancer Patients

Z. Hasbek, I. Salk, S. A. Erturk, B. Yücel, Ö. Ulaş Babacan, G. Gökçe, R. T. Bulut;

Sivas Cumhuriyet University School of Medicine, Sivas, TURKEY.

Aim/Introduction: Lactate Dehydrogenase (LDH) and Alkaline Phosphatase (ALP) are known to have prognostic significance in patients with prostate cancer. Our aim in this study was to evaluate the relationship between the SUVmax values obtained with Ga-68 PSMA PET/CT and LDH and ALP. **Materials and Methods:** Patients with prostate adenocarcinoma who underwent Ga-68 PSMA PET/CT for

primary staging or restaging in our department in 2019-2020 and whose LDH and ALP levels were studied in the same month were included in the study. **Results:** There were 61 patients in this study and median age was 73(range: 57-89). Distribution of metastasis localization in the patients was as follows:Bone-lymph node 22(36.1%),only-bone 13(21.3%), only-lymph node 4(6.6%),bone-lung 3(4.9%),bone-lymph node-lung 3(4.9%),lymph node-lung 2(3.3%), only-lung 1(1.6%),bone-liver 1(1.6%),bone-liver-brain 1(1.6%),no distant metastasis 11(18%).There was a significant positive correlation between serum PSA and ALP and LDH levels ($p=0.0001,r=0.43$ and $p=0.033,r=0.26$,respectively).There was a significant but weak correlation between the prostate SUVmax value and ALP levels of the patients ($p=0.019,r=0.271$).There was no significant correlation between patients' prostate SUVmax value and LDH levels ($p=0.345$).Also, no significant correlation was found between the SUVmax of the metastatic lesion with the highest PSMA uptake and LDH and ALP levels in patients with distant metastasis ($p=0.238$ and 0.277 , respectively). No statistically significant correlation was found between prostate SUVmax value and presence of distant metastasis ($p=0.729$).When the LDH cut-off value was taken as 240, no significant relationship was found between the rate of metastasis and LDH ($p=0.811$).When ALP cut-off value was taken as 120, a significant relationship was found between the rate of metastasis and ALP ($p=0.039$).Considering the presence of bone metastases alone; in patients with ALP levels of 120 and above, there was no significant relationship between the rates of bone metastasis and ALP levels ($p=0.052$).However, in patients with ALP levels of 120 and above, there was a significant relationship between the presence of diffuse bone metastasis and ALP levels ($p=0.052$).However, there was no significant relationship between LDH levels and the presence of diffuse bone metastases ($p=0.109$). **Conclusion:** In our study, it was found that ALP was high in the presence of both bone and other organ metastases, and there was a significant relationship between ALP levels and the prostatic SUVmax values. However, according to the data of our study, there was no such relationship with LDH.It is thought that this may be due to a limited number of patient populations in our study. **References:** None

EP-189

Dual-phase 68Ga-PSMA-11 PET/CT may increase rate of detected Lesions in Low PSA Levels of Prostate Cancer

M. Assadi¹, H. Dadgar², N. Norouzbeigi², F. Emami², H. Ahmadzadehfar³;

¹Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, ²Razavi Cancer Research Center, Razavi Hospital, Mashhad, IRAN, ISLAMIC REPUBLIC OF, ³Klinikum Westfalen, Knappschaft Hospital, Dortmund, GERMANY.

Aim/Introduction: Recently, 68Ga-PSMA-11 has been introduced as a promising tracer for evaluation of recurrences in prostate cancer (PC). While standard whole-body scans (one hour post injection (p.i.)) are performed routinely, because of high accumulation of radiotracer in the bladder interpretation of the results must be considered with caution. Regarding to this issue, early static imaging can show higher uptake in PC lesions earlier than tracer accumulation in the urinary bladder. Therefore, the aim of the current study was to compare the early static (3-6 min post-injection (p.i.)) and standard whole body (1h p.i.) 68Ga-PSMA-11 PET/CT imaging for detection of recurrences in PC patients. **Materials and Methods:** PC patients with prostate-specific antigen (PSA) less than 2.0 ng/ml choose for 68Ga-PSMA-11 PET with mean injected activity 170 MBq. Early static imaging contained the pelvis and the lower abdomen while whole body scan was performed as a routine site from the skull to the mid-thigh one hour after injection. Semi-quantitative analysis (SUVmax) was performed in suspicious lesions. **Results:** PSMA uptakes were observed at the small sites of primary tumor and lymph node metastases in patients. Comparing early and one-hour pelvic images in patients demonstrated that no significant differences were detected in the number of lesions. **Conclusion:** Early imaging (5 min p.i.) of 68Ga-PSMA-11 PET/CT in addition to whole-body scans (60 min p.i.) may increase the detection rate of local recurrence in PC patients with biochemical recurrence where the urinary bladder has a high uptake during the scan acquisition time. **References:** None

Measurement of blood flow of thoracic vertebral body using O-15 water PET

K. Matsunaga, M. Yanagawa, E. Shimosegwa, J. Hatazawa; Osaka University, Suita city, JAPAN.

Aim/Introduction: There were few reports about human bone blood flow (BBF)(1). The relationship between human BBF and blood cell counts has not been examined. Inhibition of vascular endothelial growth factor (VEGF) was reported to reduce BBF in mice (2), however the BBF change in human after anti-VEGF treatment has been rarely reported (3). The objectives of this study were to measure human BBF using ¹⁵O-H₂O PET, to examine the relationship between BBF and age, sex, blood cell counts, and to examine the BBF change after the anti-VEGF treatment (bebacizumab:BEV). **Materials and Methods:** Twelve patients with advanced lung cancer

underwent 10 min dynamic $^{15}\text{O}\text{-H}_2\text{O}$ PET before/after the chemotherapy. Using nonlinear regression, time activity curve of thoracic vertebral body was fitted to the single-tissue compartment model using image derived input functions, which were determined using volumes of interest over ascending aorta. We also evaluated the relationship between BBF, age and blood cell counts. In patients treated BEV (n=6), we compared the difference before/after administration of BEV including chemotherapy. **Results:** The mean of BBF was 0.1 ml/min/cm³, which was consistent with reported values derived from other methods (1,3). There was no significant correlation between BBF and age or BBF and blood cell counts. Significant BBF changes 1–2 days after BEV including chemotherapy were not observed. **Conclusion:** Human BBF could be measured using $^{15}\text{O}\text{-H}_2\text{O}$ PET. The sex, age, blood cell counts would not be the main regulatory factors in BBF. Anti-VEGF treatment did not affect BBF in human. **References:** (1)Lahtinen, T et al. EP-192

Paget's Disease on Bone Scintigraphy: the Role of Scintigraphic Patterns and Bone SPECT/CT in Diagnosis

H. Turoglu, S. Kesim, C. O. Engur, N. Filizoglu, S. Ozguven, K. Oksuzoglu, S. Inanir, T. Ones, T. Y. Erdil;
Marmara University Istanbul Pendik Training and Research Hospital, Istanbul, TURKEY.

Aim/Introduction: Paget's disease of Bone (PDB) is a chronic and benign bone disease with unknown etiology, which is more common in men and middle-aged or older adults. PDB is usually polyostotic and most of the bone lesions are asymptomatic. The scintigraphic and radiographic appearances of pagetoid bones depend on the disease stage. In this study, the frequency of PDB in bone scintigraphy, the role of SPECT/CT and scintigraphic patterns were investigated. **Materials and Methods:** Two hours after the intravenous injection of 20 mCi Tc99m-MDP, routine whole body skeletal survey and if necessary SPECT/CT images were acquired. For 14 patients who were clinically suspicious of PDB, immediate dynamic blood flow images and 2-5 minutes after injection, static blood pool images were also performed. **Results:** A total of 2665 patients, referred to the nuclear medicine clinic for bone scintigraphy, between years 2012 and 2019, were retrospectively investigated. Out of 2665 patients, 28 patients (17 males, 11 women) were identified as known/clinically suspicious or asymptomatic PDB. The age of patients ranged from 25 to 90 (mean 66.1±15.8). Five cases diagnosed by radiography, CT and bone scan were also confirmed by histopathology. In eight patients, malignancies and metastatic work-up were present. Although both were seen in elderly aged

men, it was noteworthy that the number of patients who have coexisting metastatic prostate cancer and PDB was small. Hearing loss, fracture and deformity complications of PDB were present, in five patients, in one patient and in five patients, respectively. In our patient series, "Mickey Mouse sign" was found in one patient and hemi-pelvis involvement was seen in 13 patients. It was observed that increased total ALP levels and metabolic active PDB on scintigraphy correlate well (p=0.002). Monostotic and symptomatic lesions were more frequent in our patient series, than that reported in the literature; which can be considered as a result of selection of the patients in a tertiary hospital setting. **Conclusion:** Clinical indications are the diagnosis and evaluation of the extent of PDB, assessment of treatment response and detecting complications in the follow-up. It was revealed that with the recognition of scintigraphic patterns ("Mickey Mouse sign" in the vertebrae, "Lincoln" sign in the mandible, hemi-pelvis involvement), and the addition of SPECT/CT in metabolic active PDB cases; high diagnostic accuracy can be achieved with prevention of unnecessary biopsies in monostotic cases. **References:** None

EP-193

Audit Of Reporting Ventilation-Perfusion (V/Q) Lung Scans In Pregnancy Over A Decade Apart And Across Two Different Institutions

G. Shabo;
University Hospital Lewisham, London, UNITED KINGDOM.

Aim/Introduction: Pregnancy is associated with a five-fold increase in the prevalence of venous thromboembolism (VTE) and pulmonary embolism (PE). The diagnosis of PE is challenging as the physiologic changes during pregnancy can mimic pulmonary embolism. The ventilation-perfusion lung scintigraphy (V/Q scan) is a well-established investigation of suspected PE in pregnancy with low radiation burden. In pregnancy, up to 5% of scans are positive and 75% of scans are normal. This audit looks at the reports from earlier and recent years, using planar and tomographic imaging in two different hospital settings, to evaluate whether the findings are in line with those of the literature. **Materials and Methods:** Data were collected retrospectively (via PACS, CRIS and Patient Centre), covering two years from January 2006 to December 2007 and two years from January 2018 to December 2019. The scans from 2006, 2007 and 2018 were performed at East Kent hospitals (UK) whereas the scans from 2019 were performed in a South East London hospital. The scans in 2006 and 2007 were planar imaging whereas those in 2018 and 2019 were SPECT imaging. All scans were ventilation-perfusion studies. **Results:** Total of 182 scans were reviewed. 51 studies in 2006 and 2007, aged 17 to 44 (mean 27.65, median 26.5 in 2006; mean 27.65, median 27 in 2007), 62 studies in 2018, aged 19 to 45 (mean 28.5; median 28) and 69 studies in 2019, aged

17 to 47 (mean 31.36; median 32). In 2006 and 2007, 31 scans (60.8%) were reported “normal” and 20 scans (39.2%) were “low probability”. No “positive” scans were reported during this period. In 2018, 51 scans (82.3%) were reported “normal”, 3 scans (4.8%) were “negative for PE”, 5 scans (8%) were “positive”, 2 scans (3.2%) were “low probability” (performed as planar imaging) and 1 scan (1.6%) was reported “uncertain whether recent or old PE”. In 2019, 56 scans (81.2%) were reported “normal”, 5 scans (7.3%) were “negative for PE” and 8 scans (11.6%) were “positive”. Overall, 138/182 scans (75.8%) were “normal” and only 13/182 scans (7.1%) were reported “positive”. **Conclusion:** The reports are largely in line with the literature findings in pregnancy. Reporting “low probability” in planar imaging can be subjective and these scans may be considered “normal” by other reporters. SPECT-V/Q scintigraphy is unquestionably superior to planar imaging. Positive scans can occur and the perception that V/Q scans in pregnancy are always normal is erroneous. **References:** None

EP-194

Incidental Findings on Single-Photon Emission Computerized Tomographic (SPECT) Studies

J. Koutsikos^{1,2}, S. Episkopopoulou¹, S. Mpakalis¹, S. Vasileiou¹, K. Athanasiou¹, S. Giourgouli², A. Kokkini-Pashou¹;
¹401 General Army Hospital, Athens, GREECE, ²Henry Dunant Hospital Center, Athens, GREECE.

Aim/Introduction: SPECT is a complementary and, in many cases, a necessary technique in the Nuclear Medicine studies. An important step in the interpretation of SPECT images is to study of the unprocessed imaging data, known as raw data. The raw imaging data contain the original information about captured physical quantities, which describe internal aspects of the body. This is followed by the application of the appropriate processing filters and algorithms to display the reconstructed final image. In some cases, an incidental finding is observed out of the region of investigation. The purpose of this study is to identify random findings on SPECT studies. **Materials and Methods:** A retrospective study was conducted. A total of 352 SPECT images were evaluated, including 233 myocardial perfusion scans, 14 bone scintigraphies, 5 inflammatory detection scans, 13 somatostatin receptors studies and 87 brain tomographies. Special attention was given in the evaluation of unprocessed data, in order to highlight possible random findings. **Results:** Nine unexpected findings were observed; thymoma, breast tumor, myelodysplastic syndrome, lung tumor, adenoma of the parathyroid gland, brain tumor and lymphoma. Seven of them were confirmed histologically or with other imaging techniques, such as MRI and PET. The other findings were an accessory spleen and sarcoidosis. Myocardial perfusion scintigraphic studies were the most common studies where an incidental finding was observed

(6/9). **Conclusion:** In our study, the occurrence of incidental findings in SPECT scans that should lead to additional medical care is 2,5%. Even if this is a small percentage, we can't ignore the fact that any further information may be crucial for the patient. So nuclear medicine physicians should keep in mind to study carefully the unprocessed data, while evaluating the tomographic nuclear medicine studies, to avoid overlooking such findings. **References:** None

EP-195

Exploratory study of the utility of clinical images with half dose ¹⁸F-FDG in a Biograph Vision PET/CT system

S. Tagawa, A. Ohnishi, A. Ohhashi, K. Hayashi, M. Nobuhara, N. Sakamoto, T. Nakamura;
 Kakogawa Central City Hospital, Kakogawa, JAPAN.

Aim/Introduction: The Biograph Vision PET/CT device is equipped with a silicon photomultiplier (SiPM), which has higher photodetection efficiency and faster processing speed than a conventional photomultiplier (PMT). Effective sensitivity is greatly increased due to its high time-of-flight (TOF) timing resolution. In addition, the smaller crystal size in SiPM results in improved spatial resolution and higher quality clinical images compared with PMT. The recent focus on dose reduction to the patient in the clinical setting requires a reduction in ¹⁸F-FDG dosage. Accordingly, we explored the clinical value of PET images obtained using Biograph Vision in half-dose ¹⁸F-FDG. **Materials and Methods:** In two sessions 2 days apart, three healthy subjects (body mass index [BMI] 18.7, 22, and 27.2) were injected with ¹⁸F-FDG of 3.7 MBq/kg (normal dose) or 1.85 MBq/kg (half dose) and underwent whole-body PET/CT starting at 60 minutes post-injection. Whole-body PET/CT images were acquired in step-and-shoot mode for 3 min/bed. One subject (BMI 22) underwent whole-body PET/CT in whole-body dynamic mode for 78 minutes (3 min/pass) after ¹⁸F-FDG injection at normal and half doses. In each subject, PET images obtained with normal and half dose ¹⁸F-FDG were compared and evaluated using liver signal-noise ratio (SNR; cut-off value, 10) and visual evaluation. In the whole-body dynamic scan images, summation images of passes 1-6 from 60 minutes post-injection were generated and evaluated. **Results:** In two of the subjects (BMI 18.7 and 22), liver SNR was slightly lower in the half-dose than normal-dose images, but above the cut-off value. In the other subject (BMI 27.2), liver SNR was 7.0 in the half-dose images, which is below the cut-off value. In all subjects, visual evaluation revealed almost no difference between the half-dose and normal-dose images. In whole body dynamic scanning, liver SNR was less than the cut-off value (6.0 and 9.1) in the summation images of the 6 passes from 60 minutes post-injection in both the half-dose and normal-dose images. However, in visual evaluation, even the summation images

of 3 passes from 60 minutes post-injection with half dose were relatively clear, and these images showed almost no difference from images with normal dose. **Conclusion:** These results indicate the quality of half-dose images is sufficient for clinical use. Clinically acceptable images can be obtained even in subjects with a large physique and with a short scan time. The use of Biograph Vision enables a reduction in dose and scan time in PET examinations. **References:** None

EP-196

Can we really trust bone scan for condylar hyperplasia?

D. Calabro¹, R. Mei¹, G. Argalia¹, L. Vetrone¹, N. Fraccascia¹, R. Bonfiglioli², E. Tabacchi², M. Levorato², S. Fanti¹;

¹Nuclear Medicine, S.Orsola-Malpighi Hospital, DIMES University of Bologna, Bologna, ITALY, ²Nuclear Medicine, S.Orsola-Malpighi Hospital, Bologna, ITALY.

Aim/Introduction: Condylar hyperplasia (CH) is a pathology of the temporomandibular joint resulting in a progressive unilateral non-neoplastic growth. Single photon emission computed tomography (SPECT) with Tc-99m-3,3-diphosphono-1,2-propanodicarboxylic acid (Tc-99m-DPD) has a pivotal role in the diagnosis of CH since the decision to perform condylectomy is almost exclusively based on finding a % condylar uptake difference $\geq 10\%$. Aim of this study was to compare two different quantitative evaluation methods to interpret the 99Tc-DPD SPECT/CT in patients (pts) with clinically suspected unilateral CH. **Materials and Methods:** Pts who performed a 99Tc-DPD SPECT/CT for clinical suspicion of unilateral CH between January 2016 and March 2020 were included. % condylar uptake difference was evaluated with two different quantitative methods: 1) total counts of 5 fixed-size regions of interest (ROI) drawn on 5 consecutive transaxial images for each condyle 2) total counts calculated on a fixed-size volume of interest (VOI) on fused transaxial SPECT/CT images. All the exams were reviewed by two nuclear medicine experts. Reproducibility (inter-operator variability) was assessed for both methods using contingency tables and K-coefficient. **Results:** Overall, 26 pts were included in the final analysis. % condylar uptake difference values were significantly different between the two methods ($p=0.08$). A low grade of diagnostic agreement was obtained in both ROI method ($K=0.07$) and VOI method ($K=0.03$). Limitations of this analysis are: i) the small population, ii) the lack of clinical follow-up data supporting a real evaluation of sensitivity and specificity for both methods. **Conclusion:** 5 fixed-size ROI method is the most commonly used in nuclear medicine departments. Despite its more easily evaluation, VOI method provides data that significantly differ from the 5 ROI method. Both methods also showed a poor reproducibility in terms of inter-observer agreement, so it is mandatory to identify a standardized method of quantitative evaluation of this test that offers the best possible CH diagnostic precision and

accuracy. **References:** None

EP-197

Whole-body PET/CT recognizes two distinct patterns of osteolytic lesions in adult Langerhans cell histiocytosis

R. Wang, M. Su, R. Tian;

Sichuan University West China Hospital, Chengdu, CHINA.

Aim/Introduction: Langerhans cell histiocytosis (LCH) is a histiocytosis disease which always accompanied multisystem lesions. Previous studies have assessed the role of FDG PET/CT in the management of adult multisystem LCH. The aim of our article is to explore the ability of ¹⁸F-FDG PET/CT in distinguishing two distinct patterns of osteolytic lesions in LCH patients. **Materials and Methods:** Ten consecutive adult patients with histologically proven LCH was included in this respective study, ¹⁸F-FDG PET/CT scan was performed for staging. The findings of other imaging features and treatment history were collected. The images of PET/CT were analyzed and compared between two different patterns of osteolytic lesions in LCH. The relationship between these clinical and PET/CT findings also analyzed. **Results:** Forty-two osteolytic bone lesions were detected on whole-body CT, mostly involving skull, ribs, spine and pelvis. These lesions separated two types of metabolic lesions containing of 16 high metabolisms and 26 low or no metabolisms on whole-body PET. According to the results of ¹⁸F-FDG PET/CT, low or no metabolic osteolytic lesions presented low SUVmax and SUVmean values (2.03 ± 0.62 and 1.84 ± 0.51), whereas high metabolic osteolytic lesions showed the pattern of high FDG intake, characterized by higher SUVmax and SUVmean values (6.36 ± 1.14 and 5.71 ± 0.9). we also found that the metabolic features in PET/CT have no relationship with treatment history. **Conclusion:** Two different metabolic patterns of osteolytic lesions were detected by ¹⁸F-FDG PET/CT in adult LCH. The lesions with high metabolism may be indicative for active or progressive disease, no metabolic lesions may present no-active or resolved disease. These two types of lesions were indicative for the diagnose of LCH, although only high metabolic lesions presented increased FDG uptake on ¹⁸F-FDG PET/CT. **References:** None

EP-198

Small steps driving big changes - How we implemented a new Gastric Emptying Protocol

M. Botelho Cruz, A. Pereira, A. Nunes, D. Bailey, C. Sibley-Allen, D. Dasgupta, F. Ul-Hassan, A. Eccles;

Guy's and St. Thomas' Hospital, London, UNITED KINGDOM.

Aim/Introduction: Gastric emptying (GE) scintigraphy is commonly used as a diagnostic procedure for the assessment of gastric motility and function. A plethora of literature is available to evaluate different meals for this

procedure, nevertheless standardisation is still lacking. The latter has been well demonstrated by Notgi, A. et al (2018) in their national survey. To optimise the quality and consistency of gastric emptying reporting and patient compliance with our standard meal (porridge with milk), we made it our goal to identify areas requiring improvement. Our initial focus was turned to the adult patient cohort. **Materials and Methods:** Multiphase gradual approach based on Kaizen methodology was adopted. This methodology is a process where workers at all levels of the department are engaged in constantly identifying opportunities for change and improvement. A motivated and skilled taskforce worked together to address current GE hurdles. This involved members of different staff groups with varying levels of seniority and expertise within Nuclear Medicine. The entire team was made aware of the aim and progressive results via departmental meetings. Phase 1 consisted in literature review of multiple meal options and reference ranges. An audit on consistency of reports and variation from our standard meal was conducted. On Phase 2 the impact of GE procedure on different staff groups workflow was analysed. This was followed by weighing pros and cons to drive a protocol change. The Nottingham test meal (NTM) was agreed upon as the test solution. Phase 3 encompassed contacting the Nottingham team to obtain authorisation and establish collaboration. On Phase 4 we performed protocol and software validation with a gastric phantom, produced in-house. The results were satisfactory; hence the protocol was accepted for clinical trial. Local standard operating procedures were produced. **Results:** The new protocol was clinically approved and fourteen adult patients have already been successfully scanned. A staff training programme is being developed and further qualitative research to evaluate staff and patient experience is the next step of this taskforce. Moreover, evaluation of suitability for paediatric population will also be addressed. **Conclusion:** In conclusion, multidisciplinary and co-operation between staff groups and bridging with other departments' knowledge is crucial to improve practices and drive changes in the Nuclear Medicine community. The use of Kaizen method was shown to be very effective in this project. **References:** Notghi, A. and Hansrod, S., 2018. National survey of gastric emptying studies in the UK. Conceptions of quality of nuclear medicine care services: A prospective two-center study

E. Giannoula¹, I. Katsikavelas², N. Papadopoulos³, C. Sachpekidis⁴, A. Doumas¹, F. Spyroglou¹, V. Chatzipavlidou⁵, I. Iakovou¹;

¹Nuclear Medicine dpt of Aristotle University AHEPA

Academic hsp, Thessaloniki, GREECE, ²Faculty of Engineering,

Aristotle University of Thessaloniki, Thessaloniki, GREECE,

³G.Gennimatas hsp, Thessaloniki, GREECE, ⁴Clinical

Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY, ⁵Nuclear Medicine dpt of THEAGENEIO Anticancer hsp, Thessaloniki, GREECE.

Aim/Introduction: Nuclear Medicine has a unique characteristic: the use of radiopharmaceuticals and exposure to ionizing radiation. Hence, quality and safety assurance is considered a sine qua non. Although, several reports have been issued, on how qualitative and safe management of patients in nuclear medicine departments (NMD) should be done, limited data are available in terms of the level of the quality of service and patients' perceptions regarding them. In this context, the objective of the current study was the assessment of patient satisfaction level and all aspects of perceived quality for medical, nursing and organization in NM settings as well as the evaluation of patients' attitude to exposure to ionizing radiation for medical purposes. **Materials and Methods:** The survey was contacted by using two SERVQUAL type questionnaires. The inpatient and outpatient questionnaires, were transformed and validated to reach out to thyroid cancer patients, submitted to nuclear medicine departments. A total number of 551 patients (354 who received therapeutic doses of ¹³¹I and 197 who underwent diagnostic ¹³¹I-scintigraphy) enrolled in this study. **Results:** High level satisfaction was measured from the medical services (98.8% of the inpatient and 99.5% of the outpatient survey participants were satisfied or very satisfied) and the nursing facilities (81.6% and 67.7% respectively were very satisfied). Patient satisfaction was obviously lower in respect with organization (55.1%) and hotel facilities (42.7% and 45.9%). The score of the overall perceived quality of services was high (98.5% and 91.8%). Waiting had a great impact on the perception of service quality for 34.4% of the participants. There were statistically significant differences in patient satisfaction and perceived quality of services observed according to sex, age, rural or urban residency, nationality, marital status, education level and profession, as well as health status. Patients' attitude towards radiation treatment efficacy and safety matters was revealing of the poor awareness towards the effects of exposure to ionizing radiation for medical reasons, showing the necessity for further informative campaign. **Conclusion:** Most NMD provide the same type of services but not equally qualitative. Quality assurance procedures, compliance with regulations and clinical practice based on evidence-based medicine do not seem to be enough, since perceptions in terms of safety, quality and satisfaction from the provided services differ between patients. Patient-centered practice, communication and proper information play a decisive role in ensuring satisfied patients. **References:** None

EP-200

Relevance of investigation of deep lymphatic vessels in lower limbs lymphoscintigraphy: a single Center experience

C. Dolci¹, R. Dentici², A. F. Scarale¹, A. Capozza¹, A. Franchini³, I. Gotuzzo³, E. Gay¹, G. Cabrini¹, M. Milella¹, C. Rossetti¹;

¹Nuclear Medicine Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY, ²Nuclear Medicine Unit, ASST Rhodense, Caduti Bollatesi Hospital, Bollate, ITALY, ³Nuclear Medicine, University Milano-Bicocca, Milan, ITALY.

Aim/Introduction: Lymphoscintigraphy (LSG) is a reliable tool for diagnosis of lymphedema but its execution protocol is not standardized and differs among diagnostic centers. Aim of this study was to evaluate the value of deep lymphatic circulation assessment together with superficial one in lower limbs (LL) LSG. **Materials and Methods:** One hundred and four patients (68 females, 36 males; mean age 40 years, range 11-78) with LL LSG performed at Caduti Bollatesi Hospital from 2016 to 2019 were retrospectively analyzed. Indications were suspect primary and secondary lymphedema in 87 and 17 patients respectively. Deep and superficial lymphatic circulation were investigated sequentially on the same day. One deep injection of 37 MBq technetium-99m labeled albumin nanocolloids was performed in the plantar arc of each foot and scintigraphic planar images were obtained at 5 and 25 minutes, after centripetal stimulation (walking). Superficial circulation was then examined with the same protocol after subcutaneous injections in first and fourth interdigital spaces and peroneal malleolus area (37 MBq overall for each foot). Pathologic findings were absent or reduced visualization of lymphatic vessels/nodes and dermal backflow. **Results:** Twenty-three out of 104 (22%) LSGs were negative, while 81/104 (78%) were positive for alterations of LL lymphatic system. Among positive LSGs, only 1/81 (1%) showed alterations of superficial lymphatic circulation alone; 42/81 (52%) showed alterations of both deep and superficial circulation and in 38/81 (47%) pathologic findings concerned only deep lymphatic system. In 33/38 (87%) LSGs with deep lymphatic system impairment, superficial compensation was observed as early visualization of superficial lymphatic channels/nodes after radiotracer deep injection. In 47/81 patients (58%) clinical presentation of limb swelling (left, right, bilateral) was concordant with lymphoscintigraphic abnormalities; among the 34/81 “nonmatch” patients (42%) 28 had bilateral lymphoscintigraphic abnormalities but unilateral clinical swelling, while in only 6 cases there was a discrepancy between clinical manifestation and scintigraphic findings. **Conclusion:** In this series most patients presented alterations of deep lymphatic vessels, with or without alterations of superficial one, so in these cases investigation of superficial circulation alone could cause lack of clinical information: in LL LSG it is useful to study

both deep and superficial circulation because alterations of deep circulation can be offset by a superficial one that functionally corrects a deficiency of primary or secondary nature. LSG can show bilateral lymphatic abnormalities in patients with unilateral lymphedema, thus detecting subclinical changes to lymphatic pathways before clinical evidence of disease. **References:** None

EP-201

FDG-PET/CT in neurofibromatosis type 1: the experience of a reference center

D. Peres e Leiro Gonçalves Ferraz, I. Patrocínio Carvalho, P. Ratão, J. Passos, M. Rio Carvalho, M. Silvestre, D. Fraga, I. Vitorino, F. Norton Brandão, R. Sousa, T. Cruz Ferreira, L. Salgado; Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, PORTUGAL.

Aim/Introduction: Neurofibromatosis type 1 (NF-1) is an autosomal dominant neurocutaneous pathology, which results in the loss of function of the oncosuppressant gene NF and predisposes affected individuals to develop tumors. This pathology has an incidence at birth of 1-2500 to 1-3000 and also carries a risk of malignization in the range of 8-12% during the patient's expected life span. The objective of the present study is to assess the degree of metabolic activity of neurofibromatous lesions and the correlation with malignant transformation. The preliminary results of the study are presented. **Materials and Methods:** A single-center retrospective study was carried out, with 85 patients (pts) with NF-1 undergoing FDG-PET/CT between February 2014 and January 2020, to assess possible malignant transformation of neurofibromatous lesions in the context of: pain, increase in size, change in consistency, associated neurological deficits. Seven pts were excluded: four, for having previously undergone systemic / surgical therapy and three, for not being followed at our institution. We included 78 pts (median age 23 years 6-69 years, 40 females and 38 males), corresponding to a total of 78 exams, with 149 lesions identified. [¹⁸F]FDG was administered at a dose of 37Mbcq / 10 kg weight and the average time between injection and image acquisition was 72 minutes [45-120 min]. The lesions were divided into three groups according to the maximum SUV: Group A: <2.5 (not suspect), Group B: 2.5-3.5 (doubtful), Group C: > 3.5 (suspect). Etiological confirmation was obtained by histological characterization or by a follow-up of more than 24 months (27 lesions). Lesions with a follow-up of less than 24 months and without histological evaluation to date, were classified as indeterminate and excluded from the present analysis. **Results:** Group A- 6 lesions: two benign (histological characterization) and four benign (follow-up). Group B- 5 lesions: three benign (histological characterization) and two benign (follow-up). Group C- 16 lesions: 11 benign (histological characterization), two malignant

(histological characterization) and 3 atypical (histological characterization). **Conclusion:** In this preliminary study, maximum SUV value of 3.5 appears to be a good cut-off to indicate benignity. Benignity was confirmed in all lesions with maximum SUV below 3.5. However, the reduced sample, as a consequence of the short follow-up time and the absence of histological characterization of all lesions, does not allow us to determine at this time the nature of the lesions through their metabolism. **References:** None

Radioguided Occult Lesion Localization of Pulmonary Nodules in Video-Assisted Thoracic Surgery: Initial Experience

A. Cánoves-Llobart¹, H. Rodríguez-Parra¹, I. Casáns-Tormo¹, M. Redal-Peña¹, V. Carrero-Vásquez¹, J. Sabater-Sancho¹, P. Cárcamo-Ibarra¹, M. Rengel-Ruiz², S. Figuerola-Almanzar³, R. Wins-Birabén³, G. Galán-Gil³;

¹Nuclear Medicine, Valencia, SPAIN, ²Radiology, Valencia, SPAIN, ³Thoracic Surgery, Valencia, SPAIN.

Aim/Introduction: To evaluate the results obtained in our initial experience in the radioguided occult lesion localization (ROLL) of small and solitary pulmonary nodules in video-assisted thoracic surgery (VATS). **Materials and Methods:** We analyzed 6 patients, age 24 - 78 y/o (mean 56), with single, small and peripherally located pulmonary nodules by computed tomography (CT). In all cases radiotracer administration and surgery were performed on the same day. We administered 1mCi of ^{99m}Tc-macroaggregated albumin in a volume of 0.2ml through CT-guided injection. Before the surgery, the radiotracer localization was verified by lung SPECT and SPECT-CT fusion. During the surgery, a gamma probe and portable gamma camera were used to locate and verify the nodule and to check the removed piece. After the surgery, it was obtained the pathological confirmation. **Results:** In 3 patients, the suspected diagnosis was primary lung neoplasia, and lung metastases in the other 3. Two nodules were localized in the right lower lobe, one in the right upper lobe and three in the left upper lobe. The distance to the pleural surface was 0.38-2.3cm (mean 1.3cm). The size of the nodules ranged from 3 to 12.8mm (mean 7.8mm). The intraoperative detection and excision rate were 100%. In all cases, the presence of radiotracer in the resected piece was confirmed. The pathological study confirmed the localization of the nodule in the removed

piece, with the results of one cancer, two metastases, one atypical adenomatous hyperplasia and two benign tumors. Patients' tolerance of the procedure was good. Regarding the technique, there was an extravasation of the radiotracer to the pleural space in one case, but the incident did not suppose any difficulty in radioguided localization of the nodule. After surgery, one patient had late postoperative complications, not related with ROLL technique. **Conclusion:** Radioguided occult lesion localization of pulmonary nodules allows a safe removal of no-detectable lesions by video-assisted thoracic surgery, without the need of thoracotomy. It reduces morbidity, allowing a minimally invasive surgery, with preservation of large volume of health pulmonary parenchyma and improves the patient recovery. **References:** None

EP-203

Role Of Double-Phase Parathyroid Scintigraphy With SPECT-TC, Probe And Portable Gamma Camera In The Detection And Extraction Of Parathyroid Adenomas

P. Turbay Eljach, M. González Soto, B. Pérez López, A. Sainz Esteban, N. Álvarez Mena, F. Sebastián Palacid, M. Alonso Rodríguez, C. Gamazo Laherrán, M. Ruíz Gómez, R. Ruano Pérez; Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To assess the diagnostic capacity of parathyroid scintigraphy with planar ^{99m}Tc-MIBI and SPECT-CT (GP) and the portable gammacamera in radioguided parathyroid surgery. **Materials and Methods:** Nineteen patients referred for suspicion of parathyroid pathology have been studied. A double-phase parathyroid scan was performed with ^{99m}Tc-MIBI and early cervicothoracic SPECT-CT. On the day of surgery, a 370 MBq dose of ^{99m}Tc-MIBI was administered one hour before surgery. During surgery, a probe and a portable gammacamera were used. Demographic data, scintigraphy detection capacity, SPECT-CT detection capacity and location, portable gammacamera and probe detection capacity, other imaging tests, pathological results and clinical evolution were evaluated. **Results:** All the cases were studied with ultrasound /CT before surgery, being negative for parathyroid disease in ten patients. The GP detected 19 unique adenomas (upper right 3, lower right 10, upper left 2 and lower left 3), one of them ectopic. All of them were extracted during surgery with the help of the probe and portable gammacamera. In 10 patients, the portable gammacamera was of great help in removing doubtful pathological glands. The pathological results confirmed the existence of 16 adenomas and 3 hyperplastic glands. During the surgical act, other parathyroid glands were removed (5), of which none had uptake with the portable gammacamera with pathological result of clear cell hyperplasia (1) and without pathological changes (4). Scintigraphic localization was confirmed during surgical excision in all cases. A significant decrease in

PTHi values was confirmed after excision and normalization of calcium levels. **Conclusion:** GP is useful in the detection and presurgical location of parathyroid pathology. The probe and portable gammacamera have proven to be very useful during the excision, successfully solving doubtful cases. **References:** None

EP-204

γ-probe guided minimally invasive parathyroidectomy in selected cases of solitary parathyroid adenomas

I. Iakovou¹, T. Papavramidis², E. Giannoula¹, F. Spyroglou¹, G. Gerasimou¹, E. Papanastasiou³, A. Doulmas¹;

¹Nuclear Medicine dpt of Aristotle University AHEPA Academic hsp, Thessaloniki, GREECE, ²1st Propedeutic Surgery dpt of Aristotle University AHEPA Academic hsp, Thessaloniki, GREECE, ³Laboratory of Medical Physics dpt of Aristotle University AHEPA Academic hsp, Thessaloniki, GREECE.

Aim/Introduction: Our objective was to assess the efficacy of γ-probe guided minimally invasive parathyroidectomy (γP-MInP) in selected cases of solitary parathyroid adenomas without intra-operative quick parathyroid hormone (qiPTH) measurement. **Materials and Methods:** Our cohort comprised 24 patients (21 female), 53±12yrs old, with primary hyperparathyroidism (HPT) without history of familial HPT nor MEN syndrome, no ultrasound thyroid nodule presence and ^{99m}Tc-MIBI scan and ultrasound concordant localisation of a solitary parathyroid adenoma. They were all operated by a high volume, parathyroid dedicated surgeon of the endocrine surgery department of our hospital from March 2017 to January 2019. All patients were operated within 1-3 weeks after the detection of a solitary parathyroid adenoma by ultrasound and confirmation by dual phase ^{99m}Tc-MIBI scintigraphy. γP-MInP was performed under local anesthesia, without qiPTH measurement, 1.5-2 hours after the i.v injection of 740 MBq ^{99m}Tc-MIBI. γ-probe Navigator GPS (RMD-Instruments) was used. A follow-up of at least one year was performed. **Results:** All patients discharged from the hospital after one day of hospitalization. A significant (higher than 50%) reduction of the 1st postoperative day serum PTH in respect to the preoperative PTH levels was noticed in all cases while an easily-treated transient hypocalcemia was detected in just one patient. Operation duration time was 31.1±6 min significantly shorter than the 1,5 hours duration of typical approach with the use of qiPTH measurement, under general anesthesia. There was no hyperparathyroidism relapse during the one year of follow-up period. **Conclusion:** γP-MInP is a really trustful operative technique in selected patients with hyperparathyroidism due to solitary parathyroid adenomas as defined by preoperative concordant ^{99m}Tc-MIBI and ultrasound findings. In such cases the use of qiPTH measurement is of little value. **References:** None

EP-205

18F-FDG PET/CT in staging and delineation of tumoral volume in radiotherapy planning

F. Manchon Adsuar, V. Lopez Prior, R. Diaz Exposito;

Fundacion Instituto Valenciano De Oncologia, Valencia, SPAIN.

Aim/Introduction: The aim is to investigate the use of 18F-FDG (fluorine-18 fluorodeoxyglucose) PET/CT in cancer staging and its effect on the therapeutic strategy and radiotherapy (RT) planning. **Materials and Methods:** Twenty four patients were included. 12 man and 12 women. Primary tumor sites: 10 lung, 4 head and neck, 5 gastrointestinal, 3 gynecological and 2 others (1 renal and 1 prostate). The mean age was 63.4 years. All of them had a CT and / or MRI. A contrast-enhanced CT and a 18F-FDG PET/CT acquired under radiotherapy position were performed. Both exams were compared to analyze patients staging reclassification. Changes in therapeutic strategy were analyzed. **Results:** 18F-FDG PET-CT changed the treatment management in 13 patients (54.16%); in 6 it modified the treatment (4 canceled the radiotherapy and treatment intention changed to palliative, chemotherapy was added in one patient and another a synchronous tumor of the rectum was operated). In 3 patients GTV (Gross Tumor Volume) decreased (PET ruled out malignancy in one of two pulmonary nodules, local recurrence in the cancer renal and differentiated pulmonary atelectasis vs tumor), in 4 patients the treatment volume increased (in unsuspected lymph node territories and nodular pulmonary lesions). Also two synchronous rectum tumors, were detected. It did not mean a longer PET exploration time, in addition to the saving of the previous planning CT. **Conclusion:** 18F-FDG PET-CT changed the treatment management in 13 patients (54.16%); in 6 it modified the treatment (4 canceled the radiotherapy and treatment intention changed to palliative, chemotherapy was added in one patient and another a synchronous tumor of the rectum was operated). In 3 patients GTV (Gross Tumor Volume) decreased (PET ruled out malignancy in one of two pulmonary nodules, local recurrence in the cancer renal and differentiated pulmonary atelectasis vs tumor), in 4 patients the treatment volume increased (in unsuspected lymph node territories and nodular pulmonary lesions). Also two synchronous rectum tumors, were detected. It did not mean a longer PET exploration time, in addition to the saving of the previous planning CT. **References:** None

Women with cN0 Breast Cancer and Negative Hormonal Receptors: Is It Time to Reconsider the Use of Sentinel Lymph Node Biopsy After Neoadjuvant Chemotherapy?

J. Alors-Ruiz¹, B. D. Patrùt¹, S. Sanz-Viedma¹, A. Montellano-Fenoy¹, F. Fernández-García², F. Sendra-Portero³;

¹UGC Medicina Nuclear. Hospital Clínico Universitario Virgen de la Victoria, Málaga, SPAIN, ²UGC Cirugía General y Digestiva. Unidad de Patología Mamaria. Hospital Clínico Universitario Virgen de la Victoria, Málaga, SPAIN, ³Departamento de Radiología. Universidad de Málaga, Málaga, SPAIN.

Aim/Introduction: High rates of negative sentinel lymph node (SLN) biopsies in women with cN0 breast cancer with triple negative (TNBC) or ERBB2 gene overexpression (ERBB2-positive) subtypes, with complete clinical and radiologic response (CCRR) after neoadjuvant chemotherapy (NACT), have been described. Our purpose is to evaluate the association between clinical and molecular variables and presence of SLN metastasis. **Materials and Methods:** 152 women was included prospectively in this study. The inclusion criteria was patients with breast cancer cN0 who underwent NACT before the breast surgery and SLN biopsy. Complete axillary dissection was performed if no drainage of the radiotracer or in case of SLN metastasis in intraoperative biopsy. We analyzed the relation between the SLN result with the ERBB2-positive, TNBC, positive hormonal receptors with negative ERBB2 (HR+/ERBB2-) and the NACT response. **Results:** From the 152 patients included (51±11.2 years old), 23.7% had SLN metastasis. The HR-negative subtypes (TNBC and HR-/ERBB2+) had lower rates of SLN metastasis (9.8% and 10.7%), compared to HR-positive subtypes (HR+/ERBB2+ and HR+/ERBB2-): 30.4% and 51.9% each. From the 74 women ERBB2+, 41.9% reached CCRR, and only one presented SLN metastasis (3.2%; IC-95%: 0.4%-19.1%; p=0.0005). In TNBC group who reached CCRR (27/51; 52.9%) there was no case of SLN metastasis. The residual breast disease was 92.3% in HR+/ERBB2- group, and the SLN metastasis rate in this group was 58.3%, notably higher than in ERBB2+ and TNBC groups with residual breast disease (33.3% and 24% each, p=0.0025). The multivariable regression analysis has proven that initial tumor size >30mm (OR=3.42; IC-95%:1.45-8.06; p=0.005) and HR+ (OR=5.53; IC-95%: 2.27-13.49; p=0.0002) are related to SLN metastasis (p<0.0001). **Conclusion:** In our series, the initial tumor size >30 mm and HR+ relate significantly to SLN metastasis. Patients with HR-/ERBB2+ and TNBC have

higher rates of complete clinical and radiological response, with very low rates of SLN metastasis, which suggests the need to individually evaluate the axillary surgery indication after NACT in these patients. **References:** None

EP-207

Sentinel lymph node biopsy in oral squamous cell carcinoma: SPECT-CT over planar lymphoscintigraphy

B. Luna¹, C. Sampil^{1,2}, V. Lasa¹, M. Pastor¹, A. Repetto¹, N. Orta^{1,2}, C. Peña^{1,2};

¹Hospital Universitari Son Espases, Palma, SPAIN, ²IdISBa, Palma, SPAIN.

Aim/Introduction: Analyze the value of ^{99m}Tc-labelled nanocolloid SPECT-CT over planar lymphoscintigraphy for sentinel lymph nodes (SLN) detection in Oral squamous cell carcinoma (OSCC). Evaluate the lymphatic drainage by surgical levels of the neck with SPECT-CT and assess the value and the reliability of sentinel lymph node biopsy (SLNB) over lymphadenectomy. **Materials and Methods:** Retrospective study (2011–2019) of 38 patients (7 women/31 men; median age: 71.5 years) referred for SLNB of OSCCT1–2 cN0. Dynamic images were acquired immediately after peritumoral/submucosal injections of 148 MBq ^{99m}Tc-labelled nanocolloid. Static images and SPECT-CT were acquired at 30 minutes–1h p.i. in all patients. The acquisitions were obtained using a dual-head camera (NM/CT D670, GE). The number and anatomical localization of SLN by surgical levels of the neck were compared. A gamma probe (Navigator GPS) was used for intraoperative localization of SLN at a maximum of 24 hours p.i., and then it was referred for intraoperative anatomopathological analysis. Long-term follow-up (mean: 26.7 months) and recurrence analysis were performed. **Results:** The tumor localization were lower lip (14), upper lip (1), tongue (12), palate (1), floor of the mouth (9) and retromolar trigone (1). SLN identification rate was 100%. 132 SLN were obtained in planar study (mean 3.47 SLN/patient) vs 155 SLN in SPECT-CT (mean 4.08 SLN/patient). 152 SLN were excised from the total necks (mean 4 SLN/patient); 12 SLN were malignant (7.89%). All of the 23 SLN extra provided by the SPECT-CT were negative. Only 2 of 17 lymphadenectomies showed other affected nodes (3/325 nodes). After surgery 31/38 patients were T1, being the most frequent levels of lymphatic drainage Ib, IIa and III. Unsuspected contralateral lymphatic drainage was obtained in 13 patients: lower lip (4), tongue (4), palate (1) and floor of the mouth (4). One of them had a micrometastasis (8%) with a tumour on the tip of right tongue and unilateral drainage to the left side. The ipsilateral lymphadenectomy in this patient was negative. In addition, aberrant drainage was obtained in 2 patients: 1 SLN in parapharyngeal space (palate tumour) and 1 SLN localized between bellies of the digastric muscle (tongue tumour), both negative in the anatomopathological analysis. During

follow-up, just one patient had bilateral cervical lymph node recurrence with bone metastasis at 13 months after surgery (tumour localized on the right side of the tongue and bilateral drainage with SLN negatives). **Conclusion:** ^{99m}Tc -labelled nanocolloid SPECT-CT detects a higher number of SLN and in more surgical levels of the neck than planar imaging. Furthermore, it can detect atypical and unexpected lymphatic drainages, positive in a 8% of cases. The most frequent lymphatic drainage was in levels Ib, IIa y III. SLNB has proved to be a useful and reliable technique in OSCC over lymphadenectomy. **References:** None

EP-208

The Diagnostic Value Of Hybrid SPECT/CT For Sentinel Lymph Node Mapping In Patients With Malignant Melanoma. Comparison To Dynamic Planar Radioisotopic Lymphoscintigraphy

M. Stathaki¹, N. Kapsoritakis¹, D. Michelakis², O. Bourogianni¹, E. Papadaki¹, A. Tsaroucha¹, E. De Bree², S. Koukouraki¹; ¹Nuclear Medicine Department, University Hospital, Heraklion-Crete, GREECE, ²Department of Surgical Oncology, University Hospital, Heraklion-Crete, GREECE.

Aim/Introduction: Sentinel lymph node (SLN) biopsy and preoperative imaging constitute an important component in surgical treatment of oncologic patients. This study aims to evaluate the added diagnostic value of hybrid SPECT / CT with 16 slice CT in the detection and localization of SLN in patients with melanoma compared to dynamic planar radioisotopic lymphoscintigraphy (dLS). **Materials and Methods:** Between January 2019 - February 2020, 56 patients with malignant melanomas (head-neck:8, trunk: 28, limbs: 10 upper and 10 lower) underwent dLS as well as SPECT/CT imaging. Dynamic images were acquired first after intradermal administration of 2-4 injections of ^{99m}Tc -nanocolloidal albumin, around the lesion. Qualitative analysis was based on evaluating the exact number and anatomical localization of SLNs detected on each imaging method. Sensitivity, specificity, PPV and NPV were calculated. **Results:** SPECT/CT demonstrated 40 (33,3%) additional SLNs vs dLS in 24 pts (2 patients with head-neck, 16 with truncal, 4 with upper limb, 2 with lower limb melanoma). In 2 cases of truncal melanoma, dLS failed to detect one SLN found on SPECT/CT (false negative). In 4 patients with head-neck melanomas, no SLNs were identified with any of the above-mentioned imaging techniques. Moreover in 2 cases of truncal melanoma, the foci of increase activity interpreted on planar scintigraphy were found to be non-nodal site of uptake on SPECT/CT (false positive). Analysis of dLS imaging revealed sensitivity, specificity, PPV and NPV of 96%, 66,6%, 96%, and 66,6% respectively. For SPECT/CT imaging all the above-mentioned parameters were excellent, reaching 100%. **Conclusion:** SPECT/CT is an important complementary imaging modality to dLS

imaging improving detection and anatomical localization of SLN in patients with melanoma. Moreover, it helps to reduce false positive and false negative results, especially in cases of head-neck and truncal melanoma, aiding in more accurate patients' staging, treatment planning and prognosis. **References:** 1. EP-209

Survival Analysis in Patients with cN0 Breast Cancer who underwent Selective Lymph Node Biopsy after Neoadjuvant Chemotherapy

J. Alors-Ruiz¹, S. Sanz-Viedma¹, A. Montellano-Fenoy¹, B. D. Patrùt¹, R. Gómez-Pérez², F. Sendra-Portero³;

¹UGC Medicina Nuclear. Hospital Clínico Universitario Virgen de la Victoria, Málaga, SPAIN, ²UGC Cirugía General y Digestiva. Unidad de Patología Mamaria. Hospital Clínico Universitario Virgen de la Victoria, Málaga, SPAIN, ³Departamento de Radiología. Universidad de Málaga, Málaga, SPAIN.

Aim/Introduction: There is a need for more survival analysis in women with cN0 breast cancer who have received neoadjuvant chemotherapy (NACT). Our objective is to contribute by collecting survival data and locoregional recurrence rates which associate results from the sentinel lymph node (SLN) biopsy with the response to NACT and the different molecular subtypes. **Materials and Methods:** It is a prospective study with 123 female patients with cN0 breast cancer, who received NACT before the axillary SLN surgery. Previous lymphoscintigraphy with periareolar injection of ^{99m}Tc -nanocolloid and radioguided surgery with a surgical gamma probe was performed. Complete axillary dissection was performed in case there was no radiotracer drainage or if the intraoperative examination of the SLN was positive for metastasis. The complete pathological response (CPR) was defined according to the criteria from the Residual Cancer Burden system (RCB). Survival rates was calculated from the date of diagnosis until death, recurrence or last follow-up. A Kaplan-Meyer analysis was performed in order to evaluate the association between overall and disease-free survival rates, molecular subtype, NACT response and SLN biopsy result. **Results:** The median follow-up was 53.8 months (98.9-8.6). There was no axillary relapse in the 95 female patients (77.2%) who had negative SLN. Overall and disease-free survival rate from our series

was 92.7% and 85.4%, respectively. These rates was 88.5% and 76.9%, respectively, for the non-CPR group. The patients with negative SLN showed a higher disease-free survival rate compared to the patients with SLN metastasis (91.6% vs 64.3%, Log-Rank $p=0.0003$), reaching 98% if they presented also overexpression of the ERBB2 gene. There were no recurrence cases in women with CPR after NACT.

Conclusion: In our series, the highest global, disease-free survival rates were shown by women with negative SLN, who did not present axillary relapse. The follow-up showed that certain groups of patients had excellent survival rates related to the NACT response and overexpression of ERBB2 gene. The results suggest a personalized strategy when it comes to recommend axillary surgery after NACT.

Sentinel lymph node detection in breast cancer patients depending on the tracer application site

M. Rodrigues, F. Schmidt, R. Moncayo, I. Virgolini;
Department of Nuclear Medicine, Innsbruck
Medical University, Innsbruck, AUSTRIA.

Aim/Introduction: Breast cancer is the most often diagnosed malignant tumour in women worldwide. The assessment of the regional lymph nodes is an essential factor to notice a potential tumour spread into the lymphatic system and furthermore to plan the following therapeutical approach. Sentinel lymph node (SLN) scintigraphy aims to mark the first few lymph nodes into which the tumour drains before these SLN become excised and histopathologically examined. We aimed to compare the efficacy of periareolar and peritumoral injections for SLN detection in breast cancer patients. **Materials and Methods:** Anonymised data of 231 female patients investigated with SLN scintigraphy for breast cancer were retrospectively evaluated. All patients underwent planar (anterior) and SPECT/CT (360°, low dose CT) imaging of thorax 1h after injection of 30 MBq Tc-99m human serum albumin nanocolloids (injection volume: 0,2-1,0 ml). Tracer application was periareolar in 117 patients and peritumoral (ultrasound-guided) in 114 patients. Tracer application was performed 18-24h before breast surgery and SLN biopsy. **Results:** SLN detection rate was 95,73 % in the periareolar group and 86,84 % in the peritumoral group. Histopathologic confirmed false negative rate in the periareolar group A was 0 % while in the peritumoral group B it was 12,12 %. **Conclusion:** The periareolar injection showed to be more sensitive for SLN mapping and for avoiding false negative results as compared with the peritumoral application. For routine investigation the periareolar injection should be applied in as much as the method is easier to carry out than the peritumoral procedure. **References:** None

EP-211

Sentinel Lymph Node Detection In Patients With Breast Cancer And Positive Axillary Lymph Node After Neoadjuvant Chemotherapy

P. Cárcamo-Ibarra¹, H. Rodríguez-Parra¹, M. Redal-Peña¹, I. Casáns-Tormo¹, V. Carrero-Vásquez¹, A. Cánoves-Llombart¹, J. Sabater-Sancho¹, U. López-González², M. Soria-Merino¹;
¹Nuclear Medicine. University Clinic Hospital, Valencia, SPAIN, ²Preventive Medicine. University Dr Peset Hospital, Valencia, SPAIN.

Aim/Introduction: To assess the results of sentinel lymph node biopsy (SLNB) after neoadjuvant chemotherapy (NACT) in patients with breast cancer and initial axillary affectation, evaluating the coincidence with the axillary radiological marker (ARM) and comparing the anatomopathological analysis (APA) of the sentinel lymph node (SN) with the rest of lymph nodes of the axillary lymph node dissection (ALND). **Materials and Methods:** Cross-Sectional study (September 2016 to November 2019) in patients with infiltrating breast cancer and axillary lymph nodes with positive metastatic affectation by FNA/CNB and with ARM. After NACT, SLNB and ALND were performed, analyzing in 42 women (36-76 years old, mean 53) with scintigraphic detection of SN, the coincidence of SN with ARM, anatomopathological response of SN and the other axillary lymph nodes. **Results:** In 33/42 patients (78.6%) the histological type was ductal and 21/42(50%) Luminal B. SN coincided with ARM in 39/42(92.9%). The APA of the ALND showed complete remission of the axillary lymph nodes in 14/42(33.3%), partially in 18(42.8%) and no response in 10(23.8%), one of the latter group showed no coincidence between the SN and ARM. Among the 28 patients with partial or no response, SN was the only affected node in 10/28(35.7%), while in the other 18 patients there was 1-11 additional lymph nodes affected in ALND. Among the 14 patients with complete response, none of them had affectation of SN nor in other lymph nodes in ALND. The analysis of validity of SLNB in the 39 cases of coincidence SN-ARM with relation to APA of the ALND, shows sensitivity 94%, false negative rate 6%, negative predictive value (NPV) 95%, and OR of 19 between TN and FN (CI 95% 2,1-171,2, $p:0.004$). **Conclusion:** In our group of patients with breast cancer and initial positive axillary lymph node, SNLB after NACT showed a high percentage of concordance with the radiological marker and high NPV. Thus, it is possible to consider that SLNB could provide valuable and reliable information of the state of the axillary nodes, and allows to avoid unnecessary ALND when the SN is negative.

EP-212**Alydra Index, a Tool for Quantifying the Drainage in the Preoperative Lymphoscintigraphy for Breast Cancer**

J. Alors-Ruiz¹, F. Sendra-Portero², B. D. Patrùt¹, A. Montellano-Fenoy¹, F. Fernández-García³, S. Sanz-Viedma¹;

¹UGC Medicina Nuclear. Hospital Clínico Universitario Virgen de la Victoria, Málaga, SPAIN, ²Departamento de Radiología. Universidad de Málaga, Málaga, SPAIN, ³UGC Cirugía General y Digestiva. Unidad de Patología Mamaria. Hospital Clínico Universitario Virgen de la Victoria, Málaga, SPAIN.

Aim/Introduction: The purpose of this study was to improve the results of the lymphoscintigraphy by developing a semiquantification tool which is able to evaluate the axillary drainage of the radiotracer, in order to investigate the variables that affect the lymphatic pathophysiology of breast cancer. **Materials and Methods:** It is a prospective study of 108 women with clinically node-negative breast cancer (cN0) who received neoadjuvant chemotherapy (NCT). Lymphoscintigraphy with periareolar injection of ^{99m}Tc-nanocolloid was performed before the sentinel lymph node (SLN) biopsy. The Alydra (Axillary Lymph Drainage) Index was calculated by estimating the quantity of radiotracer migrated from the injection site, using the proportion of injected activity that is present in the axillary area. The logistical regression analysis determined the correlation between the Alydra Index with the lymph nodes number in the images and the SLN results. **Results:** The Alydra Index value was significantly higher as more lymph nodes were visualized in the lymphoscintigraphy ($p < 0,0001$). 7.27 ± 2.51 vs 20.47 ± 7.11 between 0 and 1 lymph nodes ($p = 0.035$); 20.47 ± 7.11 vs 42.9 ± 10.68 between 1 and 2 lymph nodes ($p < 0.0001$) and 42.9 ± 10.68 vs 75.47 ± 23.68 between 2 and 3 or more lymph nodes ($p = 0.004$). The patients with negative SLN had significantly higher values of the Alydra index compared to the patients with SLN metastasis (Median differences = 21.76; IC 95%: 5.13–38.39; $p = 0.0035$). The multivariant logarithmic regression showed that the number of lymph nodes in lymphoscintigraphy (OR = 1; IC 95%; 0.51–1.95; $p = 0.999$) didn't show differences regarding the SLN results; however, lower values of the Alydra Index (OR = 4.56; IC-95% 1.58–13.2 $p = 0.005$) were related to SLN metastasis. **Conclusion:** Alydra, as a new semiquantitative index measured in lymphoscintigraphy, was able to evaluate the quantity of lymph drainage in women with cN0 breast cancer and NCT candidates, with better discrimination than using the number of sentinel lymph nodes visualized. The results suggested potential value in clinical research, with the objective of comparing subpopulations and variables related to lymphatic physiopathology of breast cancer, as the presence of SLN metastasis. **References:** None

EP-213**Our experience in Sentinel lymph node biopsy after neoadjuvant chemotherapy treatment**

Hospital la Fe, Valencia, SPAIN.

Aim/Introduction: The aim of the study is to follow patients with locally advanced breast cancer after neoadjuvant chemotherapy and being clinically negative on axillary, following Sentinel lymph node biopsy (SLNB). **Materials and Methods:** 47 patients with locally advanced breast cancer and SLNB were studied after chemotherapy during 5 years (December 2014 to January 2019). whose ages range from 25 to 70. The histological classification showed the following results: Invasive Ductal (91%), Lobular (4%), others (4%);. The 55% were triple negative. The response to chemotherapy according to Miller & Fisher scale was 51% G5 and 12% G4., SLNB with OSNA technique (One Step Nucleic Acid Amplification) was performed and , if the node had 250 or more > copies, was considered positive node and is required to complete lymphadenectomy . After surgery, patients went through with annual checks. Breast cancer was controlled in 85% while 15% had progression, and one even died. **Results:** The detection rate of sentinel node was 80% (38/47), with an average of 1.27 lymph nodes removed. The tracer did not reach the lymph nodes in 9 out of 47 patients (20%), Six of them presented cancer spread to axillary lymph nodes SLN was detected in 38 patients., 7 were positive nodes followed complete lymphadenectomy. Only 2 out of 7 presented metastasis during their annual checks, and one eventually died. During the study of 31 negative sentinel nodes; 87% of them were BIRADS 2 ;and 13 % had metastatic progression. Two of the patients presented cerebral metastasis; other patient had local affection BIRADS 5; and only one had lymph node affection. **Conclusion:** The SNLB results in patients with breast cancer after neoadjuvant treatment, has demonstrated to be of help reducing the number of unnecessary lymphadenectomies **References:** None

EP-214**Sentinel lymph node biopsy in oral cavity squamous cell carcinoma: our experience**

D. Monachello Araujo, C. Escabias del Pozo, L. García Zoghby, D. Travaglio Morales, E. López Llobet, J. Cebrian Carretero, P. Losa Muñoz, A. Guzmán Cruz, L. Domínguez Gadea;

Hospital Universitario La Paz, Madrid, SPAIN.

Aim/Introduction: To asses our experience in the implementation of sentinel lymph node biopsy (SLNB) in oral cavity squamous cell carcinoma (OCSCC). **Materials and Methods:** Retrospective study of 11 patients (p), 6 women, mean age 63 years (51–79), with the diagnosis of OCSCC,

all of them localized in mobile tongue, cT1-T2/N0 by head and neck CT, referred to our nuclear medicine unit for SLNB between December 2017 and August 2019. All patients underwent the procedure according to standard protocol: four submucosal injections of the radiotracer (74 MBq of ^{99m}Tc Albumin Nanocoloid), immediate acquisition of dynamic images, early and late acquisition of planar images and SPECT-CT of the neck. Elective neck dissection (END) was performed in 4p after SLNB as initial validation. The average follow-up was 11 months (1–24). **Results:** The sentinel node (SN) was detected by lymphoscintigraphy in all patients, 9p (82%) had 2–3 SN. The most frequent locations were levels II–IV (15 SN), followed by level I (5 SN), supraclavicular fossa (2 SN) and level V (1 SN). 4p had bilateral drainage in unilateral lesions. SNs were found during surgery in all cases and were concordant with the locations provided by SPECT-CT. Pathologic evaluation of SN was negative in 10/11p. END of patient with SN metastasis was negative for other node metastasis (0/29). Pathologic evaluation of the other 4p who underwent END was concordant with the SN (negative). During follow-up, only 1p with negative SN showed non-lymph node locoregional relapse (soft tissue) 10 months after. **Conclusion:** In our series, SN detection was possible in all cases, being a useful technique in patients with clinically localized OSCC. Lymphoscintigraphy identified unsuspected contralateral drainage, being the SPECT-CT the one that allowed a precise localization of the SN, facilitating its identification during surgery. **References:** None

EP-215

Role of selective sentinel node biopsy in T2–3 breast carcinomas converted to T0–1 after receiving neoadjuvant chemotherapy

P. Turbay Eljach, A. Sainz Esteban, B. Pérez López, M. González Soto, N. Álvarez Mena, F. Sebastián Palacid, M. Alonso Rodríguez, C. Gamazo Laherrán, M. Ruiz Gómez, R. Ruano Pérez; Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To assess the usefulness of selective sentinel node biopsy (BSGC) in patients with T2 (greater and less than 3 cm) and T3 breast carcinoma, converted to T0 and T1 (a, b or c), after receiving treatment with neoadjuvant chemotherapy. **Materials and Methods:** We included all the patients referred to our service (from 2017 to 2019) for the performance of BSGC, with biopsy-confirmed infiltrating breast carcinoma and previously treated with neoadjuvant chemotherapy. All of them underwent lymphoscintigraphy after injection of 185 MBq of ^{99m}Tc -nanocoloids (if the breast lesion has disappeared or was not palpable after the action of neoadjuvant, the injections were administered periareolar). Static planar images were performed 60 min post-injection for the analysis of the lymphatic drainage. **Results:** Forty seven patients, all women with a mean age

of 54.1 years (range 26–74 years), were studied. The CG was visualized in the lymphoscintigraphy in 95.7% (45/47). The BSGC technique was performed in all patients, locating the sentinel node intraoperatively in 95.7%. The sentinel node was negative in 29 patients; positive in 18 patients, of whom 3 presented micrometastases and 11 macrometastases (> 10,000 cp), with axillary lymphadenectomy being performed in all cases of macrometastases. In the 2 cases of absence of intraoperative localization of the sentinel node, lymphadenectomy was performed directly (1 negative case and one positive case for metastasis). **Conclusion:** The BSGC in breast cancer with conversion to T0–1 post-neoadjuvant presents good results, with a low false negative rate. **References:** None

EP-216

In the sites of blinding lights: the role of lymphoscintigraphy in melanoma

A. Farina¹, R. Bonfiglioli¹, M. Levorato¹, M. Maccagnani¹, F. Giorgini², R. Cipriani², S. Fanti¹; ¹Nuclear Medicine Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, ²Plastic and Reconstructive Surgery Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY.

Aim/Introduction: The sentinel node (SL) lymphoscintigraphy may show multiple sites of drainage and hypercaptant lymph-nodes in patients with histologically proven melanoma skin cancer localized in the trunk. In this case the nuclear physician indicates the projection of multiple lymphatic sites (MLS). The aim of this retrospective single centre study is to analyze the concordance between the histological exam of SL removed and compared to those marked by lymphoscintigraphy in a group of patients with different sites described by the procedure. **Materials and Methods:** From March 2018 to February 2020, overall 80 consecutive patients (21F, 33M, age 21–93, mean 59) showing histologically proven melanoma skin cancer at the first excision of atypical nevus. All patients had lesions localized in trunk and underwent lymphoscintigraphy for the SL localization performing an early anterior dynamic acquisition followed by anterior, lateral and oblique static acquisitions. The procedure starts with a subcutaneously injection of ^{99m}Tc -NanoAlbumon (range 1–2 mCi, depending by the timing gap to the surgery, according to EANM guidelines) around the melanoma removal scar, immediately followed by first dynamic acquisition. For this examination we used GE-Discovery NM/CT 670 ES. The same day or the next day all patients underwent enlargement with removal of the SL. All of the specimens tissues were analyzed by our pathological anatomy department. **Results:** Out of 80, 57 lymphoscintigraphy indicated only one site for SL (53 unilateral axillary cable, 3 unilateral groin, 1 deep supraclavicular); in 23/80 lymphoscintigraphy we

indicated 2 different sites of SL (16 bilateral axillary cable, 1 bilateral groin, 3 unilateral axillary cable and simultaneous unilateral groin; 3 unilateral axillary cable and periscapular or back-nape side). In 21/23 cases the surgeon has removed all the lymph-nodes marked. Pathological analysis demonstrated: in 11/21 patients all lymph-nodes were reactive, 10/21 had at least one metastatic lymph-node (in 3/10 all lymph-nodes removed were metastatic). In case of the pathological analysis demonstrated micro or macro-metastasis, we have seen in 60% of cases (6/10) that the closest site to the injection one was only interested by reactive lymph-nodes, instead of the more unusual and farthest site of drainage was site of metastatic lymph-nodes. **Conclusion:** As previously described, lymphoscintigraphy of SL is an important diagnostic tool for the surgeons to identify and remove all lymph-nodes with micro or macro-metastasis, especially in case of different uptake in multiple sites indicating unusual and distance site of drainage. The possible detection of metastatic MLS in unusual sites of drainage could guide the surgeons to modify the surgery approach from a localized to an extended surgical exeresis. **References:** None

Application Of The Sentinel Lymph Node Biopsy In Patients With Axillary Lymph Node Metastasis (cN1) Of Breast Carcinoma After Neoadjuvant Chemotherapy. Triple Marking Protocol

C. Sampol^{1,2}, P. Camarasa³, O. Cordoba⁴, L. Carrillo⁴, A. Lopez⁵, G. Matheu⁶, A. Pozo³, A. Perello⁷, A. Repetto¹, C. Peña^{1,8};

¹Nuclear Medicine. Hospital universitario Son Espases, Palma De Mallorca, SPAIN, ²IDISBA, Palma de Mallorca, SPAIN, ³Radiology. Hospital universitario Son Espases, Palma De Mallorca, SPAIN, ⁴Gynecology department. Hospital universitario Son Espases, Palma De Mallorca, SPAIN, ⁵Plastic Surgery. Hospital universitario Son Espases, Palma De Mallorca, SPAIN, ⁶Anamopathology department. Hospital universitario Son Espases, Palma De Mallorca, SPAIN, ⁷Oncology. Hospital universitario Son Espases, Palma De Mallorca, SPAIN, ⁸IDISBA, Palma De Mallorca, SPAIN.

Aim/Introduction: Application of a triple axillary marking protocol in cN1 patients with a complete axillary pathological response after NAQT and analysis the coincidence of the clipped positive lymph node with the SLNB obtained from the combination technique of ^{99m}Tc-Albumin nanocolloid and Blue-dye. **Materials and Methods:** After confirming cN1 previously to NACT, the positive node was marked. After completing therapy, the axillary response is assessed by ultrasound. If response, triple axillary marking protocol is applied. In contrary, lymphadenectomy is performed. Planar lymphoscintigraphy and SPECT/CT were performed after the injection of ^{99m}Tc-Albumin nanocolloid for SLNB and methylene blue dye was injected in the surgery room. During surgery, by ultrasound-guide the clipped node is removed

and sentinel lymph node by gammaprobe scanning. The technique is considered optimal if the clipped node and at least one other SLN (radioactive and/or blue) are removed. If the clipped node is not located, will be optimal if at least 3 SLNs are identified. We avoided lymphadenectomy when technique is optimal and the anatomopathological result is negative. **Results:** Included 35p (mean age 56 years [40–78]), with a diagnosis of locally advanced Breast Cancer (cN1, 2 with intramammary nodes). Axillary marker placed in 33p before treatment. In re-staging ultrasound: 9p no/partial response (positive lymphadenectomy only in 5) and 26p complete response whose underwent triple axillary marking protocol, with a mean SLN/p: 3.19 (marker and/or radioactive and/or blue); of which 3p was not possible to identify the marker on the ultrasound, but we could identify a minimum of 3 SLNs in all cases. Of the remaining 23p where the marker is identified, 19 were detected intraoperatively (82.6%), in 100% we detected radioactive nodes and in 78% we found at least one blue node. Of the 19p with marker is located in the surgical piece, 13 are concordant with Technetium. Blue and technetium do coincide in all, excepting 1 which coincide marker and blue dye. Discordance between clipped node and Technetium is 31.5% and 53.8% with blue. From this group, 3 lymphadenectomies were performed and just in 1p more affected nodes apart from the SLNs were found. The marker itself detected 11 positive, technetium 12 and blue dye 7. A total of 22/35 lymphadenectomies were performed (10 after non-response and 12 for positive SLN after triple tagging). Finally we could avoid 13 lymphadenectomies (37.1%). **Conclusion:** In our sample the triple tagging protocol has allowed us to avoid 37% of lymphadenectomies in cN1 patients after NACT with complete pathological response. Despite of 31% of disagreement between the marked positive node and the SLN, the triple marking protocol was optimal in 95% of patients thanks of the detection of a minimum of 3 SLNs in most cases. **References:** None

EP-218

Relevance of Lymphoscintigraphy for Detection of the Sentinel Lymph Node in Males with Breast Cancer

N. Álvarez Mena, F. Sebastián Palacid, P. Turbay Eljach, B. Pérez López, M. Alonso Rodríguez, C. Gamazo Laherrán, A. Sainz Esteban, M. Ruiz Gómez, M. González Soto, R. Ruano Pérez; Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: To assess the usefulness of lymphoscintigraphy for detecting the sentinel lymph node (SLN) in men with breast cancer. **Materials and Methods:** Retrospective series of 14 male patients with breast cancer who underwent lymphoscintigraphy for the detection of the sentinel lymph node (SLN), between October 2010 and December 2019. 111 MBq of ^{99m}Tc-albumin nanocolloid were injected the day before surgery, into the affected

breast and a lymphoscintigraphy was subsequently performed until the SLN was visualized. Variables such as age, carcinoma histology, size and location of the lesion, the expression of hormonal receptors and HER2, lymphoscintigraphy result, intraoperative SLN biopsy result and the existence of recurrence until April 2020 were analyzed. **Results:** Average age of our patients was 67 years. The main histological type was infiltrating ductal carcinoma (13 patients) followed by 1 intracystic papillary (1 patient). Regarding tumor characteristics we found that: the mean size of the lesions was 17 mm (range 10-26 mm), being retroareolar the most frequent location (58% of cases). All of them showed positive hormonal receptors and 2 expressed the HER2/neu proto-oncogene. Lymphoscintigraphy detected the SLN after the first injection in 12 patients (86%). 2 patients needed reinjection, being unable to detect SLN in 1 of them so lymphadenectomy was performed directly (2/9 nodes with macrometastases). Intraoperatively, the SLN removed from the 13 patients with sentinel node visualization on the lymphoscintigraphy were analyzed by using OSNA method (One Step Nucleic Acid Amplification): - 8 patients showed positive SNL biopsy (including 1 with intramammary sentinel lymph node and drainage in the internal mammary chain) so axillary lymph node dissection (ALND) was performed. - 5 patients showed negative SNL biopsy so axillary lymph node preservation was decided. Until April 2020, no tumor recurrence was observed in any of the patients studied, with special attention in the 5 patients in whose ALND was not performed. **Conclusion:** Lymphoscintigraphy for the detection of sentinel lymph node is an acceptable and feasible technique in men with breast cancer, avoiding unnecessary lymphadenectomies without increasing the incidence of tumor recurrence.

Re-staging post therapy with radioactive iodine and follow-up in pediatric patients with thyroid cancer

T. Tairo-Cerron^{1,2}, R. Morales-Guzman-Barron¹, R. Ledesma-Vasquez¹, P. Saavedra-Sobrados¹, L. Araujo-Cachay¹, D. Valdivia-Alvarado¹;

¹Department of Nuclear Medicine, National Institute of Neoplastic Diseases, Lima, PERU, ²Universidad Peruana Cayetano Heredia, Lima, PERU.

Aim/Introduction: To provide an overview of the management with I-131 in our institution, to evaluate pre

and post radioactive iodine (RAI) staging, follow-up one year and long term after the first therapy./The evaluation of the response to treatment with images (cervical ultrasound and/or thyroid tissue scan) and biochemical markers (TSH, Tg, AbTg) have been described. Differentiated thyroid cancer (DTC) in patients under 18 years old is relatively rare, accounting for 1.4% of pediatric malignancies, with a standardized incidence rate in Peru of 0.4 per 100,000, predominantly female (GLOBOCAN 2018). They usually debut with and distant metastases (25% to the lungs). Fortunately, papillary thyroid cancer (PTC) shows an avid absorption of RAI. An excellent prognosis is achieved when proper treatment is administered. To date there are no clear prospective studies on the management of this disease. The American Thyroid Association (ATA) addresses a series of guidelines; however, many open questions remain. **Materials and Methods:** A retrospective observational study was performed, twelve patients under the age of 18 years old submitted to total thyroidectomy with diagnosis of DTC were identified from 2012 to 2018. **Results:** This study included 10 women and 2 men (5:1), with a mean age of 10.25 years old (range between 4-17 years old). All the patients were diagnosis with papillary cancer. A median dose of 30-100 mCi (1110-3700 MBq) was administered in the first session. The examination was performed between the 5th and 7th day after the RAI, where 5 patients were re-staged as EC-II for lung metastases. During the one-year follow-up, 5 patients (41.7%) had an excellent response with Thyroglobulin (Tg) <1ng/ml and remained free of recurrence after 3 years of follow up, 5 patients (41.7%) remained with lung metastases (micronodular pattern) with decreased Tg in a follow-up of 3 to 7 years (with a cumulative dose of 130 to 370 mCi), and 2 (16.7%) presented lymphatic disease progression with stationary pulmonary metastasis **Conclusion:** This study shows the value of post-therapy scan, not only as a diagnostic tool, but also as re-staging. Furthermore, the Tg measured at one year of follow-up is the most reliable for evaluating the response to RAI. These results cannot be extrapolated to the pediatric population, but show the importance of the appropriate use of dynamic stratification of recurrence risk and individualized monitoring of patients with DTC, since approximately 30% have recurrence in the first 5 years of follow-up **References:** None

EP-220

The effect of manual and automatic motion correction on the result of radiorenography in infants

T. Czékus¹, S. Urbán¹, D. Hirling², J. Csirik², L. Pávics¹;

¹Department of Nuclear Medicine, University of Szeged, Szeged, HUNGARY, ²Department of Computer Algorithms and Artificial Intelligence, Szeged, HUNGARY.

Aim/Introduction:

Technetium-99m

diethylenetriaminepentaacetic acid ($^{99m}\text{TcDTPA}$) renography is widely available diagnostic method, for the evaluation of separate renal function and urodynamic. The selection of appropriate background and kidney ROI-s (region of interest) are essential for the correct interpretation of the investigations. Patient movement effect significantly the results. The aim of our study was to investigate the efficacy of manual and automatic motion correction algorithms on the radiography parameters. **Materials and Methods:** From 360 dynamic renography we re-evaluated the studies of 14 infants (age: 5 months -7 years; male: 8, female: 6). In all these cases with conventional technique it was impossible to get appropriate time activity curves because of the restlessness of the children. We used an in-house developed method for motion corrections and to generate renogram curves, which based on pairwise registration of the image frames. During the course of manual correction the frames were moved only horizontally and vertically to get the kidneys on the series of images in the same position. The automatic correction beside horizontal and vertical movements rotated the frames as required. The differences of the renography curve parameters were compared and significance were calculated by Wilcoxon-test. **Results:** The manual movement correction took 15 minutes time while the automatic version less than a minute. With both correction methods we received appropriate time activity curves ready for evaluation. The T-max (mean \pm SD) were 8.48 ± 6.65 min, the T1/2: 9.75 ± 6.72 min with manual correction, vs. 8.6 ± 6.87 min. and 10.02 ± 6.94 min by the automatic correction. The differences were insignificant ($p=0.90$ and 0.82). The counted left and right kidneys' relative functions were $50.1 \pm 5.01\%$; $49.9 \pm 5.01\%$ with manual correction and $50.46 \pm 4.55\%$; $49.54 \pm 4.55\%$ with automatic method. The differences were insignificant ($p=0.71$ and 1.0). Both method helped the visual interpretations of the images as well. **Conclusion:** Both manual and automatic correction method used by us is helpful in the evaluation of radiorenography of restless infants, but the automatic program is more faster, than the manual one. **References:** None

EP-221

Added value of SPECT/CT for diagnosing biliary atresia

T. Andersen, R. Aleksyniene, L. J. Pedersen;

Department of Nuclear Medicine, Aalborg, DENMARK.

Aim/Introduction: Hepatobiliary scintigraphy (HBS) is an important tool in diagnosing biliary atresia in infants. There is limited evidence on the use of SPECT/CT as additional imaging method to the dynamic and static images. We evaluated the value of SPECT/CT in unclear cases of planar HBS. **Materials and Methods:** Consecutive patients with suspected biliary atresia who underwent guideline-compliant HBS from January 2010 until March 2020 were

reviewed, and cases with SPECT/CT were identified. Each step within the imaging procedure (dynamic, static [early and late], and SPECT/CT) were blindly re-read in consensus by two observers and categorized on a 5-point scale; 0, definitely no bowel excretion (i.e., atresia confirmed); 1, probably positive; 2, equivocal; 3, probably negative, and 4, definite negative (i.e., atresia not confirmed). In this analysis, categories were dichotomized as negative for biliary atresia (score 3-4) or positive (scores 0-2, including equivocal scans). Available follow up information constituted the standard of truth (SoT). **Results:** Twenty-three infants had a HBS among which ten (4 boys and 6 girls; mean age 36 days; range 8-108) had a SPECT/CT. SPECT/CT was performed as early examination (<8 h) in 3 subjects, late (8 to 24 h) in 7 infants. The re-read SPECT/CT was categorized as positive for atresia in three infants, negative in seven. The SoT showed biliary atresia in one of ten patients. SPECT/CT was true positive in one case, false positive in two, true negative in seven; there was no false negative cases. The diagnostic performance of SPECT/CT showed sensitivity 100%, specificity 78%, positive predictive value (PPV) 33%, negative predictive value (NPV) 100%, and accuracy 90%. For comparison, the diagnostic performance of planar HBS showed sensitivity 100%, specificity 67%, PPV 25%, NPV 100%, and accuracy 70%. In summary, the addition of SPECT/CT to planar HBS improved specificity and PPV, and marginally improved PPV. SPECT/CT provided more confidence in the final conclusion; the category score changed in 8/10 patients; seven changed one category (e.g., 3 to 4), and one showed a 3-point change (1 to 4, a true negative case). In 7 of 8 patients, the SPECT/CT improved confidence by changing categories in the middle to the more confident categories, e.g. 1 to 0 or 3 to 4. **Conclusion:** The diagnostic performance without SPECT/CT was very good. SPECT/CT improved reader confidence. These preliminary data indicated predominantly improved specificity of add-on SPECT to planar HBS. **References:** None

EP-222

Early Diagnosis of Focal Congenital Hyperinsulinism: a Fluorine-18-labeled L-dihydroxyphenylalanine (^{18}F -DOPA) PET/CT study

L. Burroni¹, F. Fringuelli¹, G. Biscontin¹, A. Palucci¹, C. Romagnolo¹, C. Cottignoli¹, A. Iannilli², M. Marino², V. Cherubini²;

¹Nuclear Medicine, Ancona, ITALY, ²Pediatric

Endocrinology and Diabetology, Ancona, ITALY.

Aim/Introduction: Congenital hyperinsulinism (CHI) is a rare but complex disorder caused by unregulated secretion from the beta-cells of the pancreas. Maintenance of euglycemia is necessary to minimize neurologic damages like cerebral palsy, epilepsy, neurodevelopmental deficits and even death. CHI occurs due to mutations in key genes and now is classified into three groups: diffuse, focal and atypical forms. The diffuse form is medically unresponsive and will

require a near total (>95%) pancreatectomy; the focal form, requires a limited pancreatectomy. Thus, the pre-operative differentiation of these two subgroups is necessary. Because US, CT and/or MRI are unable in distinguishing the diffuse and focal forms of CHI, the imaging modality of choice to diagnose CHI is ^{18}F DOPA PET/CT scan. **Materials and Methods:** An infant boy, body weight 4,446 g, length 52 cm, head circumference 35 cm, showed normal APGAR scores. Due to the early detection of hypoglycemia the infant was transferred to the neonatal intensive care unit, was on full enteral feeding, and received intravenous glucose treatment at 1.2 gr/kg/day dose to maintain normal blood glucose values. Therefore, genetic analysis and ^{18}F -DOPA PET/CT scan were organized. The patient received 4 MBq/kg of ^{18}F -DOPA intravenously. After 60 min, a whole-body scan was obtained in 3 bed positions. Iterative reconstruction was performed and the images were evaluated in a 3D display using axial, coronal, and sagittal views to define pancreas. **Results:** Laboratory tests showed persistent high insulin levels (over 30 mcg/ml), negative ketonemia, low free fatty acid (213 mcml/l), normal IGF-1, cortisol, and ammonia levels in the setting of hypoglycemia, suggesting diagnosis of CHI. Diazoxide treatment produced limited response while subcutaneous octreotide allowed a significant decrease of intravenous glucose infusion. The diazoxide unresponsiveness suggested a potassium channel gene mutation. Next generation sequencing method allowed the identification of a mutation variant in ABCC (p.Leu 40 Arg). ^{18}F -DOPA PET/CT images showed intense ^{18}F -FDOPA uptake in the head of the pancreas, confirmed by a semi-quantitative evaluation (SUVmax = 6.67). **Conclusion:** We confirm that ^{18}F -DOPA-PET/CT is a safe, non-invasive and the investigation of choice in distinguishing between the focal and diffuse forms of CHI; the prompt and accurate localization permits the correct enucleation of the focal lesion preventing the risk of developing iatrogenic diabetes mellitus and pancreatic insufficiency. We confirm that advances in molecular genetics, imaging methods (^{18}F -DOPA PET-CT), medical therapy and surgical approach have completely changed the management and improved the outcome of these children. **References:** None

EP-223

The role of split function quantification of kidney segments using DMSA scan in the choice of appropriate treatment in children with ren duplex or duplicated collecting system - a retrospective study

D. Chroustova¹, L. Cerna¹, J. Trnka², J. Langer³, R. Kocvara⁴, D. Zogala¹, L. Lambert⁵;

¹Institute of Nuclear Medicine, Charles University - 1st Faculty of Medicine and General University Hospital, Prague, CZECH REPUBLIC, ²Department of Medical Physics, General University Hospital, Prague, CZECH REPUBLIC, ³Clinic of Paediatrics and Adolescent Medicine, Charles University

- 1st Faculty of Medicine and General University Hospital, Prague, CZECH REPUBLIC, ⁴Clinic of Urology, Charles University - 1st Faculty of Medicine and General University Hospital, Prague, CZECH REPUBLIC, ⁵Radiodiagnostic clinic, Charles University - 1st Faculty of Medicine and General University Hospital, Prague, CZECH REPUBLIC.

Aim/Introduction: Ren duplex or renal duplicated collecting system (DCS) is one of the most common congenital renal tract abnormalities. They can be associated with a variety of other abnormalities such as obstruction, ureterocele or vesicoureteral reflux (VUR). Early diagnosis followed by an appropriate therapeutic procedure in children at an early age is essential for the prevention of persistent renal impairment. In our retrospective study, we focused on the functional assessment of renal segments using $^{99\text{m}}\text{Tc}$ -DMSA scintigraphy and its influence on the choice of therapy including surgical solution. **Materials and Methods:** A total of 138 patients (48 boys and 90 girls aged from 3 months to 10 years) with ren duplex or DCS were retrospectively evaluated. Static renal scintigraphy was performed 2 hours after i.v. administration of the $^{99\text{m}}\text{Tc}$ -DMSA (18-70 MBq) on gamma camera MB 9200 (Mediso) or a dual-head gamma camera Infinia (GE). The total kidney counts and total counts per renal segment were determined using the geometric mean of anterior and posterior projections to compensate for kidney depth. The split total renal and segmental functions were calculated according to the established formulas. **Results:** The method detected DCS on left (51), right (60), and bilateral (27) sides. Most patients (118) had asymmetrical distribution of renal function, from whom 36 had decreased function in right upper segment (US), 23 in left US, 11 in right lower segment (LS), and 21 in left LS. Bilateral DCS was detected in 27 children. Based on scintigraphy combined with ultrasonography and micturating cystourethrogram, 34 of 118 children with asymmetrical segmental results required no intervention, the rest underwent surgery: heminephrectomy with or without ureteropyeloanastomosis was performed in patients with ureterocele or obstructive megaureter of the US; surgical solution of VUR in patients with VUR into LS. **Conclusion:** The assessment of the parenchymal function of the separate parts of the kidney with a duplex system by $^{99\text{m}}\text{Tc}$ -DMSA scintigraphy has value for subsequent management of the patients. **References:** None

EP-224

Simplify scoring System vs SIOPEN in prognosis risk assessment in Neuroblastoma

C. Olianti¹, M. Allocca², A. Martini², A. Tondo³, H. Gauthier⁴;

¹University Hospital of Florence, Florence, ITALY, ²University of Florence, Florence, ITALY, ³University Hospital Meyer, Florence, ITALY, ⁴Oscar Lamberet Center, Lille, FRANCE.

Aim/Introduction: SIOOPEN scoring is commonly used to semi-quantify metastatic tumor load in HR-NB to stratify patients with good/poor response to therapy (1). A cut-off score of ≤ 3 is the most useful predictor to define good responders after induction-chemotherapy (I-CH). Perhaps a simplified method is likely able to stratify risk. The study compares the SIOOPEN scoring and three proposed Simplified Scoring System (SSS) and assess the prognostic value of scoring in terms of progression free survivor (PFS) and relapse. **Materials and Methods:** The study included 16F and 27M, mean age 3.5 ± 3.2 years at the first scintigraphy, 18HR-NB-1 (VI stage) and 25 intermediate (III stage) or low risk (II stage)—NB referred for I-123 MIBG scintigraphy (January 2009–December 2019) were investigated by 123I-MIBG scans for staging (ST) and I-CH for a total of 86 whole-body+SPECT scans. SIOOPEN scoring (for 12 anatomical body segments with a 0–6 scale and 72 as maximal score) was compared with three proposed Simplified Scoring System (SSS), and the cut-off SCORE-value at ST and I-CH was evaluated respect PFS and relapse in whole cohort. Log-rank Cox analysis was used for cut-off assessment and Kaplan-Maier Curves were build for each cut-off at ST and I-CH, for each simplified method. SSS1 analyzes three great sector: neural, body and arms, with the same SIOOPEN 0–6 scale, SSS2 analyzes the same sectors with a simplified 0–4 scale, SSS3 analysis 12 body segments as SIOOPEN scoring, with a simplified 0–2 scale. **Results:** At staging no significant predictive SCORE value was found for PFR and Relapse. After-I-CH log-rank Mantel-COK showed a cut-off value >3 as expected (*1) able to divide the population into a group with a of 6Y PFS versus a group with 3Y PFS. The mean Score into 3 sectors were significant different for neural and body sectors mean 0.88 ± 2.5 and 0.75 ± 2.2 respectively vs 3.07 ± 7.3 of arms sector ($p < 0.001$ HSD Turkey ANOVA). **Conclusion:** SSS1 and SSS3 don't bring a real advantage respect SIOOPEN scoring cause the first has the same grading in lesions-extension characterization, and the second has the same numbers of segments : they result superimposable. All 3 methods seems to gain the same prognostic value with a cut-off Score >3 at post-induction chemotherapy scan in stratify PFS. This prognostic value should be tested on larger population of HR-NB. **References:** Eur J Nucl Med Mol Imaging. 2018 February; 45: 292-305, Eur J Nucl Med Mol Imaging DOI 10.1007/s00259-017-3829-7)

EP-225

Experience in our center of pediatric thyroid scintigraphy: a useful tool for the etiologic diagnosis of congenital hypothyroidism

G. Castillo Simón, V. Rodríguez Morales, C. Martínez Ramos, B. Núñez Arana, I. Domínguez-Prado, J. Muñoz Iglesias, F. Loira Bamio; Hospital Meixoeiro, Vigo, SPAIN.

Aim/Introduction: Demonstrate the efficacy of thyroid scintigraphy as a non-invasive method with a great sensitivity for the etiologic diagnosis of congenital hypothyroidism. **Materials and Methods:** Retrospective study from 2010 to 2019 of 41 pediatric patients (7 days to 8 years old) who underwent thyroid scintigraphy after suspected congenital hypothyroidism. Review of the newborn blood spot screening, thyroid function at diagnosis, treatment and its duration, ultrasound and X-ray, genetic test, concomitant pathologies and scintigraphy findings. Thyroid scintigraphies were performed following regular protocol: static image acquisition of the anterior cervical region, with Pin-hole and/or planar collimator, in different projections, 20 minutes after the intravenous administration of [^{99m}Tc] NaTcO₄ (activity calculated according to weigh: 11,1–199,8 MBq, average: 72,52 MBq). Our studies were performed after 3-weeks hormonal-treatment suppression, excluding neonates. **Results:** Among the 41 patients, 27 (65,85%) were female. 14 had a scintigraphy performed during the first month of life, 22 between 2 and 4 years old and 5 patients were older than 5 years old. The scintigraphic findings showed 22 (53,65%) thyroid dysgenesis (15 ectopic glands, 4 hypoplastic glands, 2 agenesis and 1 hemiagenesis) and 19 (46,34%) eutopic glands (6 of those patients had a positive genetic test for mutations related with dysmorphogenesis and 5 patients were eventually diagnosed with a transient hypothyroidism). 7 patients showed a discrepancy between the ultrasound and scintigraphy results, being the scintigraphy more accurate regarding the final clinical diagnosis, particularly among those patients with a diagnosis of ectopic gland (5 of the 7 patients showing this discrepancy). Continuation of the levothyroxine treatment in neonates did not interfere in the scintigraphy results. **Conclusion:** Thyroid scintigraphy is a non-invasive test with great sensitivity for the etiologic diagnosis of congenital hypothyroidism, even during the neonatal period, showing superior performance than ultrasound, with no need of levothyroxine treatment delay. **References:** None

The role of three-phase bone scintigraphy in identifying complications after hip replacement in liquidators of accident at the Chernobyl Nuclear Power Plant with septic and aseptic osteoarthritis

P. Korol¹, M. Tkachenko², N. Ponomarenko¹; ¹Kiev Clinic City Hospital # 12, Kiev, UKRAINE, ²A.A. Bohomolets National Medical University, Kiev, UKRAINE.

Aim/Introduction: To evaluate the prognostic role of kinetic parameters of three-phase bone scintigraphy in identifying complications after hip replacement of liquidators of accident at the Chernobyl Nuclear Power Plant (ChNPP) with septic and aseptic osteoarthritis (OA). **Materials and Methods:** 241 patients (185 men and 56 women) aged 31 to 85 years were imaged by three-phase bone scintigraphy: I stage - angiographic phase, II stage - early static phase, III stage - delayed static phase. Intestinal uptake was observed visually 3 hours after the intravenous administration of 740 MBq ^{99m}Tc MDP. **Results:** According to the results of microbiological analysis of diagnostic puncture of the hip joints, the patients were divided into two cohorts. The first cohort included 152 patients with aseptic OA of the hip joint, the second - 89 patients with septic OA. Significant increase of the parameters of arterial inflow ($t = 2.27$; $p < 0.05$) and integral perfusion ($t = 2.52$; $p < 0.05$) in the angiographic phase of patients with septic OA, due to the intensification of osteoblastic activity and angiogenesis, in comparison with indicators of aseptic OA. The kinetic of ^{99m}Tc MDP in lesions of septic OA is characterized by significant predominance of retention ($t = 3.04$; $p < 0.05$) and specific accumulation of the drug in the early static phase ($t = 2.17$; $p < 0.05$) and delayed static phase of scintigraphy ($t = 2.11$; $p < 0.05$), compared with indicators for aseptic OA. According to the results of kinetic analysis, aseptic OA results in rapid elimination of ^{99m}Tc MDP from the lesion, due to the active leaching of the radiopharmaceutical, due to the decrease in blood supply to the tissues of the area - a retentive "failure". In septic OA there was a gradual increase in the percentage of accumulation of the radiological indicator in the lesion, which is due to the intensification of integral perfusion, increased permeability of blood vessels due to the action of infectious agents, activation of resorption factors and synthesis of mineral components. **Conclusion:** The use of three-phase bone scintigraphy contributes to the early detection of paraendoprosthetic complications in the postoperative period, the reduction of the number of revision endoprosthetics and the shortening of the rehabilitation measures after the hip replacement in the liquidators of accident ChNPP. **References:** None

EP-227

Usefulness of ^{99m}Tc -Besilesomab in infection after fracture osteosynthesis: our experience

P. Guardia Jimena, M. Martínez del Valle Torres, M. Bermúdez Morales, R. Arenas Aguaza, M. Sánchez Torrente, A. Castro López, E. Moratalla Aranda, A. Villena García, R. Nieto Serrano, D. Becerra García;
Hospital Universitario Clínico San Cecilio, Granada, SPAIN.

Aim/Introduction: To contribute our experience in the diagnosis of post-fracture osteosynthesis material infections in the peripheral skeleton with ^{99m}Tc -Besilesomab. **Materials**

and Methods: We included 31 patients with age ranges from 26 to 75 years with suspicion of osteomyelitis due to the presence of osteosynthesis material after fracture in the lower extremities (femur, tibia, fibula and tarsus). Three phase bone scan (^{99m}Tc -oxidronate) was previously performed on all patients with positive result in all cases. The infection study was performed after injection of 555 MBq ^{99m}Tc -Besilesomab with static imaging 4 and 24 hours post injection, once the absence of human anti-murine antibodies (HAMA) was confirmed. The evaluation of the study was made qualitatively and after semiquantitative analysis, making regions of interest (ROIs) on the suspicious areas of infection both in early and late images, using a total counts intensity scale with the same intensity threshold. The studies whose quantification was superior in the 24 hour images in comparison with 4 hour images were considered as positive, considering the decay of the radiopharmaceutical. SPECT-CT studies were performed to locate the anatomical areas of infection in the bone or outside the bone (soft-tissue infection). The definitive diagnosis was established after the clinical monitoring of all patients, either following the result of the microbiological culture, after response to the medical and/or surgical treatment, as well as the result of other imaging studies. **Results:** 18 negative results (18 TN and 0 FN) and 13 positive results (12 TP y 1 FP) were obtained. According to these results, 100 % sensitivity and 94 % specificity were obtained. A positive predictive value of 92 % and a negative predictive value of 100 %. The FP result corresponded to a patient with a large inflammatory component in tarsus. **Conclusion:** The scintigraphy with ^{99m}Tc -Besilesomab shows a high diagnostic precision for infections due to post-fracture osteosynthesis material in the peripheral skeleton in our patient sample. **References:** None

EP-228

Hybrid imaging in muscular sarcoidosis

I. Grozdic Milojevic¹, D. Sobic-Saranovic², V. Artiko²;

¹Clinical Center of Serbia, Belgrade, SERBIA,

²Clinical center of Serbia, Belgrade, SERBIA.

Aim/Introduction: To determine the prevalence of muscle sarcoidosis (MUS) and evaluate the role of hybrid molecular imaging in MUS. **Materials and Methods:** Between 2010 and 2011, 90 patients with chronic sarcoidosis and presence of prolonged symptoms of active disease were referred to FDG PET/CT. Active disease was found in 74 patients, and they were all screened for the presence of MUS. All the patients underwent MDCT and the assessment of the serum ACE level. Follow-up FDG PET/CT examination was done 12.0±5.2 months after the baseline. **Results:** MUS was present in 7.6%. Patients usually had thoracic disease (57%), nonspecific symptoms and high ACE levels. Most of the patients had more than one symptom of the disease and

muscle pain was present in 29%. The disease was usually present in lower limbs (4/7 patients), with nodular FDG avid lesion. Less frequent localisation were: skeletal striated muscles and heart muscle. ACE levels were not in correlation with the SUVmax level ($p > 0.05$). Follow-up PET/CT revealed complete remission in one patient and partial remission in two. **Conclusion:** FDG PET/CT can be useful in the detection of MUS and in the evaluation of the therapy response. It can resolve which muscular pattern of the disease is present in patient, which can affect the therapy and prognosis of the disease. **References:** None

EP-229

The diabetes impact on the course of community-acquired pneumonia according to ventilation scintigraphy

V. Udodov, A. Zaitseva, V. Zavadovskaia, E. Bukreeva, I. Degtyarev, M. Zamyshevskaya, M. Zorkaltsev, T. Saprina;
SSMU, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: To evaluate ventilation scintigraphy results of diabetic patients with community-acquired pneumonia as more severe disease with frequent complications and high mortality rates in this category of patients. **Materials and Methods:** 10 patients (6 males and 4 females) with diabetes mellitus and community-acquired pneumonia both and 13 patients with community-acquired pneumonia without diabetes (8 males and 5 females) were studied. Mean age of patients was 55.8 ± 5.4 years. All patients underwent ventilation scintigraphy with ^{99m}Tc MAA (370 Mbq in aerosol, SPECT Philips Brightview). **Results:** By using ventilation scintigraphy the measurement of radioactive impulses number was calculated in the area of pneumonia in comparison with the symmetric intact region (count difference) in two groups of patients. At the first group consisted of diabetic patients with community-acquired pneumonia count difference was 2.99 [1.54–5.41]. Patients with community-acquired pneumonia without diabetes were in the second group which was characterized count difference 1.47 [1.13–2.05]. It was shown a statistically significant ($p < 0.05$) count difference increase in patients with diabetes mellitus and community-acquired pneumonia. The value of the count difference reflects in this situation the degree of bronchial patency, the higher the score difference, the lower the bronchial patency, therefore, the more severe the course of community-acquired pneumonia. When assessing $T_{1/2}$ in both groups, this indicator was reduced: in the first group 45.5 min [31.0–60.3] and in the second group 47.0 min [38.0–53.5], with no statistically significant differences. **Conclusion:** The count difference as result of ventilation scintigraphy confirm a more pronounced abnormality of bronchial patency in patients with diabetes mellitus, which may indicate a more severe course of community-acquired pneumonia in

these patients. **References:** None

EP-230

Metabolic Features of Patients with COVID-19 Lung Infection: Contribution of ^{18}F FDG-PET / CT

J. Ardila Mantilla, A. Rotger Regí, M. Baquero Oliveros, A. Marí Hualde, J. Orcajo Rincón, I. Gómez Fernández, C. Durán Barquero, D. Zamudio Rodríguez, Y. Henao Celada, J. Atance García de la Santa, J. C. Alonso Farto;
Hospital General Universitario Gregorio Marañón, Madrid, SPAIN.

Aim/Introduction: One of the most frequent complications that increases the morbidity of patients infected with COVID-19 is lung infection. The radiological patterns and their evolution are already being studied and described. However ^{18}F FDG-PET / CT metabolic image may also offer valuable information about the inflammatory / infectious process. Since the declaration of the state of alarm in Spain, our service has only performed urgent PET / CT scans. Our aim is to study the metabolic characteristics of lung disease in patients with COVID-19. **Materials and Methods:** From March 14 to April 24, 2020, we performed 240 urgent ^{18}F FDG-PET / CT most of them with an oncological indication. All of them underwent PET / CT using the usual protocol, performing a questionnaire for screening for covid-19 infection before the examination. They were considered asymptomatic when they did not present any of the following clinical manifestations: myalgia, cough, headache, fever, dyspnea or others, and oligosymptomatic those presenting with only one of them. Imaging was considered positive for infection in the presence of hypermetabolic lung infiltrates unjustified by other causes. **Results:** 19 patients were diagnosed with COVID-19 infection. 6 of the patients were clinically diagnosed and the other 13 with a positive result of reverse transcriptase polymerase chain reaction (PCR) for covid-19. Image characteristics were as follows: unilateral pneumonia 2/19 (1 right, with pleural and hiliomedastinal involvement resulting in exitus, and 1 left); bilateral 2/19; multifocal 12/19 one of them with pleural involvement (63.2%); without pulmonary alterations 3/19. The predominant location was in the lower lobes 10/16 (62.5%); 5/16 in the upper lobes and 1/16 in the middle lobe. There was agreement between PET and CT findings in lung parenchyma in all patients except one that showed abnormalities in CT without increased uptake in PET, this patient was oligosymptomatic with negative PCR. There was more discordance in hilio-mediastinal lymph node involvement; 12 had pathologic FDG uptake compared to 4 who had increased lymph node size on CT (all positive in PET). The median SUVmax of lung lesions was 4.05. **Conclusion:** The typical pattern of presentation of Covid-19 lung disease is multifocal involvement, predominantly in the lower lobes. Lung lesion detection is highly concordant in PET and CT, however lymph node detection seems to be

higher in PET imaging. **References:** None

EP-231

Clinical Manifestations of Patients with Pulmonary Abnormalities in ¹⁸F-DG-PET with COVID-19 Infection

J. Ardila Mantilla, A. Rotger Regí, M. Baquero Oliveros, A. Mari Hualde, J. Orcajo Rincón, I. Gómez Fernández, C. Durán Barquero, D. Zamudio Rodríguez, Y. Henao Celada, J. Atance García de la Santa, J. C. Alonso Farto;
Hospital General Universitario Gregorio Marañón, Madrid, SPAIN.

Aim/Introduction: With more than 200,000 infections and 20,000 deaths from covid-19, Spain is one of the countries most affected by this virus. During the declaration of alarm status, all non-urgent PET / CT scans were suspended. Our aim is to describe the relationship between patients' symptomatology and PET / CT findings. **Materials and Methods:** From March 14th to April 24th, 2020, we performed 240 urgent ¹⁸F-DG-PET / CT scans. All of them underwent PET / CT using the usual protocol, performing a questionnaire for screening for covid-19 infection before the examination. They were considered asymptomatic when they did not present any of the following clinical manifestations: myalgia, cough, headache, fever, dyspnea or others, and oligosymptomatic those presenting with only one of them. Imaging was considered positive for infection in the presence of hypermetabolic lung infiltrates unjustified by other causes. **Results:** 19 patients were diagnosed with Covid-19 infection, 16 with oncological disease and 3 with infectious indication. 6 of the patients were clinically diagnosed and the other 13 with a positive result of reverse transcriptase polymerase chain reaction (PCR) for covid-19. In 9 of the patients Covid-19 diagnosis was suspected on the findings of the PET CT. Regarding clinical manifestations 4 were asymptomatic, 6 oligosymptomatic and 9 symptomatic. 15 patients presented with positive imaging of which 8 were asymptomatic or oligosymptomatic and only 7 were symptomatic. Only in one oligosymptomatic patient with negative PCR, CT abnormalities were found without increased FDG uptake. No statistically significant differences were found between clinical manifestations and the presence of hypermetabolic infiltrates on PET ($p = 0.65$ Yates correction; Fisher 0.66). **Conclusion:** Despite being a small and very defined sample, we found no statistically significant differences between clinical manifestations and the presence of hypermetabolic abnormalities in lungs of patients diagnosed with Covid-19. **References:** None

EP-232

¹⁸F-FDG and ¹⁸F-Fluorocholine PET/CT findings in symptomatic and asymptomatic patients with COVID-19, a French case series

S. Mekhail, J. Chalaye, B. Emsen, L. Lerman, E. Evangelista, M. Abulizi, J. M. Israel, S. Bonnot-Lours, M. Marie, M. Borel, M.

Gueremy, S. Hamel, C. Juin, S. Larrous, N. Latouche, N. Marin, P. Blanc-Durand, E. Itti;
Nuclear Medicine Department, Henri Mondor Hospital APHP, UPEC, Créteil, FRANCE.

Aim/Introduction: With more than 3 millions confirmed cases and more than 200 000 deaths worldwide, the COVID-19 outbreak became quickly a public health emergency of international concern. Diagnosis relies - among others - on RT-PCR and chest CT showing typically multiple and bilateral patchy ground glass opacities and bilateral pulmonary consolidations (1). Some studies (2,3) have reported the glycolytic activity of these pulmonary abnormalities on ¹⁸F-FDG PET/CT in small cases series and, to our knowledge, no case was reported to date with ¹⁸F-Fluorocholine (FCH) PET/CT. The aim of our study was to illustrate FDG and FCH PET/CT findings in patients affected by COVID-19. **Materials and Methods:** We retrospectively reviewed the PET/CT results from 11 consecutive patients diagnosed with COVID-19 on the basis of clinical, radiological and laboratory data, between March 24 and April 30, 2020. Studies were performed for routine oncologic indications ($n=8$) and infectious/inflammatory disease ($n=3$). Symptoms, RT-PCR results and biological data were retrospectively collected if available. **Results:** Ten of the 11 patients had CT imaging features of COVID-19 pneumonia with variable FDG-uptake (SUVmax range, 1.2 to 5.8) and a strong uptake of FCH in one patient (SUVmax = 6,3). The patient without pulmonary abnormalities was on day-13 of the infection when PET/CT was performed. We reported mediastinal lymph node involvement in 8 of the 11 patients with mild to high FDG uptake (SUVmax range, 3.4 to 8.6) and high FCH uptake (SUVmax = 5,5). Two others patients demonstrated FDG uptake in mediastinal lymph nodes that could be reported either to neoplastic involvement or to COVID-19. Four of the 11 patients were asymptomatic. RT-PCR was positive in 4/6 patients. Diagnosis was first suspected based on the PET/CT findings in 5 patients. **Conclusion:** Although PET/CT is not recommended in routine practice to evaluate COVID-19 pneumonia, knowing the pattern of FDG and FCH uptake within the lungs and mediastinal nodes can help to identify infected patients, even when asymptomatic. **References:** 1. EP-233**3D Volume Rendering Model and Pixelated Quantitative CT for Accurate Assessment of the Extent and Severity of Patients with COVID-19**

M. Masoomi, L. Alkhandari, I. Alshammeri, H. Elrahman, H. Ramsy, S. Almutairi;
ADAN Hospital- MOH, Kuwait, KUWAIT.

Aim/Introduction: Coronavirus disease 2019 (COVID-19), caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has become an increasingly prevalent worldwide, declared a pandemic on March 11, 2020 by WHO. Early diagnosis of novel COVID-19 is crucial to detect the disease at the early stage for disease treatment and control which has medical and economic impact regardless of how well you are prepared. In this multi-center study, we are aiming to develop a combination of 3D-360 visual rendering model of lung COVID-19 disease and the quantitative CT data to better categorize the CT findings with regard to the extent and severity of COVID-19 lung and to provide an objective approach to rapidly and accurately identify patients in need of hospital admission.

Materials and Methods: We use a multistep Materialize Mimics Care Suite-3D to produce unrestricted 360 orientations of the patient lung disease, where one can see through the lungs, the pattern of disease distributions in a virtual reality concept. In addition, we use DICOM file and a Matrix Laboratory (MATLAB) to generate a unique colour pixelated visual map and semi quantitative analysis of the CT of disease regions to create a data base for quantitative scoring based on HU value for 50 proved COVID-19 patients initially and therefore to set an optimal threshold value for assessing and categorizing negative, mild, moderate and severe cases. **Results:** We are anticipating that combination of 3D-360 rendering model of lung disease (COVID-19) and the quantitative of the COVID-19 CT data provide a more accurate assessment of extent and severity of COVID lung disease for better categorizing patients as typical appearance, indeterminate appearance, atypical appearance or negative and therefore plan a better program to handle the flux of COVID-19 patients at locality with regard to health/safety and financial burden in mind. The initial results are promising. **Conclusion:** Combining 3D Modelling and quantitative CT of COVID-19 Lung has a potential for significant impact within the Healthcare, with its ability to create personalized healthcare and cost effective solutions.

EP-234**Prevalence of incidental pneumonia consistent with COVID19 infection an 18F-Fcholine (FCH) PET/CT in patients referred for prostate cancer**

L. Turpin¹, Q. Pouliot¹, J. Zhang¹, B. Sgard¹, M. Glikman², F. Denise¹, J. Talbot¹, F. Montravers¹;

¹Hôpital Tenon, Paris, FRANCE, ²Medical office, Pantin, FRANCE.

Aim/Introduction: COVID-19-induced lung lesions are already known to frequently take-up FDG, but such a finding has not yet been described with FCH, first line radiopharmaceutical in France for prostate cancer, that may be taken-up by inflammatory lesions. Our aim was to evaluate the prevalence of incidental interstitial pneumonia consistent with COVID19 infection on CT and the FCH uptake of the lesions in patients referred to FCH PET/CT for prostate cancer. **Materials and Methods:** We retrospectively reviewed all the PET/CTs of patients referred to FCH PET/CT between 22nd February and 30th April 2020 for prostate cancer imaging. They had no respiratory symptoms at the time of PET/CT. We selected the cases showing lung lesions evocative of COVID-19 interstitial pneumonia on CT (ground-glass opacities, multifocal patchy consolidation, and interstitial changes with a peripheral distribution predominating in lower and posterior regions) and we determined the radiotracer uptake by these lesions. **Results:** 96 FCH PET/CT were performed during this period of time. We noticed lung lesions on CT consistent with COVID 19 infection in 4 of the 96 patients. Median age of these patients was 72.5 years (range 68 to 76). All 4 patients were asymptomatic at the time of FCH PET/CT, but 2 of them reported a history of symptomatic pneumopathy compatible with COVID infectious syndrome, 4 weeks and .6.5 weeks before FCH PET/CT, respectively. One of them had been sampled for RT-PCR when he was symptomatic and the diagnosis of Covid-19 infection was settled. The lung lesions took-up FCH in all 4 patients with a mean SUVmax of 4.2 (range: 2.8 to 6.6). Ground-glass opacities were more hypermetabolic (SUVmax 6.6 and 3.9 respectively) and more diffuse (over more than 30% of pulmonary surface) in the 2 patients who had presented with symptomatic pneumonia. **Conclusion:** During the COVID 19 outbreak in France, we incidentally observed hypermetabolic lung lesions consistent with COVID-19 infection in 4.1% of patients referred to FCH PET/CT for prostate cancer. Patients with recurrent prostate cancer belong to a population at high risk of aggressive Covid-19 infection (male patients aged over 60) and the incidental discovery of pneumopathy evocative of COVID-19 on CT could be expected. However, FCH uptake by the lung lesions was not expected in asymptomatic patients several weeks after the contamination. Its prognostic significance (delayed recurrence? parenchymal fibrosis?) needs to be determined by patients' follow-up. **References:** None

EP-235**Deployment of a Dedicated "Covid-19" CT in Nuclear Medicine : Strategic Issues in the Context of an Epidemic Emergency**

E. Itti, T. Pillon, D. Giacometti, E. Brimboeuf, T. Barbosa, N. Ambiehl,

D. Bazas, S. Mekhail, J. Chalaye, M. Milliner, A. Quilichini, C. Lhermite, A. Maraval, H. Kobeiter, A. Luciani, P. Blanc-Durand; CHU Henri Mondor, AP-HP, U-PEC, Creteil, FRANCE.

Aim/Introduction: With rapid spread of the new SARS-CoV-2 Coronavirus (Covid-19) and high prevalence of pulmonary involvements leading to respiratory failure, clinical needs for thorax CTs have dramatically increased in our hospital. The Nuclear Medicine department is equipped with a hybrid SPECT/CT camera ideally located at an extremity of the department, close to the Emergency Room (ER).

Materials and Methods: In this context, and owing to the close collaborations between all imaging departments already set up, we decided to deploy a “Covid-19” CT in Nuclear Medicine, dedicated to ER out-patient workflow, another “Covid-19” CT in the Neuroradiology department being deployed for in-patient workflow, the remaining CTs in the Radiology department being reserved for non-Covid patients. This deployment required to take into account several strategic issues. First, creating 3 distinct pathways would help reducing internal spread of the infection. Regulation of these pathways was ensured by a senior radiologist with a dedicated phone number. Then, we thought preferable for ER patients to be scanned as close as possible from the ER department, without using the elevator to reach the Neuroradiology CT. Nuclear Medicine technologists were rapidly formed to the disinfection procedures and were paired with Radiology technologists. **Results:** This organization was set up in only 24 hours thanks to the collaboration between technologists, physicians, physicist, radiation protection specialist, biomedical engineer and staff: a contrast media injector was connected to the SPECT/CT, all necessary CT protocols were programmed and validated on a phantom to ensure dose level conformity and DACS integration, and written declaration of this activity was performed to the Nuclear Security Agency (ASN) as the CT from the SPECT/CT does not have an authorization for diagnostic examinations, but a temporary derogation could be obtained if technical performances and medical organization were clearly stated. During 10 weekdays (08:00-18:00) of deployment at the pandemic peak, 111 CT scans were performed on the SPECT/CT, including 50% thorax CT angiographies and 50% thorax CT without contrast. A typical Covid-19 lung pattern was found in 63% of patients and pulmonary embolism was diagnosed in 11% of patients who underwent thorax CT angiography. **Conclusion:** In the context of an epidemic emergency, multidisciplinary cooperation between imaging professionals allowed us to arm a dedicated “Covid-19” CT in Nuclear Medicine within 24 hours and to optimize patient pathways. This reactive organization is a pledge for increased collaborations especially when healthcare pathways are essential for population safety. **References:** <https://ebulletin.radiologie.fr/covid19>

The Novel Coronavirus: Our Experience in Facing an Invisible Enemy

L. Cunha¹, P. Ratão^{1,2}, A. Roda^{1,3}, M. Capoulas^{1,4}, F. Ferreira¹, M. Sousa⁵, H. Vasconcelos⁶, A. S. Moreira¹, L. F. Metello^{1,7};

¹IsoPor-Azores, Angra do Heroísmo, PORTUGAL, ²Nuclear Medicine Department, IPOFG, Lisbon, PORTUGAL, ³Medical Physics Department, IPOFG, Coimbra, PORTUGAL, ⁴Pharmacy Department, HBA, Loures, PORTUGAL, ⁵Interdisciplinary Studies Research Center, ISEP/IPP, Porto, PORTUGAL, ⁶Sc. Techn. Fac., Univ. Azores, Ponta Delgada, PORTUGAL, ⁷ESS-IPP, Porto, PORTUGAL.

Aim/Introduction: Early this year, Chinese authorities identified a new type of coronavirus that was causing a disease named COVID-19. It disseminated quickly, and immediate action was needed to control the further spread of the infection. Many Governments imposed severe restrictions on people's and on companies' actions. After almost two months of lockdown, we had to prepare our Nuclear Medicine Department for a new reality. This paper aims to share the implemented measures and policies. **Materials and Methods:** We defined our action in three axes: 1) people; 2) spaces/infrastructures; 3) practices; and three moments: A. before; B. during and C. after the procedure (diagnostic or therapeutic). Each of these axes has branches: 1.1) social distancing; 1.2) epidemiological and health questionnaire; 1.3) communication and welfare; 2.1) definition of entrances and routes; 2.2) signs and posters regarding handwashing, respiratory etiquette and COVID-19 alert symptoms; 3.1) assessment of the procedure urgency level; 3.2) patient appointment order; 3.3) procedures' time slot; 3.4) infection prevention and control; 3.5) remote meetings and reporting. **Results:** Due to the universal application of the three basic rules of radioprotection: time, distance, and shielding, we believe that somehow the adoption of the above-mentioned special measures in Nuclear Medicine Departments might have been easier. Regarding people axis, social distancing among patients and staff was implemented as a rule of thumb, as well as the use of personal protective equipment (for staff: head cap, goggles, and disposable gown, face mask, and gloves, the latter two were indicated for outpatients not tested for COVID-19). Waiting rooms were rearranged to increase distances between people and members of staff avoided having meals together. Patients were contacted by phone before the procedures, to ascertain the presence of any symptoms, and to be informed about dedicated entrances and routes. Confirmed or suspected COVID-19 patients were managed according to institutional and national rules. The urgency level of the procedure was carefully assessed by both the referring physician, the patient himself, and the Nuclear Medicine physician, with non-urgent tests postponed. Inpatients who tested negative for COVID-19 were the first in the daily agenda, followed

by non-suspected outpatients, with positive inpatients for last. Suspected outpatients were advised to seek first for being tested for coronavirus. The time slot per patient was increased to allow cleaning and disinfection procedures after each patient. **Conclusion:** The preparedness for the current coronavirus outbreak required the review of procedures as well as the adoption of special measures to assure health professionals and public safety, to prevent infection transmission and spread. **References:** None

EP-237

The importance of being retrospective”: medical directivities in COVID-19 time

A. Farolfi, R. Bonfiglioli, A. Paccagnella, F. Mattana, S. Fanti; Nuclear Medicine Unit, S. Orsola Hospital, University of Bologna, Bologna, ITALY.

Aim/Introduction: More than 2 million people worldwide had tested positive for COVID-19, and more than 200,000 deaths are attributed to this virus. In order to minimize the diffusion of the infection through hospital operators, that are people with highest risk, we analyzed the efficient impact of medical directivities in our hospital unit. **Materials and Methods:** 66 operators have worked at our high volume PET center located in a red zone from February 2020 until today: 55 in the nuclear medicine unit, 11 in the radiopharmaceutical unit at cyclotron site. In this setting, in order to limit patients and especially operators' exposure, adoption of preventive measures was needed. Our directives were: everyday change of individual protection devices, use of alcohol solution for disinfection (hand and equipment), repeated sanification of ambients during the day, respect of social distancing and limitation of operators contact with patients to the minimum necessary. In addition, we set up a new entrance triage protocol in order to try to reduce the risk of contact with possible infective patients: nurses measured patients' temperature at their arrival, the head chief checked if the exam requests were appropriate, excluding suspected infective patients in which nuclear imaging tools were not necessary. All the operators underwent serology lab rapid tests on peripheral blood to check the presence of SARS-CoV-2019 IgG and IgM. **Results:** we reduced the number of PET performed every day from 70 before COVID time to around 40. Out of 66, 62 (94%) of our operators had negative tests not only for IgM but also for IgG. Only 4 operators resulted to have IgG positivity; of these, one had positive COVID nasopharyngeal swab (one before and one after blood test) while 2/4 were negative. **Conclusion:** Changing our daily clinical practise we have created a new filter in addition to the face mask, resulting in a free COVID-zone in our department until now. At this point the readers may be thinking that the limit of this study is its retrospective design. But this is the rhythm of the science (oh science, oh yeah): retrospective view is indeed

the real power of this study. We hope that a prospective design, to confirm these data, will not be possible thanks to the advent of a new definitive treatment and if you are now here, reading this study, maybe the dream has become truth. **References:** None

Nuclear Medicine in the times of COVID-19 - expected and possible (unexpected) risks and new safety standards-single institution experience

M. Vljakovic, M. Rajic, M. Stevic, M. Kojic, N. Topic, F. Velickovic, L. Kojic, L. Vranic, N. Todorovic, J. Vidojevic, G. Ignjatovic, S. Cvetic, P. Stojilkovic; Center of Nuclear Medicine, Clinical Center Nis, Nis, SERBIA.

Aim/Introduction: The first cases of coronavirus disease (COVID-19) were seen in Wuhan, China, in late December 2019 before spreading globally. The current outbreak was officially recognized as a pandemic on 11 March 2020. The aim of this paper is to demonstrate the changed mode of operation, safety measures and procedures at the Center of Nuclear Medicine, Clinical Center Niš (CNM), the only nuclear medicine center in Serbia that had no work lockdown during the epidemic, and to propose a system of protective measures to be taken in the face of potential new pandemic waves. **Materials and Methods:** At the beginning of March, CNM had already scheduled all diagnostic and therapeutic procedures for March and April. Out of an average of 250 scintigraphies, 238 were scheduled for March and 88 for April. Twenty-six out of 34 treatment procedures were scheduled for the therapy unit. An epidemiological survey was conducted on all patients. More serious protective measures were introduced at the height of the coronavirus epidemic in the Republic of Serbia. PPE II was used when receiving the scan or treatment according to WHO guidelines. In addition to the standard epidemiologic survey conducted by telephone 1-2 days prior to admission to the hospital, blood samples were obtained from patients in order to test blood counts, CRP and LDH. **Results:** In March, 123/238 diagnostic procedures were performed (51%), while in April 35/88 (40%) diagnostic procedures were performed, exclusively bone scintigraphy. Twenty one out of 26 therapy procedures were performed in the therapy unit, mainly iodine treatment of differentiated thyroid carcinomas, whereas 4 patients were canceled due to the inability to import ¹⁷⁷Lu-DOTA-TATE, and one was canceled due to suspended traffic and inability to reach the hospital. The number of radioimmunology and complementary analyses had also dropped from an average of 5,000 a month to 910 in March and 93 in April. None of the staff involved in performing diagnostic or therapeutic procedures tested positive for Covid-19 disease. **Conclusion:** The emerging situation at the time of the pandemic requires additional protection of personnel working in nuclear medicine to

be undertaken and, in addition to radiation protective equipment, epidemiological protective equipment must be used until an effective and safe SARS-CoV-2 virus drug and vaccine is found. In the coming months, only patients with a negative test for the presence of the virus no older than 24 hours should be admitted for hospital treatment.

Casual cases of nuclear medicine examinations in Patients with concurrent/subsequent diagnosis of COVID-19

C. Olianti¹, D. Malandrino², T. Tagliente², M. Allocca²;

¹University Hospital of Florence, Florence, ITALY,

²University of Florence, Florence, ITALY.

Aim/Introduction: The study is a retrospective cross-referencing clinical data on a cohort of Patients admitted to University Hospital of Florence in 8 COVID-19 departments from 6.03.20 to 20.04.20, to find patients underwent to nuclear medicine scans than diagnosed for SARS-CoV-2 infection. **Materials and Methods:** We crossed diagnostic and clinical data of 172 patients (40-97y; 108 M, 64 F) hospitalized in COVID-19 dedicated/reconverted department with different intensity of care, 3 internal medicine (60pz), 1 cardio-anesthesia and cardio-resuscitation (8pz), 1 trauma intensive care and severe organs failure (14pz), 1 infectious and tropical diseases (17pz), high intensity internal medicine (12pz), 1 Thoracic-pulmonary physio pathology and pneumology (8pz). Each Patient underwent to different imaging diagnostic examinations with a wide variability on the basis of care intensity and the different clinical presentation of disease. We evaluated how many nuclear medicine examinations were performed in the whole cohort. **Results:** Only 4 Patients with SARS-CoV-2 positivity underwent nuclear medicine exams, 2 of them some days before the confirmed infection: 1) a 84 Male hospitalized on 8.03.20 for bowel subocclusion in laryngeal/esophageal neoplasm and suspected intestinal primary cancer who underwent an FDG-Pet/CT scan for lung thickening showing a very complex oncologic situation. He underwent also 8 RX-thorax, 3 abdominal echo-sonography and 2 abdomen CT, before dying on 23.3.20. 2) a 85 Male hospitalized 28.3.20 for recurrence of congestive heart and respiratory failure, not sustained ventricular tachycardia in presence of normally functioning ICD cardioverter defibrillator. He underwent to a pulmonary perfusion scan for D-dimer very high levels with abnormal not-segmental bilateral perfusion defects, incongruent with pulmonary embolism (PE), 3 RX-thorax and 2 thorax-CT before dying on 31.3.20. 3) a 84 Male guest of an assisted elderly residence and hospitalized on 9.4.20 for dispnea, respiratory failure, bilateral pleural effusion and bibasal pneumonia and initially negative COVID-19 buffer. Perfusion lung scintigraphy demonstrated a homogeneous

MAA distribution. 4) a 86 Male hospitalized 11.4.20 for bilateral pneumonia and recurrence of renal and heart failure in recent PTCA and high-frequency atrial fibrillation. He underwent a myocardial SPECT positive for viable perinecrotic tissue. He died on 13.4.20. **Conclusion:** Our results demonstrates that only 4/172 (2,3 %) hospitalized patient underwent nuclear medicine examinations, 2 during SARS-CoV-2 infection, 2 just-before COVID-19, indicating a very good clinical selection of dispnoic patients referred for suspect PE. Interestingly the lung scans of Pz2) not-typical for PE and that of Pz3) without perfusion abnormalities.

EP-241

Longitudinal change in dopamine transporter availability in idiopathic REM sleep behavior disorder

Y. Kim¹, J. Shin¹, J. Lee¹, S. Shin¹, H. Nam¹, H. Kim¹, B. Jeon²;

¹Seoul National University Boramae Medical

Center, Seoul, KOREA, REPUBLIC OF, ²Seoul National

University Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: To elucidate the longitudinal change in the nigrostriatal dopamine transporter (DAT) availability in idiopathic rapid-eye-movement sleep behavior disorder (iRBD) patients predicted by the baseline motor and non-motor biomarkers through prospective analysis over 4 years. **Materials and Methods:** This study cohort consisted of 40 polysomnography-confirmed iRBD patients, 31 drug-naïve Parkinson's disease (PD) patients and 19 healthy controls. All participants were evaluated for olfactory function test, neuropsychological tests and the Movement disorders society-Unified PD Rating Scale, and underwent 18F-FP-CIT PET scan. Participants were re-evaluated every 2 years, prospectively. We calculated DAT-pattern with principal component analysis from tracer uptakes in 6 striatal regions at each time point. **Results:** Baseline DAT-pattern in PD and healthy controls formed distinct clusters whereas that in iRBD group were distributed over the two clusters. DAT-patterns in iRBD patients with hyposmia, constipation, urinary dysfunction or mild parkinsonian sign were significantly biased toward PD pattern at baseline. Hyposmia was the only biomarker significantly associated with progression of DAT-pattern toward PD pattern during the follow-up. During the follow-up, 10 iRBD patients developed neurodegenerative diseases and they were all hyposmic at the baseline, except for 1 MSA converter. Baseline DAT-pattern predicted 70% of disease converters, and annual DAT-pattern change greater than 2.0 predicted

another 20% of disease converters those who had healthy control pattern at baseline. **Conclusion:** Hyposmia is the most efficient predictor of impending DAT decline in iRBD. DAT-pattern can identify individuals at risk reliably with longitudinal PET scan data, even those with normal DAT uptakes at baseline. **References:** 1. Postuma RB, Berg D. EP-242

Role of Functional Neuroimaging in early onset Parkinson's disease, 123I-MIBG - DaTscan, a multicenter study

J. Lazri¹, A. Di Rocco¹, S. Nuvoli², M. L. Stazza², M. Rondini², M. S. De Feo¹, L. Cosma¹, V. Frantellizzi¹, A. Farcomeni³, G. De Vincentis¹, A. Spanu²;

¹Sapienza University of Rome, Rome, ITALY, ²University of Sassari, Sassari, ITALY, ³University of Rome Tor Vergata, Rome, ITALY.

Aim/Introduction: Neuroimaging markers for Parkinson's disease (PD) or other neurodegenerative parkinsonian syndromes (non-PD) include 123I-ioflupane SPECT (DaTscan) to detect presynaptic dopamine neuronal dysfunction, and myocardial 123I-metaiodobenzyl guanidine (MIBG) scintigraphy to evaluate the cardiac sympathetic nerve fibers. The aim of this multicenter study is to assess if the use of both of these molecular imaging techniques can predict PD with higher sensitivity in early onset disease patients which diagnosis was confirmed after 3 years of clinical follow-up. **Materials and Methods:** This was a retrospective study of two centers. In a two years period patients with suspected diagnoses of PD or non-PD syndromes were enrolled. Also, patients had to have undergone both DaTscan and MIBG imaging. The caudate nuclei (C/O) and putamina (P/O) to the non-specific occipital region ratios in both the basal ganglia were analysed. Early and Late Heart to Mediastinum ratio (eH/M and IH/M) were calculated for MIBG examination. **Results:** 260 subjects were analysed. Patients baseline characteristics were: mean age 66 ± 9.8 years, symptoms appeared for less than one year, male 147 (56.5%). The patients' neurologic diagnoses after 3 years of clinical follow-up were PD in 143 and non-PD (including essential tremor, Multiple system atrophy and other parkinsonisms) in 117. Diagnostic odds ratio (OR) with 95% confidence interval (CI) was calculated for both the exams. As regards the MIBG scan OR was 0.22 (95% CI 0.19-0.26)

for eH/M and 0.29 (95% CI 0.25-0.32) for IH/M ($p=0.001$) while the DaTscan OR was 0.98 (95% CI 0.93-1.03) for Right C/O ($p=0.55$); 0.98 (95% CI 0.93-1.03) for Right P/O ($p=0.46$); 0.97 (95% CI 0.91-1.02) for Left C/O ($p=0.28$) and 0.97 (95% CI 0.91-1.02) for Left P/O ($p=0.25$). The ROC showed an AUC 0.954 for both eH/M and IH/M. **Conclusion:** MIBG examination has a higher diagnostic accuracy in early onset PD patients than DaTscan. Given the superiority of the heart study, the combined use of the DaTscan in association with the MIBG in this phase of disease does not appear to be mandatory. **References:** None

EP-243

Impact of dopamine depletion on gait initiation in Parkinson's disease

G. Marotta¹, C. Palmisano², G. Brandt², M. Vissani³, N. G. Pozzi², A. Canessa⁴, J. Brumberg², J. Volkmann², A. Mazzoni³, C. A. Frigo⁵, I. U. Isaías²;

¹Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ITALY, ²University Hospital Würzburg and Julius-Maximilian-University, Department of Neurology, Würzburg, GERMANY, ³Scuola Superiore Sant'Anna, The Biorobotics Institute, Translational Neural Engineering Area, Pontedera, ITALY, ⁴Department of Informatics, Bioengineering, Robotics and System Engineering, Università di Genova, Genova, ITALY, ⁵Politecnico di Milano, Department of Electronics, Information and Bioengineering, MBMC Lab, Milan, ITALY.

Aim/Introduction: The contribution of the basal ganglia and dopamine on postural control is still largely unknown, but indirect evidence points towards their possible involvement in the production of anticipatory postural adjustments. In addition, the influence of initial stance condition on gait initiation in Parkinson's disease (PD) has never been consistently assessed. The aim of this work was to define which biomechanical resultants at gait initiation are PD-related and dopamine (putamen)-dependent, accounting for the influence of anthropometric measures and the base of support. **Materials and Methods:** The biomechanical resultants of anticipatory postural adjustments contributing to gait initiation (imbalance, unloading and stepping phase) were studied in 26 unmedicated subjects with idiopathic PD (18 males, mean age 61.0 years) and in 27 healthy subjects (17 males, mean age 61.2 years). A subset of 13 patients (8 males) was analysed under standardized medication conditions and the striatal dopaminergic innervation was studied in 22 patients using FP-CIT SPECT. The imaging data were processed with the Basal Ganglia Matching Tool. We investigated the correlation between the biomechanical values and the DAT density of the putamen, as the main motor structure in the striatum, contralateral to the swing foot (putamen_{SWING}) and contralateral to the stance foot (putamen_{STANCE}). **Results:** PD patients showed a significant reduction in center of

pressure displacement and velocity during the imbalance phase, reduced first step length and velocity, and decreased velocity and acceleration of the center of mass at toe off of the stance foot. All these measurements correlated with the dopaminergic innervation of the putamen ($p < 0.01$) and substantially improved with levodopa. These results were not influenced by anthropometric parameters or by the initial stance condition. In contrast, most of the measurements of the unloading phase were influenced by the foot placement and did not correlate with putaminal dopaminergic innervation. **Conclusion:** Our results suggest a significant role of dopamine and the putamen particularly in the elaboration of the imbalance phase of anticipatory postural adjustments and in the execution of the first step. The basal ganglia circuitry may contribute to defining the optimal referent body configuration for a proper initiation of gait and possibly gait adaptation to the environment. **References:** None

EP-244

Brain metabolic alterations herald falls in patients with Parkinson's disease

G. Marotta¹, J. Brumberg², N. Pozzi², J. Volkmann², G. Pezzoli³, I. U. Isaias²;

¹Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ITALY, ²University Hospital Würzburg and Julius-Maximilian-University, Department of Neurology, Würzburg, GERMANY, ³ASST G.Pini-CTO, Centro Parkinson, Milan, ITALY.

Aim/Introduction: The specific factors that are critical to fall prediction and prevention in Parkinson's disease (PD) remain elusive and the best single variable to predict falls is two or more falls in the previous year. Pathophysiological understanding of gait and balance disorders in Parkinson's disease is insufficient; late recognition of fall-risk patients limits efficacious follow-up to prevent/delay falls. The aim of this study was to identify specific metabolic patterns with brain FDG PET associated with motor and cognitive symptoms. **Materials and Methods:** We retrospectively evaluated the clinical records and molecular imaging findings of over 200 patients with a diagnosis of idiopathic Parkinson's disease (PD) who underwent FDG PET at our center between 2012 and 2017. We identified one group of 11 right-handed patients (8 males; disease duration: 7 ± 4 years; age at onset: 57 ± 11 years; UPDRS-III: 35 ± 14) who experienced their very first fall episode between 6 and 8 months after the execution of the FDG PET. We then collected the clinical and imaging data of a second group of 19 right-handed patients (13 males; disease duration: 8 ± 4 years; age at onset: 54 ± 8 years; UPDRS-III: 32 ± 13) and a group of 12 healthy controls (HC) matched for demographic and clinical data. Brain metabolic differences between fallers, non-fallers and HC were tested by Statistical Parametric Mapping (SPM) with age and disease duration as

covariates, and a post hoc volume-of-interest (VOI) analysis. **Results:** Clinical and demographic data did not differ significantly between groups. PD fallers showed distinctive hypometabolism in the left parietal cortex (inferior and superior parietal lobules) and increased bilateral cerebellar glucose consumption. **Conclusion:** We demonstrate a distinctive reduction of glucose metabolism in the left posterior parietal cortex, with increased metabolic activity in the cerebellum, in parkinsonian patients 6-8 months before their first fall. Falls in PD might arise from altered cortical processing of body spatial orientation, possibly predicted by abnormal cortical metabolism. **References:** None

Response Assessment At One Year After 131I Treatment In Patients With Grave's Disease And Multinodular Goiter

V. Carrero-Vásquez, H. Rodríguez-Parra, M. Redal-Peña, I. Casáns-Tormo, A. Cánoves-Llombart, P. Cárcamo-Ibarra, J. Sabater-Sancho, R. Maestre-Cutillas, M. Soria-Merino; Nuclear Medicine, University Clinical Hospital, Valencia, SPAIN.

Aim/Introduction: The administration of 131I is an effective therapeutic option for the control of hyperthyroidism. We assessed the response at one year after treatment, analyzing the influence of age, sex, thyroid function (clinical-CH and subclinical hyperthyroidism-SH), anti-TSH receptor antibodies (AB), thyroid volume (TV) through echography, glandular characteristics in thyroid scan, and administered 131I activity (A) in patients with Graves' disease (GD) and multinodular goiter (MNG). **Materials and Methods:** From 100 consecutive patients (p) (2017-2018) treated with 131I, 70 (38 MNG-32 GD) were selected who received a first 131I treatment and had clinical follow-up for one year, evaluating euthyroidism-hypothyroidism as a therapeutic response (R) and persistent hyperthyroidism as the absence of it (noR). In 38 MNG (28 women, 30-87 years y/o (mean 65), there were 23/38 with SH. In 32 GD (24 women, 31-75 y/o (mean 52), there were 19/32 with SH. AB determination was available in 37/70p, TV could be calculated in 51/70p, establishing 3 subgroups: <20ml, 21-50ml and >50ml. Overall A was 8-18mCi (mean 12mCi), that was calculated according to patient age and weight, TV, and scintigraphic characteristics. **Results:** Patients with MNG: there was R in 34/38 (89.4%), with A: 8.5-16.6mCi (mean 12.5), TV: 20-50ml, SH in 31/34, AB: 0.3-4.29 (mean 1.8 UI/L), available in 6/34, and noR in 4/38 (10.5%), A: 12-18 mCi (mean 14.6), with TV: 52.9-149.4ml, SH in 1/4, AB not available. Patients with GD: there was R in 28/32 (87.5%) with A: 8-15mCi (mean

10.7), TV: <20–80.9ml, SH in 17/28, AB: 0–6.87 (mean 2.58 UI/L) available in 20/28, and noR in 4/32 (12.5%), with A: 10–17mCi (mean 12.8), TV: 21.8–46.3ml, SH in 2/4, AB 2.68–28.53 (mean 11.63UI/L) available in 3/4. No significant differences between R and noR in terms of age, sex, A, CH or SH. **Conclusion:** After one year of follow-up, in our group of patients there was a good therapeutic response and without significant differences between MNG (89.4%) and GD (87.5%). Persistent hyperthyroidism was associated with a higher thyroid volume in MNG and in the group of GD with a tendency for higher AB levels, but without relation with the other assessed factors. **References:** None

EP-246

10-Years Results After 90-Yttrium and 166-Holmium Radiosynoviorthesis In Chronic Knee Synovitis Of Different Origin /820 patients/

M. Szentesi, Z. Nagy, G. Csőre;

Hospital of the Hospitaller Brothers of St. John of Budapest, Budapest, HUNGARY.

Aim/Introduction: In the case of chronic synovitis, the synovial membrane proliferates, producing fluid, then creeps onto the cartilage, causing first pannus formation, then serious destruction to both cartilage and bone. Our aim is to stop this process. **Study objectives:** Examination of anti-inflammatory effect of 90-Yttrium and 166-Holmium injections. **Materials and Methods:** Out of these 820 patients 460 suffered from rheumatoid arthritis, 68 ankylosing spondylitis, 52 other seronegative spondylarthritis, 188 suffered from inflamed osteoarthritis, 4 hydrops articulorum intermittens, 4 synovitis villonodularis, 44 from chronic traumatic synovitis. Evaluation was based on the criteria as described by Müller, Rau and Scütte the score system was developed by the authors. **Results:** In the first 10 years excellent and good results were recorded in 71%. They achieved excellent as well as good results at 83% of patients with rheumatoid arthritis, at 50% of patients with ankylosing spondylitis and at 55% of patients with osteoarthritis. 10 years after radiosynoviorthesis 72% of patients did not need another puncture. **Conclusion:** Radiosynoviorthesis is an effective method of treating chronic synovitis as surgical synovectomy. Even after a 10 years period 71% the findings were rated as excellent or good. 72% of the patients do not need another puncture even after a 10 years period. The effectiveness is worsened significantly by the stadium of the disorder and the local x ray phase and diagnosis. $P < 0.00001$. The treatment must be done in rheumatoid arthritis Steinbrocker stadium I-II, local stadium I-II. **References:** no Szentesi M¹, Papp I¹, Farbaky Zs², Nagy Z³, Berkes I.4, Nagy Gy¹: Treatment of Chronic Knee Synovitis with Radiosynoviorthesis After Failure of Surgical Interventions. Knee radiosynovectomy with Sm-153 hydroxyapatite compared to Y-90 hydroxyapatite: initial results of a prospective trial

E. Etchebehere¹, M. Lima¹, L. Pereira¹, R. Pagnano¹, E. Bortoletti², J. Mengatti², S. Q. Brunetto¹, M. Takahashi¹, E. Brunetto¹, M. Ozelo¹, A. Santos¹;

¹The University of Campinas, Campinas, BRAZIL, ²Institute of Research and Nuclear Energy (IPEN), Sao Paulo, BRAZIL.

Aim/Introduction: **Introduction:** The most common clinical presentation in hemophilia patients consists of hemarthrosis. Various treatment strategies aim to control hemarthrosis to prevent secondary arthropathy, among them, radiosynovectomy with Y-90 hydroxyapatite (⁹⁰Y-HA). A few studies have shown a lower efficiency of knee radiosynovectomy with Sm-153 hydroxyapatite (¹⁵³Sm-HA) compared to ⁹⁰Y-HA. **Purpose:** The purpose of this investigation was to assess the efficacy and safety of knee radiosynovectomy with ¹⁵³Sm-HA compared to ⁹⁰Y-HA. **Materials and Methods:** Forty patients were prospectively assigned to undergo knee radiosynovectomy with ¹⁵³Sm-HA (19 patients) or with ⁹⁰Y-HA (21 patients). The frequency of hemarthrosis episodes before and after treatment was compared. **Results:** The response to knee radiosynovectomy stratifying according to radiotracer showed that after 6 months the median response rate with ¹⁵³Sm-HA was not significantly different from ⁹⁰Y-HA (87.5% vs 80.9%; $p = 0.576$). However, after 12 months the median response rate of knee radiosynovectomy with ¹⁵³Sm-HA was significantly better than with ⁹⁰Y-HA (87.5% vs 50%; $p = 0.037$), respectively. The reduction of joint bleeding by at least 50%, after 12 months, was greater in the group of patients treated with ¹⁵³Sm-HA compared to ⁹⁰Y-HA (74% vs 52%), respectively. **Conclusion:** Knee radiosynovectomy with high doses of ¹⁵³Sm-HA is safe, with an efficiency rate similar that is described in the literature by the ⁹⁰Y-HA. **References:** None

Disentangling conscious visual processing by a multimodal approach in disorders of consciousness

G. Marotta¹, D. Sattin², D. Rossi Sebastiano², L. D'Incerti², D. Guido², E. Orunesu¹, R. Benti¹, S. Tirelli², F. G. Magnani², A. Bersano², D. Duran², S. Ferrero², L. Minati², A. Nigri², C. Rosazza², S. B. Marzoli³, M. Leonardi²;

¹Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ITALY, ²Fondazione IRCCS Neurologico Carlo Besta, Milan, ITALY, ³Istituto Auxologico Italiano, Milan, ITALY.

Aim/Introduction: Differentiating between Vegetative (VS) and Minimally Conscious State (MCS) is a challenge for scientists. Recent studies have highlighted that the visual responses to tailored stimuli might be one of the first evidence of a transition from VS to MCS. Furthermore, the visual fixation, visual pursuit, and reproducible movement to command responses were observed in more than 50% of patients in MCS. We aimed at exploring the functional and structural integrity of neural structures of the visual system of VS and MCS, namely who shows visual blink and who shows visual pursuit, with a multimodal approach by collecting several measures deriving from both behavioral, neurophysiological, and neuroimaging tools. **Materials and Methods:** The difference between groups in instrumental data (flash Visual Evoked Potentials, structural MRI and FDG-PET) was explored in 54 patients with disorders of consciousness, all diagnosed with VS according to the Coma Recovery Scale-revised (CRS-r) without considering its visual sub-scale score. The Wilcoxon test was used to assess hemispheric differences in MRI within subjects. For FDG-PET imaging, a voxel-by-voxel two-sample t test between patients with the visual blink response only and patients with visual pursuit was performed using SPM12, applying a threshold of FDR corrected $p < 0.001$ for cluster containing at least 100 voxels. **Results:** Forty-two (77.7%) patients out of 54 showed only visual blink reflex in the CRS-r visual function subscale, and twelve (22.2%) showed visual pursuit. Among non-traumatic aetiologies, sixteen (29.62%) patients had a hemorrhagic etiology, two (3.7%) ischemic, and nineteen (35.18%) had post-anoxic damage. Flash Visual Evoked Potentials were absent in 88.9% and in 11.1% for the visual blink and visual pursuit groups respectively. For MRI, a significant statistical differences between the two groups (p -values < 0.01) were found for the right V1 area and the right optic radiation scores. For FDG-PET, a significant difference ($p < 0.001$ FDR-corrected) was also found between the two groups: the visual blink

group showed a significant decrease metabolism in right calcarine and lingual gyrus cortex then visual pursuit group. **Conclusion:** We showed that patients manifesting visual blink have different patterns, as detected by instrumental tools, compared with patients manifesting visual pursuit especially in occipital areas. These results set the rationale to identify those markers associated with consciousness that could be of help in the next future to better understand if a certain visual behavior is determined by conscious or non-conscious processing. **References:** None

EP-249

A multimodal assessment of residual language processing in disorders of consciousness patients

G. Marotta¹, S. Ferraro², A. Nigri², L. D'Incerti², C. Rosazza², D. Sattin², D. Rossi Sebastiano², E. Visani², D. Duran², G. Demichelis², E. Catricala³, S. Kotz⁴, L. Verga⁴, M. Leonardi², S. Cappa³, M. Schiavini¹, M. F. Bardo¹, M. G. Bruzzone²;

¹Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ITALY, ²Fondazione IRCCS Neurologico Carlo Besta, Milan, ITALY, ³Scuola Universitaria Superiore, Pavia, ITALY, ⁴Maastricht University, Maastricht, NETHERLANDS.

Aim/Introduction: The impact of language impairment on the clinical assessment of patients suffering from disorders of consciousness (DOC) is unknown or underestimated, and may mask the presence of conscious behavior. The aim of the study was to investigate the main neural functional and structural underpinnings of linguistic processing, and their relationship with the behavioral measures of the auditory function, using the Coma Recovery Scale-Revised (CRS-R) and to assess the integrity of the brainstem auditory pathways of the left superior temporal gyrus and arcuate fasciculus, the neural activity elicited by passive listening of an auditory language task and the mean hemispheric glucose metabolism. **Materials and Methods:** We included 11 patients with DOC included 4 with vegetative state (VS) and 7 with minimally conscious state (MCS): 5 MCS- and 2 MCS+ (4 males; median age: 57 years, range: 19-69 years; etiology: 4 traumatic brain injury, 5 hemorrhagic brain injury, 2 anoxic brain injury; median time post-injury: 27 months). The clinical assessment of the patients was performed with the CRS-R. The multimodal evaluation comprised BAEPs, sMRI, DTI, fMRI during the administration of a passive hierarchical auditory language paradigm, and FDG-PET. **Results:** One VS and 3 MCS- patients, showed the auditory startle at the CRS-R auditory function subscale: in VS patient the lack of fMRI related activity was possibly supported by a very low-level metabolism; in MCS- patients the lack of fMRI-related activity was possibly sustained by severe anatomical damage of the left-sided investigated structures or by a very severe impairment of the brainstem auditory pathways. Three VS and 2 MCS- patients presented the localization to sound at the CRS-R auditory function

subscale: these patients presented a relative integrity of BAEPs and a certain degree of fMRI-related activity with metabolism was quite variable. Two MCS+ presented or integrity of the core structures of language processing or a complete preservation of bilateral BAEPs and both patients presented high-level left-lateralized fMRI activity. **Conclusion:** The results support the hypothesis that MCS- patients presenting the auditory startle might be aphasic in the receptive domain, independently from the level of cerebral metabolism and, therefore, from the level of consciousness. Moreover, our results support the hypothesis that MCS- patients exhibiting the localization to sound, might present a lower level of consciousness in comparison to MCS+ patients. **References:** Nigri A et al. Sex difference in Cerebral blood flow and Cerebral glucose metabolism: An activation likelihood estimation Meta-analysis

K. Pak¹, S. Kim², S. Lee³;

¹Pusan National University Hospital, Busan, KOREA, REPUBLIC OF, ²Pusan National University Yangsan Hospital, Yangsan, KOREA, REPUBLIC OF, ³Kyungpook National University Hospital, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: We investigated the sex difference in cerebral blood flow and cerebral glucose metabolism using positron emission tomography and single photon emission computed tomography. **Materials and Methods:** We performed a systematic search of MEDLINE and EMBASE for English-language publications using the keywords of "positron emission tomography", "single-photon emission computed tomography", and "sex". The inclusion criteria were original research articles that reported the difference between males and females in cerebral blood flow or cerebral glucose metabolism. For each experiment, the modeled activation map is calculated by finding the maximum across each focus's Gaussian. On the basis of empiric estimates of between-subject variability from the number of subjects in each study, the width of the Gaussian probability distribution is determined individually for each experiment. A threshold of uncorrected $p < 0.001$ (minimum volume of 200mm³) was applied to the resulting ALE map. **Results:** 7 studies were eligible for inclusion in the study. Four studies of CBF with 15O-H₂, 99mTc-ECD, and 99mTc-HMPAO, and 3 studies of CMRglu were included. A. Cerebral blood flow- In females, significant increases in CBF were identified in 6 clusters including right precuneus, left superior temporal gyrus, left inferior temporal gyrus, left inferior frontal gyrus, right cerebellar tonsil, and right middle temporal gyrus. In males, a significant increase in CBF was observed in 1 cluster of left anterior cingulate. B. Cerebral metabolic rate

of glucose- In females, significant increases in CMRglu were identified in 7 clusters including left thalamus, left cingulate gyrus, right inferior parietal lobule, left medial frontal gyrus, right middle frontal gyrus, right midbrain, and left inferior parietal lobule. In males, no significant increase in CMRglu was observed. **Conclusion:** With the help of neuroimaging of PET and SPECT, significant sex difference of cerebral blood flow and cerebral metabolic rate of glucose was identified. **References:** *Journal of Neuroscience Research* 95:189-199 (2017)

EP-251

Determination of embolic brain distribution caused by right to left shunt in people with patent foramen ovale

M. Assadi, R. Nemati, M. Jalali, H. Salimipour, A. Amini, E. Jafari; Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: One of the etiologies for stroke, especially in younger patients, is patent foramen ovale (PFO). It is found in about 25% of healthy people and it is asymptomatic most of the time but during a valsalva maneuver, a transient right to left shunt can occur and if there would be emboli in it, it can bypass the lungs and enter the aorta and if it migrates to the brain, it can cause stroke. Some recent studies have been shown that these strokes mostly occur in posterior circulation, although a few says no. The overall epidemiology of posterior circulation strokes is about 20% of all strokes which seems to be much higher in PFO patients. There are not sufficient data about it. This study is about determination of distribution of emboli in brain in patients with PFO. **Materials and Methods:** We studied 51 patients with PFO. We injected 99mTc-macroaggregated Albumin, then we asked them to accomplish valsalva maneuver, then they underwent brain SPECTs in right lateral and left lateral views. **Results:** The most flow of MAA was respectively in cerebellar, occipital, frontal and temporoparietal regions. **Conclusion:** We showed that posterior circulation is dominant in PFO people, in contrary to non-PFO people. It may be because of valsalva maneuver that makes the posterior blood flow more dominant. Further studies about cerebral blood flow with and without valsalva maneuver is highly recommended. **References:** None

Association of dizziness and brain perfusion SPECT : voxel-based analysis of a pilot sample

M. Assadi¹, R. Nemati¹, M. Nayeri¹, N. Chabi¹, E. Jafari¹, H. Dadgar²; ¹Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, ²Razavi Cancer Research Center, Razavi Hospital, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The presence of perfusion and structural abnormalities on brain imaging in people with dizziness

has not been widely studied. The purpose of this study was to investigate the brain perfusion in patients with dizziness using single photon emission computed tomography (SPECT). **Materials and Methods:** We studied 34 people with self-reported dizziness who had experienced intermittent or constant dizziness within the past month or more. The study was carried out between January 2014 and November 2015. Dizziness-related impairment was assessed with the dizziness handicap inventory (DHI) and short physical performance battery (SPPB). Carotid intima-media thickness (CIM) also measured by ultrasonography. Brain perfusion data were analyzed either qualitatively in all cases or semi-quantitatively in 11 cases using statistical parametric mapping (SPM) software. **Results:** Overall, 34 patients (mean age 72.01 years, SD = 8.28 years) with a history of dizziness precipitated in the study. Dizziness severity of 34 patients was classified as 20(58.8%) cases were in mild group, 9(26.5%) cases in moderate group and 5(14.7%) cases in severe group. Finding of brain perfusion scan revealed that 4 (11.2) patients had a normal scan and 30(88.2%) patients had an abnormal scan. In SPM analysis of the brain perfusion imaging, patients showed a significantly decreased brain perfusion in right precuneus, cuneus, superior and inferior occipital lobe, inferior frontal, middle frontal, temporal, inferior parietal and left superior parietal, precuneus, cerebellar, insula, and putamen. In qualitative assessment of brain SPECT, significant association was seen between perfusion defect severity with SPPB test ($p=0.019$), gait speed test 4 meter ($p=0.003$) and balance test ($p=0.021$) parameter, but not with chair stand ($p=0.11$). **Conclusion:** Our results showed that multiple regions of the brain involvement in patients with dizziness that supported dizziness may be manifestation of an abnormal integration of multisensory modality. We found that parietal hypoperfusion associated with impairment of balance and gait. In addition, frontal lobe involvement predominately affects gait speed. Key words: brain SPECT, dizziness, statistical parametric mapping (SPM), ^{99m}Tc -ECD.

DWI and SPECT findings in patients with acute ischemic stroke

*M. Assadi, A. Moradi, M. Emami, K. Mirzaei;
Bushehr University of Medical Sciences (BUMS),
Bushehr, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Stroke or stroke is a common disease characterized by a rapid development of neurodegenerative defects that can lead to illness and death. Considering the increasing incidence of this disease, we look at the events that occur during MRI imaging in the form of weight distribution (DW MRI) and SPECT. **Materials and Methods:** 30 patients with acute ischemic stroke referred to a neurologist clinic confirmed their diagnosis by a neurologist. Then, two types of DWI and SPECT imaging were performed for these patients to investigate the events occurring during acute stroke. **Results:** In this study, 40 patients with stroke were enrolled in the study. Among them, 30 patients had SPECT and DWI scans, of which 16 were female and 14 were male. Of these, 14 were left hemiparesis and 14 patients with right hemiparesis and 4 patients with dysarthria, of which 4 had 2 simultaneous hemiparesis (a patient with dysarthria and right hemiparesis and one patient with dysarthria and left hemiparesis). DW MRI is also found in 40% of the patients with acute left frontal infarction, 33.3% of the acute infarction in the right frontal, 20% in the right parietal, 13.3% of the patients with acute left parietal infarction, 10% in the brain stem and right cerebellum. SPECT and DWI findings with patient complaints and the side of the conflict in the hemiparesis. Significant differences were found in the SPECT and DWI findings in patients with hemiparesis. **Conclusion:** This study showed that high percentage of patients with ischemic stroke had lesion in the left temporal and parietal lobes and right frontal and frontal lobes in DWI. It was also found that SpSPECT in showing areas of reduction an impression that indicates ischemia is more sensitive than DWI. Also, the findings of the SPECT and DWI have also been correlated with complaints from patients and the side of the hemorrhagic conflict. DWI and SPECT compounds in showing ischemic lesions and the brain infarction was very sensitive. The DWI is useful for detecting TIA from stroke, and SPECT is more beneficial for differentiation due to the higher sensitivity, and when combined, there is a very high sensitivity to the differentiation of TIA from stroke.

Biological Characterization of the ^{47}Sc Labelled PSMA Ligand

D. Pawlak, W. Wojdowska, M. Żółtowska, M. Wyczółkowska, U. Karczmarczyk, P. Garnuszek, J. L. Parus, R. Mikołajczak; National Institute for Nuclear Research Radioisotope Centre POLATOM, Otwock, POLAND.

Aim/Introduction: In recent years, ^{47}Sc has attracted attention due to its favorable decay characteristic ($T_{1/2} = 3.35\text{d}$, $E_{\beta\text{max}} = 600\text{ keV}$; E_{γ} , 159 keV) and chemical properties similar to lutetium or yttrium, since it can be useful for therapy and allows imaging using SPECT. Herein we present the preclinical assessment of chemical and biological properties of our new PSMA analogue (PSMA-D4) when labelled with ^{47}Sc . **Materials and Methods:** ^{47}Sc was produced by irradiation of ^{46}Ca enriched targets in $^{46}\text{Ca}(n,\gamma)^{47}\text{Sc}$ nuclear reaction, either at target at ILL (Grenoble) or NCBJ (Otwock). ^{47}Sc was separated from the irradiated target by extraction chromatography on DGA resin [1]. Radiochemical purity of [^{47}Sc]Sc-PSMA-D4 was assessed by iTLC and HPLC. The affinity to the PSMA antigen was assessed using cell membranes isolated from LNCaP (PSMA+) and PC3 (PSMA-) cells by saturation binding assays to evaluate the specific binding, dissociation equilibrium constant (Kd), and maximal receptor concentration on cell surface (Bmax). For comparison, the same testing procedures applied to [^{90}Y]Y-PSMA-D4. Biodistribution of both [^{47}Sc]Sc-PSMA-D4 and [^{90}Y]Y-PSMA-D4 was studied in Balb/c nude mice bearing LNCaP xenografts. **Results:** Irradiation of 50 mg of ^{46}Ca resulted in approximately 350 MBq of ^{47}Sc . ^{47}Sc was separated from excess of Ca on DGA resin with about 90% yield. Radiolabeling of [^{47}Sc]Sc-PSMA-D4 resulted in over 90% radiochemical yield and the specific activity up to 5,5 MBq/nmol. Both [^{47}Sc]Sc-PSMA-D4 and [^{90}Y]Y-PSMA-D4 revealed high specific affinity to PSMA antigen in vitro with over 99% of the total binding. The Kd and Bmax values for [^{47}Sc]Sc-PSMA-D4 were $5,0 \pm 1,9\text{ nM}$ and $7,8 \pm 3,1\text{ nmol/mg}$, while for [^{90}Y]Y-PSMA-D4 they were $5,6 \pm 1,5\text{ nM}$ and $20,4 \pm 6,3\text{ nmol/mg}$, respectively. In vivo radioactivity uptake of [^{47}Sc]Sc-PSMA-D4 in the tumor reached maximum value of $9,24 \pm 2,21\% \text{ID/g}$ at 4hp.i.v. in Balb/c nude mice bearing LNCaP xenografts. Retention of radioactivity in the blood and in non-targeted organs and tissues decreased rapidly over time, reaching background levels after 6 h. **Conclusion:** We demonstrated that ^{47}Sc can be obtained via $^{46}\text{Ca}(n,\gamma)^{47}\text{Sc}$ nuclear reaction and

successfully used for preparation of radiopharmaceuticals. Our newly developed PSMA-D4 ligand labelled with ^{47}Sc shows potential for targeted radionuclide therapy of prostate cancer metastasis. **References:** [1] D. W. Pawlak, et al. Molecular Imaging as a Quantitative Tool to Assess the in Skin Malaria Parasite Deposition: Mosquito Bites vs. Needle Injection

C. de Korne, B. M. F. Winkel, M. N. van Oosterom, S. C. Chevalley-Maurel, J. C. Sijtsma, E. Baalbergen, B. M. D. Franke-Fayard, F. W. B. van Leeuwen, M. Roestenberg; LUMC, Leiden, NETHERLANDS.

Aim/Introduction: An effective malaria vaccine could potentially prevent >200 million malaria cases each year. Vaccines comprising live attenuated malaria parasites (sporozoites; spz) are currently considered most promising. However their feasibility and efficacy critically depends on the means of administration; spz are much more efficacious in inducing protection when deposited by mosquito bite as opposed to needle injection[1,2]. This difference in efficacy is thought to be explained in part by the enhanced migratory capacity of mosquito-delivered spz. To understand what causes the difference in efficacy of the administration routes we used fluorescence imaging and custom image analysis software to study the injection site appearance and spz migration after injection. **Materials and Methods:** Plasmodium berghei spz expressing mCherry and luciferase were administered to mice by 30 mosquito bites (MB) or by intradermal needle injection of 3k spz in 10 μl (NI). The parasite burden in the liver of mice, assessed by bioluminescence imaging 44h post injection, was determined for the different administration routes. The intradermal injection sites were visualized using a spinning disk confocal microscope. Movies were obtained of migrating spz (NI: n=1251, MB: n=566) and quantitatively analyzed with our in-house written analysis tool SMOOT_{mouse}. Comparison of spz motility after delivery by MB vs. NI was performed based on key motility parameters: movement pattern, track tortuosity and velocity. **Results:** The number of spz able to migrate from the skin to the liver after NI was 3-fold lower compared to MB. Mapping the injection sites revealed that NI resulted in a spz hotspot (nearest neighbor distance (NND): 23 μm , IQR: 13-43) and increased interstitial space, while MB resulted in a higher spz spread (NND: 55 μm , IQR: 18-132) and small hemorrhages. SMOOT_{mouse} analysis revealed that 88% of the spz tracked in mouse skin were motile. Following delivery by NI, the spz velocity

decreased (mean: 1.84 $\mu\text{m/s}$, SD: 0.24) and they travelled with a more random turn angle (angular dispersion: 0.57, SD: 0.14) compared to spz delivered by MB (mean velocity: 2.41 $\mu\text{m/s}$, SD: 0.31; angular dispersion: 0.73, SD: 0.10). **Conclusion:** Comparing routes of spz administration using molecular imaging combined with quantitative image analysis revealed differences in spz distribution and motility, which might explain the low efficacy of spz administration by intradermal needle injection. This indicated that alternative intradermal administration routes (e.g. microneedles) should be explored to better mimic the spz distribution and motility seen after delivery by mosquito bite. **References:** 1.doi.org/10.1086/339409; 2.doi.org/10.1126/science.1211548

Targeted pharmacological inhibition and kinetic modeling to improve the performance of [$^{99\text{m}}\text{Tc}$] mebrofenin as probe to study MRP2 activity at the liver-bile interface

S. Marie¹, I. Hernández-Lozano², L. Breuil¹, W. Saba¹, M. Goislard¹, A. Novell¹, J. Gennisson¹, O. Langer², C. Truillet¹, N. Tournier¹;
¹Laboratoire d'Imagerie Biomédicale Multimodale (BIOMAPS), Université Paris-Saclay, CEA, CNRS UMR9011, Inserm UMR1281, Service Hospitalier Frédéric Joliot, Orsay, FRANCE, ²Department of Clinical Pharmacology, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Multidrug resistance-associated protein 2 (MRP2, ABCC2) mediates the biliary excretion of drugs from hepatocytes. Deficiency of this efflux transport may result in drug-induced liver injury. Quantitative imaging techniques are needed to explore the MRP2 transport in vivo. The interplay of other hepatic transporters and the liver metabolism of most probes complicate the interpretation of imaging data. [$^{99\text{m}}\text{Tc}$]mebrofenin (MEB) is a metabolically stable probe for hepatic imaging, predominantly transported by MRP2 at the canalicular (liver-bile) interface. However, its liver kinetics also depends on sinusoidal transporter-mediated uptake (blood-liver) by organic anion-transporting polypeptides (OATP, SLCO) [1]. A safe protocol for targeted inhibition of hepatic MRP2 is needed to study the intrinsic transport capacity of this transporter apart from other transporter systems, as would be achieved using MRP2-deficient animals versus wild-type animals. **Materials and Methods:** MEB was injected (39 \pm 4MBq iv, n=5-6 per condition) in control rats (CTRL) or

after pretreatment with rifampicin (RIF 40mg/kg iv, OATP/MRP2 inhibitor) or ciclosporin (CsA, 0.01, 0.1, 0.5, 1 or 5mg/kg iv). Planar dynamic acquisitions were acquired during 40 minutes. Regions of interest were drawn over the heart blood-pool, liver and intestine to generate time-activity curves. Pharmacokinetic modeling was performed to describe the transfer rate constants between compartments [2]. The liver perfusion was measured before and after injection of the maximal dose of each inhibitor using Doppler ultrasound. Outcome parameters were compared using one-way ANOVA for imaging data and a paired t-test for ultrasound results. **Results:** A significant and comparable decrease in k_3 (rate constant for transfer from hepatocytes to excreted bile) was observed for all tested conditions (from $\text{CsA}_{0.01}=0.03\pm 0.00\text{min}^{-1}$ to $\text{RIF40}=0.05\pm 0.02\text{min}^{-1}$) suggesting effective MRP2 inhibition compared to CTRL ($k_3=0.15\pm 0.08\text{min}^{-1}$). RIF and the highest doses of CsA significantly decreased k_1 (rate constant for blood-to-liver transfer, $\text{RIF}_{40}=0.88\pm 0.09\text{min}^{-1}$, $\text{CsA}_5=2.82\pm 0.87\text{min}^{-1}$) compared to CTRL ($k_1=7.37\pm 1.62\text{min}^{-1}$). The effect on k_1 was dose-dependent with no impact of the lowest dose of CsA ($\text{CsA}_{0.01}=8.69\pm 1.90\text{min}^{-1}$). Highest dose of CsA did not affect the liver perfusion. **Conclusion:** Low dose CsA is a potent inhibitor in vivo of the MRP2-mediated canalicular efflux of MEB with impact on neither the OATP-mediated sinusoidal influx nor liver perfusion. MEB \pm CsA provides a safe, available and clinically feasible protocol to selectively unveil the MRP2 transport activity at the liver-bile interface in vivo. **References:** [1]S. Neyt et al., J. Nucl. Med., vol. 54, no 4, p. 624630, 2013. [2]I. Hernández Lozano et al., AAPS J., vol. 21, no 4, 2019.

Aim/Introduction: Surface-modified nanoparticles (NP) including nanodiamonds (ND), mesoporous silica (MSN) and superparamagnetic iron oxide nanoparticles (SPION) are of growing interest for medical applications. The different NP-

structures facilitate the potential use for high-resolution/high-sensitivity in vivo imaging (ND), for drug delivery (MSN) and as contrast agent (SPION). The assessment of biodistribution and accumulation in organs and target regions of those particles is crucial for their evaluation as medical compound. Using the HET-CAM (Hen's Egg Test - Chorioallantoic Membrane) model allows the reduction of usually necessary animal experiments in accordance with the 3Rs principles (reduction, refinement, replacement). Combined PET and MRI was used for evaluation of NPs in the HET-CAM model. **Materials and Methods:** NDs (microdiamond, IOM Leipzig) coated with PEGylated HSA and p-SCN-Bn-deferoxamine (DFO, Macrocylics), SPION modified using polyethylenimine and MSN surface-modified with a fragment of CD47 and DFO were used. All particles were radiolabelled with ^{89}Zr . Labelling stability was monitored by thin-layer chromatography in sodium chloride (0.9%), cell culture medium and human serum over a 5 days period. Tumour xenografts of cell lines LNCaP C4-2, PC-3, HeLa, TZM-bl and AR42J were established. After intravenous injection of NPs, MRI data was acquired with an 11.7T small animal system (BioSpec117/16, Bruker) followed by PET measurements (Focus120, Siemens Medical Solutions, Inc.). Studies were performed between embryo development day 12 and 16. For quantification of radioactivity accumulation in xenografts, tumours were analysed in a gamma counter (Cobra II, Perkin Elmer). **Results:** An ^{89}Zr -labelling efficiency of at least 76% was obtained for all particles. Labelling stability was validated in human serum over a period of 5d, ranging from 77% (SPION) to 93% (MSN). However, SPIONs indicated instability in human serum at day 2 (35%). MSN and ND biodistribution was measured in eggs using PET and MRI. By superimposing the images, particle accumulation was assigned to the heart and liver area. Similar results were obtained for SPIONs in T1 weighted images. Signal intensity ratios (SIR, muscle/liver) of 2.7 ± 0.2 before and 10.2 ± 1.2 (0h) to 9.6 ± 3.7 (4h) after injection, indicate a particle accumulation in the liver region. **Conclusion:** The HET-CAM model was successfully used to assess the biodistribution of different radiolabelled NPs by high-resolution MRI and highly sensitive PET imaging in ovo. Analysed NPs predominantly accumulated in organs of the reticuloendothelial system. Information on the biodistribution of nanoparticles can be obtained in ovo at early stages of drug development, thus reducing the number of animal experiments required. **References:** None

EP-258

The 5-HT_{2A} receptor antagonist altanserin affects motor activity and hippocampal D₂ receptor binding in the rat

S. Nikolaus¹, H. Wittsack¹, M. Beu¹, C. Antke¹, H. Hautze², Y. Mori¹, E. Mamlins¹, G. Antoch¹, H. Müller¹;

¹University Hospital Düsseldorf, Düsseldorf, GERMANY,

²University Hospital Essen, Essen, GERMANY.

Aim/Introduction: 5-HTergic projections run from the raphe nucleus to dopaminergic (DA) cells in substantia nigra/ventral tegmental area and to their terminal fields in nucleus accumbens, caudateputamen and prefrontal cortex. Altanserin (ALT) acts as a 5-HT_{2A} receptor (R) antagonist. In the present study, we assessed the effect of ALT on motor and exploratory behavior and on cerebral D₂R binding in the same rats with the method of small animal SPECT. **Materials and Methods:** In 21 male Wistar rats, D₂R binding was measured after injection of ALT (10 mg/kg ip) as well as vehicle (VEH; dimethylsulfoxide, 0.5 ml/kg ip). After injection of ALT, motor/exploratory behavior was registered for 45 min in an open field using EthoVisionXT. In 20 further rats, D₂R binding and behavior were assessed after pre-treatment with VEH. Iodine-123-IBZM ($29\pm 3\text{MBq}$ iv) was injected 45 min post-challenge. Imaging data were acquired at 90 min post-challenge with the TierSPECT. Furthermore, rats were scanned with a dedicated small animal MRI (MRS3000 Pre-clinical MRI, 3.0 T, MR Solutions, Guildford, UK). Based on the Paxinos rat brain atlas, regions of interest were defined on SPECT-MRI overlays. Binding potentials (BPs) were computed for ALT and VEH in various regions (nucleus accumbens, caudateputamen, substantia nigra, thalamus, frontal, motor and parietal cortex, anterior and posterior hippocampus), for which the presence of D₂Rs has been confirmed (1). **Results:** After ALT, the BP in the posterior hippocampus was increased relative to VEH ($p=0.03$). No other regional differences were observed between treatments. However, ALT reduced ambulation (min 1-35), rearing (min 6-40), head-shoulder-motility (min 6-45) and grooming (min 6-45) relative to VEH ($0.001\leq p\leq 0.050$). **Conclusion:** The 5-HT_{2A}R antagonist ALT reduced motor/exploratory behavior, whereas nigrostriatal and neocortical D₂R binding was unaltered relative to VEH. However, an increase of D₂R binding was observed in the posterior hippocampus, which may reflect a reduction of DA availability in this region. **References:** (1) Bouthenet et al., Neuroscience. 1987;20:117-55.

EP-259**Different effects of the 5-HT_{2A} receptor agonist DOI and the 5-HT_{2A} receptor antagonist altanserin on D₂ receptor binding in the rat brain**

S. Nikolaus¹, H. Wittsack¹, M. Beu¹, C. Antke¹, H. Hautzel², Y. Mori¹, E. Mamlins¹, G. Antoch¹, H. Müller¹;

¹University Hospital Düsseldorf, Düsseldorf, GERMANY,

²University Hospital Essen, Essen, GERMANY.

Aim/Introduction: The serotonin 5-HT_{2A} receptor (R) is known to modulate the release of dopamine (DA) in the mammalian brain (1). 2,5-Dimethoxy-4-iodoamphetamine (DOI) and altanserin (ALT) act as 5-HT_{2A}R agonist and antagonist, respectively. In the present study, we assessed the effects of DOI and ALT on D₂R binding in the rat brain with the method of small animal SPECT. **Materials and Methods:** In 19 male Wistar rats, D₂R binding was measured after injection of DOI (0.5 mg/kg ip) as well as vehicle (VEH; 0.9% NaCl, 0.5 ml/kg ip). In 21 further rats, D₂R binding was measured after treatment with ALT (10 mg/kg ip) and the respective VEH dimethylsulfoxide (0.5 ml/kg ip). Iodine-123-IBZM (30±3MBq iv) was administered 30 min after injection of DOI and 45 min after injection of ALT. Imaging data were acquired with the TierSPECT starting at 74 and 90 min post-challenge, respectively. Additionally, all rats were scanned with a dedicated small animal MRI (MRS3000 Pre-clinical MRI, 3.0 T, MR Solutions, Guildford, UK). Based on the Paxinos rat brain atlas, regions of interest were defined on SPECT-MRI overlays. Binding potentials (BPs) were computed for each treatment in various regions (nucleus accumbens, caudateputamen, substantia nigra, thalamus, frontal, motor and parietal cortex, anterior and posterior hippocampus), for which the presence of D₂Rs has been confirmed. **Results:** DOI increased BPs in caudateputamen (p=.018), frontal cortex (p≤.001), motor cortex (p≤.001) and posterior hippocampus (p=.020) relative to VEH, while ALT increased the BP in the posterior hippocampus relative to VEH (p=.03). **Conclusion:** The 5-HT_{2A}R agonist DOI increased D₂R binding in caudateputamen, frontal cortex, motor cortex and posterior hippocampus. The 5-HT_{2A} antagonist ALT merely increased D₂R binding in the posterior hippocampus. The observed elevations of D₂R binding may be conceived to reflect reductions of synaptic DA in these regions. Previous microdialysis studies have reported that both 5-HT_{2A}R agonists and antagonists increase DA efflux (1). It may be hypothesized that the regional reductions of DA in the present study were due to D₂ autoreceptor activation in response to initially increased DA levels, incurring compensatory decreases of DA efflux in the caudateputamen and in the cortical and limbic target regions of DAergic projections. **References:** (1) Di Matteo et al. Prog Brain Res 2008; 172:7–44

EP-260**[⁸⁹Zr]-labeled mesenchymal stem cells biodistribution in rats with local radiation injuries**

O. Klementyeva, K. Luneva, A. Larenkov, V. Bubenschikov, T. Astrelina, V. Brunchukov;

Federal Medical Biological Agency, Federal State Budget Institution, State Research Center "Burnasyan", Moscow, RUSSIAN FEDERATION.

Aim/Introduction: The aim of this work: study of biodistribution of mesenchymal stem cells (MSC) labeled [⁸⁹Zr]Zr-oxine in animals at different times after the local irradiation. The local radiation injuries are one of the serious complications of external beam radiation therapy. There is no possible to integrate cellular technologies in the radiation burns treatment without information about the stem cells migration pathways in the body. PET imaging with [⁸⁹Zr]-labeled stem cells is the most informative method for preclinical studies and clinical applications. **Materials and Methods:** [⁸⁹Zr]Zr-oxine complex had been synthesized from [⁸⁹Zr]Zr-oxalate (Cyclotron Co., Ltd, Obninsk, Russia). Radiochemical purity (RCP) was tested using ITLC. [⁸⁹Zr]⁸⁹Zr-oxine with RCP not less 95% was used for labeling MSC. All animal experiments were performed based on the Russian Animal Protection laws and guidelines for scientific animal trials. Local irradiation of Wistar rats (male) was carried out using X-ray with dose of 110 Gy (dose rate of 21.4 Gy/min). This led to acute radiation skin damage (RSD). The biodistribution of [⁸⁹Zr]⁸⁹Zr-oxine-labeled MSC was studied in latent and acute phase of RSD (1 and 14 days after irradiation). [⁸⁹Zr]⁸⁹Zr-oxine-labeled MSC (0.4-10⁶ cells, 37.2-52.8 kBq) were transferred to rats by intradermal injection in irradiation area. Rats (5 ones per time point) were killed in 3h, 24h and 48h after injection. Each sample (blood, lungs, liver, spleen, kidneys, femur, RSD site, intact skin) was counted with a γ-counter to obtain percentage of the injected dose (% ID/g) and differential uptake ratio (DUR) in locus of RSD to intact skin. **Results:** The MSC labeling efficiency was about 60%. In the latent phase [⁸⁹Zr]Zr-oxine-MSC uptake at the RSD site decreased from 82% ID (3h p.i.) to 52% ID (48h p.i.). DUR values ranged from 66 (3h p.i.) to 151 (48h p.i.). In the acute phase [⁸⁹Zr]Zr-oxine-MSCs were linked firmly at the RSD site. Uptake levels up to 48 hours after injection were 70-90% ID. There were DUR values: 333.4 (3h p.i.), 768.5 (24h p.i.) and 344.8 (48h p.i.). It's fact suggests about inflammatory response development in the RSD site promotes retention of MSCs. MSCs migration to the liver was observed (up to 2.8% ID 48h p.i.). There was minimal ⁸⁹Zr uptake in the bone tissue for 48 hours after injection (less 0.4% ID/g). **Conclusion:** Local injection of [⁸⁹Zr]Zr-oxine labeled MSCs will allow using PET imaging of the radiation lesion focus at the earliest possible time after irradiation. **References:** None

EP-261**Time after synthesis does not affect 4FMFES biodistribution and PET imaging**

M. Paquette, S. Phoenix, B. Guérin, É. E. Turcotte;
Université de Sherbrooke, Sherbrooke, QC, CANADA.

Aim/Introduction: The Estrogen Receptor (ER)-targeting molecule 4-fluoro-11 β -methoxy-16 α -[18F]fluoroestradiol (4FMFES) is currently under investigation in combination with FDG-PET for the diagnosis of breast and uterine cancer patients in 2 separate phase 2 clinical trials. Its post-synthesis shelf-life was previously set to 2 hours, which limits the number of patients imaged per production and hinders its distribution to peripheral sites. In order to extend its shelf-life, we sought to demonstrate that 4FMFES does not lose its imaging properties and does not change its biodistribution even after many half-lives have passed.

Materials and Methods: Athymic female nude mice were implanted with the human ER+ breast cancer cell line MCF7, and tumors were grown up to 3–4 mm diameter. Cohorts of mice (n = 4 each) were injected with 4FMFES at 1 hour (100 kBq and 10 MBq), 3 hours (100 kBq), 6 hours (100kBq) and 20 hours (10 kBq) post-synthesis, then dissected to assess biodistribution. Other groups (n = 4 each) were injected with 1.2 \pm 0.3 MBq 4FMFES at 1-, 3- and 6- hours post-synthesis, then imaged for 15 minutes at 60 minutes post-injection in a small animal PET scanner. ROIs were drawn on the tumor, the pituitary, muscle and liver, and %ID/g were extrapolated. In parallel, product stability was tested by radio HPLC at the same post-synthesis time points. **Results:** Tumor uptake did not vary according to the time post-synthesis or the injected dose, as assessed by both biodistribution and PET. Other specific ER+ organs (uterus and ovary by dissection, pituitary by PET) had slight uptake fluctuations through the post-synthesis time points but were non-significant. Non-specific tissues, such as blood pool, muscle and liver yielded consistent uptake regardless of the time after synthesis, and as such tumor-to-muscle ratio was also unaffected. PET image looked of equal quality irrespective of the post-synthesis time. Radio-HPLC analysis of the compound at different time did not reveal any sign of degradation. The injection of 10 kBq at 20 hours post-synthesis yielded a normal biodistribution and tumor uptake, despite the large excess of decayed by-products which are likely to have low or nonexistent affinity for ER. **Conclusion:** 4FMFES can generate optimal PET images up to at least 6 hours after radiosynthesis. This breakthrough will increase the clinical throughput per synthesis, decrease the cost per scan and allow loco-regional distribution of the tracer. **References:** None

EP-262**Isotonic saline and dimethylsulfoxide differentially affect motor behavior and nigrostriatal and mesolimbic D2 receptor binding in the rat**

S. Nikolaus¹, H. Wittsack¹, M. Beu¹, C. Antke¹, H. Hautzel², Y. Mori¹, E. Mamlins¹, G. Antoch¹, H. Müller¹;

¹University Hospital Düsseldorf, Düsseldorf, GERMANY,

²University Hospital Essen, Essen, GERMANY.

Aim/Introduction: In scientific investigations, including behavioral and in vivo imaging studies on small laboratory animals, treatment effects are generally related to a “baseline”, which is either the state before or after the pharmacological intervention, or the state induced by the administration of the “vehicle”. In the present study, D2 receptor (R) binding was determined with small animal SPECT with no precedent treatment (BAS) and after challenge with isotonic saline (SAL) and dimethylsulfoxide (DMSO). **Materials and Methods:** In 51 male Wistar rats, D2R binding was measured either in BAS or after injection of SAL (0.9%, 1 ml/kg i.p.) or DMSO (100%, 0.5 mg/kg ip). Motor activity (travelled distance) was analyzed for 30 min after SAL and DMSO with EthoVisionXT. Subsequent to behavioral tests, rats were injected Iodine-123-IBZM (30 \pm 5MBq iv). Imaging data were acquired with the TierSPECT starting at 74 min post-challenge. Additionally, all rats were scanned with a dedicated small animal MRI (MRS3000 Pre-clinical MRI, 3.0 T, MR Solutions, Guildford, UK). Based on the Paxinos rat brain atlas, regions of interest were defined on SPECT-MRI overlays. Binding potentials (BPs) were computed for each condition in various regions (nucleus accumbens, caudateputamen, substantia nigra, thalamus, frontal, motor and parietal cortex, anterior and posterior hippocampus), for which the presence of D₂Rs has been confirmed. **Results:** After SAL, BPs were decreased in nucleus accumbens (p=0.011), caudateputamen (p=0.005) and thalamus (p=0.031) relative to BAS and decreased in nucleus accumbens (p=0.028) and caudateputamen (p=0.028) relative to DMSO. After DMSO, the BP was diminished relative to BAS in the posterior hippocampus (p=0.016). The distance travelled in the open field was increased after SAL relative to DMSO (p \leq 0.0001). **Conclusion:** Findings show that vehicles may differentially affect motor activity and D2R binding in relevant regions of the nigrostriatal and mesolimbic system. This must be considered after treatment with substances dissolved in SAL as well as when comparing substances dissolved in different vehicles. **References:** None

Microglial activation in the right amygdala-entorhinal-hippocampal complex is associated with improved spatial learning in App^{NL-G-F} mice

G. Biechele¹, K. Wind¹, T. Blume², C. Sacher¹, L. Beyer¹, F. Eckenweber¹, S. Lindner¹, F. Gildehaus¹, B. von Ungern-Sternberg¹, S. Tahirovic², M. Willem³, C. Haass², P. Bartenstein¹, P. Cumming⁴, A. Rominger⁴, J. Herms¹, M. Brendel¹;

¹University Hospital of Munich, Munich, GERMANY, ²DZNE Munich, Munich, GERMANY, ³Biomedical Center LMU Munich, Munich, GERMANY, ⁴Inselhospital Bern, Bern, SWITZERLAND.

Aim/Introduction: Asymmetries of neuropathology, including β -amyloid burden and microglial activation, in patients of Alzheimer's disease (AD) are a well-known phenomenon. Recently we described a high frequency of asymmetric plaque burden and microglial activation in amyloid mouse models of AD as assessed by positron-emission-tomography (PET). Though yet, it has not been investigated, if there is a correlation between asymmetry of neuropathology and spatial learning performance in β -amyloid mouse models. **Materials and Methods:** Cross-sectional 18 kDa translocator protein (TSPO-PET, ¹⁸F-GE-180) and β -amyloid-PET (¹⁸F-florbetaben) scans of 30 App^{NL-G-F} mice (15 female, 15 male) were acquired at 10.3±0.6 months of age. Spatial learning was assessed by Morris water maze within two weeks before or after PET scanning. PET and spatial learning results were correlated by voxel-wise and bilateral region-based (frontal cortex, entorhinal/piriform cortex, amygdala and hippocampus) analyses. Control data was obtained from 18 age- and sex-matched C57Bl/6 wild-type mice. Spatial learning results were compared between App^{NL-G-F} mice with left and right lateralization of PET quantification. **Results:** App^{NL-G-F} mice revealed association clusters of improved spatial learning performance with higher TSPO-PET signals in the amygdala, entorhinal and piriform cortices, the hippocampus and the hypothalamus. Region based quantification indicated significant correlations between TSPO expression and spatial learning in the right entorhinal/piriform cortex (escape latency: $R = -0.441$, $p = 0.017$; frequency: $R = 0.529$, $p = 0.003$) and the right amygdala (frequency: $R = 0.377$, $p = 0.044$), whereas associations in the left hemisphere did not reach significance. β -amyloid-PET showed no relevant associations with spatial learning. App^{NL-G-F} mice with right lateralized TSPO expression in the amygdala showed improved performance in Morris water maze when

compared to mice with left lateralization, independently of absolute bilateral TSPO expression and amyloidosis (escape latency: 9.1 [0.6 - 17.6] vs. 22.4 [17.2 - 27.5] seconds, $F_{(1,25)} = 7.470$, $p = 0.011$; platform frequency: 4.4 [3.3 - 5.5] vs. 2.8 [2.2 - 3.5] seconds, $F_{(1,25)} = 6.503$, $p = 0.017$). **Conclusion:** Microglial activation in the right amygdala-entorhinal-hippocampal complex of App^{NL-G-F} mice is associated with improved spatial learning. Our findings provide new insights into the lateralized nature of hemispheric predominance of neuropathology and its consequences for cognitive function. **References:** None

EP-264

The heterogeneous effect of chronic hyperglycaemia on brain 18F-FDG uptake: an experimental study

A. Miceli¹, M. Donegani¹, S. Raffa¹, S. Marra¹, V. Cossu¹, L. Emionite¹, S. Morbelli¹, C. Marini², G. Sambucetti¹, M. Bauckneht³; ¹DISSAL, Genoa, ITALY, ²CNR Institute of Molecular Bioimaging and Physiology (IBFM), Milan, ITALY, ³IRCCS Ospedale Policlinico San Martino, Genoa, ITALY.

Aim/Introduction: Hyperglycaemia severely influences the quality of 18F-FDG PET images due to a competitive mechanism lowering brain metabolic signal. It's debated if this reduction is regional rather than uniform and if it can reduce the accuracy of reporting when evaluating neurodegenerative diseases. Indeed, previous studies showed that hyperglycaemia lowers 18F-FDG uptake preferentially in the posterior cortical areas, thus mimicking an Alzheimer-like (AD) pattern. However, other authors suggested that the regional hyperglycemia effect is negligible and mostly dependent on the images normalization method. The present experimental study aims to evaluate if chronic hyperglycaemia can produce different metabolic effects according to the brain region. **Materials and Methods:** 40 mice were enrolled (23 with streptozotocin-induced type-I diabetes -STZ- and 17 healthy controls) and submitted to a dynamic 18F-FDG PET scan lasting 50 minutes. Induced diabetes was tested using the OGTT curve in STZ mice. The serum glycaemic level was tested few minutes before the scan in each animal. Image analysis was performed employing PMOD application. Three different volumes of interest (VOI) were manually placed, named whole brain (WB), anterior cortex (ANT), and posterior cortex (POST), respectively. SUV_{avg} and $mrGLU_{avg}$ data were extracted. The ratio between anterior cortex to the whole brain (A/WB), posterior cortex to the whole brain (P/WB), and posterior to the anterior cortex (P/A) were also calculated to normalize obtained results. **Results:** While OGTT curve confirmed diabetes in all STZ mice, the serum glycaemic level at the time of imaging was 105±37 and 88.7±27.2 mg/dl in STZ and controls, respectively ($p=ns$). WB- $mrGLU_{avg}$ was significantly reduced in the STZ group compared to controls ($p<0.01$). Moreover,

when compared to healthy mice, the A/WB mrGLU_{avg} was higher in the STZ group ($p < 0.01$), while P/WB and the P/A ratio were considerably lower ($p < 0.001$). Similarly, while WB-SUV_{avg} was only slightly lower in STZ ($p = \text{ns}$ vs. controls), A/WB-SUV_{avg} was significantly higher in this subgroup ($p < 0.01$ vs. controls). In contrast, P/WB and P/A SUV_{avg} were significantly lower ($p < 0.01$ vs. controls). **Conclusion:** Chronic hyperglycaemia, rather than pre-injection episodic hyperglycaemia, heterogeneously affects brain regional FDG uptake. In particular, it selectively lowers the posterior cortical metabolic activity. The difference in the local brain cytoarchitecture may cause an impact on the expression of glucose transporters and hexokinase activity, thus determining a regional variation in the lumped constant. This phenomenon may, ultimately, affect the accuracy of reporting when ¹⁸F-FDG PET is performed in humans for suspected neurodegenerative diseases. **References:** None

EP-265

Metabolic changes in an animal model of Amyotrophic Lateral Sclerosis by [¹⁸F]-Fluorodeoxyglucose

B. Giacobbo, T. Mediavilla, J. Axelsson, M. Ericsson, D. Marcellino, F. Sultan;
Umeå University, Umeå, SWEDEN.

Aim/Introduction: Amyotrophic Lateral Sclerosis (ALS) is a fatal neurodegenerative disorder that affects motor neurons, leading to muscle atrophy, paralysis, and eventually respiratory failure. As with many other neurodegenerative disorders, neuronal apoptosis is often associated with a loss of neuronal function and metabolic changes. [¹⁸F]-FDG is a well-validated biomarker to observe metabolic changes in several brain disorders in humans, but its use in preclinical ALS research is not yet widespread. We aim to compare [¹⁸F]-FDG uptake in SOD1^{G93A} and wild-type before the development of terminal ALS symptoms. **Materials and Methods:** animals (6 SOD1^{WT}, 7 SOD1^{G93A}) were previously genotyped for mutant SOD1 using qPCR. When SOD1^{G93A} animals started to develop ALS-like symptoms, animals were fasted for 4 hours and then injected intravenously with [¹⁸F]-FDG (injected dose of 10.8 ± 2 MBq). One hour after injection, animals were placed in a microPET-CT scanner (Mediso nanoPET-CT) and scanned (5 minutes for CT, 10 minutes for PET). CT data was used for attenuation correction. After reconstruction, data were coregistered to an MRI template and brain VOIs were created for several regions and divided between left and right hemispheres using the Allen mouse brain atlas as a VOI template and the uptake of each ROI was calculated to the whole-brain (SUVr) with T-test. $P < 0.05$ was used for statistical significance. **Results:** Our SUVr data suggest a significant metabolic deregulation in SOD1^{G93A} animals when analyzing [¹⁸F]-FDG in the brain. There was significant hypometabolism in anterior cingulate cortex (9% decrease in SOD1^{G93A} vs. SOD1^{WT} for both left

and right hemispheres), in left entorhinal cortex (14% decrease), left hippocampus (12% decrease), right nose-associated primary somatosensory cortex (6% decrease), left supplementary somatosensory cortex (8% decrease), thalamus (11% and 8% for left and right, respectively), and right vermal region of the cerebellum (9% decrease). Hypermetabolism was, on the other hand, found in pallidum (12% increase in SOD1^{G93A} vs. SOD1^{WT}), lateral amygdala (41% and 64% increase in left and right, respectively), and cortical amygdala (98% increase for both left and right). **Conclusion:** These preliminary findings suggest a significant metabolic deregulation in animals with mutant SOD1 that develop ALS disease. Since animals were scanned after developing ALS symptoms, further studies aimed to study brain metabolism with [¹⁸F]-FDG in prodromal stages of disease are warranted. This would provide us better insight into the usefulness of metabolic radiotracers for the detection of disease onset and progression, as well as the efficacy of therapeutic treatment strategies. **References:** None

Quercetin as a potential psychotherapeutic agent in a mouse model with acute exposure to cocaine: a preclinical PET study

F. Ribeiro¹, C. Nicolucci², M. Lapo Pais^{3,4,5}, A. C. Santos^{4,5,6}, P. M. C. C. Encarnação¹, A. L. M. Silva^{1,7}, I. F. Castro⁷, P. M. M. Correia^{1,7}, V. I. Assunção¹, J. F. C. A. Veloso¹, D. G. Priolli²;

¹Institute for Nanostructures, Nanomedelling and Nanofabrication (i3N), University of Aveiro, Aveiro, PORTUGAL,

²Multidisciplinary Research Laboratory, São Francisco University, Bragança Paulista, BRAZIL, ³Faculty of Sciences and Technology, University of Coimbra, Coimbra, PORTUGAL,

⁴Institute for Clinical and Biomedical Research (iCBR), Center for Innovative Biomedicine and Biotechnology (CIBB), Coimbra, PORTUGAL, ⁵Institute of Biophysics, University of Coimbra, Coimbra, PORTUGAL, ⁶Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, ⁷Radiation Imaging Technologies Lda (RI-TE), Ílhavo, PORTUGAL.

Aim/Introduction: The use of cocaine is increasing worldwide and currently represents one of the most frequent indications for drug treatment. Although cocaine chronic addiction shows neurovascular complications associated with high morbidity and mortality rates, its recreational use, leading to addicted consumption, is often neglected. In the absence of a specific treatment for addiction, there is an urgent need to develop therapeutic alternatives, having also a brain-protective effect from injuries caused by cocaine abuse. Flavonoids are pharmacological bases of drugs used to treat drug addiction, having antioxidant, neuroprotective, neurovascular, GABAergic and benzodiazepine properties. Quercetin, a flavonoid found in fruits and vegetables, has unique biological properties that can improve mental/physical performance and reduce infection risk, also acting

as an important antioxidant, a blocker of neuronal toxicity and neurovascular changes¹. This work aims to assess the functional activity of quercetin as a protective psychotropic drug, in animals exposed to a single and low dose of cocaine.

Materials and Methods: A total of 48 male Balb/c (6 weeks) mice were randomly divided into 4 groups according to the administration of Saline (0.9%), Cocaine (0.5mg/kg), Quercetin (50mg/kg) or Cocaine followed by Quercetin (referred dosages). Behaviour tests (Open Field Maze) were performed for functional analysis. Mice underwent ¹⁸F-FDG PET imaging using the easyPET.3D scanner (RI-TE Lda, Portugal²) to assess brain glucose metabolic activity according to the stimuli. Anatomopathological studies were performed to ascertain morphological brain changes.

Results: Mice receiving quercetin or cocaine revealed similar global behaviour, while the ones receiving quercetin after exposure to cocaine showed similar behaviour to controls, in tests which identify the level of anxiety or avoidance. The easyPET.3D images revealed a higher ¹⁸F-FDG uptake mainly in the striatum for the quercetin or cocaine groups, while the cocaine group associated with quercetin was similar to controls. The hippocampus region and prefrontal cortex of animals exposed to cocaine presented morphological changes, which were minimized when quercetin was administered immediately after cocaine. For the first time, it has been demonstrated that cocaine, even in single and low doses, has the potential to induce structural neurological damage^{3,4}. **Conclusion:** In vivo ¹⁸F-FDG PET imaging proved to be a crucial tool to measure the brain metabolic activity resulting from the stimuli to which mice were exposed. Quercetin proved to be a neuropsychoprotective agent against this exposure. Cocaine changes, both in behaviour and brain structure, must be considered regardless of the used dosage. **References:** 1.doi:10.2174/1871527317666171221110139 2.WO2016147130(PCT/IB2016/051487), www.ri-te.pt 3.doi:10.1038/npp.2017.109 4.doi:10.3389/fpsy.2017.00218

Preliminary Evaluation of (S)-7-[¹⁸F]Fluorotryptophan as a Tracer for the Imaging of Serotonin Synthesis in Pig Brain

V. Shalgunov^{1,2}, N. R. Rava³, L. L. Donovan³, A. Nasser³, B. D. Zlatopolskiy⁴, B. Neumaier⁴, G. M. Knudsen³, M. M. Herth^{1,2}; ¹Department of Drug Design and Pharmacology, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, DENMARK, ²Department of Clinical Physiology, Nuclear Medicine & PET, Copenhagen University Hospital, Rigshospitalet, Copenhagen, DENMARK, ³Neurobiology Research Unit and CIMBI, Rigshospitalet and University of Copenhagen, Copenhagen, DENMARK, ⁴Institute of Neuroscience and Medicine, Forschungszentrum Jülich, Jülich, GERMANY.

Aim/Introduction: Tryptophan is an essential amino acid of key importance for brain function. It is a precursor of the

neurotransmitter serotonin. ¹¹C-labeled tryptophan analogs (e.g. [¹¹C]AMT and [¹¹C]HTP) have been used to measure serotonin synthesis by positron emission tomography (PET) both clinically and preclinically [1]. However, complicated synthesis procedures and short half-life of carbon-11 limit the potential scale of application for these tracers. Recently, (S)-7-[¹⁸F]-fluorotryptophan (7-[¹⁸F]FTrp), a tracer labeled with a longer-lived fluorine-18 and prepared via a simple ¹⁸F-fluorination-deprotection scheme, was reported. In rats, 7-[¹⁸F]FTrp showed good brain penetration and accumulated in the raphe nuclei - known area of serotonin production [2]. We assessed the brain uptake of 7-[¹⁸F]FTrp in pigs and investigated if fenfluramine, a drug that depletes neurons of serotonin, could increase 7-[¹⁸F]FTrp binding in the raphe nuclei. Serotonin transporter tracer [¹¹C]DASB was used to locate the raphe nuclei, which have high densities of the serotonin transporter. **Materials and Methods:** 7-[¹⁸F]FTrp was prepared as described in [2] with slight modifications. [¹¹C]DASB was prepared as described in [3]. Anesthetised pigs (~20 kg body weight) received bolus injections of either [¹¹C]DASB (478 MBq, 1.06 nmol, N=1) or 7-[¹⁸F]FTrp (194-486 MBq, 1.17-2.7 nmol, N=2). The pigs were subsequently PET-scanned for either 120 min ([¹¹C]DASB) or 180 min (7-[¹⁸F]FTrp). Uptake of 7-[¹⁸F]FTrp in the brain was investigated at baseline and after a within-scan challenge with fenfluramine (0.5 mg/kg, given intravenously 60 min after tracer injection). Arterial blood samples were analyzed for radioactivity and radiometabolites to obtain an input curve. **Results:** Preparation of 7-[¹⁸F]FTrp lasted 100-110 min, producing 7-[¹⁸F]FTrp in RCY of 30-40% from dried [¹⁸F]fluoride with molar activity of 70-425 GBq/μmol at end of synthesis. In the porcine brain, 7-[¹⁸F]FTrp accumulated in the raphe nuclei (to SUV 0.8-0.9). Fenfluramine injection did not influence 7-[¹⁸F]FTrp uptake in the raphe nuclei. **Conclusion:** 7-[¹⁸F]FTrp penetrates the porcine blood-brain barrier and accumulates in the raphe nuclei where serotonin synthesis is known to take place. However, treatment with fenfluramine had no discernible effect on 7-[¹⁸F]FTrp uptake in that region. In order to conclusively demonstrate that 7-[¹⁸F]FTrp uptake in the raphe nuclei reflects serotonin synthesis rate, other methods to manipulate serotonin synthesis are being tested. **Acknowledgements:** This work was supported in part by DFG (grant: ZL 65/3-1). **References:** 1. Social stress-dependent changes on behavior and inflammatory parameters in animals with HPA-axis disruption

B. Giacobbo¹, R. Moraga-Amaro², L. Reali Nazario², A. Schildt², R. A. J. O. Dierckx², J. Doorduyn², E. F. J. de Vries²;

¹Umeå University, Umeå, SWEDEN, ²University Medical

Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Chronic stress is associated with a deregulation of the hypothalamus-pituitary adrenal (HPA) axis and can result in behavioral abnormalities, such as depressive behavior. Adrenalectomy (ADX) inhibits the production and release of corticosterone, impairing the response towards stressors, and thus may prevent stress-induced depressive behavior. We aim to determine behavioral and neuroinflammatory effects of HPA-axis disruption via bilateral adrenalectomy (ADX) in animals submitted to repeated social defeat (RSD). **Materials and Methods:** 8-weeks old male Wistar rats were divided into four groups: ADX+RSD; ADX+Control; Sham+RSD; Sham+Control. Seven days after ADX surgery, animals were submitted to a 5 days RSD or Control protocols. One- and two days after the last RSD trial, animals went through an open field and social interaction test, respectively. 14 days after RSD, animals went through a 30 minutes [^{11}C]-PBR28 scan for microglia activation. Multifactorial ANOVA was performed for statistical assessment. **Results:** There was a significant effect of RSD ($p=0.038$) and ADX ($p=0.049$) on the social interaction of the animals, as well as an interaction between surgery and RSD ($p=0.042$). Post-hoc analysis showed a significantly lower social interaction of Sham+RSD when compared with the other groups (vs. Control+ADX, $p=0.032$; Control+Sham, $p=0.023$; ADX+RSD, $p=0.035$). Open field analysis showed no anxiety-like behavior nor locomotion effect of RSD or ADX ($p>0.05$). Microglial activation assessed through [^{11}C]-PBR28 also showed no effect of RSD or ADX ($p>0.05$). **Conclusion:** HPA-axis signaling disruption is able to counterbalance the impairment on the social behavior of these animals. In contrast, no effects of ADX or RSD were observed in other behavioral paradigms. Neuroinflammation was also not observed two weeks after the RSD, suggesting that the inflammatory response of microglial cells is too mild to be detected by PET or that neuroinflammation was only transient and already resolved at the time of measurement. **References:** None

EP-269

A Single Day of Accelerated rTMS Causes No Cerebral Glucose Metabolism Change Assessed by FDG-PET in Beagle Dogs

Y. Xu¹, R. Dockx¹, B. J. G. Broeckx², A. Dobbeleir³, K. Peremans³, J. H. Saunders³, C. Baeken¹;

¹Department of Psychiatry and Medical Psychology, Faculty of medicine and health sciences, Ghent University, Ghent, BELGIUM, ²Department of Nutrition, Genetics and Ethology, Faculty of veterinary medicine, Ghent University, Merelbeke, BELGIUM, ³Department of Veterinary Medical Imaging and Small Animal Orthopedics, Faculty of veterinary medicine, Ghent University, Merelbeke, BELGIUM.

Aim/Introduction: Repetitive transcranial magnetic stimulation (rTMS) is an FDA-approved technique for major depressive disorders (MDD), but the underlying neurobiological mechanisms of action are not yet unraveled, and the stimulation parameters need to be optimized. According to our previous research, rTMS applied to the left frontal cortex alters regional cerebral perfusion in dogs using HMPAO-SPECT; more, the serotonin transporter (SERT) binding indices alterations in different brain regions were reported with [^{11}C]DASB-PET. Similar changes have been observed in humans. This strengthens the idea that further functional imaging techniques in dogs could be used to investigate the neurobiological mechanism and refine the rTMS treatment parameters and efficacy. This study aims to investigate the effect of one-day rTMS on cerebral glucose metabolism by FDG-PET in healthy beagle dogs. **Materials and Methods:** Twelve beagle dogs were randomly divided into two unequal groups: five active high frequency (HF) rTMS (20Hz) sessions ($n=8$) and five sham sessions ($n=4$). The protocol for each dog is: an anatomical magnetic resonance imaging (MRI) scan and neuronavigation were conducted to locate the left frontal cortex; FDG-PET scan was applied before and 24-hour, 1-month and 3-month after the rTMS treatment; A linear mixed model and a likelihood ratio test were used to evaluate significance of the interaction. **Results:** No significant differences in glucose metabolism between active and sham accelerated HF rTMS were noted for just after the stimulations (24h), nor for the stimulated area, the left frontal cortex, or other brain regions compared to the baseline. And no long-term metabolic change was noticed in both active and sham group. **Conclusion:** Though the single day of accelerated HF rTMS study did not show a significant cerebral glucose metabolism change in beagle dogs, probably due to the limited rTMS sessions and the relatively small sample size, additional accelerated HF rTMS days should be added to evaluate the effects of accelerated HF-rTMS treatment in beagles. **References:** None

Technology, Chiba, JAPAN, ²Nihon Medi-Physics Co., Ltd., Tokyo, JAPAN, ³National Cancer Center Hospital East, Kashiwa, JAPAN.

Aim/Introduction: Pancreatic cancer (PC) has one of the poorest prognoses among all types of cancer. Surgery is the standard treatment for patients with resectable PC. However, positive resection margins were often found after surgery, which is associated with increased local recurrence and decreased survival in PC patients. Therefore, development of methods to observe spread of PC lesion within the pancreas under surgery is quite significant. We have developed a novel open-typed positron emission tomography (PET) system (called “OpenPET”), which enables high-resolution PET-guided surgery in real time. Our previous study has also demonstrated that the OpenPET-guided surgery with ip-administered ⁶⁴Cu-labeled anti-epidermal growth factor receptor (EGFR) antibody cetuximab was useful to detect and resect PC in a small (less than 1 cm) resectable PC orthotopic xenograft mouse model (Yoshii et al. Scientific Reports 2020). In the present study, we further investigated usefulness of the OpenPET-guided surgery for intraoperative detection and resection of residual tumors using a locally advanced PC (over 1 cm) orthotopic xenograft mouse model. **Materials and Methods:** To make the model, the cell suspension of human PC xPA cells stably expressing red fluorescent protein (xPA-RFP) (5×10^6) with an extracellular matrix were injected into the mouse pancreas at 1 week before the experiments. ⁶⁴Cu-labeled-cetuximab (7.4 MBq / mouse) was intraperitoneally administered and the OpenPET-guided surgery was performed 24 h later (n=7). One-pass list-mode DRAMA (dynamic row-action maximum-likelihood algorithm) on graphics processing unit was used for high-speed reconstruction, which enables updating cycle of image less than one second while accumulating list-mode data. **Results:** The OpenPET-guided surgery was able to detect and resect not only primary tumors but also small residual tumors during the surgery. In this experiment, 10 residual tumor specimens were isolated in total with OpenPET guidance; 3 tumors were 10-5 mm and 7 tumors were 5-3 mm in size. The all isolated tumor specimens by the OpenPET-guided surgery were detected tumor RFP signals. In contrast, the naked eyes could not clearly identify location of these tumors within the pancreas in this model. **Conclusion:** We demonstrated the feasibility of OpenPET-guided surgery with ⁶⁴Cu-labeled-cetuximab for intraoperative resection of residual tumors in the orthotopic PC mouse model. This technology would be useful to avoid the occurrence of positive resection margins in PC during surgery. **References:** Yoshii et al. In vivo imaging of mast cell infiltration to lung cancer lesion by sodium iodide symporter gene

Y. Jeon¹, J. Lee¹, S. Kim¹, S. Lee²;

¹Laboratory Animal Center, Daegu-Gyeongbuk Medical Innovation Foundation, Daegu, KOREA, REPUBLIC OF,

²Kyungpook National University, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: Herein, we demonstrated the mast cell infiltration into lung cancer lesion in living mice using sodium iodide symporter gene (NIS) and I-124 Positron emission tomography-computed tomography (PET/CT).

Materials and Methods: Murine mast cell line MC-9 cells was transduced with lentivirus co-expressing NIS and enhanced green fluorescent protein (EGFP), which called as MC-9/NG cells. Iodide uptake was determined in MC-9/NG cells with inhibition study of KClO₄. Cell proliferation of luciferase expressing Lewis Lung Cancer (LLC/Luc) cells was evaluated in the presence of serum free media (SFM) or conditioned media (CM) of MC-9/NG cells using a bioluminescence imaging (BLI). The migration ability of MC-9/NG cells was evaluated in the presence of SFM or CM of LLC cells. LLC-tumor bearing mice received MC-9/NF cells via retro-orbital injection and its migration to tumor lesion was determined with I-124 PET/CT, which was accompanied by bio-distribution analysis. **Results:** Iodide uptake was higher in MC-9/NG cells than in MC-9 cells and increased iodide uptake in MC-9/NIS cells was inhibited by KClO₄ treatment. In vitro BLI showed higher proliferation of LLC/Luc cells in CM of MC-9 cells than SFM. Trans-well migration assay revealed enhanced mast cell migration in CM of LLC cells than SFM as a negative control. In vivo I-124 PET/CT imaging demonstrated the infiltrated MC-9/NIS cells to lung tumor lesion at 24h post-transfer, which was consistent with the finding of bio-distribution analysis. **Conclusion:** These finding suggest that sodium iodide symporter is feasible nuclear medicine reporter gene to visualize the biological behavior of mast cells in living mice with lung tumor. The mast cell imaging with nuclear medicine reporter gene enables us to better understand their biological role in tumor microenvironment. **References:** None

Relevance of molecular tracer based on Fludarabine for detection and monitoring of primary brain lymphomas evolution

V. Tran¹, S. Antoine^{2,3}, M. Mekhfi¹, G. Torquet¹, F. Assayag^{2,3}, F. Pouzoulet³, F. Caillé¹, B. Kuhnast¹, A. Kas⁴, V. Lebon¹, C. Soussain², C. Truillet¹;

¹Université Paris-Saclay, CEA, CNRS, Inserm, BioMaps, Orsay, FRANCE, ²Institut Curie, Site de Saint-Cloud, Saint-Cloud, FRANCE, ³Institut Curie, PSL Research University, Translational Research Department, Experimental Radiotherapy Platform, Orsay, FRANCE, ⁴AP-HP Sorbonne

Université, Pitié-Salpêtrière hospital, Department of Nuclear Medicine, and LIB, Inserm U1146 F-75013, Paris, FRANCE.

Aim/Introduction: [^{18}F]Fludarabine ([^{18}F]Fluda) appears to be a promising PET tracer for detecting specifically different types of B-cell non-Hodgkin lymphoma. It also showed less susceptibility to inflammation-induced false-positive and much lower basal signal in normal brain tissue compared to [^{18}F]FDG.^{1,2} In this study, we investigated the potential of this tracer to evaluate over time the progression of primary central nervous system lymphoma (PCNSL) in an orthotopic xenograft mouse model. Detailed whole body pharmacokinetic characterization was performed. We have also investigated the ability to monitor the pharmacological change on PCNSL under the effect of a Bruton Tyrosine Kinase inhibitor (Ibrutinib) using [^{18}F]Fluda. **Materials and Methods:** TMD8 human lymphoma cells were injected into the right striatum of the NMRI nude mice. A three-week longitudinal study (n = 8) was conducted in tumor-bearing mice by i.v. injecting [^{18}F]Fluda (364.3 ± 12.9 kBq/g) using dynamic PET acquisitions. Tumor evolution was determined by SUV_{max}. The results were compared with [^{18}F]FDG PET scan. Tumor volume was determined by applying a threshold equal to $\text{SUV}_{\text{mean}} + 2\text{SD}$ of $\text{VOI}_{\text{cerebellum}}$. Pixel-wise kinetic modeling was applied to calculate volume of distribution (V_T) images. Immunofluorescence (IF) was performed on frozen sections of mice brains using antibody against human CD20 overexpressed in malignant B-cells. Finally, the efficacy of daily oral dose of ibrutinib (60 mg/kg) was evaluated by [^{18}F]Fluda and [^{18}F]FDG imaging compared to placebo solution (n = 8 for each group). Survival rate in each group were monitored until humane endpoints were reached. **Results:** [^{18}F]Fluda provided higher tumor-to-background ratios than [^{18}F]FDG (1.7 ± 0.1 versus 1.2 ± 0.1). Tumor delineation on [^{18}F]Fluda PET images were confirmed by CD20 immunofluorescent images. Longitudinal [^{18}F]Fluda PET images showed a clear evolution of tumor volume and uptake of [^{18}F]Fluda from week 1 ($V = 31.0 \pm 12.8$ mm³, $\text{SUV}_{\text{max}} = 0.37 \pm 0.13$) to week 3 ($V = 152.0 \pm 64.3$ mm³, $\text{SUV}_{\text{max}} = 0.56 \pm 0.18$) post inoculation. V_T images confirm the specific binding of [^{18}F]Fluda to tumor. In ibrutinib treated group, the uptake of [^{18}F]Fluda is significantly lower than in placebo group, which correlated with the survival curves. **Conclusion:** Our results confirmed the potential of [^{18}F]Fluda for early diagnosis of B-cell lymphatic malignancies especially PCNSL as well as for evaluating therapeutic efficacy of new treatments for PCNSL such as Ibrutinib. **References:** 1. Comparative preclinical biodistribution, dosimetry and endoradiotherapy in mCRPC of ^{177}Lu -rhPSMA-7.3 and ^{177}Lu -PSMA I&T

N. Yusufi¹, S. Nekolla¹, A. Wurzer², M. Herz¹, C. D'Alessandria¹, W. Weber¹, H. J. Wester², M. Eiber¹;

¹Technical University Munich, Klinikum rechts der Isar, Department of Nuclear Medicine, Munich, GERMANY,

²Technical University Munich, Chair of Pharmaceutical Radiopharmacy, Garching, GERMANY.

Aim/Introduction: Radiohybrid prostate-specific membrane antigen (rhPSMA)-ligands are currently under evaluation as prostate cancer theranostics. Based on preliminary experiments the single isomer rhPSMA-7.3 is regarded as a promising candidate for potential endoradiotherapy. The aim of this preclinical evaluation was to assess biodistribution, dosimetry and therapeutic efficacy of ^{177}Lu -rhPSMA-7.3 in comparison to with established therapeutic agent, ^{177}Lu -PSMA-I&T. **Materials and Methods:** Biodistribution of ^{177}Lu -rhPSMA-7.3 and ^{177}Lu -PSMA-I&T was performed in LNCap tumour bearing SCID-mice after sacrifice at defined time points up to 7 days (n=5). Organs and tumours were dissected, injected dose per gram (%ID/g) was determined and dosimetry calculations were performed using OLINDA/EXM1.0. The therapeutic efficacy of a single dose of 30 MBq ^{177}Lu -rhPSMA-7.3 (222.6 ± 49.7 mm³; n=7) was compared with ^{177}Lu -PSMA-I&T (457.9 ± 286.1 mm³; n=7) and control groups (n=6-7) using C4-2 tumour bearing SCID-mice by evaluating tumour growth, tumour uptake and survival over 7 weeks post treatment. **Results:** The biodistribution of ^{177}Lu -rhPSMA-7.3 revealed fast blood clearance (0.67 %ID/g at 1 h p.i.) and highest activity uptake in the spleen and kidneys, particularly in the first hours (35.63 %ID/g and 223.6 %ID/g, respectively at 1 h p.i.) indicating a renal excretion pathway. A similar longitudinal biodistribution pattern was shown for ^{177}Lu -PSMA-I&T with a higher initial blood level (3.05 %ID/g), but lower kidney uptake (165.5 %ID/g). Compared with ^{177}Lu -PSMA-I&T, ^{177}Lu -rhPSMA-7.3 exhibited an initially (1 h) 2.6-fold higher tumour uptake in LNCap xenografts and a longer retention (4.5 %ID/g vs. 0.9 %ID/g at 168 h). The tumour dose of ^{177}Lu -rhPSMA-7.3 was substantially higher ($1.96\text{E}+03$ mGy/MBq vs. $7.47\text{E}+02$ mGy/MBq at a volume of 200 mm³) compared with ^{177}Lu -PSMA-I&T, with similar effective doses for both ligands ($6.93\text{E}-03$ mSv/MBq vs. $7.81\text{E}-03$ mSv/MBq). A single dose of ^{177}Lu -rhPSMA-7.3 showed a significantly higher tumour size reduction compared with ^{177}Lu -PSMA-I&T (abs. volumes: 170.3 ± 122.1 mm³ vs. 712.2 ± 206.8 mm³, respectively; or relative change to initial volumes: 1.2 ± 0.8 - vs. 6.2 ± 4.7 -fold increase, respectively; p=0.0167). At the pre-defined termination of the experiment (43 days), 7/7 and 3/7 mice were still alive in the ^{177}Lu -rhPSMA-7.3 and ^{177}Lu -PSMA-I&T groups, compared with a median survival of 10.5 and 14 days for the control

groups. **Conclusion:** ^{177}Lu -rhPSMA-7.3 can be considered as suitable candidate for clinical translation due to the similar clearance kinetics and radiation dose, and the superior tumour uptake and retention compared with ^{177}Lu -PSMA-l&T. Preliminary treatment experiments showed favourable anti-tumour response. **References:** None

⁵Department of Molecular Genetics, Erasmus MC, Rotterdam, NETHERLANDS, ⁶Department of Pathology and Medical Biology, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Meningiomas are the most frequently occurring primary intracranial tumors in adults. Although these tumors are most often benign, symptoms arise due to compression of brain tissue, leading to for example focal neurological deficits or mental status changes. Treatment is only curative with complete surgical resection, which is not possible in all cases. To facilitate safe and complete resection, intraoperative guidance should be optimized, e.g. by applying molecular fluorescence guided surgery (MFGS). This technique utilizes the targeting of a biomarker, which is overexpressed on meningiomas, with a fluorescent tracer. Somatostatin receptor type 2 (SST₂) is overexpressed on all meningiomas, regardless of WHO grade or subtype. In this study, SST₂ was targeted with tyr³-octreotate-IRDye800CW. In order to investigate whether this compound can be applied in MFGS in intracranial meningiomas, we have determined binding affinity of this tracer in vitro, and tumor targeting and binding specificity in a mouse model. **Materials and Methods:** Binding affinity of octreotate-IRDye800CW was evaluated using displacement assays with H69 xenograft slides. ^{177}Lu -DOTATATE was displaced with various concentrations of DOTATATE or octreotate-IRDye800CW. For determining tumor targeting, 3 μg octreotate-IRDye800CW was injected in (SST₂-positive) human H69 xenograft bearing mice. To evaluate binding specificity, H69 xenograft bearing mice were injected with 3 mg DOTATATE and 3 μg octreotate-IRDye800CW. As a control, (SST₂-negative) CH157MN xenograft bearing mice were injected with 3 μg octreotate-IRDye800CW.

In vivo imaging was performed using the FMT2500 at 1, 2, and 4 hours post injection. Mice were terminated after the last scan and tissues and organs were imaged ex vivo using two fluorescence imagers: the PEARL and OdysseyCLx. Lastly, SST₂-expression was determined using immunohistochemistry. **Results:** Octreotate-IRDye800CW showed an affinity of 72 nM, sufficient to support further in vivo testing. Fluorescence was blocked for 61.5±5.8% after the additional administration of 3mg DOTATATE. In the (SST₂-negative) CH157MN model, fluorescence was 81.5±8.7% lower compared with the (SST₂-positive) H69 model. Furthermore, in and ex vivo, fluorescence was mainly located in the tumor, kidneys, urine and liver, whereas the brain, skull, muscle, blood and skin showed low fluorescence intensity. The tumor-to-brain-ratio (TBR) was high: 24.4 (95%CI: 19.7-29.1). Lastly, fluorescence uptake was compared to SST₂ expression levels based on immunohistochemistry. **Conclusion:** Considering the binding affinity, SST₂-mediated tumor uptake, biodistribution and high TBR, octreotate-IRDye800CW seems very promising for clinical application in the future. It could potentially aid in safer and completer resection of meningioma tissue, especially in the high grade meningiomas or in complex anatomical localizations. **References:** None

EP-276
PET Imaging of Lung Cancer with $^{64}\text{CuCl}_2$: A Pilot Study
L. Jiang;
Shanghai Pulmonary Hospital, Shanghai, CHINA.

Aim/Introduction: Recently, human copper transporter 1 (CTR1) has been proven to be overexpressed in many types of cancer cells, and copper (II)-64 chloride ($^{64}\text{CuCl}_2$) has been used as an effective tracer for positron emission tomography (PET) imaging in tumor-bearing animal models. Thus, this study aimed to investigate the potential application of $^{64}\text{CuCl}_2$ in PET imaging of lung cancer through targeting CTR1. **Materials and Methods:** The expression of CTR1 in a series of lung cancer cell lines was measured by quantitative real-time polymerase chain reaction (Q-PCR), western blot, enzyme-linked immunosorbent assay (ELISA), and immunofluorescent staining. Then in vitro cell uptake assay of $^{64}\text{CuCl}_2$ was investigated in lung cancer cell lines with different levels of CTR1 expression. And small animal PET imaging and quantitative analysis were performed in lung cancer tumor-bearing mice after intravenous injection of $^{64}\text{CuCl}_2$, respectively. **Results:** The CTR1 expression in multiple lung cancer cells was identified and confirmed, and lung cancer cell lines H1299 with high CTR1 expression, H460 with moderate CTR1, and H1703 with low CTR1 were selected for further experiments. In vitro cellular uptake assay displayed that the $^{64}\text{CuCl}_2$ uptake by these three kinds of cells was positive correlated with their CTR1 expressed levels. And the blocking experiments testified

the specificity of $^{64}\text{CuCl}_2$ to target CTR1. Moreover, small animal PET imaging and quantitative results showed that $^{64}\text{CuCl}_2$ accumulation in H1299, H460, and H1703 tumor-bearing mice was consistent with CTR1 levels and cell uptake experiments. **Conclusion:** The expression of CTR1 in lung cancer could be successfully visualized by $^{64}\text{CuCl}_2$ PET examination. With the expected growth of PET/CT examination to be an essential strategy in clinical lung cancer management, $^{64}\text{CuCl}_2$ has the great potential to be a promising PET imaging agent of lung cancer. **References:** None

Influence of macrocyclic bifunctional chelators on Self-assembling supramolecular dendrimer nanosystem biodistribution and in pancreatic adenocarcinoma patient derived cells L-IPC

B. Louis¹, L. Ding², Z. LYU², A. Moyon³, A. Bouhlel¹, L. Balasse¹, S. Fernandez¹, J. Yifan², S. Simoncini⁴, G. Hache³, F. Dignat-George⁵, L. Peng², P. Garrigue³, B. Guillet³;

¹C2VN INSERM 1263 INRA 1260 CERIMED Aix-Marseille Université, Marseille, FRANCE, ²CINaM CNRS, UMR 7325 Aix-Marseille Université, Marseille, FRANCE, ³C2VN INSERM 1263 INRA 1260 CERIMED, APHM, Aix-Marseille Université, Marseille, FRANCE, ⁴C2VN INSERM 1263 INRA 1260 Aix-Marseille Université, Marseille, FRANCE, ⁵C2VN INSERM 1263 INRA 1260, APHM, Aix-Marseille Université, Marseille, FRANCE.

Aim/Introduction: Because of EPR effect, dendrimers can preferentially accumulate in tumor tissues, this kind of nanotechnology constitute a tool in diagnostic probe development and in the future, in a possible nanotheranostic strategy ¹⁻⁶ Based on our previous nanotechnology developments for PET ⁷, this study aimed at developing [¹¹¹In]In-nanotechnology-based bioimaging and at optimizing dendrimers biodistribution in a human primary pancreatic adenocarcinoma tumor mice model, and therefore compared the influence of two macrocyclic bifunctional chelators (DOTA and NODAGA) enabling the modification of global nanoparticle surface charge.

Materials and Methods: Both dendrimers were produced and radiolabeled with [¹¹¹In]InCl₃ in ammonium acetate buffer 1M, with a supplemental 15-minute 57°C heating for [¹¹¹In]In-DOTA-dendrimer. Radiochemical purities were assessed in 37°C human serum up to 48h after synthesis by radiochromatography on iTLC-SG paper and 0.1M sodium citrate buffer (pH=5). μ SPECT/CT acquisitions were performed 2h, 24h and 48h p.i under isoflurane anesthesia in six-week-old L-IPC tumor-bearing mice (n=3) on a NanoSPECT/CT camera (Mediso). SPECT signal quantifications were performed on Vivoquant software (Invivo). Data were analyzed with 2way-ANOVA statistical test after being checked for normality. **Results:** Satisfying radiochemical purities over 93% were obtained up to

48 h after radiosynthesis. [¹¹¹In]In-NODAGA enabled a significant reduction of μ SPECT signal quantification in the liver compared to that of [¹¹¹In]In-DOTA-dendrimer as soon as 2h post-injection (3.78 %ID/g \pm 0.27 vs 6.02 %ID/g \pm 0.32 ; ****P < 0.0001), maintained 24 h (3.14 %ID/g \pm 0.19 vs 6.37 %ID/g \pm 0.33; ****P < 0.0001) and 48 h post-injection (2.70 %ID/g \pm 0.1 vs 5.74 %ID/g \pm 0.85; ****P < 0.0001). Tumor-to-muscle ratio was significantly higher for [¹¹¹In]In-NODAGA-dendrimer at 48 h p.i. compared to [¹¹¹In]In-DOTA-dendrimer respectively 324.57 \pm 35.3 and 212.47 \pm 38.13 (**P =0.0052). Contrariwise, Tumor-to-liver ratio was significantly higher for [¹¹¹In]In-NODAGA-dendrimer 24 h p.i. (30.11 \pm 3.37 vs 16.66 \pm 0.61 ; ****P < 0.0007), 48 h p.i. (27.06 \pm 4.09 vs 17.89 \pm 1.56; **P = 0.0075). **Conclusion:** In line with previous results focusing on radiolabeled peptides or proteins, this SPECT study highlights the importance of chelator's influence for the biodistribution of radiolabeled nanoparticles ⁸⁻¹⁰. These findings provide perspectives of importance in the field of nanotheranostics for reducing nanoparticle trapping in the liver. **References:** (1) <https://doi.org/10.1002/sml.201600635>. The significance of intraperitoneal administration of 18F-FDG in a preclinical mouse model

Z. Ritter¹, K. Zámbo¹, P. Balogh², D. Szöllösi³, J. Xinkai², D. Dezsö¹, H. Alizadeh⁴, I. Horváth³, N. Hegedűs³, D. Máthé³, E. Schmidt¹;

¹University of Pécs, Department of Diagnostic, Division of Nuclear Medicine, Pécs, HUNGARY, ²University of Pécs, Department of Immunology and Biotechnology, Pécs, HUNGARY, ³Semmelweis University Faculty of Medicine, Department of Biophysics and Radiation Biology, Budapest, HUNGARY, ⁴University of Pécs, 1st Department of Internal Medicine, Pécs, HUNGARY.

Aim/Introduction: Bc-DLFL1 is a novel spontaneous, reproducible, well-characterized high-grade lymphoma isolated from BALB/c mice. After intraperitoneal inoculation this lymphoma attaches to the omentum and mesentery and shows dissemination towards the mesenteric lymph nodes. We aimed to compare detection methods for spreading of Bc-DLFL1 lymphoma using in vivo FDG PET or ex vivo autoradiography of FDG. The results of these imaging techniques were compared with results of immunohistochemistry. **Materials and Methods:** BALB/c mice were used as lymphoma recipients aged between 8-12 weeks. One million lymphoma cells were injected intraperitoneally per animal. Twenty-four hours after

injection, FDG was administered either intravenously or intraperitoneally. In both groups we investigated nine animals. For the immunohistochemistry detection, ex vivo carboxyfluorescein (CFSE) labeled lymphoma cells were injected to each animal. This allowed immunohistochemical diagnosis of lymphoma presence using anti-FITC antibodies. In order to monitor the expansion of the tumor in a later stage, next we examined whether PET would allow lymphoma detection. To assess whole-body spread of the disease, one day and 6 days after lymphoma inoculation in 3-3 animals, FDG was administered intravenously and PET examination was performed. **Results:** We could not detect specific tracer accumulation with PET in the early stage (1 day post-inoculation) either by intraperitoneal or intravenous tracer administration. Autoradiography results were also negative after intravenous FDG injection, circumscribed accumulation of FDG could not be detected in the mesentery or omentum, whereas clearly marked selective foci were observed after intraperitoneal FDG treatment. To confirm these results with IHC, we have observed focal anti-FITC signals which were exactly corresponding to the distribution of FDG accumulating foci. While specific tracer accumulation could not be detected with these imaging methods in the early stage (1 day after lymphoma inoculation), we found that tracer accumulation could be clearly detected at a later stage of tumor growth (beyond day 6 post-injection) by intravenous administration of FDG. FDG accumulating lymphoma foci were observed in the enlarged mesenteric lymph nodes. **Conclusion:** Based on our results, it can be hypothesized that even with early adhesion of tumor cells in the abdomen, the delivery of FDG (glucose) into the cells intravenously is partially restricted. This highlights the importance of local use of FDG in diagnostic procedures for the diagnosis of early peritoneal manifestations or metastases of certain diseases (colon, stomach, ovary) and raises the importance of local therapy in addition to systemic treatments. **References:** None

The Feasibility of ^{68}Ga Replacing ^{89}Zr for CART Cell PET Monitoring

X. Wang, Y. Wang, D. Pan, Q. Wu, J. Liu, M. Yang;
Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Aim/Introduction: Chimeric Antigen Receptor (CAR) T-cells are important players in immunotherapy for oncology. In vivo characterizations of the spatio-temporal distribution and homing dynamics of CAR-T-cells would facilitate the customization of treatment regimens. In vivo PET imaging of CAR-T-cells have been reported with radionuclides ^{89}Zr and ^{64}Cu , which have long half-life. Although long-term tracking of CAR-T-cells would offer more information about homing and distribution dynamics, the overdose of irradiation made it almost impossible in clinical translation.

Thus, replacement of radionuclides with shorter half-life may overcome this challenge. Here, we use ^{68}Ga -oxine for CAR-T-cells labeling and track it in vivo for the first time. **Materials and Methods:** ^{68}Ga solution was obtained from ITG $^{68}\text{Ge}/^{68}\text{Ga}$ generator. After pH adjustment by 1 N NaAc, the ^{68}Ga solution was mixed with oxine solution to form ^{68}Ga -oxine. CAR-T-cells were then incubated with ^{68}Ga -oxine solution for radiolabeling. In vivo distribution was assessed by PET imaging in NSG mice. ^{89}Zr -oxine labeled CAR-T-cells were used as control. **Results:** ^{68}Ga -oxine labeled CAR-T-cells have good stability in FBS within several hours with cell viability >90%. The ^{68}Ga -oxine labeled CAR-T-cells mainly distributed in lung, liver and spleen, which was similar with that of ^{89}Zr -labeled CAR-T-cells. For ^{68}Ga -oxine labeled CART cells, the lung uptake (%ID/g) was decreased from 76.68 ± 7.07 at 10 min to 35.72 ± 4.27 at 4 h post intravenous injected (pi) with 1×10^6 cells per animal, the liver and spleen uptake (%ID/g) were up to 27.49 ± 6.89 and 17.03 ± 6.52 at 4 h pi. While for ^{89}Zr -labeled CAR-T-cells, lung uptake (%ID/g) was decreased from 85.57 ± 26.28 at 10 min to 26.67 ± 7.22 at 4 h pi, liver and spleen uptake (%ID/g) were 23.85 ± 3.56 and 14.44 ± 4.90 at 4 h pi, respectively. With time increased, the liver and spleen uptakes of ^{89}Zr -labeled CAR-T-cells kept high and stable until 48 h pi, still were 34.44 ± 10.20 and 21.24 ± 12.01 , respectively. Significant correlation appeared between PET imaging with ^{68}Ga and ^{89}Zr -labeled CAR-T-cells, the Pearson correlation coefficient in lung, liver and spleen uptake were 0.780, 0.872 and 0.959, respectively. Early phase of CAR-T-cells distribution and migration monitoring with ^{68}Ga was similar with ^{89}Zr -labeled CAR-T-cells. Effective dose of total body irradiation for ^{68}Ga -labeled CAR-T-cells is $5.30\text{E}-02$ mSv/MBq, which is 24-fold lower than that of ^{89}Zr -labeled CAR-T-cells. **Conclusion:** We successfully proposed ^{68}Ga -labeling for CAR-T-cells in vivo tracking by PET imaging. It can offer spatio-temporal distribution and homing dynamics information just like ^{89}Zr , but reduce the effective dose of total body irradiation substantially. **References:** None

Multi-modal PET and MRI biodistribution studies of ^{89}Zr -labelled nanodiamonds in mice

N. Eberhardt¹, J. Löffler^{1,2}, M. Raabe³, M. N. A. Alam³, H. Li², A. Abaei², H. Herrmann¹, C. Solbach¹, F. Jelezko⁴, T. Weil³, A. J. Beer¹, V. Rasche^{5,2}, G. Winter¹;

¹Ulm University Medical Center, Department of Nuclear Medicine, Ulm, GERMANY, ²Ulm University, Core Facility Small Animal Imaging, Ulm, GERMANY, ³Max Planck Institute for Polymer Research, Synthesis of Macromolecules Department, Mainz, GERMANY, ⁴Ulm University, Institute for Quantum Optics, Ulm, GERMANY, ⁵Ulm University Medical Center, Department of Internal Medicine II, Experimental Cardiovascular Imaging, Ulm, GERMANY.

Aim/Introduction: Due to their biocompatibility,

nanodiamonds (ND) are of great interest for medical applications. They are chemically inert and can harbour nitrogen vacancies (NV-centres) that potentially facilitate highly sensitive MRI measurements after hyperpolarization. Protein-coating is used to provide coupling sites for ligands/therapeutics and to improve the biodistribution by appropriate masking. To evaluate and optimize these surface modifications, *in vivo* biodistribution studies of radiolabelled NDs were performed. Combined PET and MR imaging with image fusion allowed a quantitative localization of NDs in organs and tumour over time. **Materials and Methods:** PEGylated human serum albumin surface-coated fluorescent NDs (\varnothing 100nm, Microdiamant, IOM Leipzig) were coupled with the chelator p-SCN-Bn-deferoxamine (Macrocyclics) and radiolabelled using zirconium-89 or gallium-68. Tumour xenografts of prostate carcinoma cell lines LNCaP C4-2 and PC-3 (each 1×10^6 cells) were established in the subscapular region of a CB17/Icr-Prkdc-scid/CrI (Charles River) mouse model. (42.4 ± 4.4) μ g of radiolabelled NDs were applied intravenously. Dynamic 60-min PET scans (Focus120, Siemens Medical Solutions, Inc.) were performed 1h and 3h (^{68}Ga -labelled), or 3h, 24h, 3d and 7d (^{89}Zr -labelled) *p.i.*. Anatomic MR imaging was performed at 11.7T (BioSpec117/16, Bruker Biospin) in a subgroup. Activity accumulation at each time point ($n=4$) was measured in excised organs using a gamma counter (Cobra II, Perkin Elmer). PET/MR image superposition and data analysis were performed with 3DSlicer and AsiPro. **Results:** ^{89}Zr -labelling was stable in sodium chloride (0.9%), cell culture medium and serum during a 4d observation period. In the first 60min of observation, activity accumulated in liver and spleen, while simultaneously decreased in the heart region. The activity in the blood, responsible for the heart signal, decreased over time. A slight increase of activity was detected in LNCaP C4-2 tumours starting at $(0.4 \pm 0.3)\%$ ID up to $(1.5 \pm 0.6)\%$ ID after 3d followed by a decrease to $(0.9 \pm 0.6)\%$ ID after 7d. For PC-3 a short peak of $(0.6 \pm 0.4)\%$ ID followed by a constant level of $(0.2 \pm 0.1)\%$ ID were detected. Fast increase $(40.4 \pm 17.7)\%$ ID to $(66.9 \pm 3.4)\%$ ID after 3h and decrease over time to $(49.5 \pm 8.6)\%$ ID after 7d were observed for the liver. In the spleen an increase was detected from $(2.1 \pm 0.5)\%$ ID to $(6.0 \pm 1.4)\%$ ID at 24h followed by a decrease at 7d $(3.4 \pm 0.9)\%$ ID. **Conclusion:** Successful ^{89}Zr -radiolabelling and initial *in vivo* studies regarding biodistribution and accumulation of specifically coated NDs were performed. Main organs of accumulation were part of the reticuloendothelial system. Crucial data for the further optimization of the surface modifications with regard to pharmacokinetic and pharmacodynamic properties of the protein-coated NDs were obtained. **References:** None

The feasibility of ^{64}Cu -PSMA I&T for specific PSMA PET imagings

I. Lim, S. Woo, C. Lee, K. Song, S. Lim;

Korea Cancer Center Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: To investigate the feasibility of ^{64}Cu labeling with PSMA I&T for PSMA PET imaging and biodistribution evaluation. **Materials and Methods:** PSMA I&T was labeled with ^{64}Cu and stability in human and mouse serum was evaluated. Prostate cancer cell lines were used for specific uptake assay (22RV1 for PSMA positive, PC-3 for PSMA negative). Both PC-3 and 22RV1 cells were transplanted left and right thigh in a mouse for PET/CT imaging. Biodistribution was performed using 22RV1 tumor models. **Results:** ^{64}Cu -PSMA I&T was successfully labeled (more than 95%) compared to free ^{64}Cu peak. Serum stability of ^{64}Cu -PSMA I&T was maintained more 90% until the 60 h. The specific binding of 22RV1 cells to ^{64}Cu -PSMA I&T was 7.5-fold higher than that of PC-3 cells ($p < 0.001$). From PET/CT imaging, more specific ^{64}Cu -PSMA I&T uptake was observed in 22RV1 tumor than PC-3 tumor. In PSMA blocking study using 2-PMPA, ^{64}Cu -PSMA I&T signal was significantly decreased in 22RV1 tumor region. In biodistribution study, kidney uptake at 2 h after the intravenous injection was the highest ($52.6 \pm 20.8\%$ ID/g) but sharply decreased, and liver uptake was similar from 2 h to 48 h (ranges from 10 to 12% ID/g). On the other hand, ^{64}Cu -PSMA I&T uptake in the tumors increased as time went by and peaked at 48 h ($5.6 \pm 0.1\%$ ID/g). **Conclusion:** ^{64}Cu -PSMA I&T can be labeled and demonstrated specific binding to PSMA *in vitro* and *in vivo*. Furthermore, ^{64}Cu -PSMA I&T might be used for evaluating the distribution of PSMA I&T labeled with metals. **References:** Weisen M, Schottelius M, Simecek J, et al. ^{68}Ga - and ^{177}Lu -labeled PSMA I&T: optimization of a PSMA-targeted theranostic concept and first proof-of concept human studies. *J Nucl Med.* 2015;56:1169–1176. Forschungszentrum Jülich, D-52425 Jülich, GERMANY.

Aim/Introduction: Tryptophan is an essential amino acid in mammals including humans. Tryptophan metabolism is altered in cancer, and the imaging of these alterations with positron emission tomography (PET) has been successfully used for tumor detection and staging. Such imaging can be done with ^{11}C -labeled tryptophan analogs, e.g. [^{11}C]AMT and [^{11}C]HTP [1]. However, complicated synthesis procedures and short half-life of carbon-11 limit the potential scale of application for these tracers. Recently, (S)-7-[^{18}F]-fluorotryptophan (7-[^{18}F]FTrp), a tryptophan analogue labeled with a longer-lived isotope fluorine-18 and prepared via a simple ^{18}F -fluorination-deprotection scheme, was shown to accumulate in tumor xenografts grown in chick embryos [2]. We aimed to assess the ability of 7-[^{18}F]FTrp to detect tumors in a mouse xenograft model, which is more advanced in a translational sense. **Materials and Methods:** 7-[^{18}F]FTrp was prepared as described in [2] with slight modifications. Nude Balb/c mice, 7–8 weeks of age, with LS 174T human colon adenocarcinoma xenografts (170–240 mm³ volume), received injections of 3.7–4.7 MBq of 7-[^{18}F]FTrp into the lateral tail vein. At 10 and 90 min post-injection, the mice were placed into the PET camera and scanned for 20 min. CT scanning was performed to obtain anatomical information. Radioactivity concentration was measured in the tumor, in the leg muscle and in the heart (as a surrogate for blood uptake). **Results:** Average tumor uptake of 7-[^{18}F]FTrp was 5.9 ± 1.1 %ID/g in the first scan (20 min post-injection) and 4.8 ± 1.1 %ID/g in the second scan (100 min post-injection). Tumor-to-muscle ratios measured in the first and the second scans were 1.6 ± 0.3 and 1.5 ± 0.6 , respectively. Corresponding tumor-to-heart ratios were 1.0 ± 0.2 and 1.2 ± 0.2 . **Conclusion:** Despite decent absolute uptake in LS 174T xenografts, the contrast between tumor and healthy tissue for 7-[^{18}F]FTrp was poor in the chosen model. Evaluation of 7-[^{18}F]FTrp in tumors with greater known elevation of tryptophan metabolism (e.g. neuroendocrine tumors) is pending. **Acknowledgements:** This work was supported in part by DFG (grant: ZL 65/3-1) **References:** 1. EP-283

Preclinical tumor imaging with ^{89}Zr -labeled monoclonal antibody ramucirumab

Z. Novy¹, J. Janousek², P. Barta², M. Petrik¹, M. Hajdich¹, F. Trejtnar²;
¹Faculty of Medicine and Dentistry, Olomouc, CZECH REPUBLIC,
²Charles University in Prague, Hradec Kralove, CZECH REPUBLIC.

Aim/Introduction: The angiogenesis suppression has become one of the key anti-tumor strategies. This also includes blocking of VEGFR2 binding site by the monoclonal antibody ramucirumab (RAM). The aim of this study was

to prepare RAM radiolabeled with positron emission tomography (PET) imaging radionuclide zirconium-89 and subsequently determine in vitro and in vivo biological properties of ^{89}Zr -labeled ramucirumab. **Materials and Methods:** The conjugation of RAM with the bifunctional chelator p-SCN-Bn-deferoxamine (DFO) was carried out at pH 9.0 in sodium bicarbonate. DFO-RAM was radiolabeled with (^{89}Zr)Zr-oxalate at pH 5.5 in sodium acetate solution. The binding affinity of prepared ^{89}Zr -DFO-RAM to VEGFR2 was tested in vitro on prostate adenocarcinoma (PC-3) and ovary adenocarcinoma (SK-OV-3) cell lines. The PET/CT imaging and ex vivo biodistribution studies were performed in mice engrafted with PC-3 and SK-OV-3 tumors. **Results:** The in vitro experiments showed preserved binding ability of ^{89}Zr -DFO-RAM to VEGFR2 with the KD values 38.93 ± 2.04 and 36.59 ± 8.36 nM for PC-3 and SK-OV-3 cells respectively. The obtained ex vivo biodistribution data revealed the activity uptake in PC-3 and SK-OV-3 tumors at about 8.7 ± 0.2 and 12.1 ± 1.6 %ID/g respectively. The tumor-to-blood ratio for 1, 3 and 6 days p.i. was 0.4, 0.6 and 0.8 for PC-3 and 0.5, 1.0 and 1.3 for SK-OV-3 tumors respectively. The PET/CT images showed high radioactivity accumulation in the tumors starting already at first day p.i. **Conclusion:** The labeling of DFO-RAM with Zr-89 provided anti-VEGFR2 radiopharmaceutical with promising binding to the target receptors both in vitro and in vivo. The results of in vivo experiments proved the potency of ^{89}Zr -DFO-RAM to target and image VEGFR2-positive tumors. However, several non-target organs like e.g. heart, spleen and liver showed also increased accumulation of the radioactivity. **References:** None

Quantification using 2D scintigraphic versus 3D SPECT imaging in pre-clinical oncology studies: A Comparative Analysis

M. Rouchota¹, P. Tsalios², S. Sarpaki¹, M. Georgiou¹, L. Fysikopoulos¹, I. Pilatis³, P. Papadimitrioulas¹, G. Loudos¹;
¹BIOEMTECH, Athens, GREECE, ²Medical School, National and Kapodistrian University of Athens, Athens, GREECE,
³University of West Attica, Athens, GREECE.

Aim/Introduction: Preclinical studies hold the most prominent tool in oncology research. The gold standard in any oncology experiment is still ex vivo biodistributions, an invasive method that requires a large number of animals. Studies have shown that both planar (2D) and tomographic (3D) imaging provide high correlation to ex vivo studies and can be trusted as an alternative to bio kinetics [1]. Usually, tumours are subcutaneous thus do not overlap with other organs. In this study, a set of oncology imaging studies, performed both on 2D and 3D commercial systems and are compared against biodistribution data, to evaluate the correlation between the two methods. **Materials**

and Methods: We have studied 6 oncology experiments, with more than 30 mice and 3 different isotopes, in 2D and 3D SPECT and ex vivo bio-distributions. Real-time, dynamic screening was performed on a commercial high resolution, 2D scintigraphic system, while quantification on its embedded analysis software. Tomographic SPECT/CT imaging was performed with a commercial microSPECT/CT scanner and post-processing on commercial processing software. ROIs or VOIs respectively, are drawn on major organs and the counts are translated to %ID/organ. For the biodistributions studies, organs were measured in a gamma counter and results calculated as %ID/organ. The agreement between the two methods was assessed using pairwise comparisons with repeated-measures ANOVA and the Bland - Altman plot. **Results:** The difference in uptake values between 2D and 3D imaging was $(4.9 \pm 3.2)\%$. The correlation between imaging and ex vivo bio-distribution values differs on average by $(8.1 \pm 2.6)\%$. Both imaging techniques present a very similar trend in comparison to ex vivo biodistributions. However, 2D imaging offers a number of additional advantages, such as speed, simplicity, real time imaging, and ability to provide very short time frames and extraction of time activity curves by the end of the experiment. **Conclusion:** This study demonstrates that for applications where organs are well separated, 2D scintigraphy provides similar results to 3D SPECT. In addition, it allows the reproduction of time activity curves with the same accuracy as ex vivo biodistributions, while significantly reducing in the number of animals required and increasing overall statistical accuracy. **References:** [1]. EP-285

Preliminary study on the value of ^{18}F -FDG, ^{18}F -PSMA and ^{68}Ga -FAP PET in the evaluation of hormone dependence in prostate cancer

J. Ning¹, C. Yang^{1,2}, X. Zhang¹, J. Zhang¹, J. Liu¹, Y. Yin¹, B. Xu¹;
¹Chinese PLA General Hospital, Beijing, CHINA, ²Institute of Systems Biomedicine, Department of Pathology, School of Basic Medical Sciences, Beijing Key Laboratory of Tumor Systems Biology, Peking-Tsinghua Center for Life Sciences, Peking University Health Science Center, Beijing, CHINA.

Aim/Introduction: To visualize the different biological behaviors of androgen-dependent and androgen-independent prostate cancer (PCa), drug-resistant and non-resistant PCa via multimodal PET imaging (^{18}F -FDG, ^{18}F -DCFPyL, ^{68}Ga -FAP-04). **Materials and Methods:** We planned to establish subcutaneous and orthotopic mouse models of androgen-dependent PCa (LNCaP: 12 subcutaneous masses in 6 mice) and androgen-independent PCa (PC-3: 12 subcutaneous masses in 6 mice),

and docetaxel-resistant PCa (22RV1-DR: 12 subcutaneous masses in 6 mice and 12 orthotopic masses in 6 mice) and non-resistant PCa (22RV1: 12 subcutaneous masses in 6 mice and 12 orthotopic masses in 6 mice). Among these PCa cell lines, 22RV1-DR and 22RV1 were genetically modified to cell lines with fluorescent protein (mCherry) overexpression so as to differentiate tracer concentration in the prostate foci from tracer accumulation in the bladder of orthotopic mouse models. Then, perform ultrasound imaging, fluorescence imaging, and PET imaging of ^{18}F -FDG, ^{18}F -DCFPyL, ^{68}Ga -FAP-04, and analyze and compare the imaging characteristics of different types of mouse models from different perspectives. After euthanizing the mice, every mass was extracted for immunohistochemistry analysis, whose indicators include PSAP, CD31, CD56, CgA, CK7, Ki-67, NKX3.1, NSE, P504S, CK20, PSMA and Syn. **Results:** For some reason, the construction of orthotopic mouse model all failed. So, the following results came from subcutaneous mouse models. On PSMA PET, LNCaP PCa was shown positive while PC-3 was none concentrated. As for PC-3 mice, PSMA PET indicated no tracer concentration while the FDG and FAPI imaging came out positive. 22RV1 and 22RV1-DR PCa were both shown negative on FAPI PET and positive on FDG and PSMA PET. And on FDG and PSMA PET, SUVmax of 22RV1-DR PCa were both higher than that of 22RV1 PCa ($P_{\text{FDG}}=0.012$, $P_{\text{PSMA}}=0.007$). Among all the tested IHC indicators, some difference of CD56, CgA, CK7, Ki-67, NKX3.1, P504S and PSMA were observed between 22RV1-DR and 22RV1 PCa neoplasms. **Conclusion:** Multimodal molecular imaging has certain potential in the evaluation of androgen dependence in prostate cancer. Further studies are required to clarify the mechanism of PCa drug-resistance with the added value of molecular imaging to basic science. **References:** None

FAP radioligand therapy in a pancreatic adenocarcinoma patient-derived xenograft

C. Mona, K. Lückerrath, R. Riahi, F. Hikmat, K. M. Current, R. Slavik, T. R. Donahue, C. G. Radu, D. W. Dawson, J. Czernin;
 UCLA, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: There are no effective treatments for pancreatic ductal adenocarcinoma (PDAC), accounting for the abysmal statistic of fewer than 9% of patients surviving 5 years post diagnosis. Fibroblast Activation Protein (FAP) is almost exclusively expressed on cancer associated fibroblasts

that reside in the stroma of cancers. FAP is a key effector that promotes tumorigenesis and immunosuppression. Preclinical studies suggested that depletion or pharmacological inhibition of FAP-positive cells lead to decreased tumor growth and invasion. Thus, FAP-targeted radioligand therapy (RLT) may represent a promising modality to achieve tumor control. Aim: evaluating FAP-RLT FAPi-46 radiolabeled with alpha or beta particle as new therapeutic agent to treat PDAC. **Materials and Methods:** To study the relevance of ^{177}Lu -FAPi-46 and ^{225}Ac -FAPi-46 in PDAC, we used a PDAC patient-derived xenograft (PDX; AM1283) model. We performed both biodistribution and activity escalation study. In vivo FAP stromal expression was confirmed by ^{68}Ga -FAPi-46 positron emission tomography, immunohistochemistry (IHC), FACS and immunoblot. In the biodistribution study, mice bearing AM1283 were sacrificed 1, 2, 4, 6, and 24 h post treatment with ^{225}Ac -FAPi-46 (n=5 mice/group). At the indicated timepoints, multiple organs and tumor were resected, weighed and subjected to ex vivo gamma-counting. In the activity escalation study, NCG mice (n=8/group) were intravenously injected with 20, 40, or 60 MBq ^{177}Lu -FAPi-46, or 10, 20, or 40 kBq ^{225}Ac -FAPi-46. Acute toxicity and efficacy were evaluated by body weight measurements and tumor volumes determined by micro-CT. Two days post-RLT, tumors were resected in a subset of mice (n=3) to quantify FAP expression and DNA double-strand breaks. **Results:** Biodistribution analysis revealed an increased uptake of ^{225}Ac -FAPi-46 in the tumors versus pancreas. However, we noted an important uptake in the kidneys and liver. All groups treated with FAP RLT exhibited a delayed tumor growth onset with respect to the vehicle-treated mice for both isotopes. We observed an activity-dependent inhibition of tumor growth with both isotopes. A more drastic effect was observed using ^{225}Ac -Actinium radiolabeled FAPi-46 at an activity of 40kBq without any toxicity. **Conclusion:** We report PDAC-PDX tumor growth inhibition in mice treated with single injection of ^{177}Lu - or ^{225}Ac -FAPi-46 in a subcutaneous tumor model. We observed a tendency toward an increased inhibition of tumor growth when using ^{225}Ac rather than ^{177}Lu . This study shows that FAP-RLT and more specifically alpha therapy targeting FAP appears to be a novel promising avenue for the FAP-positive PDAC and paves the way for new combination treatment strategy. **References:** None

EP-287

^{225}Ac -Pertuzumab Enhances Efficacy Against a Trastuzumab/Pertuzumab Resistant HER2-Positive Breast Cancer Xenograft Model

B. Khan¹, F. Sanaulla¹, M. Khan¹, S. Karkare¹, P. Causey², R. Perron², D. Gendron², H. Fonge¹;

¹University Of Saskatchewan, Saskatoon, SK, CANADA,

²Canadian Nuclear Laboratories, Chalk River, ON, CANADA.

Aim/Introduction: Background: Cell signaling through the epidermal growth factor family of receptors (EGFR, HER2, and HER3) promotes tumour cell proliferation and survival in a variety of epithelial malignancies notably in metastatic breast cancer (MBC). 25-30% of MBC overexpress HER2 and this is associated with aggressive disease and poor prognosis. A combination of trastuzumab and pertuzumab is approved for the treatment of HER2 positive MBC. However, very few patients qualify for this treatment and 20 - 50% of patients initially selected for therapy do not respond to treatment, while up to 70% of initial responders subsequently acquire resistance. In this study we hypothesize that targeting HER2 using ^{225}Ac -pertuzumab can enhance the therapeutic efficiency of pertuzumab. **Materials and Methods:** Pertuzumab was conjugated with an eighteen-membered macrocyclic chelator p-SCN-Bz-macropa and radiolabeled with ^{225}Ac for alpha particle therapy. The radiochemical yield of ^{225}Ac -pertuzumab was >95%. The (radio)immunoconjugate was characterized by flow cytometry, radioligand binding assays, HPLC and internalization rate (live-cell imaging). In vitro cytotoxicity was studied in HER2 positive JIMT-1 cells, a pertuzumab/trastuzumab resistant model with medium to low HER2 expression. In vivo radioimmunotherapy using ^{225}Ac -pertuzumab was studied using JIMT-1 xenograft following treatment with three doses of 350 nCi/dose administered 10 days apart. In vivo study endpoint was tumor volume $\geq 1500 \text{ mm}^3$. Control treatment groups included PBS, pertuzumab and ^{225}Ac -labeled isotype control IgG. **Results:** Flow cytometry showed > 90% binding to the cells. In vitro studies in JIMT-1 showed enhanced cytotoxicity (IC_{50}) of ^{225}Ac -pertuzumab ($5.7 \pm 1.2 \text{ nM}$) which was 41 folds less than pertuzumab ($215 \pm 1.01 \text{ nM}$). ^{225}Ac -pertuzumab was effective at inhibiting the growth of JIMT-1 tumors. 9/8 mice treated injected with ^{225}Ac -Pertuzumab had tumor decreased to $< 50 \text{ mm}^3$. Median survival after > 90 days since start of treatment are: ^{225}Ac -Pertuzumab (not yet reached); PBS-treated (51 days). **Conclusion:** ^{225}Ac -labeled Pertuzumab displayed promising therapeutic efficiency towards HER2 positive BC. Efficiency of this radioimmunoconjugate in 3D spheroids and other Her2 positive xenografts is ongoing **References:** None

²Department of Protein Technology, KTH - Royal Institute of Technology, Stockholm, SWEDEN, ³Research Centrum for Oncotheranostics, Research School of Chemistry and Applied Biomedical Sciences, Research Tomsk Polytechnic

University, Tomsk, RUSSIAN FEDERATION, ⁴Department of Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, ⁵Science for Life Laboratory, Uppsala University, Uppsala, SWEDEN, ⁶Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: ADAPT6 is a small (5 kDa) scaffold protein, which binds to HER2 with high affinity. Radiolabeled ADAPT6 provides a high-contrast imaging of HER2-expressing tumors in clinics, but a high renal reabsorption prevents its use for radionuclide therapy. We tested a hypothesis that a fusion with an albumin-binding domain (ABD) from protein G would result in a binding of radiolabeled ADAPT6 to albumin in blood. Such binding would prevent glomerular filtration and reabsorption. In this way, an absorbed dose to kidneys will be reduced, which would enable radionuclide therapy. **Materials and Methods:** ABD₀₃₅-ADAPT6 (N-terminal position of ABD) and DOTA-ADAPT6-ABD₀₃₅ (C-terminal position of ABD) were produced recombinantly and maleimido-derivative of DOTA was coupled site-specifically to C-terminal cysteines of constructs. The conjugates were labeled with ¹⁷⁷Lu and characterized in vitro using HER2-expressing SKOV-3 and BT474 cells. To select the best variant, their biodistribution 48 h p.i. was measured in mice bearing SKOV-3 xenografts. Biodistribution of ¹⁷⁷Lu-DOTA-ADAPT6-ABD₀₃₅ was measured at 4, 24, 48, 72, 168 and 236 h p.i. and absorbed doses were calculated. In experimental therapy, one group of mice was treated with a single injection of 18 MBq (6 µg) ¹⁷⁷Lu-DOTA-ADAPT6-ABD₀₃₅ and another with two such injections, three weeks apart. Control groups were treated with PBS, 6 µg of non-labeled DOTA-ADAPT6-ABD₀₃₅ and 18 MBq (6 µg) control protein ¹⁷⁷Lu-DOTA-ADAPT_{Neg}-ABD₀₃₅, which binds to albumin but not to HER2. **Results:** Both ¹⁷⁷Lu-DOTA-ADAPT6-ABD₀₃₅ and ¹⁷⁷Lu-DOTA-ABD₀₃₅-ADAPT6 bound to HER2-expressing cell lines specifically and with high affinity (485 ± 88 and 432 ± 158 for ¹⁷⁷Lu-DOTA-ADAPT6-ABD₀₃₅ and ¹⁷⁷Lu-DOTA-ABD₀₃₅-ADAPT6, respectively). ¹⁷⁷Lu-DOTA-ADAPT6-ABD₀₃₅ provided higher tumor uptake and lower renal uptake than ¹⁷⁷Lu-DOTA-ABD₀₃₅-ADAPT6 at 48 h p.i. Uptake of ¹⁷⁷Lu-DOTA-ADAPT6-ABD₀₃₅ in HER2-positive SKOV-3 xenografts (35 ± 12 %ID/g) was significantly (p < 0.005) higher than in HER2-negative Ramos xenografts (2 ± 12 %ID/g) at 48 h p.i. Absorbed doses were 94, 1060 and 3479 mGy/MBq for bone marrow, kidneys and tumor, respectively. Median survival in the control groups was 25, 25, and 31 d for treatment with PBS, unlabeled DOTA-ADAPT6-ABD₀₃₅, and ¹⁷⁷Lu-DOTA-ADAPT_{Neg}-ABD₀₃₅, respectively. A single injection of 18 MBq of ¹⁷⁷Lu-DOTA-ADAPT6-ABD₀₃₅ resulted in a significant (p < 0.0001) extension of a median survival to 70 d. In the mice treated with 20 injections ¹⁷⁷Lu-DOTA-ADAPT6-ABD₀₃₅, only 1 mouse died at the time of experiment termination. **Conclusion:** In the preclinical setting, ¹⁷⁷Lu-DOTA-ADAPT6-ABD₀₃₅ has a strong effect on HER2-expressing xenografts

and has no long-term toxicity. This variant should be considered for clinical translation. **References:** None

EP-289

Preclinical evaluation of targeted alpha therapy using ²²⁵Ac-DOTA-E[c(RGDfK)]₂ for pancreatic cancer

M. Yoshimoto¹, K. Washiyama², Y. Yoshii³, K. Ohnuki¹, H. Fujii¹; ¹Division of Functional Imaging, EPOC, National Cancer Center, Kashiwa, JAPAN, ²Advanced Clinical Research Center, Fukushima Medical University, Fukushima, JAPAN, ³National Institute of Radiological Sciences, National Institutes for Quantum and Radiological Science and Technology, Chiba, JAPAN.

Aim/Introduction: There is no curable therapeutic strategy for advanced pancreatic cancer up to now. This has led to its low survival rate. Many studies have revealed that targeted alpha therapy, radionuclide therapy using alpha particles such as ²²⁵Ac and ²¹¹At, would be a new attractive cancer treatment strategy. We have reported that SPECT imaging using ¹¹¹In-DOTA-c(RGDfK) as an α_vβ₃ imaging agent could successfully detect small tumors in a pancreatic carcinogenesis model, indicating that RGD containing peptides would be possible candidates as a radionuclide carrier for pancreatic cancer. In this study, we investigated tumor uptake of ¹¹¹In-DOTA-E[c(RGDfK)]₂ in human pancreatic cancer xenograft mice. Besides, the therapeutic efficacy and side effects of ²²⁵Ac-DOTA-E[c(RGDfK)]₂ were estimated in human pancreatic cancer BxPC-3 xenograft mice. **Materials and Methods:** In this study, AsPC-1, BxPC-3, Capan-1, PANC-1, and PSN-1 as human pancreatic cancer cell lines, were used. Biodistribution of ¹¹¹In-DOTA-E[c(RGDfK)]₂ was determined at 1, 4, and 24 h after the injection. In the therapeutic experiment, ²²⁵Ac-DOTA-E[c(RGDfK)]₂ (20, 40, and 65 kBq/mouse) was injected. Body weight and tumor size were measured. Hematological, hepatic, and renal toxicity was also examined. **Results:** The biodistribution study indicated the high uptake of ¹¹¹In-DOTA-E[c(RGDfK)]₂ in BxPC-3 and PANC-1 (7.04 and 5.76 %ID/g at 1 h). AsPC-1 was the lowest uptake (3.41 %ID/g at 1 h). More than 50 % of the tumor uptake was retained up to 24 h. In the therapeutic experiment using BxPC-3 xenograft mice, ²²⁵Ac-DOTA-E[c(RGDfK)]₂ successfully suppressed the tumor growth. The 65 kBq of ²²⁵Ac-DOTA-E[c(RGDfK)]₂ significantly inhibited the tumor growth, while the decrease in the body weight was observed from 40 days after the administration. In the blood toxicity, ²²⁵Ac-DOTA-E[c(RGDfK)]₂ decreased in white blood cells and platelets. The liver toxicity dose-dependently appeared, though the kidney toxicity was not obvious. **Conclusion:** These results suggested that ²²⁵Ac-DOTA-E[c(RGDfK)]₂ has great potential to treat intractable pancreatic cancers. However, we need to further investigate administration protocols to reduce the radiotoxicity. **References:** None

EP-290**Size-controlled ²²⁴Ra-labelled calcium carbonate microparticles against peritoneal carcinomatosis**

R. Li^{1,2,3}, T. B. Bønsdorff³, I. S. Jorstad³, K. Lindland³, S. K. Tonstad³, Ø. S. Bruland^{1,4}, S. Westrom³, R. H. Larsen³;

¹Institute of Clinical Medicine, University of Oslo, Oslo, NORWAY, ²Department of Radiation Biology, Institute of Cancer Research, the Norwegian Radium Hospital, Oslo University Hospital, Oslo, NORWAY, ³Oncoinvent AS, Oslo, NORWAY, ⁴Department of Oncology, the Norwegian Radium Hospital, Oslo University Hospital, Oslo, NORWAY.

Aim/Introduction: Calcium carbonate microparticles functioning as carriers of ²²⁴Ra provide intraperitoneal retention of the alpha emitter to deliver its radiation dose to micrometastases originating from cancers with peritoneal seeding. Addition of excipient is done with the purpose of stabilizing the size of ²²⁴Ra-labelled microparticles in suspension. Further, the method of radiolabelling can be varied as ²²⁴Ra may be either surface labelled or inclusion labelled into the calcium carbonate microparticles. We have evaluated whether these steps of optimization influence the therapeutic efficacy in two different models of peritoneal carcinomatosis: one xenograft ovarian cancer model and one syngeneic colorectal cancer model. **Materials and Methods:** Calcium carbonate microparticles for surface labelling of ²²⁴Ra were produced by spontaneous precipitation, where after ²²⁴Ra was adsorbed on the microparticles. Inclusion labelling was performed by simultaneous incorporation of ²²⁴Ra into the bulk of the microparticles during CaCO₃ precipitation. Labelled microparticles were suspended in 0.9% NaCl, with or without the presence of size controlling excipients, followed by terminal sterilization in an autoclave. Models for peritoneal carcinomatosis were established by intraperitoneal inoculation of either human ovarian cancer cells (ES-2) in athymic nude mice, or murine colorectal cancer cells (CT26.WT) in immunocompetent BALB/c mice. Antitumour efficacy was evaluated by a single injection of 14–26 kBq of each variant of the ²²⁴Ra-labelled microparticle suspension. **Results:** Addition of size controlling excipients to the radiolabelled microparticle suspension stabilized the median particle diameter at 5–9 µm for up to 8 days, while the diameter increased more than 2-fold when no excipient was present. Suspensions containing excipients were easier to handle because of longer microparticle sedimentation times. The ²²⁴Ra-labelled CaCO₃ microparticles extended the survival compared to control in both tumour models, and there was no difference among groups receiving the different variants of the labelled suspension, neither with respect to addition of excipient nor the method of labelling. **Conclusion:** Radium-224-labelled CaCO₃ microparticles represent a promising therapy against peritoneal carcinomatosis. The tested excipients yield control of microparticle size and a product which remained

well suspended, while maintaining the therapeutic effect in preclinical tumour models. **References:** None

EP-291**Feasibility of MR-guided intratumoral treatment with Holmium-166 microspheres in a brain tumor model**

N. Klaassen¹, N. Morsink², M. de Vries³, J. van den Dobbelsteen³, M. Boswinkel¹, S. van Nimwegen², J. Nijsen^{1,4};

¹Radboud university medical center, Radboud Institute for Molecular Life Sciences, Department of Radiology, Nuclear Medicine and Anatomy, Nijmegen, NETHERLANDS, ²Utrecht University, Department of Clinical Sciences of Companion Animals, Faculty of Veterinary Medicine, Utrecht, NETHERLANDS, ³Delft University of Technology, Department of BioMechanical Engineering, Delft, NETHERLANDS, ⁴Quirem Medical B.V., Zutphen, NETHERLANDS.

Aim/Introduction: Brain cancer is one of the most aggressive and difficult-to-treat malignancies. Standard of care includes neurosurgery, radiotherapy, and chemotherapy. However, treatment is rarely curative. A minimally invasive intratumoral treatment, in which radioactive particles are injected directly into the tumor, might improve the overall outcome. Intratumoral needle-injection of holmium-166 (¹⁶⁶Ho) microspheres (MS) has potential to be a successful therapy. ¹⁶⁶Ho (half-life 26.8h) emits high-energy beta rays (mean 0.67 MeV, max 1.85 MeV) with a limited penetration depth (mean 2.2 mm, max 8.7 mm) enabling high local tumor ablative radiation dose with minimal side effects. Visualization of holmium can be performed by SPECT, MRI and CT, due to emission of gamma rays (6.7%, 81 keV), paramagnetic properties, and high mass attenuation coefficient, respectively. These multimodal imaging options offer the possibility to visualize and quantify distribution of ¹⁶⁶Ho-MS directly after injection and during follow-up. Initial results of this ‘microbrachytherapy’ approach are promising. However, due to the relatively shallow penetration, a proper distribution of microspheres in tumor tissue is crucial for lethal dose-coverage of the entire tumor. This can be achieved by using image-guided injection of ¹⁶⁶Ho-MS and realtime quantitative imaging-dosimetry to guide additional injections during the treatment procedure (dose-painting). The purpose of this study was to evaluate feasibility of intratumoral dose-painting with ¹⁶⁶Ho-MS in a brain tumor mimicking phantom with dedicated delivery device. **Materials and Methods:** A tissue phantom, resembling a brain with embedded tumor, was developed mimicking the specific imaging and mechanical responses of both brain and tumor tissues. Among others, the phantom was composed of polyvinyl alcohol and phytigel. Predefined volumes of ¹⁶⁶Ho-MS suspended in an injection fluid, were injected in a controlled manner at different positions in the phantom tumor using a dedicated delivery device. The procedures were performed under full MR-guidance. To

evaluate the dose distribution, simulated dosimetry was performed using Q-suite. **Results:** The phantom resulted in a model with MR imaging properties comparable to normal brain and tumor tissue. Administration of ^{165}Ho -MS resulted in a controlled near-real-time MR-guided injection with the dedicated delivery device. MR guided administration resulted in the possibility to observe the ^{165}Ho -MS distribution within the phantom during and after injection. The direct quantitative distribution feedback enabled the spatial deposition of ^{165}Ho -MS in the target area, resulting in a dose distribution covering the artificial tumor volume. **Conclusion:** We demonstrated the feasibility of controlled MR-guided tumor dose-painting using ^{165}Ho -MS in a tissue phantom. **References:** None

EP-292

Conjugation of GRPR-targeting antagonist RM26 to albumin-binding domain extends antagonist's blood circulation and residence in tumours

A. Abouzayed¹, S. S. Rinne¹, F. Wadea¹, H. Tano², Á. Nagy², A. E. Karlström², V. Tolmachev¹, A. Orlova¹;
¹Uppsala University, Uppsala, SWEDEN, ²KTH Royal Institute of Technology, Stockholm, SWEDEN.

Aim/Introduction: imaging of gastrin-releasing peptide receptors (GRPR) can be used for diagnostic of prostate cancer. Recently it was proposed for targeting radiotherapy. However, due to rapid blood clearance, multiple frequent injections of radioagent would be required. The aim of this study was to extend blood circulation of GRPR antagonist RM26 (D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH₂) by its conjugation to an albumin-binding domain (ABD) and to evaluate utility of new conjugate for therapy. **Materials and Methods:** DOTA-ABD-RM26 conjugate was produced by peptide synthesis and labelled with ^{111}In . The [^{111}In]In-DOTA-ABD-RM26 was evaluated in vitro for binding specificity, stability, competitive inhibition (IC₅₀), and cellular retention (with or without the addition of human serum albumin (HSA)) using PC-3 cells. The in vivo specificity and biodistribution of [^{111}In]In-DOTA-ABD-RM26 up to 144 h pi were studied on PC-3 tumour bearing mice. For comparison, the biodistribution of [^{111}In]In-DOTA-RM26 was evaluated 1 h pi. **Results:** DOTA-ABD-RM26 was labelled with ^{111}In with moderate radiochemical yields. After purification on size-exclusion column, the radiochemical purity was >99.5%. Labelled conjugate was stable in PBS (0.9±0.2% release within 24 h). However, there was considerable release of ^{111}In in the presence of EDTA (2.6±1.8% within 1 h incubation and 15.2±1.2% within 24 h). It bound specifically to GRPR-expressing cells in presence of HSA and to PC-3 xenografts in vivo. Affinity of DOTA-ABD-RM26 to GRPR was worse than for DOTA-RM26 (30.1±2.7 nM vs 4.5±0.7 nM), and was additionally compromised when measured in presence of HSA (48.7±5.4 nM). Slow internalization of new

conjugate corroborate with antagonistic function of RM26. Residence time in blood was significantly extended for ABD-fused RM26 (1 h pi 32±4 %ID/g vs 0.27±0.03 %ID/g). In vivo, tumour activity uptake of [^{111}In]In-DOTA-ABD-RM26 reached 11±2 %ID/g and did not decrease up to 144 h pi. However, this was accompanied by high uptake over time in various organs such as liver, spleen, and bone. Activity uptake in kidneys was higher than in tumours. **Conclusion:** this proof-of-principle study demonstrated that conjugation of short GRPR-binding peptide RM26 with ABD resulted in a high and retained agent's tumour uptake. Conjugate can be used for GRPR-targeted delivery of cytotoxic drugs. However, the elevated uptake in kidneys and other organs due to label instability and compromised affinity to both GRPR and albumin abolish its use for radionuclide therapy. Further changes in the molecular design of the conjugate might improve its biodistribution profile. **References:** None

Integration of diagnosis and treatment of lymph node metastasis with radioactive upconversion luminescent nanoprobes

S. Xiumin^{1,2}, Z. Chuan^{1,2}, Q. Shanshan^{1,2}, Z. Jianfeng^{1,2}, Z. Ruijuan^{1,2}, C. Yanni^{1,2}, F. Longfei^{1,2}, L. Yamin^{1,2}, Z. Lulu³, W. Feng³, Z. Ran^{*1,2};
¹Radiation Medicine and Protection, Soochow University, Suzhou, CHINA, ²State Key Laboratory of Radiation Medicine and Protection, Soochow University, Suzhou, CHINA, ³Department of Nuclear Medicine, Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA.

Aim/Introduction: The detection and treatment of lymph node metastasis is of great importance for therapy planning and prognosis of cancers, but remains challenging in the clinic. In the current study, we report a tumor-specific imaging probe constructed with NaGdF₄:Yb,Tm,Ca@NaLuF₄ core@shell upconversion nanoparticles showing distinctive near infrared emission. The feasibility of binding of nuclide labeled the upconversion nanoparticles NaGdF₄:Yb,Tm,Ca@NaLuF₄ coupled with anti-epidermal growth factor receptor 2 (HER2) as a theranostic platform was investigated. **Materials and Methods:** The up-conversion nanoparticles NaGdF₄:Yb,Tm,Ca@NaLuF₄ with distinctive near infrared emission were prepared by thermal decomposition. Asymmetric polyethylene glycol (PEG) bearing a maleimide group at one end was used to replace the oleate ligand. And then the Herceptin antibody was conjugated to upconversion nanoparticles through a "click" reaction. Using a ^{177}Lu -labeled nanoparticle. For in vitro experiments, SKBR3 (HER2 high expression) and MCF7 (low expression) cells were incubated with ^{177}Lu -NP-mAb. For in vivo experiments, SKBR3 and MCF7 tumor-bearing lymph node metastasis mice were intravenously injected with ^{177}Lu -NP-mAb and imaged before and 24 h, 48 h, 72 h, 7 d, 14 d, 30 d post-injection. **Results:** The synthesized probe has good

biocompatibility and is stable in vivo and in vitro. For vitro experiments, The NP-mAb demonstrated high affinity toward HER2, the distribution of NP-mAb probe in SKBR3 cells was 14 times higher than that in MCF7 cells. In the vivo experiments, up-conversion luminescence imaging and SPECT imaging showed a high degree of agreement, SKBR3 tumor-bearing lymph node metastasismice treated with ^{177}Lu -NP-mAb exhibited significant tumor load reduction than MCF7tumor-bearing lymph node metastasismice ($P < 0.05$). **Conclusion:** SPECT imaging and up-conversion imaging complement each other, forming their advantages. By monitoring drug metabolism and distribution, up-conversion imaging provides imaging diagnosis and treatment basis, while SPECT imaging provides longer term monitoring. The resulting ^{177}Lu -NP-mAb nanoprobes presented excellent targeting ability and remarkable binding specificity to HER2-overexpressing cells in vitro, which enabled successful detection and treatment of metastatic lymph nodes through upconversion luminescence. Most importantly, the SPECT imaging suggest that antibody conjugation can prolong the blood half-life of UCNPs by evading the MPS uptake, which explains the outstanding performance of the resulting nanoprobes in diagnosing lymph node metastasis and therefore ^{177}Lu -NP-mAb can be used as a potential means to identify patients well-suited for treatment with theranostics nanoparticles and provides a new basic research of diagnosis and treatment strategy for tumor lymph node metastasis. **References:** None

Aim/Introduction: Medication-related osteonecrosis of the jaw (MRONJ) is characterized by progressive bone

destruction in the maxillofacial region, associated with severe drug side-effect and having a major impact on patients' quality of life. With no effective treatment or optimal therapy strategy, new approaches are highly expected. To our knowledge, few studies have applied PET to the diagnosis of MRONJ in animal models. This work aims to detect metabolic changes in soft tissue and bone using a novel microPET system in an animal model of MRONJ under photodynamic therapy, based in our recently developed photosensitizers (PS)^{1,2}. **Materials and Methods:** A previously validated MRONJ animal model was used³. Wistar female rats (10 weeks) were administered with Zoledronate (Zol) (0.1 mg/kg) for 8 weeks, to induce ONJ. At week 4, the first upper right molar was extracted and, 72 hours before this procedure, rats were medicated with PS. Since photodynamic therapy (PDT) activates PS, the animals were randomly divided into two groups to ascertain the action of PS over ONJ: group 1, animals not submitted to PDT; group 2, animals submitted to PDT. Immediately after tooth extraction, irradiation of the surgical area was performed with LASER (635 nm, 1 min, 24 J). Two weeks post-surgery, rats underwent ^{18}F -FDG PET imaging, using the easyPET.3D scanner (RI-TE Lda, Portugal⁴). Animals were occluded and samples collected for histologic and histomorphometric evaluation. **Results:** The easyPET.3D images, for group 1 (without PDT), showed a similar ^{18}F -FDG uptake compared to control, proving that PS remained inactive; while for group 2 (with PDT) presented a higher tracer uptake, which was focal and unilateral, matching the site of tooth extraction, therefore indicating the PS activation by the PDT. PS effect over ONJ was reflected by the higher metabolic activity of soft tissues. This study has not yet been completed, hence results regarding the histological evaluation of the collected samples are not yet available. **Conclusion:** This pilot results, obtained with ^{18}F -FDG PET imaging in the selected rat model, by revealing the activation of PS with PDT, suggest that PS is a potential treatment for MRONJ. Further PET studies will be performed with ^{18}F -NaF to assess the effect of PS directly over the bone. **References:** 1. Pereira N. et al., Eur J Med Chem. 2015, 103:374. 2. Yttrium-90 PET imaging with digital photon counting for radioembolization absorbed dose monitoring

J. Labour, P. Boissard, F. Khayi, P. Veyrat Durebex, D. Kryza, S. Parisse-Dimartino, T. Mognetti, D. Sarrut, J. N. Badel; CREATIS; Centre Léon Bérard; CNRS UMR 5220; INSERM U1044; Université de Lyon; INSA Lyon; Université Lyon 1, Lyon, FRANCE.

Aim/Introduction: We investigated the accuracy of image-based ^{90}Y PET dosimetry quantification with a SiPM-based PET/CT for radioembolization dose monitoring purposes. Different image reconstruction protocols from published studies [1,2] were used to compare with the clinical protocol in our centre. **Materials and Methods:** Three ^{90}Y phantoms were imaged: (1) a NEMA NU 2-1994 PET phantom with an insert filled with a uniform activity concentration (AC) = 1.71 MBq/mL, (2) a cylindrical phantom with AC = 0.29 MBq/mL, and (3) a NEMA body phantom containing six spheres of varying diameters (10–37 mm), with AC = 2.18 MBq/mL in all spheres and a sphere-to-background ratio of 9:1. Listmode PET data were acquired with a Philips Vereos digital photon counting (DPC)-PET/CT for 15 minutes in a single-bed position. Images were reconstructed using OSEM iterative algorithm with 3 iterations, 5 subsets, time-of-flight (ToF) and point-spread function (PSF). 2mm full-width at half-maximum (FWHM) Gaussian post-reconstruction filter was applied to all reconstructions. Phantoms (1) and (2), less influenced by partial-volume effects, were used for absolute quantification measurements. Phantom (3) was used to determine the AC recovery coefficients (RCs) of the hot spheres and background, based on CT-defined VOIs. We compared the results with those obtained from reconstruction parameters proposed by [1] (1 iteration, 21 subsets, ToF, PSF, 4.5mm FWHM filter) and [2] (3 iterations, 12 subsets, ToF, PSF, 5.2mm FWHM filter). Reconstructions were also performed with only the first 11 minutes of the acquisitions. **Results:** The relative differences between the reference and measured ACs in phantoms (1) and (2) were less than 1.5% and 2.5%, respectively. RCs for the hot spheres in phantom (3) for all reconstruction sets were between 0.74–0.78, 0.71–0.78 and 0.3–0.4 for the 37, 22 and 13mm spheres, respectively. RCs for the background using our parameters and the ones from [1] and [2] were 0.96, 0.86 and 0.94, respectively. RCs obtained with 11-minutes reconstructions were within 5% of the 15-minutes ones. ACs standard deviations were below 0.8 MBq/mL for the hot spheres. **Conclusion:** Reconstructions using 3 iterations provided

overall better RCs than 1 iteration. Acquisition duration could be reduced by 30% (15 to 11 minutes) without accuracy degradation, thus improving patient comfort. **References:** [1]Pasciak et al. Analysis of results of effective dose estimation obtained from RADAR 2017 dose assessment model for nuclear medicine procedures

L. Del Barco, M. Calderón Calvente, L. de la Cueva Barrao, A. Gandia Martínez, S. Moñux Salvador, G. Guzmán Prudencio, L. Nieto Morcillo, M. Falgás Lacueva, P. Navarro Beltrán, S. Álvarez Ruiz, M. Sangrós Sahún, D. Abós Olivares; Hospital Universitario Miguel Servet, Zaragoza, SPAIN.

Aim/Introduction: To analyze the results of effective dose (E) estimation of the most frequent procedures using photon emitters in Nuclear Medicine, obtained from RADAR 2017 dose assessment model. To compare these results with those obtained from ICRP 128 (2015) recommendations, and to assess how using each dose assessment model can change E results. **Materials and Methods:** E estimation data was collected from photon emitter procedures performed during the last year in our department, obtained from RADAR 2017 dose estimation model for age groups: ≤ 1 year old; >1 -5 years old; >5 -10 years old; >10 -15 years old and adults. Injected activity was the one recommended by international guidelines and EANM Pediatric and Dosimetry Committees. Hybrid exams (SPECT / CT) and procedures for which there is no RADAR 2017 dosimetry estimation were excluded. Results for (E) were compared with those obtained by using ICRP 128 (2015) recommendations. **Results:** With RADAR 2017 dose evaluation model we obtained a lower mean value of E on most of the procedures that were analyzed, being significantly lower for Renogram, Renal scintigraphy on >10 -15 years old, Thyroid scintigraphy, Meckel's scan and Bone Scan (0.12 to 1.16 mSv, 25% to 67%). Brain perfusion and Renal scintigraphy on ages under 10 obtained a significantly greater difference for E (0.33 to 2.85 mSv, 26% to 29%). **Conclusion:** These results are an updated collection of estimated E values for photon-

emitting radiopharmaceuticals commonly used in Nuclear Medicine, considering RADAR 2017 dose assessment model compared to ICRP 128) recommendations. Methodological changes on estimation lead to lower E for most of diagnostic procedures using photon emitters, this is of special interest for patients undergoing repeated ionizing radiation (dosimetry history). **References:** None

EP-297

Patient Radiation Doses from hybrid NM/CT Scans: Manitoba, Canada Vs. Europe

S. Eustace^{1,2}, Y. Kady³, M. Al-Abedi^{1,2}, I. Elbakri^{1,2};

¹CancerCare Manitoba, Winnipeg, MB, CANADA, ²Department of Radiology, University of Manitoba, Winnipeg, MB, CANADA,

³Physics Department, Beirut Arab University, Beirut, LEBANON.

Aim/Introduction: This study documented patient radiation doses from common clinical hybrid nuclear medicine / computed tomography (NM/CT) procedures in the Canadian province of Manitoba (population 1.34 million). Results were compared to European values and used to establish diagnostic reference levels (DRLs). **Materials and Methods:** All hybrid NM/CT facilities in Manitoba participated, comprising of eight SPECT/CT systems and one PET/CT system. Data were collected for six clinical SPECT/CT procedures and three PET/CT procedures: Bone (Torso only), Myocardial Perfusion, Lung V/Q, Parathyroid, Octreotide, Sentinel Lymph Node / Melanoma Mapping, then PET/CT brain, Near Whole Body(NWB), and Head/ Neck (H/N) + NWB. DLP (mGy.cm) and administered activity (MBq) data were collected for 10-20 patients weighing 70+/- 20kg. Paediatric and pregnant patients were excluded. Comparison was drawn to relevant values presented in recent European publications. **Results:** Provincial CT DRLs have been established for the following procedures; Bone (190 mGy.cm), Cardiac MPS (55 mGy.cm), Lung V/Q (140 mGy.cm), Parathyroid (115 mGy.cm), and In-111 Octreotide (155 mGy.cm) SPECT/CT procedures. Site DRLs were established for the following PET/CT procedures; Near Whole Body (NWB 335 mGy.cm), H/N + NWB (525 mGy.cm), and Brain (645 mGy.cm). Provincial NM DRLs were calculated for Bone (815 MBq), Cardiac MPS (1490 MBq), Lung V/Q (40/210 MBq), Parathyroid (785 MBq MIBI), and In-111 Octreotide (135 MBq) SPECT/CT procedures. Site DRLs were calculated for all F-18 FDG PET/CT procedures; NWB or H/N +NWB (435 MBq), and Brain (270 MBq). The Sentinel Lymph Node/Melanoma procedures were too varied to establish DRL values. These values are comparable to values published in the literature. CT DRL ranges observed were Bone (150-200mGy.cm), Cardiac MPS (36-70mGy.cm), Lung V/Q (100mGy.cm, perfusion only), Parathyroid (160-170mGy.cm), In-111 Octreotide (240mGy.cm) and PET/CT NWB (400-750mGy.cm). For the radionuclide administration, the observed activity ranges were as follows; Bone (600-800

MBq), Cardiac MPS (950-1600 MBq), Lung V/Q (40/120-200 MBq), Parathyroid (700-900 MBq MIBI), In-111 Octreotide (220 MBq) F-18 FDG Near Whole Body PET (350-400 MBq), and F-18 FDG PET Brain (250 MBq). **Conclusion:** Several dose optimization opportunities were identified and are being pursued. For example, one system had average DLPs equal to or higher than the provincial DRL for all but cardiac studies, almost 1.5 times larger for parathyroid imaging, and double the DRL for octreotide imaging. Ongoing optimization work focuses on standardizing CT protocols. Results of the survey, comparison to European values and initial optimization efforts will be presented. **References:** None

EP-298

Quantification of myocardial dosimetry and glucose metabolism using a 17 segment model of the left ventricle in esophageal cancer patients receiving radiotherapy

X. Sha¹, G. Gong¹, C. Han², Y. Yin¹;

¹Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong, Jinan, CHINA, ²Turku PET Centre, Turku University Hospital, Turku, FINLAND.

Aim/Introduction: Previous studies have shown that increased cardiac uptake of 18F-fluorodeoxyglucose (FDG) from positron emission tomography (PET) may be an indicator of myocardial injury after radiotherapy. The primary objective of this study was to quantify cardiac subvolume dosimetry and 18F-FDG uptake in oncologic PET using a 17-segment model of the left ventricle (LV) and to identify dose limits related to changes in cardiac FDG uptake after radiotherapy (RT). **Materials and Methods:** Twenty-four esophageal cancer (EC) patients who underwent consecutive oncologic 18F-FDG PET/CT scans at baseline and post-RT were enrolled in this study. The radiation dose and the 18F-FDG uptake were quantitatively analyzed based on a 17-segment model. The 18F-FDG uptake and doses to the basal, mid and apical regions, and the changes in the 18F-FDG uptake for different dose ranges were analyzed. **Results:** A heterogeneous dose distribution was observed, and the basal region received a higher median mean dose (18.36 Gy) than the middle and apical received the highest doses, all of which were greater than 10 Gy. Three patterns were observed for the myocardial 18F-FDG uptake related to the radiation dose before and after RT: an increase (5 patients), a decrease (13 patients) and no change (6 patients). In the pairing analysis, the 18F-FDG uptake after RT decreased by 28.93% and 12.12% in the low-dose segments (0-10 Gy and 10-20 Gy, respectively) and increased by 7.24% in the high-dose segments (20-30 Gy). **Conclusion:** The RT dose varies substantially within LV segments in patients receiving thoracic EC RT. Increased 18F-FDG uptake in the myocardium after RT was observed

for doses above 20 Gy. **References:** None

¹⁷⁷Lu-DOTATATE Quantification for Patient Personalised Dosimetry in Therapy of Neuroendocrine Tumours

C. Rodrigues^{1,2}, P. Ferreira¹, F. P. M. Oliveira¹, Á. Silva¹, L. Peralta^{2,3}, D. C. Costa¹;

¹Champalimaud Foundation, Champalimaud Centre for the Unknown, Lisbon, PORTUGAL, ²Faculdade de Ciências da Universidade de Lisboa, Lisbon, PORTUGAL, ³Laboratório de Instrumentação e Física Experimental de Partículas, Lisbon, PORTUGAL.

Aim/Introduction: Peptide Radionuclide Radiotherapy (PRRT) with ¹⁷⁷Lu-DOTATATE is a nuclear medicine therapeutic option with increasing interest over the last few years due to its efficacy in the treatment of metastatic and/or inoperable neuroendocrine tumors overexpressing somatostatin receptors. Toxicity may represent a limitation of this therapy. The evaluation of absorbed dose, besides being required by law, is an essential tool for the improvement of treatment plans. The present study investigates the average dose absorbed by the liver, kidneys, spleen and bone marrow, for further customization of future treatments. **Materials and Methods:** From August 2017 to March 2019, 4 patients, treated with 7.4±0.3 GBq of ¹⁷⁷Lu-DOTATATE per treatment cycle (four cycles/patient), accepted to undertake whole-body planar images, single photon emission computed tomography (SPECT) and X-ray computerized tomography (CT) images of the abdomen, at specific time points (1h, 4h, 24h and 120h), after radiopharmaceutical administration. Patient data were retrospectively selected from our institution's database. After processing, structural images were used to perform manual segmentation of the volume for all organs of interest. For each organ, the radiopharmaceutical kinetic distribution was analysed, the voxel-wise absorbed dose distribution was determined based on SPECT activity images, and the organ toxicity was assessed. **Results:** After completion of the four treatment cycles, the mean absorbed dose, for the 4 patients investigated, was as follows: liver 22±22 Gy; right kidney 20.3±8.6 Gy; left kidney 18±12 Gy; spleen 21.7±6.5 Gy and bone marrow 4.7±5.7 Gy. Additionally, we observed that approximately half of the mean absorbed dose on each cycle has occurred within the first five days after the radiopharmaceutical's administration. **Conclusion:** The mean absorbed doses in the kidneys, after all four therapy cycles, are below the established limits. On the other hand, the average value of the mean absorbed dose by the bone marrow is higher than expected^[1,2]. This indicates that, in an overall analysis, the administered activity could have been altered, not in an attempt to optimize treatment effectiveness, but rather to improve bone marrow toxicity. Despite the reduced number of patients investigated, so far,

our results are in agreement with the values presented by others. Ongoing work is designed to measure the absorbed dose by tumour lesions, and to optimize a protocol to implement personalized therapeutic medicine in patients with metastatic neuroendocrine tumours. **References:** [1] Sandstrom, M., et al. EP-300

An Analysis of Post-Therapy Lu177 Uptake Progression for Individual Volumes of Interest Across a Full Treatment Cycle

S. McGurk, D. R. McGowan, D. Morgan;
Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM.

Aim/Introduction: Lutetium-177 dotatate has been shown to significantly improve progression-free survival rates in patients with mid-gut NETs, however response to the treatment can vary between patients and between tumours in a given patient. The aim of this project is to use quantitative analysis of SPECT-CT images to monitor changes in Lutetium-177 uptake on a tumour by tumour basis throughout a 4 treatment cycle. **Materials and Methods:** Volumetric structures outlining regions of interest were generated using Hermes Hybrid Viewer on SPECT-CT studies acquired on a GE Discovery 670 24 hours after administration of the first treatment in the cycle. For each patient the liver, kidneys and spleen were outlined in addition to distinct foci of activity within or outside of these organs. The same structure sets were then applied to subsequent registered imaging studies following second, third and fourth treatments. To date in 3 patients 11 total organ volume structures were generated for liver, kidneys and spleen. In addition 17 regions of high uptake (10 within patient livers, 3 in chest and 4 in abdomen) with volumes ranging from 2.5cm³ to 206cm³ were identified and delineated. Count data from these volumes were converted to activities using a Lu177 sensitivity factor derived from phantom scanning. This data was used to calculate changes in uptake activity for each individual VOI relative to first treatment of the cycle at each post treatment scan. **Results:** To date the mean difference in measured counts across all regions was found to be -12.5% (range: -92.1% to +97.3%, n=28) from T1 to T2; +22.8% from T2 to T3 (range: -55.7% to 204.1%, n=29); -4.5% from T3 to T4 (range: -76.4% to 151.5%, n=15). The resulting total change from T1 to T4 was -4.1% (n=15), range: -95% to +148%. The rapid growth of small volume tumours can result in large proportional increases in uptake. Of the 17 tumour regions identified 5 were <10cm³. **Conclusion:** This work demonstrates variability within cycles and the need for personalised dosimetry in order to understand patient response to treatments. **References:** None

EP-301

Effect of attenuation and scatter correction of Tc99m MAA SPECT images on dose evaluations in patients treated with Y90 resin microspheres

C. Pettinato, C. Mosconi, A. Cappelli, E. Tabacchi, E. Lodi Rizzini, S. Civollani, E. Terzi, L. Strigari, R. Golfieri;
AOU S. Orsola Malpighi - Bologna, Bologna, ITALY.

Aim/Introduction: The aim of this work was to evaluate the effect of attenuation and scatter correction on Tc99m-MAA SPECT images to calculate tumor and whole liver doses. **Materials and Methods:** 20 patients, treated with Y90 resin microspheres, were randomly retrospectively selected for this study. Each SPECT/CT scan data was reconstructed without any correction (IRNC), with CT based attenuation correction (IRAC) and with attenuation correction + scatter correction based on the two windows method (IRACSC). Tumor and liver doses were calculated using partition model, assuming a uniform distribution of the activity inside each compartment. The same ROI sets were applied on the three image data to calculate activities based on MAA distribution and Y90 doses. IRNC, IRAC and IRACSC results were compared in terms of tumor and liver doses by evaluating the statistical differences using a two sample t-test and calculating the relative percentage difference among values. **Results:** When tumor dose values were compared we found no statistically significant differences between the three data sets of images (IRNC - IRAC - IRACSC). The average relative percentage differences, respectively for IRNC vs IRAC, IRNC vs IRACSC and IRAC vs IRACSC, were 2.2, 6 and 3.8% and always less than 10%. The highest tumor dose values belonged to IRACSC images while the lowest to IRNC images. On the contrary whole normal liver doses showed a statistically significant difference for all the three groups of analyses with p values less than 0.001. The average relative percentage differences, respectively for IRNC vs IRAC, IRNC vs IRACSC and IRAC vs IRACSC, were 6.7, 22.7 and 16.8%. Despite tumor doses, whole normal liver doses were higher for IRNC images and lower for IRACSC images. **Conclusion:** When partition model is used and uniform distribution is assumed in the different compartments, attenuation and scatter correction don't significantly affect the tumor dose calculations. On the other hand they can affect the whole liver dose evaluation. From the safety point of view if the SPECT/CT scanner is not available, that means that attenuation and scatter corrections can't be applied, the IRNC images give an overestimation of liver dose that is safe for the patient. **References:** None

Use of tumour control probability model for determination of treatment efficiency of head-and-neck cancer

E. Sukhikh^{1,2}, Y. Sutygina^{1,3}, L. Sukhikh³;

¹Tomsk Regional Oncology Center, Tomsk, RUSSIAN FEDERATION, ²National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, ³National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: External beam radiotherapy based on volumetric modulated arc radiotherapy technic delivery is widely used for the treatment of the locally advanced head-and-neck cancer (LAHNC). There are some approaches of irradiation of LAHNC, for example, simultaneous integrated boost (SIB) and sequential boost (SEQ). Analysis of the developed treatment plans based on tumour control probability (TCP) models (Niemierko's TCP model) could help to estimate expected efficiency of the developed plans and to find optimal treatment schemes with respect to total dose value, fractional dose and overall treatment time (OTT). In this study, the simultaneous integrated boost VMAT (SIB-VMAT) plans and sequential boost VMAT (SEQ-VMAT) plans were developed and obtained TCPs based on the anatomical data of 11 patients. **Materials and Methods:** The anatomical data of 11 patients with LAHNC (larynx, oropharynx and oral cavity) were used. For each patient two treatment plans were developed, SIB-VMAT (70 Gy to tumour, 50 Gy to lymph nodes, 25 fractions) and SEQ-VMAT (70 Gy to tumour, 50 Gy to lymph nodes, 35 fractions). The developed plans were analyzed using the Niemierko's TCP model with Maciejewski's parameters (TCD50=70.26 Gy) taking into account dose-volume histograms and OTT. **Results:** The developed SIB-VMAT and SEQ-VMAT plans had the physical coverage of the CTV tumours more than 97% of prescribed dose delivered to more than 97% of the volume, except one. The average TCP value of SIB-VMAT was equal to 99.9% due to short OTT. The average value of TCP for SEQ-VMAT was equal to 61.0%. For one patient, the both SIB-VMAT and SEQ-VMAT plans showed zero expected efficiency due to CTV coverage 95%-95%. **Conclusion:** According to the Niemierko TCP model using Maciejewski's parameters (Maciejewski B et al., 1989), the 50% efficiency of the treatment could be reached at EUD equal to EUD = 70.26 Gy, when the prescription dose values higher than 71-72 Gy or 70 Gy delivered in less than 35 fractions. The

analysis of selected clinical trials showed that the reported results of treatment efficiency rather well correspond to the model predictions. However, the results of DVHs calculated for real patients' anatomical data showed that even small volumes of the tumour that were irradiated to doses less than 70 Gy in 35 fractions could significantly decrease the expected TCP value. The results of simulation and analysis of clinical practice show that the DVH of each patient should be analyzed on the expected TCP. **References:** None

Scatter correction in ^{99m}Tc SPECT by energy window narrowing and Monte Carlo simulation

S. Arvola, M. Seppänen, T. Noponen;

Turku University Hospital, Turku, FINLAND.

Aim/Introduction: Two novel methods, energy window narrowing in digital SPECT/CT scanner and Monte Carlo simulation -based method, were evaluated for ^{99m}Tc SPECT scatter correction. **Materials and Methods:** A Jaszczak phantom was filled with 442 MBq of ^{99m}Tc -pertechnetate and scanned using Discovery NM/CT 670 CZT camera (GE Healthcare, Tirat Hacarmel, Israel) as follows: wide-energy high resolution collimators, 120 projections over 360° with 39-s acquisition time per view, 128 × 128 matrix, and 15% energy window centered at 140 keV. A low-dose CT scan was performed for attenuation map. The SPECT acquisition was performed in list mode, which allowed generation of additional sinograms with narrower energy windows. The energy window was narrowed from 15 to 6% in one percentage point intervals producing ten separate sinograms. The data of each sinogram were reconstructed with and without Monte Carlo simulation -based scatter correction using HybridRecon-Oncology (version 3.0, Hermes Medical Solutions AB, Stockholm, Sweden) and ordered-subset expectation-maximization algorithm with six iterations and 15 subsets. Attenuation and collimator response corrections were always used, and the images were post-filtered using a Gaussian filter with 7-mm full width at half maximum. From the reconstructed images, a 15 × 15-pixel uniform region was segmented as background, and the five largest cold spheres were segmented using spherical volumes of interest with the actual diameters (9.5 - 31.8 mm) of the spheres. Total counts, background noise, and cold sphere contrasts were measured from all 20 SPECT images. **Results:** Energy window narrowing from 15 to 6% reduced the number of total counts by up to 35% and

increased background noise from 6 to 16%. Depending on the energy window width (EWW), Monte Carlo -simulation further reduced total counts by 12 (EWW = 6%) to 19 % (EWW = 15%) and increased background noise by 0 to 2 percentage units. Average contrast of the five largest cold spheres was not affected by EWW until it was set narrower than 9%. Then the average contrast started to decrease from 44% (EWW = 9%) to 38% (EWW = 6%). Depending on the EWW, Monte Carlo -simulation increased the average contrast by 7 (EWW = 6%) to 15 % (EWW = 15%) compared to the images without Monte Carlo -simulation. **Conclusion:** Monte Carlo -simulation based scatter correction increases the contrast of cold spheres in ^{99m}Tc SPECT scan when energy window narrowing preserves the contrast. **References:** None

Internal Audits: an Ally in the Promotion of a Radiation Protection Culture

L. Cunha¹, A. R. Roda^{2,1}, P. Ratão^{3,1}, M. Capoulas^{4,1}, F. Ferreira¹, M. Sousa⁵, H. Vasconcelos^{6,7}, A. S. Moreira¹, L. F. Metello^{1,8};

¹IsoPor-Azores, Angra do Heroísmo, PORTUGAL, ²Medical Physics Department, IPOFG, Coimbra, PORTUGAL, ³Nuclear Medicine Department, IPOFG, Lisbon, PORTUGAL, ⁴Pharmacy Department, HBA, Loures, PORTUGAL, ⁵Interdisciplinary Studies Research Center, ISEP/IPP, Porto, PORTUGAL, ⁶Sc. Techn. Fac., Univ. Azores, Ponta Delgada, PORTUGAL, ⁷CEFITEC, Physics Dept, Universidade Nova de Lisboa, Lisbon, PORTUGAL, ⁸ESS-IPP, Porto, PORTUGAL.

Aim/Introduction: Internal audits are between the most important tools supporting the management board of any organization. Regardless if they are conducted by an internal or an external auditor, the goals are to assist the organization in defining areas of improvement, while providing precise information needed to accomplish the established goals. We aim to contribute to improving the community awareness of the value of conducting regular audits and its impact on promoting a culture of radiation protection. **Materials and Methods:** In our department, the first audit started informally, essentially consisting of a checklist of legal requisites to become licensed. Further, the implementation of a quality management system created the need for undergoing regular internal audits on a process-centered analysis. Key staff members received formal training on defining goals and conducting internal audits. The main goals for internal audits are: continuously monitoring and analyzing the risks (either new or previously identified), the implemented mitigation

measures to address those risks; verifying the compliance regarding the legal framework; identifying opportunities for improvement, and any non-conformities; making recommendations to the board. **Results:** Currently, the outcomes and the level of compliance of several processes are systematically checked. Examples of audited processes are patients' and referring physicians' satisfaction, work practices regarding radiation protection issues, nosocomial infection prevention and control, and written records and record keeping. During auditing, items of a checklist are scored according to the level of conformance. When no or partial conformance is detected, a recommendation is released. In the next auditing, particular attention is given to the previously identified items to check whether the level of conformance has improved and the specific issue has been completely solved. If not, a new recommendation is released. The regular auditing process had a significant impact on the overall quality of services. It also led to changes in work practices such as the implementation of stricter rules regarding record keeping, equipment quality control, survey areas for radioactive contamination, cleaning procedures, waste management, and the correct use of shielding devices. **Conclusion:** The auditor's role in challenging the implemented practices in a pedagogic, non-penalizing way, as well as the involvement of the management board and the entire staff, demonstrated to be THE key to a successful outcome. By challenging the implemented practices and looking at them from a different angle, we created a safer, more effective, and efficient working environment, solidifying a stronger culture on radiation protection. **References:** None

EP-305

Attitude and commitment of Nuclear Medicine staff towards Safety Culture working in Nuclear Medicine department

N. Marwat;

Nuclear Medicine Oncology and Radiotherapy Institute, Islamabad, PAKISTAN.

Aim/Introduction: This study aimed to measure and access the knowledge, attitude and commitment that Nuclear Medicine staff had toward safety culture in Nuclear Medicine department **Materials and Methods:** The study is survey based upon a questionnaire designed to access attitude towards Safety Culture. This questionnaire consisted of 10 safety culture aspects: job satisfaction, knowledge, feedback and communication about errors, teamwork, communication openness, management support, frequency of error reported, non punitive response to errors and working conditions. Nuclear Medicine staff grouped into 4 as physicians, technologists, Pharmacists and Physicists. 28 questionnaires forms have been distributed with a response rate of 100%. **Results:**

Analysis provided an insight into attitude and commitment towards safety culture. Analysis of 10 of the broad domains of safety culture resulted: 4 of them showed strength, 4 of them has potential improvement and 2 has come up as weakness towards safety culture. Team work resulted as greatest strength while in contrary communication openness identified as weakest link towards safety culture. The survey result indicates that technologists working in Nuclear Medicine department consider the support from department and management inadequate, they report fewer incidents among the 4 professions. Punitive response analysis signifies that significant number restrain from reporting errors and events, and highlights that disciplinary response to events are major barrier to reporting. Staff have positive attitude towards safety culture, technologist have insufficient knowledge about safety culture. Positive attitude towards communicating errors is seen in maximum number of staff. Technologists do not have the required knowledge regarding safety culture as participant respondents shows the absence of training courses and unavailability of any protocols directing the staff behavior toward safety measures **Conclusion:** Safety Culture is vital component of safety in Nuclear Medicine. The survey suggested presence of management committed towards patient safety and encourages to report errors and near misses, who aim to improve communication and to eliminate the blame culture will serve to improve safety culture. Number of events reported can be increased by creating openness to communication. Importance of near misses is to be understood because these are powerful in identifying work process problems that can lead to an incident. Nuclear Medicine is technologically demanding field which is dependent on well trained and highly skilled staff, better safety culture demands continuous training of staff **References:** 1. Estimation of Conversion Factors for Quality Reference mAs for Child to Adult Reference Patient in Child SPECT-CT Protocols

S. Hansen¹, N. Bebbington²;

¹Rigshospitalet, Copenhagen, DENMARK,

²Siemens Healthineers, Aarhus, DENMARK.

Aim/Introduction: CT image quality and radiation dose are influenced by tube voltage (kV), tube current (mAs) and patient size and shape. CARE Dose 4D modulates mAs according to patient size and shape, performing topogram (scout scan) and angular based modulation, whilst maintaining a user-defined reference image quality. On the Symbia SPECT-CT systems, the reference patient for child scans was a 20kg child prior to software version

VB10 and is a 75kg adult thereafter. The aim was to estimate conversion factors for translating quality reference mAs between child protocols using child and adult reference patients for topogram-based patient-size-related dose level adaptations, following software upgrade or procurement of a new system. **Materials and Methods:** The thorax, abdomen and pelvis of a Kyoto Kagaku Pediatric Whole Body Phantom PBU70, representing a 20kg child, were first scanned on the T16 with child reference (software version VA60D) at 110kV and 80kV, with 100mAs quality reference, and the actual delivered effective mAs recorded. The scans were repeated on the Intevo Bold with adult reference (VB20B), with the phantom scanned at a range of quality reference mAs settings. The delivered average mAs values were plotted against the quality reference mAs settings for both scanners. The required quality reference mAs on the Intevo Bold (adult reference) that was necessary to achieve the same delivered mAs on the T16 (child reference) was then interpolated. The factor of difference between the quality reference mAs settings for both scanners giving the same delivered mAs was then calculated. **Results:** To give comparable delivered mAs to the child phantom across both systems, the CT quality reference mAs for the child protocols using the child reference (T16 VA60D) should be divided by the following factors, to provide the necessary quality reference mAs setting using the adult reference (Intevo Bold VB20B): Arms up at 110kV: 3.9 (thorax), 4.3 (abdomen), 5.1 (pelvis); arms up at 80kV: 4.1 (thorax), 4.0 (abdomen), 4.7 (pelvis); arms down at 110kV: 3.5 (thorax), 3.6 (abdomen), 4.5 (pelvis); arms down at 80kV: 3.2 (thorax), 3.3 (abdomen), 4.0 (pelvis). **Conclusion:** Conversion factors are provided for translating quality reference mAs from child to adult reference patients in child protocols in which topogram-based patient-size-related dose level adaptations are applied, to achieve the same delivered mAs to a child phantom. The conversion factors vary slightly according to tube voltage, body region and whether the arms are up or Down. **References:** None

EP-307

Dose Rate from Patients after Bone and Myocardial Perfusion Scintigraphies

B. Martins, C. Varela Pinto, D. Calado, R. Jorge, M. Correia, A. Duarte, N. Alves, M. Rézio, C. Loewenthal;
Hospital da Luz, Lisboa, PORTUGAL.

Aim/Introduction: Our Nuclear Medicine (NM) department follows good practice recommendations, in particular regarding administered activities to patients. The aim of this study is to ascertain whether after administering recommended activities of Technetium-99m agents, the dose rate from patients leaving the unit is below the limit suggested in the literature ($50\mu\text{Sv/h}$ at 1 meter). The dose rate values were obtained from patients that underwent

Bone Scintigraphy (BS) with $^{99\text{m}}\text{Tc}$ -HMDP and Myocardial Perfusion Scintigraphy (MPS) 1 day protocol with $^{99\text{m}}\text{Tc}$ -Sestamibi, since these two are the most commonly performed conventional studies. The study was abruptly suspended by the COVID-19 pandemia, in which only absolutely necessary tasks were performed. For this reason the number of patients included is less than initially planned. Nonetheless, the study will soon resume, as the unit gradually returns to its normal workflow. **Materials and Methods:** The dose rate ($\mu\text{Sv/h}$) was measured in 68 patients (BS:31; MPS:37) just before leaving the department. Measurements were made with a geiger-muller detector at 1 meter from the patient anteriorly at the level of the urinary bladder, always after micturition. The administered activity, time of administration, dose rate values adjusted to the background and time of measurement were registered. Renal function was verified, whenever available, to better understand higher than expected values. **Results:** As expected, dose rate values were lower with longer intervals between injection and dose rate measurement. After Bone Scintigraphy, the majority of patients left the unit more than 3h after radiopharmaceutical injection and the mean dose rate was measured at $5.6\mu\text{Sv/h}$. Following Myocardial Perfusion Scintigraphy, the majority of patients left 1-2h after the second injection of $^{99\text{m}}\text{Tc}$ -Sestamibi with an average dose rate of $14.2\mu\text{Sv/h}$. **Conclusion:** Keeping in mind the most recent concerns regarding administered activities to patients, as well as reducing the environmental impact factor of NM clinical practice, the data obtained demonstrates that the patients evaluated were well below the established dose-rate limits. Our aim is to continue to verify the dose rate from patients leaving the department for these procedures and extend it to the rest of the procedures that we normally perform, as a standard of good clinical practice. **References:** 1 - Florida Administrative Code - 64e-5.622 Release of Patients or Human Research Subjects Treated with Radiopharmaceuticals, Implants or Remote Afterloader Units

EP-308

Barriers and challenges in incident reporting faced by healthcare staff of Nuclear Medicine department in Rawalpindi Islamabad region

N. Marwat;
Nuclear Medicine Oncology and Radiotherapy
Institute, Islamabad, PAKISTAN.

Aim/Introduction: The aim of the study was to explore the under reporting of incident by health care staff **Materials and Methods:** The study was qualitatively designed in a form of interviews with all the health care staff working in Nuclear Medicine department individually. It was a voluntary study, Nuclear Medicine working group in twin city were approached and the one who agreed were

interviewed. Interview were design With a technique of conversation, health professionals were invited to discuss their experiences, perceptions and behavior about the practice and process of incidents reporting, what challenges they come across while reporting an Incident, factors that refrain them from reporting an Incident. **Results:** Response rate of the study was 64 % from the overall group of health care staff , where the maximum of the response rate was 68% from the technologists working in Nuclear Medicine and minimum was from Physicians which was 58 %. The reason for not being part of the study by 26 % was unclear as they remain non respondent. The analysis of this study showed that healthcare professionals, particularly doctors, are reluctant to report adverse events to a superior because of the fear of bad and irresponsible image they might develop. The biggest barrier faced by the technologists that refrain from reporting was the blame culture. Coordination between the healthcare staff and superior is second major barrier in reporting. Lack of appreciation or no appreciation to staff who come forward and report. Competency can be judged on the bases of number of incident reported by a person or a department another factor to limit incidents being non reported. No follow up of incidents being reported, lack of interest by seniors and supervisors in reported incident and stakeholders not taking responsibility for reported incident. **Conclusion:** Incident reporting can be a powerful tool for developing and maintaining an awareness of risks in healthcare practice in Nuclear Medicine departments. Reporting of near misses over adverse events offers numerous benefits, for that frequency of these events has to be increased. This can only be possible by increasing the trust between management and staff. Blame culture needs to be discouraged strongly. Small incentives can be given to staff who reports incidents. Balance shall be maintained between blame and feeling responsible. Safety Culture shall be promoted, openness to communication and more trust shall be developed between all the healthcare staff. **References:** 1. https://www.researchgate.net/publication/234703108_Can_incident_reporting_improve_safety_Healthcare_practitioners%27_views_of_the_effectiveness_of_incident_reporting 2. https://www.researchgate.net/publication/265213107_What_to_do_With_Healthcare_Incident_Reporting_Systems

EP-309

Investigation into the excretion rates and contact restrictions of Lu¹⁷⁷ Dotatate patients

L. Hutton¹, D. Morgan¹, D. McGowan^{1,2}, A. Hallam¹;

¹Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM, ²University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: ¹⁷⁷Lu Dotatate is a radiopharmaceutical which gained approval in August 2018 from the National

Institute for Health and Care Excellence (NICE) and therefore there is a need for more data to be collected to investigate the radiation protection issues associated with patients undergoing this treatment. The aim of this project is to obtain detailed data to better quantify excretion rates of ¹⁷⁷Lu Dotatate from patients. **Materials and Methods:** Dose rate data was obtained from seven patients (1st treatment - 3, 2nd treatment - 4) to date who were given radiation monitors, calibrated against a secondary standard by Public Health England. They took dose rate/count rate readings at regular time intervals after administration of the radiopharmaceutical. Two patients were given dose rate monitors which automatically recorded their dose rate at regular intervals. The other seven patients were issued with Geiger Muller tube detectors and recorded readings in counts per second. These seven patients were encouraged to record data as often as possible with a minimum of twice per day. Two patients were issued with both types of monitors. **Results:** It was found that the clearance of ¹⁷⁷Lu follows a biphasic model with average effective half-life of the fast phase 25.9 hours (range: 8.4 - 73.9 hours; 3rd quartile: 27.6 hours) and the slow phase average effective half-life was 100.1 hours (range: 75.6 - 145.1 hours; 3rd quartile: 104.64 hours). This differs in comparison to values published by Levert et al. of 4.7 ± 1.4 hours for the fast clearance phase and 87.2 ± 14.7 hours for the slow phase clearance¹. The fast clearance effective half-life is significantly longer than that quoted by Levert et al. The implications of this on patient contact restrictions is that there is an increase in their length due to family & friends and members of the public being exposed for longer and therefore to higher external dose rates. **Conclusion:** Although there is no published data regarding contamination from these patients, we found that significant amounts of excretion happen after patients left the hospital, potentially resulting in contamination on household items. This is due to the longer clearance times and needs to be taken into consideration when calculating contact restrictions. **References:** ¹ D. Levert, E. Kalogianni, B. Corcoran, N. Mulholland and G. Vivian. Radiation precautions for inpatient and outpatient ¹⁷⁷Lu-Dotatate peptide receptor radionuclide therapy of neuroendocrine tumours. *EJNMMI Physics*. 2019;6(1):7 doi: 10.1186/s40658-019-0243-1.

EP-310

Optimisation of Lu-177 therapy administration

R. Fernandez¹, S. Rai¹, A. Perry², J. Johnson¹, P. Croasdale¹, N. Eftychiou¹;

¹Guy's and St Thomas' Hospital, London, UNITED KINGDOM, ²King's College London, London, UNITED KINGDOM.

Aim/Introduction: With the rapid increase in utilisation of Lutetium-177 (¹⁷⁷Lu) for molecular radiotherapy (e.g. labelling with dotatate, or more recently, PSMA or monoclonal antibodies), safe administration is crucial - both for patients

and staff involved. Various methods for ^{177}Lu treatment delivery exist. This study, based on a large UK single-centre experience, considers various scientific aspects of our established method which ensure effective ^{177}Lu therapy administration. **Materials and Methods:** Approximately 200 ^{177}Lu -dotatate administrations are performed annually at our centre. For a prescribed treatment activity of 7400MBq, pre-labelled ^{177}Lu -dotatate is dispensed into a plastic syringe (under sterile conditions) and infused via a 3-way tap/PVC extension tubing set and shielded syringe driver. Recent hospital-wide adoption of a different syringe driver model prompted re-evaluation of the ^{177}Lu -dotatate administration protocol, to ensure that correct activity was administered without causing significant increase in staff radiation dose. In addition to routinely worn whole-body and extremity dosimeters, all staff involved in the procedure (Radiopharmacists, Physicists, Clinicians) wore automatic real-time fingertip electronic personal dosimeters (EPDs), to determine the specific tasks contributing to their extremity exposure. **Results:** The administration method adopted is flexible, if required, and generates minimal solid radioactive waste (both in terms of volume and activity). Using the new syringe driver resulted in slight, but statistically significant, increase in median residual ^{177}Lu solid waste activity - 180MBq from 130MBq. Dead space of tubing/syringe was approximately 1ml. This delivery method is sufficiently sensitive to venous line patency/occlusion issues mid-therapy administration - to date only one extravasation incident has occurred using this system. Radiation dose rate at the surface of the unshielded 50ml plastic administration syringe was 75.6mSv/hour which was reduced by >99% through the use of a bespoke 12mm thick lead 'barrel shield'. All staff extremity doses as measured by EPD were reassuringly low. The level of involvement during assay/administration/dismantling/disposal meant that of all craft groups, Physicists recorded the largest extremity dose per procedure of 28.1[16.6] μSv (Mean[SD]). Although this is a non-trivial extremity dose, it is deemed acceptable. The greatest proportion of Physicist extremity dose arose from connection of the therapeutic syringe to the tubing. **Conclusion:** A multidisciplinary approach, together with appropriate shielding and radiation monitoring equipment, ensure that ^{177}Lu therapy can be safely and effectively administered with minimal staff radiation exposure. **References:** None

EP-311

Approach "Lean Thinking" to improving performance and efficiency in a Nuclear Medicine Department: a tool for radioprotection

L. Burroni¹, F. M. Fringuelli¹, G. Biscontini¹, A. Palucci¹, C. Romagnolo¹, C. Cottignoli¹, C. Bianciardi², J. Guercini³;

¹Nuclear Medicine, Ancona, ITALY, ²Health gestional department, Alessandria, ITALY, ³Healthcare Hospital Department, Pisa, ITALY.

Aim/Introduction: Recently Lean thinking has been introduced in healthcare for the benefit of patients, employees and hospital organisation. Applying a Lean approach in diagnostic departments, such as Nuclear Medicine, there are many opportunities for, reduce clinical and technical errors and mistakes, reduce patients and report waiting times, improve patients outcomes, increase staff productivity, decrease costs and improve employee and customer satisfaction. Aim of our work is to demonstrate that the Lean approach may be applied to a Nuclear Medicine Department improving performance and efficiency. **Materials and Methods:** The "spaghetti diagram" is a tool to help you establish the optimum layout for a department or ward based on observations of the distances travelled by patients, staff or radionuclides. By analysing the lines, you can identify any areas with unnecessary movements. This helps staff decide whether to bring two points closer together and how optimise the flow. The construction of the spaghetti diagram on the layout allows us to consider the pathways of health care workers and patients. In terms of radioprotection, the paths should be separated as much as possible between the radioactive patients and health professionals. In this regard, it is also necessary to calculate transit times and rest of the patients in the various areas of the department. **Results:** Patients wait times in hospital are long. One of the key ideas in Lean is to increase velocity by examining the revenue generating sequence of activities called VSM. When waste such as delays, errors, transportation, motion, and so forth are eliminated from these operations what remains is the ability to provide the same value in less time. Flow is the right key to increasing velocity, reducing radiations burden to the staff and population. A workcell is a work unit larger than an individual machine or workstation but smaller than the usual department. Once processing begins, they move directly from process to process. The result is very fast throughput. Communication is easy since every operator is close to the others. This improves quality and coordination. **Conclusion:** Lean is an innovative management approach that has proven successful in health care organizations. Lean principles hold the promise of reducing or eliminating wasted time, money and energy in health care, creating a system efficient, effective, and truly responsive to the needs of patients. The goal of Lean is to improve value for the patient and organization, also in term of radioprotection. **References:** None

EP-312

Improving the reliability of the assessment of the skin exposure of the hands of workers handling selected radiopharmaceuticals based on the correction of finger dosimeter readings

J. Hudzietzova¹, M. Fulop², J. Sabol³, P. Povinec⁴, A. Vondrák⁵, D. Baček⁴, P. Vlk⁴, P. Nemček⁵, L. Foltínová⁶;

¹Czech Technical University in Prague, Kladno, CZECH REPUBLIC, ²ABRS, s.r.o., Samorin, SLOVAKIA, ³Faculty of Security Management PACR in Prague, Prague, CZECH REPUBLIC, ⁴PET center BIONT, a.s., Bratislava, SLOVAKIA, ⁵IZOTOPCENTRUM, s.r.o., Nitra, SLOVAKIA, ⁶University of Economics in Bratislava, Bratislava, SLOVAKIA.

Aim/Introduction: Recently, some new devices for the preparation or application of radiopharmaceuticals have been put into operation in order to reduce the exposure of hands. Although many workplaces are equipped with modern technology, there are still situations where workers, due to the contamination or performance of non-standard operations, may receive the elevated exposure. The aim of the paper is to overview the skin exposure related to the use of some new technologies developed over the last 10 years. At the same time, the evaluation of the local skin exposure and the correction factor associated with the manipulation involving ⁶⁸Ga-labelled positron radiopharmaceuticals is analysed and compared with the situation involving the use of ¹⁸F-labelled radiopharmaceuticals. **Materials and Methods:** Two nuclear medicine departments using ¹⁸F and ⁶⁸Ga labelled radiopharmaceuticals participated in this pilot study. Thermoluminescent dosimeters placed at 10 different locations on the palm or back of the hand were used to assess personal dose equivalent H_p(0.07). The measured maximum exposure of each worker was related to the activity being manipulated. Subsequently, the average values (related to the position at the tip of the index finger) of selected groups of workers engaged in radiopharmaceutical labelling, filling into syringes and applications have been applied to establish relevant correction factors for each monitored workplace. **Results:** The paper presents a summary of the comparison of results from finger dosimeters in selected occupational groups in the period of 2009 - 2019 and highlights new findings regarding the correction factor for selected radiopharmaceuticals over the last decade. In addition, the pilot experiments with ⁶⁸Ga are discussed in terms of the average exposure of the skin of the hand in the position at the tip of the index finger of the workers. The paper also illustrates the cases of manipulation with ⁶⁸Ga-labelled radiopharmaceuticals, which resulted in the significantly higher exposure of the skin. **Conclusion:** A more detailed monitoring of the radiation exposure of the skin on more locations on the workers' hand can reveal cases of abnormal working operations or elevated local exposure, which is often found on the fingertips. Consequently, the appropriate measures should be taken to eliminate non-standard working operations in a timely manner and thus minimize this exposure. If adequate correction factors are used, the exposure at the tip of the finger can be straightforwardly estimated from the results of the routinely used finger dosimeters. **Acknowledgments:** Paper was partially supported by project SGS18/00/OHK4/1T/17. **References:** None

Dosimetric evaluation to medical workers operating in a PET/CT department after the use of dynamic techniques

K. Dalianis¹, G. Kollias¹, K. Gogos¹, T. Pipikos², F. Vlachou², J. Andreou², R. Eftymiadou², V. Prassopoulos²;

¹Medical Physics Department, Hygeia Hospital, Athens, Marousi, GREECE, ²PET/CT Department, Hygeia Hospital, Athens, Marousi, GREECE.

Aim/Introduction: Due to the high-energy tracers emitting 511 KeV used in PET/CT departments and considering the risks associated to ionizing radiation that have been derived from previous studies, special attention is needed when dealing with radiation protection aspects in a PET/CT modality. New radiopharmaceuticals such as [18F]-fluorothymidine and 18F fluoromethylcholine are used, new imaging dynamic techniques are performed new measurements concerning the doses to staff are needed. Aim of this study was to measure the effective wholebody dose of the personnel in comparison with measurements that have been made in the past. **Materials and Methods:** The estimation of equivalent dose from external dosimetry for all members of the staff was monitored with the use of TLDs badges and electronic dosimeters. In our department 18F-FDG, 18F-FCT, 18F-FCH is available in multi dose vials. **Results:** We compared the first six months of 2019 a period in which no FLT or FCH procedures were performed, with the second semester in which 97 FLT and 74 FCH examinations were performed. The average number of FDG patients was the same for every day. The measurements for the nurses show increased wholebody dose of about 7-12% and that is due to the longer time spent near the patient. Concerning the technologist doses, an increase of about 15-21% was measured because they are near to patient at the time of the injection. **Conclusion:** From our results we can observe that although there is an increase of the doses for technologists and nurses the numbers are significantly lower than the recommended annual dose limit. **References:** Dalianis K, Malamitsi J, Gogou L, Pagou M, Efthimiadou R, Andreou J, Louizi A, Georgiou E Dosimetric evaluation of the staff working in a PET/CT department, Nuclear Instruments and Methods in Physics Research A 569, 548 - 550.

Validation of an alternative measurement method to verify [131I]-Nal capsules activity by dose rate determination

C. Franco Monterroso¹, A. Hernández Fructuoso², B. Santos Montero², J. Romero Herrera¹, J. Castell Conesa¹;

¹Hospital Universitari Vall d'Hebron, Barcelona, SPAIN, ²Hospital Universitari Vall d'Hebron. Institut de Diagnòstic per la Imatge, Barcelona, SPAIN.

Aim/Introduction: Handling of [¹³¹I]-Nal capsules to check

the reference activity leads to a radiation exposition increase, especially in hands. The aim of this study was to validate an alternative method to verify each capsule activity by dose rate determination, with the purpose of reducing this exposition. **Materials and Methods:** Two study groups (A and B) were established according to capsule lead container thickness (mm). 17 capsules of 555MBq and 13 of 1110 MBq contained in 18.7mm lead shields were included in Group A (n=75) and 10 capsules of 3700 MBq and 9 of 5550 MBq in leads containers of 28, 5mm thick in Group B (n=40). Each capsule dose rate was determined keeping itself in the original container with a commercially dose rate meter (E0111280 series MiniTrace Gamma). 3 measurements were taken for each capsule, turning it around its axis. All capsules were placing on a template to 30cm from a dose rate detector to warrant the reproducibility of the measurements. The exact activity of the [¹³¹I]-NaI capsules was subsequently measured using a dose calibrator (Capintec CRC-55tR). Calibrating curves were created by linear correlation between the obtained results for each group (MBq vs μSv/h). **Results:** The average activities and dose rates obtained for 555 and 1110 MBq capsules (group A) were 601.5±8.23 MBq, 1200.17±31.06 MBq and 11.28±0.37 μSv/h, 22.06±1 μSv/h respectively. For 3700 and 5550 MBq capsules (group B) the average measurements were 4012.87±37.08 MBq, 5979.20±97.69 MBq and 21.9±0.98 μSv/h, 33.05±0.71 μSv/h respectively. Regression analysis showed a high correlation ($r = 0.992$ for group A and $r = 0.987$ for group B). The measurement uncertainty of the method was under 5%. **Conclusion:** This alternative method allows an accurate measurement activity before dispensing [¹³¹I]-NaI, keeping itself in the shielded lead container and reducing personnel dosimetry. **References:** None

Radiation Exposure of the Fingers during Preparation and Administration of ⁹⁰Y-Ibritumomab-Tiuxetan for Radioimmunotherapy of Non Hodgkin Lymphoma (NHL)

C. Happel, W. T. Kranert, B. Bockisch, D. Gröner, A. Sabet, F. Grünwald;

University Medical Center Frankfurt, Department of Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: Radioimmunotherapy of NHL with ⁹⁰Y-Ibritumomab-Tiuxetan has been increasingly implemented during the last decade. Handling of pure beta-emitters can cause significant radiation exposure due to external irradiation by Bremsstrahlung and contamination during preparation and administration. Influence of different locations of ring dosimeters on the obtained dose should be determined. **Materials and Methods:** For radioimmunotherapy of NHL ⁹⁰Y-labelled monoclonal CD20 antibodies were used. Preparation was carried out by the

technical staff in a lead shielded workbench according to the manufactures instructions and averaged 67min (50-90min). The substance was injected intravenously by a physician and lasted around 10min in each case. In both cases extra dense gloves were worn to avoid contamination. Syringes and vials were shielded with acrylic glass belonging to the preparation kit. Radiation exposure during preparation and administration was determined using thermoluminescence ring dosimeters (GSF-TL-TD Typ X). The detection limits are 7.6keV to 3MeV for photons and >50keV for beta-. Physicians and technical staff wore 5 TLDs on each hand in each case (fingertip and first phalanx of index and middle finger and on the thumb). **Results:** All the following results are given in mSv/GBq administered ⁹⁰Y-Ibritumomab-Tiuxetan. Mean finger exposure during preparation was for the right hand: 3.72 for the index fingertip, 2.57 for the phalanx of the index finger, 1.37 (fingertip) and 1.54 (phalanx) of middle finger (right hand); for the left hand: 5.15 (fingertip) and 12.3 (phalanx) of index finger and 7.20 (fingertip) and 6.05 (phalanx) for the middle finger. The thumbs showed a mean exposure of 1.72 (right) and 4.33 (left). The mean finger exposure during administration was for the right hand: 2.91 (index fingertip), 1.32 (index phalanx); 0.58 (middle fingertip) and 0.49 (middle finger phalanx); and for the left hand: 121.1 (index fingertip), 28.7 (index phalanx); 108.5 (middle fingertip) and 19.6 (middle finger phalanx). The thumbs showed a mean exposure of 1.77 (right) and 2.23 (left). All physicians and technical employees were right handed. **Conclusion:** In both cases the highest exposures were detected at the index finger of the left hand. Therefore the index finger of the left hand is the best location to wear a ring dosimeter for handling, labelling and administration of ⁹⁰Y-Ibritumomab-Tiuxetan. **References:** None

EP-316

Effective dose of for medical workers operating in a PET/CT department

K. Dalianis¹, G. Kollias¹, K. Gogos¹, T. Pipikos², M. Vogiatzis², F. Vlachou², V. Prassopoulos²;

¹Medical Physics Department, Hygeia Hospital, Athens, Marousi, GREECE, ²PET/CT Department, Hygeia Hospital, Athens, Marousi, GREECE.

Aim/Introduction: The PET/CT applications have been continuously increasing for diagnostic procedures. Although such an increase is a positive trend for the benefit of patients, the associated risk of radiation exposure of staff needs to be properly evaluated. The aim of this study was to measure the radiation exposure of the staff and evaluate the doses in the first PET/CT department in Greece at Hygeia S.A. **Materials and Methods:** To estimate the effective dose from external exposure all 6 members of the staff (2 nurses, 2 medical physicists, 2 technologists, had TLD badges worn at the upper pocket of their overall, TLD

rings on the second finger of each hand consisting of disk measuring diameter by 0,9 mm thickness. The basics stages for the PET/CT procedures involve 4 steps: segmentation of the dose, injection of the radiopharmaceutical, nursing care during uptake and positioning of the patient. **Results:** The results of our study for the average cumulative whole body dose for 100 patients ($\mu\text{Sv}\pm\text{SD}$) at different stages were: segmentation of the dose $189\pm 7,23$, injection of the radiopharmaceutical $245\pm 6,67$, nursing care during uptake $70\pm 5,63$, positioning of the patient $146\pm 12,3$. The statistical analysis showed small differences between stages 1, 2 and 4 ($p>0,05$) but a great statistical difference was observed between stages 2,3 $p=0,023$. The results for the finger doses ($\mu\text{Sv}\pm\text{SD}$) regarding the same stages were: segmentation of the dose $284\pm 77,4$, injection of the radiopharmaceutical $225\pm 62,3$, positioning of the patient $26,79\pm 5,87$. **Conclusion:** N) The personnel dose results are significantly lower than the recommended annual dose by International Commission for Radiological Protection. However a greater effort should be made to reduce the doses further in line with the ALARA principle **References:** Dalianis K, Malamitsi J, Gogou L, Pagou M, Efthimiadou R, Andreou J, Louizi A, Georgiou E Dosimetric evaluation of the staff working in a PET/CT department, Nuclear Instruments and Methods in Physics Research A 569, 548 - 550.

CT radiation dose in whole-body PET/CT in relation to arm position in patients with different Body Mass index

G. Marotta, M. F. Bardo, M. Schiavini, F. Buffoni, R. Leo, M. Rognoni, D. Capolongo, R. Pino, N. Basilico, E. Orunesu, E. Galli, R. Casati, I. Martina, C. Fabbri, L. D'Antonio, D. Marchelli, F. Voltini, C. Canzi;

Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, ITALY.

Aim/Introduction: In whole-body PET/CT examinations a large contribution to patient radiation exposure is due to CT scan. Automatic Exposure Control (AEC) software initially determines tube current modulation using scout images and then modifies it during CT acquisition. Aim of the study was to evaluate the role of arm position on CT exposure reduction in patients with different body mass index (BMI). **Materials and Methods:** In whole-body PET/CT, radiation exposure doses with AEC routinely used with postero-anterior view (PA) scout images with arms up and down was investigated, using a 4-ring PET/CT scanner and with a AEC proprietary software. Ninety adult patients, who underwent whole-body PET/CT twice, once with their arms up and once with their arms down, were divided into 3 groups according to the Body Mass index: 10 underweight, 42 with normal weight and 38 overweight or obese. Changes of mAs affecting CT DIvol between arms up and down were determined. **Results:** Normalised tube current

was significantly higher with the arms up than down in the head and neck and significantly lower in the shoulder, abdomen, pelvis, and proximal thigh. Analysis of variance showed that the effective dose was reduced significantly with arms up than arms down in all groups ($p<0.01$). The means of mAs and CT DIvol (in mGy) were respectively in underweight patients 53 and 3.58 with arms down and 43 and 2.95 (-22%) with arms up, in patients with normal weight 62 and 4.24 with arms down and 52 and 3.54 (-20%) with arms up, and in overweight or obese patients 78 and 5.41 with arms down and 66 and 4.58 (-19%) with arms up. **Conclusion:** Raising the arms increased radiation dose in the head and neck and decreased it in the chest and abdomen, resulting in overall reduction of effective dose, of greater relevance in underweight patients. These characteristics of AEC behaviour should be considered to determine an optimal imaging protocol for whole-body PET/CT. **References:** None

EP-318

Dose Optimization Of Brain Tomographic Studies Through Quantitative Analysis Of The ASIR Reconstruction Technique

J. Bustos, A. Ruiz;

Nuclear and Molecular Medicine Center Foundation Entre Rios, Entre Rios, ARGENTINA.

Aim/Introduction: ASIR is a hybrid Reconstruction Method that combines the Filtered Back Projection Analytical Method (FBP) and the Statistical Iterative Method that models noise. This algorithm is implemented in discrete quantities by adjusting the percentage from 10 to 100% and is used in conjunction with dose reduction. Therefore, studies were carried out whose purposes are to determine the Relationship of Compromise Between Image Quality and Radiation Dose by applying dose reduction and the ASIR reconstruction algorithm in brain tomography studies. **Materials and Methods:** The experimental development was carried out at the CEMENER facilities, in the nuclear medicine service. Discovery PET / CT 710 equipment was found with 64-slice CT. Tests were performed on phantoms of QA provided by General Electric and Capthan 500. In the first instance, the protocol for brain tomographic studies was particularly addressed. A quantitative and qualitative analysis of image quality was performed. The aspects evaluated quantitatively were noise, the signal-to-noise ratio, the high and low contrast ratio and the Hounsfield Units. Regarding the qualitative analysis, the CEMENER medical imaging specialist carried out a subjective evaluation taking into account noise, artifacts, sharpness and diagnostic acceptability. **Results:** The Results show that it is possible to remarkably improve the image quality and decrease the radiation dose to the patient by applying a dose reduction of 40% and 60% of ASIR. Therefore, it is

concluded that the application of ASIR has a positive impact with respect to the radiation received by the patient, and the impact on the useful life of the tube in relation to the milliamperage used. It was applied to the brain protocol used in the CEMENER, resulting in less radiation to the patient, going from 320mA to 190mA, with a CT DIvol of 59 mGy to 35 mGy with medical endorsement in image quality in terms of noise, sharpness and diagnostic acceptability. **Conclusion:** As a corollary, the use of the ASIR reconstruction algorithm was found to allow for a significant 40% dose reduction in brain CT studies and to use 60% ASIR or higher, without compromising image quality. **References:** None

Evaluation of Iodine-131 Labelled Lawsone (2-Hydroxy-1,4-Naphthoquinone) Compound's Transdermal and Intravenous Biodistribution

V. Tekin¹, U. Korkmaz², I. Ince¹, I. Kutlubay², G. Durmus Altun², F. Biber Muftuler¹;

¹Ege University, Izmir, TURKEY, ²Trakya University, Edirne, TURKEY.

Aim/Introduction: One of the popular therapeutic herbs is Lawsonia inermis, which has many local names such as Mhendi, Shudi, Madurang, and Goranti, known as 'Henna'. Lawsone (2-hydroxy-1,4-naphthoquinone) (LW) is one of the main compounds of the henna plant and colors with its own orange-red colorants. Many studies have reported that the LW compound has anticoagulant, anticancer, antioxidant, antibacterial and antifungal effects. The systemic distribution of LW is unknown, because of direct use to the skin surface as traditionally method. In presented study, systemic biodistribution of I-131 labeled LW, after intravenous injection and transdermal use was evaluated with the aim of highlight the potential of the clinical use of LW. **Materials and Methods:** Lawsone (LW) compound was radiolabeled with ¹³¹I. Radiolabelling yield was calculated as 92.70±4.312% by Thin Layer Chromatography (TLRC). Six female adult SD rats (mean weight 214±14g) were used in the study. Study groups were planned as 3 rats for the use of transdermal gel (TDJ LW) and 3 rats for the intravenous (IV LW) injection. I-131 labeled LW Carbomer Gel (5 mCi, 100 mg/ml) was prepared for the TDJ use and 0.5 mCi I-131 LW was injected intravenously for the systemic biodistribution study. For both study groups of TDJ and IV, 1 hour dynamic imaging and 2,4,12 and 24h static imaging were performed after use and injection. The biodistribution of LW was

quantitatively evaluated by using whole body images for all time periods. After imaging study, tissue weights were measured and the distribution of homogenized tissues was determined using a gamma counter. 1 hour dynamic imaging was performed with HE collimators (64x64 matrix) and static imaging was performed with 512x512 matrix by recording anteriorly and posteriorly. **Results:** It was observed that I-131 labeled LW compound showed high uptake in liver, kidney, stomach, muscle and blood compared to other organs after TDJ and IV. **Conclusion:** Although henna is a bioactive which is directly used to skin surface, the main component of the henna (LW) is able to use for systemic circulation. The blood level is high even after 24 hours after intravenous injection. **References:** None

Influence of the glutamate concentration on [¹⁸F]PEB binding to metabotropic receptor subtype 5 : a translational study

A. Dupont^{1,2}, S. Serrière², L. Barantin², J. Vercouillie^{2,3}, V. Gissot³, S. Bodard², G. Chicheri², S. Chalon², F. Bonnet-Brihault^{2,4}, M. Santiago Ribeiro^{5,2,3}, N. Arlicot^{1,2,3};

¹Radiopharmacie, CHRU Tours, Tours, FRANCE, ²UMR1253, iBrain, Inserm, Tours, FRANCE, ³CIC 1415, Inserm, CHRU Tours, Tours, FRANCE, ⁴Centre universitaire de Pédiopsychiatrie, CHRU Tours, Tours, FRANCE, ⁵Service de Médecine nucléaire, CHRU Tours, Tours, FRANCE.

Aim/Introduction: Glutamate is the most abundant excitatory neurotransmitter in the human brain and altered glutamate signaling is thought to be involved in a myriad of neurological disorders. Positron emission tomography (PET) imaging with [¹⁸F]PEB allows assessing dynamic changes in metabotropic glutamate receptor 5 (mGluR5) availability underlying neuropathological conditions. However the influence of endogenous glutamate levels on the receptor binding has not been well established yet. The purpose of this study was to explore the [¹⁸F]PEB binding regarding to physiological fluctuations or acute changes of glutamate synaptic concentrations by a translational approach; i.e. a PET/MRS imaging study in healthy human volunteers combined to a PET imaging after an N-acetylcysteine (NAC) pharmacological challenge in rodents. **Materials and Methods:** Glutamate (Glu) and glutamine (Gln) levels from 12 healthy adult males were assessed from MRS data collected from the anterior-cingulate cortex (ACC) with

PRESS, and mGluR5 binding (BP_{ND}) was assessed from PET data collected with [^{18}F]PEB. We correlated the [^{18}F]PEB (ACC BP_{ND} /Cerebellum BP_{ND}) with Glu/Cr, Gln/Cr ratios in the ACC. MicroPET [^{18}F]PEB dynamic acquisitions were conducted in 9 rats after an i.v. injection of either water (test/retest) or NAc 50mg/kg (challenge), a promoter of the cystine-glutamate antiporter that increases extra synaptic glutamate release. The microPET images for the regions of interest (ROI) of caudate putamen, amygdala, thalamus, cingulate and cerebellum were analyzed. Time-activity curves were obtained from ROI defined on the rat MRI T2 template and all SUV ratios were calculated using the cerebellum as the reference region. **Results:** In healthy humans, no statistically significant correlation was evidenced between the physiological concentrations of Glu and Gln and [^{18}F]PEB binding. ACC BP_{ND} /Cerebellum BP_{ND} vs Glu/Cr: $r=0.303$, $p=0.315$; Gln/Cr: $r=-0.299$, $p=0.320$. In rats, no changes in SUVr measurements were observed in the test and retest conditions nor in the NAc condition in any ROIs analyzed ($p>0.17$). **Conclusion:** In humans, [^{18}F]PEB binding did not show sensitivity to glutamate concentrations in physiological conditions as an independent outcome. In rodents, a pharmacological challenge with NAc did not affect the [^{18}F]PEB binding in rodents. These data suggest that the in vivo affinity of [^{18}F]PEB to an allosteric site of mGluR5 is not sensitive to changes in glutamate levels. [^{18}F]PEB seems therefore as a reliable radioligand to quantify the mGluR5 availability despite potential heterogeneity of glutamate concentrations. **References:** None

EP-321

Synthesis and Pre-clinical Evaluation of Novel Piperazine Amide-modified ^{18}F -Rhodamines as Myocardial Perfusion Imaging Agents

J. Inkster^{1,2}, J. L. J. Dearling^{1,2}, E. Snay¹, A. B. Packard^{1,2};

¹Boston Children's Hospital, Boston, MA, UNITED STATES OF AMERICA, ²Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA.

Aim/Introduction: Rhodamine dyes are fluorescent lipophilic cations that exhibit affinity for cells with high mitochondrial activity, such as cardiomyocytes. Rhodamine esters bearing ^{18}F -fluorinated aliphatic chains have been identified as a new class of myocardial perfusion imaging agents.^[1] Our goal is to develop "next generation" ^{18}F -rhodamines that exhibit enhanced in vivo stability. Thus, we are targeting derivatives in which the ^{18}F pendant group is a) aromatic and b) attached to the rhodamine via an amide (vs. ester) bond. In addition, the amide linkage should decrease radiotracer lipophilicity and potentially improve heart uptake while decreasing uptake in the liver. Secondary rhodamine amides have the potential to cyclize to form neutral lactams. Thus the 1-(4-[^{18}F]fluorobenzoyl)piperazine group was chosen for investigation, as piperazine amides are tertiary

and cannot cyclize. **Materials and Methods:** The precursors (RhoB-pip and Rho6G-pip) of 1-(4-[^{18}F]fluorobenzoyl)piperazine-modified rhodamine B ([^{18}F]FRhoB-pip-Ar) and rhodamine 6G ([^{18}F]FRho6G-pip-Ar) were prepared by coupling N-Boc-piperazine with rhodamine B base or rhodamine 6G inner salt, respectively, in the presence of amidation reagent HBTU and triethylamine (TEA), followed by TFA-mediated Boc-deprotection. A second HBTU/TEA amidation reaction with 4-fluorobenzoic acid (FBA) yielded the ^{19}F standards. [^{18}F]FBA was synthesized in two steps from ethyl 4-(trimethylammonium triflate)benzoate under standard ^{18}F -fluorination conditions ($K_{2.2.2}/K_2CO_3/\Delta$), then conjugated to RhoB-pip or Rho6G-pip (HBTU/TEA, DMSO, RT, 15 min). HPLC-purified [^{18}F]FRhoB-pip-Ar (3.4 MBq) or [^{18}F]FRho6G-pip-Ar (9.5 MBq) was injected into the lateral tail vein of a Sprague-Dawley rat. PET/CT data was collected over 60 minutes. **Results:** [^{18}F]FRhoB-pip-Ar and [^{18}F]FRho6G-pip-Ar were prepared in 4-21% DC-RCYs. PET images reconstructed over 5-min intervals show modest heart uptake that remains essentially unchanged over 60 min (SUVs: 0.23→0.19 and 0.14→0.15 %ID/mL, respectively). The ratio of activity concentration in heart vs. liver was <1 and increased marginally over time (0.06→0.14 and 0.08→0.20, respectively). In contrast, the heart/liver ratios of ^{18}F -diethyleneglycol-bearing rhodamine 6G ester [^{18}F]FRho6G-DEG^[1a] increased from 0.38→2.0 over the same interval. **Conclusion:** PET imaging of [^{18}F]FRhoB-pip-Ar and [^{18}F]FRho6G-pip-Ar in rats suggest that both radiotracers exhibit higher in vivo stability than the established tracer [^{18}F]FRho6G-DEG, but lower overall heart uptake. The 1-(4-[^{18}F]fluorobenzoyl)piperazine moiety is likely responsible for both of these phenomena. Thus, our next efforts will include the preparation of ^{18}F -rhodamines in which the stabilizing piperazine group is retained, but the radioisotope is attached via a hydrophilic oligo(ethylene glycol) chain rather than a lipophilic benzyl moiety. **References:** [1]a) M.D. Bartholoma et al., Nucl. Med. Biol. 2015, 42, 796;b) M.D. Bartholoma et al., J. Med. Chem. 2012, 55, 11004.

Head to head comparison of [^{15}O]H₂O and [^{11}C]MMP in non-human primates; tracers for measuring regional cerebral blood flow

J. Toyohara¹, T. Kakiuchi², H. Ohba², M. Kanazawa², T. Tago¹, M. Sakata¹, N. Harada²;

¹Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN, ²Hamamatsu Photonics, Hamamatsu, JAPAN.

Aim/Introduction: Increases in fasting plasma glucose (PG) levels lead to a decrease in [^{18}F]FDG uptake, especially in the precuneus, resulting in an Alzheimer's disease (AD)-like pattern. Therefore, patients with higher PG levels, such as those with diabetes, can be erroneously diagnosed with AD when PET imaging is done using [^{18}F]FDG, due

to reduced uptake of [^{18}F]FDG in the precuneus. To help avoid an erroneous diagnosis of AD due to differences in glucose metabolism, evaluating cerebral blood flow (CBF) in the brain is useful. However, current techniques such as SPECT and ^{15}O -water PET have limitations in early diagnosis of AD because the images of they produce are of low resolution. Recently, we developed N-isopropyl-p-[^{11}C] methylamphetamine ([^{11}C]MMP) as a carbon-11-labeled alternative of the standard CBF SPECT tracer N-isopropyl-p-[^{123}I]iodoamphetamine. In this study, we evaluated the brain kinetics of [^{11}C]MMP in the non-human primate. Head-to-head comparison with [^{15}O]H $_2$ O was also evaluated. **Materials and Methods:** Two successive PET measurements with [^{15}O] H $_2$ O and [^{11}C]MMP under vehicle and acetazolamide (AZM: 10 mg/kg or 20 mg/kg) loading conditions were performed in 3 conscious state male monkeys (*Macaca mulatta*) with arterial blood sampling. Metabolite-corrected plasma and whole-blood time-activity curves were used as an input function for pharmacokinetic modeling of [^{11}C]MMP. The preferred model was chosen according to the Akaike Information Criterion (AIC) and were used to calculate the influx constant (K_1). Moreover, standardized uptake values (SUV) were estimated using different time intervals. **Results:** The preliminary kinetic analysis of the comparison of AIC (paired t test, $P < 0.05$) in all regions investigated showed that 1-tissue-compartment model provided significantly better AIC scores than the 2-tissue-compartment model ($n = 3$). The regional K_1 values of [^{11}C]MMP in vehicle treated monkey were well correlated with that in rCBF (Pearson $r = 0.9230$, $p < 0.0001$). Furthermore, short duration scan (0–10 min) of SUV showed good correlation with rCBF ($r = 0.9042$, $p < 0.0001$), too. The data suggest that [^{11}C]MMP probably detect changes of rCBF in the low to normal range of flows. However, this correlation was decreased at higher flow range under AZM-loading (10 mg/kg: $r = 0.6581$, $p = 0.0041$; 20 mg/kg: $r = 0.7510$, $p = 0.0005$), due to the underestimation of rCBF at higher flows. **Conclusion:** The K_1 and early phase SUV (0–10 min) of [^{11}C]MMP well reflect rCBF in vehicle treated non-human primate, but that in higher flow region after AZM-loading did not. **References:** None

EP-323

Development and Preclinical Evaluation of New Theranostic ^{64}Cu -Folates for Folate Receptor-Positive Tumor

I. Aljammaz¹, B. Alotaibi¹, Y. Almalki¹, N. Alhokbani², S. Okarvi¹;
¹King Faisal Specialist Hospital and Research centre, Riyadh, SAUDI ARABIA, ²King Saudi University, Riyadh, SAUDI ARABIA.

Aim/Introduction: Membrane-folic acid receptor is a glycosylphosphatidylinositol protein that overexpressed in approximately 100% of ovarian adenocarcinomas and various epithelial cancers. Meanwhile, this receptor is highly restricted in most normal tissues which make these

tumors as excellent candidates for molecular targeting through the folate receptor system. Folic acid has been conjugated with various chelates via its carboxylate of the glutamic acid fragment. These conjugates have shown considerable success for delivering various radionuclides to folate-receptor-positive KB cell tumor xenografts in athymic mouse models. Among these radionuclides gallium-67/68, indium-111, technetium-99m and fluorine-18 appeared to be feasible in targeting folate receptor expressing tumors in-vivo. Recently, radiolabeled $^{67/68}\text{Ga}$ -DOTA and NOTA based folate conjugates were synthesized and their characteristics were similar to ^{111}In -DTPA-folate, which has been used in clinical trials. Due to the known high stability of Cu^{II}-NOTA complex and in an attempt to develop new folate radiotracers with favorable properties for detecting folate receptor-positive cancers, we here report the synthesis and preclinical evaluation of new ^{64}Cu -NOTA- and NATOAM-folate conjugates using 1,4,7-triazacyclononane-1,4,7-triacetic acid (NOTA) and 1,4,7-triazacyclononane-1,4,7-triamine (NOTAM) as chelating groups. **Materials and Methods:** The synthetic approaches for the preparation of ^{64}Cu -NOTA- and ^{64}Cu -NOTAM-folate conjugates were straightforward. Solutions of $^{64}\text{CuCl}_2$ (37–300 MBq) were reacted with NOTA- and NOTAM-folate conjugates in acetate buffer (pH ~4.5) at 80°C and different time range. Work up of these conjugates gave ^{64}Cu -NOTA- and ^{64}Cu -NOTAM-folate conjugates in quantitative radiochemical yields and purities as assessed by TLC and HPLC in less than 20 min. **Results:** The stability of these radioconjugates were determined in human plasma and revealed that radioconjugates remained stable during incubation at 37°C for at least 4 h. In vitro receptor binding studies performed using folate receptor-positive KB cell-line, showed that significant amount of these radioconjugate were associated with cell-fractions and the in vivo biological characterizations were carried out in normal Balb/c mice revealed rapid blood clearance of radioconjugates with excretion predominantly by the urinary system. Biodistribution studies in nude mice bearing human KB cell-line xenografts, demonstrated substantial tumor uptake (~20%, ID/g). This uptake was blocked by excess co-injection of folic acid suggesting a receptor-mediated process. **Conclusion:** These results demonstrate that ^{64}Cu -NOTA- and ^{64}Cu -NOTAM-folate conjugates may be useful as molecular theranostic probe for detecting and staging of folate receptor-positive cancers and possibly treatment. **References:** None

EP-324

Novel radiofluorinated silicon rhodamines for bimodal PET and NIR-optical imaging

T. Kanagasundaram^{1,2}, M. Laube¹, S. Stadlbauer¹, C. Kramer³, J. Pietzsch¹, K. Kopka¹;

¹Helmholtz Zentrum Dresden Rossendorf, Institute of Radiopharmaceutical Cancer Research, Dresden,

GERMANY,²Heidelberg University, Faculty of Chemistry and Earth Sciences, Heidelberg, GERMANY,³German Cancer Research Center, Heidelberg, GERMANY.

Aim/Introduction: Radiolabelled fluorophores are decisive for bimodal imaging and currently in demand for PET- and optical imaging. Fluorescent dyes show unique optical properties such as high quantum yields and extinction coefficients. FDA approved fluorophores (e.g. 5-ALA or ICG) are well-known for their use in fluorescence-guided intraoperative surgery. The goal of this work was the development of near-infrared (NIR) light-emitting silicon-rhodamines for PET- and optical imaging. The synthesized first-in-class dyes were prepared for their subsequent conjugation to the PET-compatible radioisotope fluorine-18 with the aim to elucidate their potential as imaging agent for the detection of tumors and their metastases. Moreover, the Si-rhodamines were bioconjugated to the PSMA-binding motif as a generic prominent tumor targeting binding vector for an enrichment in prostate tumors (1). For this reason the introduced dyes are intended to be used for non-invasive PET imaging (prestagging) followed by fluorescence/(radio)-guided R0-tumor-resection. **Materials and Methods:** The combination of PET- and optical imaging leads to new approaches in tumor imaging and resection. This powerful method enables the accurate differentiation of healthy and affected tumor tissues. We have designed fluorophores of the silicon (Si)-rhodamine family with absorption and emission properties in the near-infrared region of about 650 nm (2). The Si-rhodamines were radiolabelled by using the alcohol-enhanced and copper-mediated approach for radiofluorination (3). Finally, the dyes were characterized using NMR-, UV/VIS/NIR-spectroscopy and mass spectrometry and their radiolabelling properties were analyzed. **Results:** The classical synthesis pathway of novel Si-rhodamines through xanthone building blocks provided boronic acid functionalized Si-rhodamines with overall yields of 43%. The acid functionalized Si-rhodamines were conjugated to the PSMA-inhibitor binding motif to receive an increased selective enrichment in tumors (1). The dyes show large extinction coefficients up to 72.000 M⁻¹cm⁻¹, quantum yields of 0.33 and high photostabilities making them potentially useful for NIR-optical imaging. As shown by human serum stabilities the radiofluorinated Si-rhodamines show valuable and promising performance for in-vitro and in-vivo experiments. **Conclusion:** Novel NIR-fluorescent dyes based on the Si-rhodamine lead structure were synthesized and chemically characterized and their efficiency under radiolabelling conditions were determined. Profitable optical- and radiolabelling properties show promising performance for biological performance. For this reason, our first-in-class radiolabelled and bioconjugated Si-rhodamine dyes are subject of current and future biological evaluation. **References:** (1) K. Kopka et al., J. Nucl. Med. 2015,

Radiosynthesis and initial evaluation of [¹⁸F]FBAT for in vivo PET imaging of inducible nitric oxide synthase

H. Yeh¹, W. Huang², C. Chiu³, C. Chen⁴, K. Ma⁵, H. Tian⁶, T. Yu⁷, P. Wang⁷, Y. Kuo², C. Chang²;

¹National Yang-Ming University, Taipei, TAIWAN, ²Department of Nuclear Medicine, Taipei Veterans General Hospital, Taipei, TAIWAN, ³Department of Nuclear Medicine, Tri-Service General Hospital, Taipei, TAIWAN, ⁴Department of Biomedical Imaging and Radiological Sciences, National Yang Ming University, Taipei, TAIWAN, ⁵Departments of Nuclear Medicine and Biology and Anatomy, National Defense Medical Center, Taipei, TAIWAN, ⁶Departments of Biomedical Engineering and Radiology, Case Western Reserve University, Taipei, OH, UNITED STATES OF AMERICA, ⁷Brain Research Center, National Yang Ming University, Taipei, TAIWAN.

Aim/Introduction: The role of inducible nitric oxide synthase (iNOS), a nitric oxide synthase, in neuroinflammation—specifically the function of microglia in inflammatory processes—has been widely investigated; iNOS may be an important biomarker of the risk of neuroinflammation. Development of radiopharmaceuticals based on selective iNOS inhibitors has enabled positron emission tomography (PET) imaging of iNOS protein levels. However, the low brain levels of iNOS (even under neurodegenerative conditions), expression of iNOS by cells other than microglia (astrocytes, peripheral macrophages during blood brain barrier breakdown), genetic polymorphisms that affect the binding affinity of most iNOS PET radiopharmaceuticals, and similar levels of iNOS expression in activated microglia regardless of polarization (pro- or anti-inflammatory state) limit the potential of iNOS as a PET biomarker. **Materials and Methods:** We carefully defined a strategic plan to develop iNOS-targeted molecular PET imaging using (4'-amino-5',8'-difluoro-1'H-spiro[piperidine-4,2'-quinazolin]-1-yl) (4-fluorophenyl)methanone ([¹⁸F]FBAT) as a tracer to detect iNOS in a mouse model of lipopolysaccharide (LPS)-induced brain inflammation. **Results:** [¹⁸F]FBAT yield ranged from 2.2-3.1% (EOS), radiochemical purity was higher than 99% and specific radioactivity at the end of synthesis was typically 125 to 137 GBq/μmol. Compared to the control group, the 3 h ratios of [¹⁸F]FBAT accumulation at 30 min post-i.v. injection of the radiotracer reached 1.64 ± 0.57 in the whole brain, 1.53 ± 0.52 in the cortex and 1.34 ± 0.29 in the cerebellum. Quantitative immunostaining confirmed preferential accumulation of iNOS in the cortex and cerebellum in lipopolysaccharide (LPS)-induced mice. **Conclusion:** This study indicates [¹⁸F]FBAT has potential prognostic utility to indicate the progression of neuroinflammation-

mediated brain disease. **References:** 1. Site-directed conjugation chemistry of the hexahistidine tag

T. Tshibangu¹, M. Sillen², F. Cleeren¹, N. Geukens², P. Declerck², G. Bormans¹;

¹Laboratory for Radiopharmaceutical Research, KULeuven, Leuven, BELGIUM, ²Laboratory for Therapeutic and Diagnostic Antibodies, KULeuven, Leuven, BELGIUM.

Aim/Introduction: Despite its potential for site-specific bioconjugation (1,2), the functionalization of histag is barely explored by radiopharmaceutical scientists (3). To fill this gap, we report the controlled ligation of an histagged scFv targeting plasminogen activator inhibitor-1, by a bifunctional PEG-monosulfone. Owing to its high potential, the bioconjugation on histag could become a standard methodology for the radiolabeling of recombinant proteins. **Materials and Methods:** Based on literature procedures (1,2), hexahistidine peptide was used to explore the bioconjugation strategy. Parameters including the peptide-monosulfone ratio, temperature, pH, and duration of the reaction were monitored using LC-HRMS. The azido-monosulfone was reacted with sulfo-Cy5-DBCO to obtain a probe identifiable by a UV-vis detector. Stability of sulfo-Cy5-hexahistidine was assessed by LC-HRMS, after storage at 4°C for 5 months in PBS at pH 5 to 7 as well as at room temperature for 10 days in PBS pH 6.6. A scFv served as model for complex proteins, the bioconjugation was monitored by LC-HRMS and size-exclusion chromatography (SEC). **Results:** LC-HRMS monitoring of the reaction showed a fast bioconjugation of hexahistidine peptide, both at 4°C, room temperature and 40°C (70% conversion after 30 minutes at room temperature). The efficiency of the bioconjugation was highest at pH 6.5-7. Independently of the pH of the reaction, the entire monosulfone reagent was conjugated after 17 hours. A molar ratio 2:1 of peptide: monosulfone reagent results in exclusively mono alkylated hexahistidine. LC-HRMS analysis did not detect any release

of the sulfo-Cy5 derivative after storage at 4 °C for 5 months or at room temperature for 10 days proving the stability of the bioconjugate. The reaction condition optimized with hexahistidine peptide served as a launching pad for the site-specific bioconjugation of recombinant proteins, LC-HRMS and SEC analyzes confirmed the successful functionalization of scFv. **Conclusion:** Site-specific bioconjugation with PEG-monosulfone leads to better control of the degree of conjugation, achieving homogenous functionalization. The simplicity of the conjugation reaction makes this method suitable for the development of radio-biopharmaceuticals. The biological evaluation of site-specific radiolabeled scFv is underway. **References:** 1) Peciak, Karolina, et al. *Chemical science* 10.2 (2019): 427-439. 2) Jivan, Faraz, and Daniel L. Copper-64 based Radiopharmaceuticals as Potential Theranostic Agents

I. Khan¹, R. Zahoor¹, M. Numair¹, A. Shahid¹, A. J. Abrunhosa²;

¹Institute of Nuclear Medicine and Oncology (INMOL), Lahore, PAKISTAN, ²Institute of Nuclear Sciences Applied to Health (ICNAS), University of Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Copper radionuclides offer a varying range of half-lives and positron energies. The well-established coordination chemistry of copper allows for its reaction with a wide variety of chelator systems that can be linked to antibodies, proteins, or peptides. This paper will focus on ⁶⁴Cu radiopharmaceuticals for positron emission tomography (PET) imaging applications. Cu-64 can be safely used in imaging glioma and Alzheimer disease. **Materials and Methods:** We optimized the radiolabeling of ⁶⁴Cu with NODAGA-NOC and NODAGA-RGD at various labeling conditions, tested the stability of radioligands at room temperature and in human serum, evaluated the protein binding, lipophilicity, and tested binding affinity of radioligands on 143B and PANC-1 cells. Then the potential of these novel radioligands was tested in animal models bearing tumor xenografts. Finally, the potential of ⁶⁴CuCl₂ as a theranostic agent was tested in metastatic prostate cancer and brain glioma patients. **Results:** These scientific investigations produced very encouraging results, e.g., the radiolabeling of both NODAGA compounds with Cu-64 was done with high radiochemical purities without further purification. Both radioligands were found stable till 24h. Two peaks for ⁶⁴Cu-NODAGA-NOC were found using HPLC and it seem to be explained due to the formation of isomers. This is in contrast with ⁶⁴Cu-NODAGA-RGD, where only one peak was found. Serum stability studies showed that both radioconjugates remained more than 75% intact till 24h. Displacement assays showed that the ⁶⁴Cu-NODAGA-RGD precursor had higher retention(%) in 143B cells as compared

to ^{64}Cu -NODAGA-NOC precursor. Finally, the $^{64}\text{CuCl}_2$ tracer showed very intense uptake in metastatic prostate cancer patient which retained until 24h while no remarkable uptake could be detected in patient suffering from brain glioblastoma because he had already undergone surgery followed by several cycles of radiotherapy. **Conclusion:** Keeping in view the potential merits of Cu-64 labeled ligands and uptake of $^{64}\text{CuCl}_2$ in human patients, copper-64 based PET radiotracers seem interesting candidates which deserve to be investigated further so that they could also be clinically evaluated. **References:** 1. Aim/Introduction: Communications 16.00 Normal 0 21 false false false PT-BR JA X-NONE /* Style Definitions */ table.MsoNormalTable {mso-style-name:"Tableau Normal"; mso-tstyle-rowband-size:0; mso-tstyle-colband-size:0; mso-style-noshadow:yes; mso-style-priority:99; mso-style-parent:""; mso-padding-alt:0cm 5.4pt 0cm 5.4pt; mso-para-margin:0cm; mso-para-margin-bottom:0001pt; mso-pagination:none; mso-hyphenate:none; text-autospace:ideograph-other; font-size:12.0pt; font-family:"Times New Roman", serif; mso-bidi-font-family:Mangal; mso-font-kerling:1.5pt; mso-ansi-language:PT-BR; mso-fareast-language:ZH-CN; mso-bidi-language:Hi;} Rapamycin is a macrolide that in the past few decades have shown to be useful as an immunosuppressant and in other therapeutic applications. It is the natural inhibitor of the mechanistic target of rapamycin (mTOR), a kinase protein that plays a key role as a sensor of nutritional status at the cellular and organismal levels. Therefore, mTOR is a central node in the regulation of cell growth, proliferation, and metabolism. Several tumors are predicted to be potentially sensitive

to its inhibitors, the reason why it could be an interesting target for radiopharmaceuticals oriented to the diagnosis of several diseases. The aim of this work is to evaluate the utility of several compounds obtained from rapamycin and its semi-synthetic analogs everolimus and temsirolimus as possible radiopharmaceuticals. **Materials and Methods:** DFT calculations of these molecules were performed and further analysis of the dual descriptor, charges population and of the electrostatic potential surfaces were made. Molecular docking simulations were employed for evaluating the interactions of the protein with the studied candidates. **Results:** DFT studies allowed the proposal of two strategies of synthesis of novel compounds based on electrophilic reactions. Molecular docking results give us the opportunity to eliminate those molecules that do not interact correctly with the target. Finally, it was obtained that compounds synthesized through the electrophilic addition reaction that employed ^{18}F -selectfluor, as a fluorinating agent, the interactions with the target proteins are conserved. **Conclusion:** We propose three candidates to PET-radiopharmaceuticals targeting mTORC1. Two labeling strategies were analyzed, a direct one using ^{18}F -selectfluor as an electrophilic fluorinating agent and an indirect one in two steps through the "click chemistry" approach. Thanks to docking simulations, we conclude that directly labeled derivatives of rapalogues should maintain the biological activity of original compounds and therefore are suitable as possible PET-radiopharmaceuticals targeting the mTORC1 system. However, the compounds synthesized through the "click chemistry" approach are not suitable for this application because they are not able to correctly interact with the binding site due to the size of the prosthetic group introduced that does not allow the correct formation of the ternary complex ligand/FKBP12/FRB. **References:** None

Novel [^{18}F] FBPA synthesis method from pinacol boran precursor and [^{18}F] fluoride ion using automatic synthesizer

Y. Kanai^{1,2}, Y. Ohta^{3,4}, T. Watanabe⁵, Y. Hottori³, H. Takenaka⁴, K. Uehara⁴, S. Naka⁶, T. Sakai⁷, J. Hatazawa⁶, M. Kirihata³;

¹Osaka University of Pharmaceutical Science, Takatsuki, JAPAN, ²Kansai BNCT Medical Center, Osaka Medical College, Takatsuki, JAPAN, ³Research Center of Boron Neutron Capture Therapy, Osaka Prefecture University, Sakai, JAPAN, ⁴STELLA PHARMA CORPORATION, Sakai, JAPAN, ⁵Sumitomo Heavy Industry, LTD., Tokyo, JAPAN, ⁶Osaka University, Suita, JAPAN, ⁷Hanwa Intelligent Medical Center, Sakai, JAPAN.

Aim/Introduction: 2- [^{18}F] Fluoro-4-borono-phenylalanine (FBPA) is an important PET tracer for determination of Boron Neutron Capture Therapy (BNCT). Because it is used for BNCT applicability. [^{18}F] FBPA is mostly produced from [^{18}F] F_2 gas. Final product of [^{18}F] FBPA radioactivity is small

in amount. Recently [^{18}F] fluorination of aromatic ring with pinacol boran derivatives and copper reagent was reported. We previously reported [^{18}F] FBPA synthesis from [^{18}F] F^- which is produced by ^{18}O (p, n) ^{18}F nuclear reaction. In this study, we tried to adopt this method for automatic synthesizer. **Materials and Methods:** We used modified type of MPS-200 A β (Sumitomo Heavy Industry, Tokyo) as automatic synthesizer. Pinacol boran precursor and copper reagent was used for [^{18}F] fluorination step. After the fluorination reaction, reaction mixture was passed through silica gel cartridge column to remove copper reagent. In the borylation step, we used bis(pinacolato)diboron, bis(dibenzylideneacetone)-palladium(0), tricyclohexylphosphine and potassium acetate. Then, hydroiodic acid was added to reaction mixture for hydrolysis. Crude mixture was purified by HPLC. Finally, [^{18}F] FBPA fraction was collected. **Results:** Radiochemical yield of [^{18}F] FBPA from [^{18}F] HF was about 5~10 % (non-decay collected). Total synthesis time from End of bombardment was about 90 min. Radiochemical purity of [^{18}F] FBPA was more than 98 % and specific activity was about 1,000 GBq/ μmol . About 9 GBq of [^{18}F] FBPA was produced by our method with 60 min and 40 microA irradiation using 12 MeV cyclotron (HM-12S, Sumitomo Heavy Industry, Tokyo, Japan). **Conclusion:** We succeeded to synthesis [^{18}F] FBPA from [^{18}F] HF using automatic synthesizer. **References:** None

EP-330

Synthesis and In Vivo Behavior Study of Target-directed Zr-89 Labeled Nanorods

G. Kim, J. Chae, G. Kang, C. Lee, S. Kim;

Dongguk Univ., Gyeongju, KOREA, REPUBLIC OF.

Aim/Introduction: The purpose of this study is to selectively treat colorectal cancer by synthesizing target-oriented silica nanorods and loading anti-cancer drugs inside the rods, and to study the behavior of nanocarrier by labeling Zr-89 on nanorods. The behavior of the body varies according to the shape of the nanoparticles, and the uptake of cancer cells is also different. In the case of the hollow rod shape, the drug can be carried inside the particle, thereby making it highly useful. In addition, CT-26, a folate receptor overexpressing cancer cell line, is targeted by binding folic acid to the nanoparticle surface. **Materials and Methods:** In this study, silica nanorods were synthesized using a stober reaction using a silicon source (TEOS, tetraethoxy silane) on the AAO (Anodic Aluminum Oxide) template, chemically bound folic acid to the synthesized silica rod surface, and doxorubicin was supported inside the particles. And Zr-89 was introduced to the particle surface for the study of the In vivo behavior. **Results:** The shape and size of the silica nanorods were confirmed by SEM and TEM, and it was found through spectroscopic analysis (FT-IR and NMR) whether folic acid and doxorubicin were introduced. The Zr-89

labeling experiment showed high radiochemical purity of > 95%, and PET studies showed typical RES uptake. **Conclusion:** Rod-shaped nanoparticles were successfully synthesized uniformly, and Zr-89 could be stably introduced to the particle surface by a method without using a chelator. As a result of PET study, the distribution of silica nanorods in vivo could be confirmed, but it was not effectively accumulated in cancer site. It is thought that the target-oriented effect of folic acid was not shown by RES accumulation. **References:** None

Aim/Introduction: Glucagon-like peptide 1 receptor (GLP-1R) is preferentially expressed in pancreatic islets, especially in β -cells, but it's highly expressed in human insulinomas and gastrinomas. In recent years several GLP-1 receptor-avid radioligands have been developed to image insulin-secreting tumors or to provide a tentative quantitative in vivo biomarker of pancreatic β -cell mass. Exendin-4 is a 39-amino acid high affinity ligand of the GLP1-R with full agonist activity. It was labeled with PET isotope for imaging purposes. Here, we report results of a semi manual procedure to label [Lys40,Nle14(Ahx-NODAGA)NH2]exendin-4, as a kit, with Ga-68 ([^{68}Ga]Ga-NODAGA-Exendin-4). To develop and validate a labeling procedure to obtain [^{68}Ga]Ga-NODAGA-Exendin-4 in order to make it available for a clinical community. **Materials and Methods:** A $^{68}\text{Ge}/^{68}\text{Ga}$ Generator (GalliaPharma[®], Eckert and Ziegler) was eluted with 0.1M HCl to obtain the PET tracer Ga-68. The eluate $^{68}\text{GaCl}_3$ was purified using a cationic-exchange cartridge (SCX) on an automated synthesis module (Scintomics GRP[®]). The peptide contained in the kit vial (prepared by the Institute of Atomic Energy, Radioisotope Center POLATOM) in different amounts (10 - 20 - 30 ug) was reconstituted with 3.2 mL of HEPES solution and then 1.5 mL $^{68}\text{GaCl}_3$ (300-1850 MBq) was added to the dissolved peptide, followed by 15 min incubation at 100°C in a thermoblock. The reaction solution was purified through an HLB cartridge and the resulted product was diluted with PBS buffer and passed through a 0.22 μm sterile filter into a sterile 25 mL capped glass for the final formulation. A sample of the radiopharmaceutical product was tested for quality controls (e.g. radionuclidic purity, radiochemical and chemical purity, pH, endotoxins and sterility). **Results:** The

synthesis of [68Ga]Ga-NODAGA-Exendin-4 starting from 10 µg of peptide gets the best radiochemical yield of reaction (6.47±2.4 %), specific radioactivity (5.04 MBq/µg) and radiochemical purity (91.69 %), also representing the ideal amount for clinical application. All different quality control parameters tested were in accordance with the European Pharmacopoeia. **Conclusion:** The NODAGA-Exendin-4 was successfully labeled with Ga-68 with a semi manual procedure, fitting all the required QCs. **References:** None

Evaluation of Bivalent Fibroblast Activated Protein Inhibitor [^{99m}Tc-DTPA-(8-OH-quinoline)₂] for SPECT imaging of tumor

A. Wadhwa^{1,2}, S. Chaturvedi^{3,2}, A. K. Mishra³, F. Hussain⁴,
¹Institute of Nuclear Medicine and Allied Science, DRDO, Delhi, INDIA, ²INMAS, DRDO, Delhi, INDIA, ³Defence Research Development Organization, Delhi, INDIA, ⁴Department of chemistry, University of Delhi, Delhi, INDIA.

Aim/Introduction: Despite the progress in diagnostic and therapeutic techniques, cancer remains one of the leading causes of death. It is speculated that the tumor stromal micro-environment may present specific and sensitive targets that can aid in early diagnostics. Fibroblast activated protein (FAP) are being explored as promising targets for tumor delineation and diagnostic confirmation. FAP are expressed in more than 90 % of the epithelial carcinomas including pancreatic, colon and breast cancer. FAP, being involved in tumor migration, growth and progression presents an ideal target for diagnosis and therapy, especially in scenarios with limited FDG applicability. Imaging of FAP has better tumor demarcation, shorter scan time and is patient friendly with no dietary regulation before scan. Here, we report synthesis and preclinical evaluation of quinoline based FAP inhibitor, ^{99m}Tc-labelled-FAPI (^{99m}Tc(8-OHquinoline)₂DTPA) as SPECT tracer. **Materials and Methods:** Synthesis of bis-quinoline based FAPI inhibitor was done through conjugation of carboxylate group of DTPA with amine group of amino hydroxy quinoline. ADME properties and docking studies (PDB:1Z68) were assessed using Schrodinger software to analyze binding affinity and the fate of compound in vivo. The molecule was radiolabeled with ^{99m}Tc and the complex was characterized after purification using HPLC. Physicochemical characterization included evaluation of stability constants and non-specific binding

through fluorescence quenching of bovine serum albumin (BSA). Biocompatibility was evaluated using cellular and haemato-toxicity. Biodistribution at predefined time was done to assess the tissue distribution. **Results:** The DTPA-(8-OH-quinoline)₂ analogue was synthesized in more than 80% yield and characterized using spectroscopic methods. Docking with FAP gave GSscore of -9.67. Fluorescence quenching with bovine serum albumin revealed no to minimum non-specific binding. Non-toxicity of the tracer was established by less than 85% HEK-cell kill when incubated with 1 µM for 48 h and hemolysis data. The ^{99m}Tc-radiolabeled yield was more than 98±1% and the tracer was stable when challenged with serum for more than 24 h with 95±1% activity being retained. Biodistribution data indicate tumor specific accumulation **Conclusion:** Bis-quinoline based FAPI radiotracer was synthesized and characterized by NMR and ESI-MS spectroscopic techniques and evaluated as SPECT tracer. Radiolabeling was achieved more than 98%. In vitro studies revealed specific binding to HEK cell and less toxicity of synthesized radiopharmaceuticals. Future work will concentrate on SPECT imaging of tumor bearing mice. **References:** Thomas Lindner, Anastasia Loktev, Annette Altmann, Frederik Giesel, Clemens Kratochwil, Jürgen Debus, Dirk Jäger, Walter Mier, Uwe Haberkorn Journal of Nuclear Medicine, 2018; 59(9): 1415-1422

Radiolabelling, stability and in vivo biodistribution studies of albumin nanoparticles with gallium-67 and technetium-99m

M. De Arcocha Torres¹, G. Quincoces², A. L. Martínez-López³, A. Erhard², M. Collantes⁴, I. Martínez-Rodríguez¹, I. Luis-De Redin³, M. Ecañ⁴, I. Banzo¹, J. M. Irache³, I. Peñuelas²;

¹Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN, ²Radiopharmacy Unit, Nuclear Medicine Service, University Clinic of Navarra, IdiSNA, Pamplona, SPAIN, ³Department of Pharmacy and Pharmaceutical Technology, University of Navarra, Pamplona, SPAIN, ⁴MicroPET Unit. Nuclear Medicine Service, University Clinic of Navarra, IdiSNA, Pamplona, SPAIN.

Aim/Introduction: To optimize the radiolabelling of Gantrez-mannosamine polymer-coated (GPM2) albumin nanoparticles (NPs) with technetium-99m and gallium-67 in order to evaluate their in vivo biodistribution by SPECT/CT after intravenous administration. **Materials and Methods:** All NPs were prepared by solvent displacement They were radiolabeled at different temperatures (22°C, 40°C, 60°C) with 74±3.1 MBq of tin-reduced [^{99m}Tc]NaTcO₄. For gallium-67 radiolabeling, albumin was modified with NOTA before marking. Labelling of NOTA-modified NPs was carried out with [⁶⁷Ga]Cl₃ obtained from ⁶⁷Ga-citrate. A mixture of 2 mg NPs, 0.2M sodium acetate and 37 MBq

[⁶⁷Ga]Cl₃ was incubated at different temperatures (22°C, 30°C, 60°C) and times (10, 30 minutes). Radiolabelled NPs were purified using microconcentrators. Radiochemical purity was evaluated by radio-TLC (Whatman-1, NaCl 0.9 % for technetium-99m and Whatman-1, HCl 0.05M for gallium-67). The particle size and zeta potential were determined by photon correlation spectroscopy and laser Doppler anemometry, respectively. Stability of radiolabeled NPs was evaluated in saline and human plasma (37°C). All experiments were repeated thrice. Biodistribution studies were carried out in Wistar rats after intravenous administration (n=12, 3 per group: [^{99m}Tc]-GPM2, [⁶⁷Ga]-NOTA-GPM2, [^{99m}Tc]Tc-GPM2)[⁶⁷Ga]Ga-NOTA-GPM2[^{99m}Tc]Na₂CO₃ and [⁶⁷Ga]Cl₃). After SPECT/CT imaging, animals were humanly killed and activity in organs measured in a gamma counter. **Results:** Highest yield (97.59 ± 0.52%) for technetium-99m radiolabeling of NP was obtained at 22 °C for 10 minutes, while for gallium-67 the highest yield was roughly 70 % (69.2 ± 2.6%) and obtained at 30° C, 30 min. In both cases RCP was >97% after purification. [⁶⁷Ga]-NOTA-GPM2 NPs[⁶⁷Ga]Ga-NOTA-GPM2 showed >90% stability in saline and >80% in plasma, while it was >75% and >70% for [^{99m}Tc]-GPM2 NPs.^{99m}Tc]-GPM2 (The size of NPs was slightly increased after radiolabeling: 257±1.35 vs 244±3.40 for [^{99m}Tc]-GPM2 and 251.3±2.25 vs 243.5±6.62 for [⁶⁷Ga]-NOTA-GPM2. The potential Z increased slightly in both cases but remained within adequate values. In vivo SPECT/CT biodistribution studies showed in both cases a high accumulation of activity in the liver at 2 and 24 hours after administration (as measured by semi-quantitative analysis of VOIs derived from the corresponding CT images), with a very different biodistribution between treated and control animals. These results were coincident with those obtained ex vivo in the gamma counter. **Conclusion:** Albumin nanoparticles coated with the GPM2 polymer can be easily labeled with technetium-99m and gallium-67, obtaining high radiolabelling yield and adequate in vitro stability. In vivo SPECT/CT studies show a similar biodistribution for both isotopes, remaining stable for long periods. **References:** None

EP-334

Evaluation of mercaptoacetyl-based amino acid containing chelators for labeling of GRPR antagonist PEG2- RM26 with ^{99m}Tc

H. Sabahnou¹, A. Abouzayed¹, S. Rinne¹, V. Tolmachev², A. Orlova¹; ¹Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, ²Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Bombesin (BN) analogs bind with high affinity to gastrin-releasing peptide receptor (GRPR/BB2) that is up regulated in prostate cancer. This receptor can be used as a potential molecular target to visualize and treat

this tumor. The specific aim of this study was to investigate the influence of ^{99m}Tc-amino acids-based chelator complex on the targeting properties of the bombesin-based GRPR antagonist PEG₂-D-Phe-Gln-Trp-Ala-Val-Gly-His-StaLeu-NH₂ (PEG2-RM26). ^{99m}Tc-peptide based-chelator complexes can be improved by substituting glycol residues in the chelating sequence with more hydrophilic seryl and provided the best labeling stability by negatively charge glutamic acid residues. **Materials and Methods:** Synthetically produced analogs N-terminally conjugated with the chelator sequences mercaptoacetyl-Ser-Ser-Ser (maSSS-PEG2-RM26) and mercaptoacetyl-Ser-Glu-Ser (maSES-PEG2-RM26) were radiolabeled with ^{99m}Tc via ligand exchange using glucoheptonate. Radiochemical yield, stability in PBS, and analysis of radiocatabolites in urine and and gastrointestinal tract were determined by radio-RP-HPLC. In vitro binding specificity, kinetic properties, and cellular processing tests were performed using GRPR-expressing cells PC-3. The pharmacokinetics and in vivo binding specificity of the compound were studied in NMRI mice. **Results:** Radiolabeling of the peptides with ^{99m}Tc was efficient and stable, >98% radiochemical yield within 60 min at 90°C. Binding of ^{99m}Tc-maSXS-PEG2-RM26 was specific both in vitro and in vivo with binding affinity (K_d) of 61 pM for ^{99m}Tc-maSSS-PEG2-RM26 and 846 pM for ^{99m}Tc-maSES-PEG2-RM26. The cellular processing of all compounds indicated slow internalization. Labeled conjugates were rapidly eliminated with high degree of hepatobiliary excretion, 3 h pi most activities remained in GI tract. Analyses of activity showed that ^{99m}Tc-maSSS-PEG2-RM26 remained intact in GI content (~70%) and in urine (~30%), while for ^{99m}Tc-maSES-PEG2-RM26 only less hydrophobic catabolites were detected. **Conclusion:** The use of amino acid-based chelator could be used for stable labeling of GRPR antagonist with ^{99m}Tc. **References:** None

EP-335

A Novel Tc-99m-labeled and MAG₃-chelated Arginine-Arginine-Leucine containing Peptide for Tumor Imaging in Hepatoma Xenografts Model

R. Wang^{1,2}, Y. Du¹, Z. Chen¹, P. Yan¹, Q. Jiang¹, X. Duan¹; ¹Peking University First Hospital, Beijing, CHINA, ²Peking University International Hospital, Beijing, CHINA.

Aim/Introduction: In this study, arginine-arginine-leucine (RRL) a tumor targeting peptide is designed to link the bifunctional chelator mercaptoacetyltriglycine (MAG₃), aiming to explore the labeling conditions of Tc-99m and to evaluate the imaging of this probe in vivo. **Materials and Methods:** Tc-99m was labeled through the SnCl₂ reduction method, and the main factors affecting the labeling were investigated respectively to obtain the suitable labeling conditions. The paper chromatography was used to determine the labeling rate and radiochemical

purity. Cysteine replacement experiment and incubation experiment of normal saline/bovine serum albumin was utilized to evaluate the stability of Tc-99m-MAG₃-RRL in vitro. HepG2 tumor-bearing models were established and after tail vein injection, gamma camera imaging and biodistribution study were respectively performed periodically. **Results:** The purity of MAG₃-RRL was 98.94%. Under the suitable labeling conditions, the labeling rate was 93.67% ± 1.10%, and the radiochemical purity was 94.32% ± 0.19% (n=3). Tc-99m-MAG₃-RRL was placed in normal saline at room temperature and 50% BSA at 37°C, the radiochemical purity of Tc-99m-MAG₃-RRL was more than 90% (n=3) within 6 hours. The highest replacement rate of Tc-99m-MAG₃-RRL was 0.57% ± 0.21% in cysteine solution, and 0.41% ± 0.04% in normal saline control (n=3, P>0.05). The distribution coefficient IgP of Tc-99m-MAG₃-RRL was -0.15 ± 0.01 (n=3). Gamma camera imaging revealed substantial uptake of Tc-99m-MAG₃-RRL in tumors. The specific uptake of Tc-99m-MAG₃-RRL in tumor was significantly higher than that of control test after injection (P<0.05). In planar gamma imaging study, the tumors were imaged clearly at 2-4h after injection of Tc-99m-MAG₃-RRL, with the highest tumor-to-muscle ratio 5.63 ± 0.40 in 30min. Biodistribution data showed that Tc-99m-MAG₃-RRL was rapidly accumulated in tumor within 30min with the highest tumor-to-muscle ratio 5.50 ± 0.74. And then it was rapidly cleared from the blood and predominantly accumulated in the kidneys. **Conclusion:** The results show that MAG₃ could successfully be connected to RRL polypeptide and further improve the labeling rate, and the preparation method of Tc-99m-MAG₃-RRL is simple and fast. Tc-99m-MAG₃-RRL probe has good stability in vitro. Animal study shows that Tc-99m-MAG₃-RRL can be used as a potential candidate for visualization of malignant carcinomas. **References:** None

EP-336

Influence Of Different Factors On Labelling Yield And Image Quality Of Leukocytes Labelled With ^{99m}Tc-HMPAO

V. Mendi Barcina, E. Martínez Montalbán, E. Dobra, L. Arias Buendía, M. García Ruiz, S. Rizckallal Monzón, B. Martínez de Miguel;
Hospital Universitario La Paz, Madrid, SPAIN.

Aim/Introduction: Study the possible variables that may affect the labelling efficiency of white blood cells with ^{99m}Tc-HMPAO and the image quality. **Materials and Methods:** Retrospective study in which 123 patients in who we carried out leukocyte labelling with ^{99m}Tc-HMPAO were analysed, according to the protocol of the Radiopharmacy Unit, during 2018 and 2019. The variables to be evaluated are: age, white blood cells count present in the initial analysis and isolated white blood cells, leukocyte labelling yield and image quality. Data analysis is performed through the SPSS statistical program, using the Mann-Whitney statistical test.

Results: A low correlation is obtained between the number of pre-labelled leukocytes (2.95 * 10³ - 12.6 * 10³ leukocyte /μL) and the labelling yield (50 - 83%) (p = 0.034). About post-labelling leukocytes (17.08 * 10³ - 101 * 10³ leukocyte / μL) and the labelling yield there is a low correlation (p = 0.020). A proportional association is observed between pre-labelling leukocytes and post-labelling leukocytes (p = 0.000). In 100% of the cases, isolated leukocytes are above the ones in the initial analysis, obtained a ratio of 6.27 ± 1.15 isolated white blood cells for each initial white blood cell. A low correlation is obtained between the variation obtained in the count of both leukocytes and the yield (p = 0.019). No statistically significant association can be determined between white blood cell count and image (p = 0.440) and (p = 0.587), in the same way as between age (12-90 years) and yield (p = 0.838). **Conclusion:** The results obtained in our case show that there isn't relationship between the different variables analysed and the labelling yield and the diagnostic imaging. Thus, the number of pre-labelling and post-labelling leukocytes does not influence the labelling

efficiency, which was over 50% in all cases. **References:** None

Re-188 N-DEDC lipiodol for trans-arterial therapy in HCC: labeling efficiency and bio-distribution

S. Datta Gupta¹, P. Gupta¹, S. A. Shamim¹, J. Hussain¹, Shalimar¹, S. Gamanagatti¹, M. B. Mallia², V. Chirayil², A. K. Dash², C. S. Bal¹;
¹All India Institute of Medical Sciences, New Delhi, INDIA,
²Bhabha Atomic Research Centre, Mumbai, INDIA.

Aim/Introduction: Lipiodol labeled trans-arterial radionuclide therapy (TART) is a promising treatment in patients with hepatocellular carcinoma (HCC). Various agents are available for Re-188 lipiodol labeling. However, due to low labeling yields (50-60%), variable tumor retention and high cost, the search for an ideal agent is on-going. Novel bis-(diethylthiocarbamate) nitrido (N-DEDC) compound is an attempt at achieving high labeling yield and tumor retention at an affordable cost. We aimed at studying the labeling efficiency and bio-distribution of Re-188 N-DEDC lipiodol in HCC. **Materials and Methods:** Sodium perrhenate was eluted from W-188/Re-188 generator for labeling. Eluted perrhenate was added to kit-1 of N-DEDC and heated at 65°, followed by addition of eluted kit-2 contents. Thereafter, lipiodol was added and the complex mixed well

in vortex and centrifuged. Activity in separated lipiodol phase was measured and injected trans-arterially. Whole-body images at 24 and 48 hours and abdomen SPECT images at 24 hours post therapy were acquired for patients to assess bio-distribution. Region of interests were drawn over the tumor lesions, normal liver parenchyma, lungs and thigh (background) in planar images for semi-quantitative analysis. **Results:** Seven patients with radiological diagnosis of HCC were recruited prospectively and underwent Re-188 N-DEDC lipiodol TART. Mean dose synthesized and injected was 72.7 ± 7.7 mCi (2.6 ± 0.3 GBq). Mean labeling efficiency was found to be $80.75 \pm 9.84\%$, with short time to synthesis of 82.5 ± 5.8 minutes. It was observed during measurement, that iodinated lipiodol led to attenuation of activity in lipiodol phase by $24.18 \pm 9.76\%$. Whole-body imaging revealed distribution of radiopharmaceutical in target lesions, surrounding liver parenchyma and bladder. Mean tumor to liver ratio at 24 hours was 1.21 ± 0.12 and at 48 hours 1.24 ± 0.16 ($p=0.176$). Mean tumor to background ratio increased from 4.33 ± 1.20 at 24 hours to 5.36 ± 1.69 at 48 hours ($p=0.116$). Mean tumor to lung ratio at 24 hours and 48 hours was 1.98 ± 0.41 and 1.99 ± 0.48 , respectively ($p=0.310$). **Conclusion:** N-DEDC appears to be a promising novel agent for Re-188 lipiodol TART in HCC having similar bio-distribution with the advantage of higher labeling yield, shorter time to synthesis and lower cost. Further, clinical studies are underway to assess its efficacy in HCC. **References:** None

In vitro characterizations of ^{177}Lu -anti-CEA antibody and HSP90 inhibition for potentiated radioimmunotherapy of gastrointestinal cancer

T. Mohajer Shojai¹, P. Jha¹, A. Boström², F. Y Frejd¹, P. J Yazaki³, M. Nestor¹;

¹Uppsala University, Uppsala, SWEDEN, ²Ridgeview Instruments AB, Uppsala, SWEDEN, ³Beckman Research Institute, Duarte, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Carcinoembryonic antigen (CEA) is an antigen overexpressed in colorectal cancers, and widely used as a tumor marker. Radiolabeled anti-CEA monoclonal antibodies (mAbs) have previously been used in clinical trials with ^{90}Y as a therapeutic radionuclide, demonstrating promising results. However, ^{177}Lu may be an even more favorable therapeutic radionuclide compared to other widely clinical used radionuclides. This is owing to its unique chemical characteristics, well suited physical and biological half-life and desired energy in order to minimize off-target effects for therapy. The heat shock protein 90 (HSP90) has been shown to be overexpressed in colorectal cancer, where the HSP90 inhibitor Onalespib has previously demonstrated radiotherapy potentiation effects in combination with external radiotherapy. Consequently,

in the present study, we aimed to create and evaluate a ^{177}Lu radiolabeled anti-CEA hT84.66-M5A (M5A) mAb, and investigate the potential therapeutic effects of ^{177}Lu -M5A mAb and Onalespib, as monotherapies or in combination, in multicellular colorectal cancer spheroid models. **Materials and Methods:** ^{177}Lu -radiolabeling of DOTA conjugated M5A mAb was first optimized. Labeling yield and stability were analyzed using instant thin-layer chromatography, high-performance liquid chromatography, serum stability and EDTA challenge assays. Binding specificity and affinity was evaluated in three colorectal cancer cell lines (HT29, LS174T and HT55) and one gastric (MKN45) cancer cell line by blocking assays and LigandTracer real-time measurements. The effect on spheroid growth and cell viability from radioimmunotherapy with ^{177}Lu -M5A mAb and HSP90 inhibition was assessed alone and in combination in two different 3D multicellular tumor spheroid models. **Results:** Stable and reproducible radiolabeling was obtained, with labeling yields above 92%, serum stability above 92%, and EDTA stability above 87% at 48 hours after radiolabeling. Antigen-specific binding of the radiolabeled conjugate was demonstrated on all CEA-positive cell lines. Dose-dependent and antigen-specific therapeutic effects of ^{177}Lu -M5A mAb and Onalespib was demonstrated for the monotherapies in the spheroid models. Moreover, therapeutic effects could be further potentiated by combining ^{177}Lu -M5A mAb and Onalespib. **Conclusion:** Administration of either ^{177}Lu -M5A mAb or Onalespib as single compounds may be a promising treatment for colorectal cancer. Combinatorial therapy using both compounds could further potentiate therapeutic effects, however further in vitro and in vivo studies would be required to confirm current study findings. **References:** None

EP-339

DOTA-conjugation and ^{177}Lu -DOTA-radiolabeling optimizations of IgG4 antibodies

P. Jha, H. Berglund, T. M. Shojai, A. C. L. Mortensen, M. Nestor; Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: The high-specific tumor-affinity of IgG4 has made it one of the emerging therapeutic monoclonal antibody (Ab) subclasses employed for cancer immunotherapy. In addition to the inherent structural properties, the therapeutic efficacy of IgG4-Ab's is also affected by the post-radiolabeling specific activity or crude radiolabeling yield of the Ab-radiometal conjugates, and type of macrocyclic chelator used for radiometal incorporation. In this work, we optimized the physicochemical parameters for ^{177}Lu -labeling of various IgG4-Ab's. **Materials and Methods:** Conjugation with NHS- and p-SCN-Bn derivatives of DOTA was first tested with a commercially available IgG1 antibody followed by ^{177}Lu -labeling. Various IgG4-Ab's to a cancer-

associated antigen were conjugated with p-SCN-Bn-DOTA using the 1:10 molar ratio. The temperature-effect on DOTA-conjugation was assessed at 4°C, room temperature (RT), and 37°C. Purification of DOTA-Ab conjugates was tested using NAP-5 and Amicon Ultra 0.5 spin columns. Sodium and ammonium acetate buffers of different molarity and pH were then evaluated, as well as the incubation time for ^{177}Lu -labeling (42°C). Labeling yield was assessed using Instant Thin Layer Chromatography developed in 0.2 M citric acid and purity was determined using size exclusion (SE)-HPLC progressed in isocratic 0.1 M, pH 6.8 phosphate buffer. Binding specificity of the top candidates was assessed in vitro using LigandTracer and in vivo in mice xenografted with tumors of varying antigen density. **Results:** p-SCN-Bn-DOTA chelator produced enhanced conjugation and ^{177}Lu -labeling yields for all IgG4-Abs. RT and 4°C DOTA-Ab conjugated samples demonstrated varied ^{177}Lu -labeling yields (30-97%) for IgG4-Ab variants, whereas consistent ^{177}Lu -labeling yields (95-100%) were obtained for the DOTA-IgG4-Ab samples conjugated at 37°C. Highest specific activity (285-300 MBq/mg for 50µg of Ab) was obtained with 15 MBq of ^{177}Lu following a 2 h incubation for most of the IgG4-Abs. Optimum ^{177}Lu -labeling yields were noted for ammonium buffer (pH 5.4) rather than sodium buffer (pH 5.5) when used in 0.1-0.2 M range. The SE-HPLC of DOTA-Ab and ^{177}Lu -DOTA-Ab conjugates of the IgG4-variants, post-DOTA-conjugation (37°C) and post- ^{177}Lu -labeling (42°C) revealed little or no aggregation when stored at -20°C compared to 4°C. In vitro and in vivo studies demonstrated antigen-specific binding of the assessed radioconjugates. **Conclusion:** The first comprehensive physicochemical studies of DOTA-conjugation and ^{177}Lu -labeling of IgG4-Ab's provide reproducible results with improved labeling yields with high specific activity and no or minimal aggregate formation and retained antigen binding. This approach could lead to improved in vitro and in vivo outcomes of ^{177}Lu -loaded-IgG4-Ab's for cancer immunotherapy. **References:** None

EP-340

Radiolabeling with Tb-161 and Lu-177: defining the impact of metal impurities

M. Ooms¹, A. R. Burgoyne¹, B. Ponsard¹, D. Elema¹, T. Cardinaels^{1,2}, M. Van de Voorde¹;

¹SCK CEN, Mol, BELGIUM, ²KU Leuven, Department of Chemistry, Leuven, BELGIUM.

Aim/Introduction: ^{161}Tb and ^{177}Lu prove to be highly valuable in the fight against cancer as they can be deployed in targeted radionuclide therapy. ^{177}Lu -based radiopharmaceuticals are currently being widely explored, whereas interest in ^{161}Tb as therapeutic radioisotope is growing rapidly because of its very comparable decay properties. Moreover, ^{161}Tb is expected to have an improved therapeutic effect because

of its simultaneous emission of conversion and Auger electron emission. SCK CEN recently developed in-house production methods for ^{161}Tb [1] and ^{177}Lu with high radionuclidic purity. However, also metal impurities are of major concern since they have the potential to compete with the radionuclide during radiolabeling. In this study we aimed to identify and quantify the effect of metal impurities on the radiolabeling of ^{161}Tb and ^{177}Lu . **Materials and Methods:** The effect of metals on the radiolabeling of p-SCN-Bn-DOTA and p-SCN-Bn-DTPA with ^{161}Tb and ^{177}Lu was investigated. Radiolabeling yields in the presence of increasing amounts of common metal ion impurities (Al, Ca, Cu, Fe, Mg and Zn) were evaluated using radio-TLC. Also the effect of target matrix remnants on the radiolabeling yield of ^{161}Tb and ^{177}Lu was studied by addition of Gd and Yb impurities, respectively. Metal ion impurities were added in 250 to 10⁴ molar excess. A 10⁶ molar excess of the respective metal ion impurities was added to the radiolabeled complexes to evaluate their stability against transchelation. **Results:** The presence of low amounts of multivalent transition metal impurities showed dramatic decrease in radiolabeling yield. Target material remnants and high amounts of Ca also had a significant impact on radiolabeling. Partial transchelation of the radionuclide from the complex was observed in the presence of Al, Fe and Cu. **Conclusion:** In conclusion, this study confirms that metals can have a high impact on the radiolabeling efficiency of a radionuclide solution. This makes it possible to identify the metals that need to be closely monitored during the production process of ^{161}Tb and ^{177}Lu . Also after radiolabeling, an high impact of certain metal ions on the stability of radiolabeled compounds was found **References:** [1] A. Burgoyne et al., J. New Y Solid Target Concept for ^{89}Zr Cyclotron-based Production

S. Cisternino¹, H. Skliarova¹, E. Cazzola², G. Gorgoni², A. Baldini³, U. Anselmi-Tamburini^{3,4}, J. Esposito¹;

¹Istituto Nazionale di Fisica Nucleare - Laboratori Nazionali di Legnaro, Legnaro (PD), ITALY, ²IRCCS Sacro Cuore Don Calabria Hospital, Negrar (VR), ITALY, ³Department of Chemistry, University of Pavia, Pavia (PV), ITALY, ⁴Istituto Nazionale di Fisica Nucleare, Sezione di Pavia, Pavia (PV), ITALY.

Aim/Introduction: One of the most promising radioisotope candidate to perform immuno-PET imaging investigations

is ^{89}Zr , thanks to its main features [1]: 3.27 d physical half-life, relatively low energy positrons (maximum β^+ energy 0.897 MeV, $\beta^+ = 22.7\%$) providing high resolution PET images. At last the production is straightforward by means of medium-to-small medical cyclotrons. The $^{89}\text{Y}(p,n)^{89}\text{Zr}$ nuclear reaction route on 100% natural Y target isotope, commercially easily available, is the main one aimed at ^{89}Zr yielding. Demand for ^{89}Zr batches for research purposes is indeed growing up in the last years and different research groups have been working on it to improve radioisotope's production steps: target design and manufacturing, radiochemical purification, recovery and labelling studies. In the framework of the LARAMED research program at INFN-LNL [2], a new cyclotron solid target concept, based on Y foil bonded to Nb backing by means of Spark Plasma Sintering technique, has been investigated for the first time.

Materials and Methods: Y targets were realized through a specific bonding manufacturing process of Y foils (i.e. 150 μm thickness, 12 mm diameter) to Nb backing plate (\varnothing 23.5 mm x 1 mm) performed out by both a commercial SPS machine (in a private company) and by a prototype machine in-house developed at the University of Pavia and INFN-Pv department. Irradiation runs (energy 13 MeV, current 50 μA), automatic purification and recovery steps were carried out in collaboration with Radiopharmacy of Sacro Cuore Don Calabria Hospital. The production yield and the recovery efficiency were measured and compared with the ^{89}Zr produced by irradiating simple Y foils. **Results:** Any visible damage on targets surfaces has been seen after the irradiation runs (mean heat power areal density of around 650 W/cm^2), thus confirming the robustness of the SPS Y targets manufacturing process adopted. An integral yield of 0.4 $\text{mCi}/\mu\text{Ah}$ of ^{89}Zr was thus determined with high ^{89}Zr recovery efficiency (95%). A set of labelling procedures were performed with the ^{89}Zr produced by SPS Y target. **Conclusion:** The success and the advantage of the SPS Y targets could be the solution for a consistent ^{89}Zr radionuclide supply using small medical cyclotron. Moreover, the advantages of the SPS technique can be exploited for the manufacturing of other cyclotron targets for the production of different interesting radioisotopes. **References:** 1. Jalilian, A.R. et al., Journal of Radioanalytical and Nuclear Chemistry 2017, 314, 7–21.2. Esposito, J. et al., Molecules 2019 24, 20.

Cyclotron-Production of $^{51/52}\text{Mn}$ Isotopes: an Update on the METRICS Project

P. Martini^{1,2}, A. Boschi², E. Cazzola³, S. Cisternino¹, A. Duatti², G. Gorgoni³, L. Marvelli², M. Pasquali^{1,2}, L. Mou¹, G. Pupillo¹, C. Rossi Alvarez¹, H. Skliarova¹, G. Sciacca¹, J. Amico³, L. Uccelli², J. Esposito¹;

¹Legnaro National Laboratories of the National Institute of Nuclear Physics (INFN-LNL), Legnaro (PD),

ITALY; ²University of Ferrara, Ferrara, ITALY; ³Sacro Cuore Don Calabria Hospital, Negrar (VR), ITALY.

Aim/Introduction: The aim of the ongoing METRICS project (acronym for Multimodal pET/mRI imaging with Cyclotron-produced $^{51/52}\text{Mn}$ isotopes), is to develop all the technology needed to get a cyclotron-driven $^{52/51}\text{Mn}$ radionuclide production aimed at the so-called Multi Modal Imaging (MMI). Final goal is to achieve a perfect molecular matching between PET and MRI diagnostic techniques, by using both paramagnetic and radioactive properties shown by some manganese isotopes, which might allow for an unprecedented PET/MRI hybrid imaging modality. Such activities are funded by INFN in the framework of LARAMED (Laboratory of RADioisotopes for MEDicine) research program [1], running at Legnaro National Laboratories (LNL) on the development of cyclotron-based production strategies, either of emerging or conventional radionuclides for nuclear medicine applications. **Materials and Methods:** ^{nat}Cr metal pellets have been produced and attached to Cu/Au or Nb baking materials by means of the SPS (Spark Plasma Sintering) manufacturing technique. Both the backing selection and the design step process has been taken into account in order to achieve an, as high as possible, improvement in the backing thermal conductivity, while ensuring surface inertness required to the next chemical process (e.g. acid dissolution). To meet such a demand, we also realized a solid target dissolution system by making some technical modifications to an automatic module available on the market, which moreover allows performing the on-line dissolution process with a cassette-based system. Anion exchange chromatography has been used for the Mn/Cr separation. The efficiency of the process has been evaluated by gamma-spectrometry analysis. In addition, a series of paramagnetic Mn(II) complexes were prepared and characterized by HPLC chromatography, IR-spectroscopy, elemental analysis, and mass spectrometry. **Results:** So far, irradiation runs with TR19 cyclotron were performed to evaluate target thermomechanical resistance under a proton beam up to 50 μA ($\sim 1.2\text{kW}/\text{cm}^2$) and to perform a preliminary production test to optimize dissolution and purification process. Moreover, a series of Mn(II) complexes were prepared, in aqueous conditions, with different bidentate ligands with the goal to identify the most robust ligand arrangement, capable of stabilizing the Mn^{2+} ion in a biological environment. Along with stability, the pharmacokinetic properties of these complexes are currently under analysis. **Conclusion:** The preliminary results of the METRICS project are here presented, in terms of technology improvement, such as target, dissolution system, etc., to obtain cyclotron-produced $^{52/51}\text{Mn}$ and development of a new bimodal probe for manganese-based PET-MRI imaging. **References:** [1] J. Esposito, et al. Molecules 2019, 24, 20; DOI:10.3390/molecules24010020.

Multifunctional crown-5-calix[4]arene based phase-transfer catalysts for aromatic ^{18}F -fluorination

W. Lee^{1,2}, S. Kang³, D. Kim³, B. Lee^{2,4}, W. Lee², S. Kim^{1,2,4}

¹Department of Transdisciplinary Studies, Graduate School of Convergence Science and Technology, Seoul National University, Suwon, KOREA, REPUBLIC OF, ²Department of Nuclear Medicine, Seoul National University Bundang Hospital, Seongnam, KOREA, REPUBLIC OF, ³Department of Chemistry, Inha university, Incheon, KOREA, REPUBLIC OF, ⁴Center for nanomolecular imaging and innovative drug development, Advanced Institutes of Convergence Technology, Suwon, KOREA, REPUBLIC OF.

Aim/Introduction: Fluorine-18 has been used predominantly as a useful positron emitting isotope to prepare the radiotracer in the application of positron emission tomography (PET). In particular, incorporation of fluorine-18 into arenes is more required to avoid the metabolic defluorination of radiotracer by the reason of a high in vivo stability of a $\text{C}_{\text{Ar}}\text{-F}$ bond. Herein, we intend to achieve an effective nucleophilic aromatic ^{18}F -fluorination in various arenes by using multifunctional BTC5A-based phase-transfer catalysts (PTC). **Materials and Methods:** We prepared six different leaving groups substituted biphenyl precursors for aromatic fluorination. After evaluating the reactivity of precursors in the presence of BTC5A-based PTCs, we have chosen diaryliodonium tosylate as the desirable precursor and optimized the condition of nucleophilic aromatic fluorination by changing various solvents, PTCs and temperature. To monitor the stability of the precursor, it was reacted with PTCs and base ($\text{K}_{2,2,2}$ or BTC5A-based PTCs/ K_2CO_3) in various solvents except the fluoride sources. Aromatic [^{18}F]fluorination was conducted with various diaryliodonium tosylate substrates in different amount of PTCs ($\text{K}_{2,2,2}$, BTC5A-based PTCs), solvents, and radical scavenger (TEMPO). Radiochemical yield (RCY) was measured by the radio-TLC. **Results:** Various diaryliodonium tosylate precursors were synthesized as following the reported method. In the stability test of precursors, the BTC5A-based PTCs treated group showed approximately 30% higher stability than the $\text{K}_{2,2,2}$ treated group. When using TEMPO as radical scavenger, we found that precursor was more stable in basic condition. The optimized aromatic fluorination by using BTC5A-based PTCs showed the highest yields up to 80%, which is 10 times higher than that using $\text{K}_{2,2,2}$. In ^{18}F -labeling experiments, RCY in the

presence of BTC5A-based PTCs is 3 times higher (82%) than that of $\text{K}_{2,2,2}$. When applying this ^{18}F -labeling protocol in various substrates, RCYs were showed in maximum 3 times higher compared with the conventional method employing $\text{K}_{2,2,2}$. Especially, the well-known aromatic ^{18}F -labeled radiopharmaceuticals, [^{18}F]Flumazenil, was prepared in 95% RCY which is 2 times higher than that of followed the reported method. **Conclusion:** In this study, we have successfully optimized the condition for aromatic fluorination by using a new type of multifunctional PTC, BTC5A-based PTCs, which is far better than general PTC ($\text{K}_{2,2,2}$). With these promising results of ^{18}F -labeling experiments, we are expecting that multifunctional BTC5A-based PTCs could serve as a facile and efficient tool for the development of radiopharmaceuticals. **References:** D. Evaluation of DOTA-TATE kit formulation for multi isotope labelling

M. Maurin, P. Garnuszek, M. Radzik, W. Wojdowska, D. Pawlak, R. Mikołajczak;

National Centre for Nuclear Research, Radioisotope Centre POLATOM, Otwock, POLAND.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) using radiolabelled somatostatin analogues like DOTA-TATE peptide is a treatment option for patients with disseminated neuroendocrine tumours (NET). Depending on the type of the lesions a one isotope treatment or combination treatment using the high-energy ^{90}Y beta emitter for larger lesions and a lower energy ^{177}Lu for smaller lesions has been postulated in the literature. Additionally, recently the role of the theragnostic isotopes such as Sc-44 (4h half-life PET tracer) and Sc-47 (β^- therapeutic isotope) is increasing showing the potential for use in the diagnostic and therapeutic procedures. The aim of the study was evaluation of POLATOM designed sterile DOTA-TATE kit (MultiSom) as a kit for multi isotope labelling. **Materials and Methods:** MultiSom kit containing 100 μg of DOTA-TATE as an active substance and excipients like ascorbic acid and sodium hydroxide was tested for labelling with ^{90}Y (ItraPol), ^{177}Lu ca (LutaPol) and nca, ^{44}Sc and ^{47}Sc . The radiolabelling was performed according to the standard aseptic procedures. The kit was evaluated on basis of radiolabelling yield, resulting radiochemical purity and pH of final mixture. Radiochemical purity and radiolabelling yields were determined by RP-HPLC method (Phenomenex Kinetex 150x4.6mm column, flow of 80% 0.1%TFA in water and 20% of 0.1%TFA in acetonitrile, 1mL/min) and TLC method for unbound radionuclide determination (ITLC SG; mobile phase: 1M sodium acetate/methanol (50:50). **Results:** It has been proved that the specific content of

ascorbic acid in the kit successfully buffers 0.5 mL of 0.04 M HCl (medium for LutaPol/ItraPol). The MultiSom kit was efficiently (RCP > 98%) labelled with 4.4 GBq of c.a. ^{177}Lu (LutaPol of spec. act. ca. 700 GBq/mg) and up to 8 GBq with nca ^{90}Y (ItraPol). In case of Sc theragnostic pair it has been confirmed that the kit can be labelled to high RCP (>98%) with ^{44}Sc of radioactivity ca. 1.8 GBq and 0.95 GBq/kit for ^{47}Sc of low specific radioactivity. The resulting radiolabelled DOTA-TATE preparations are sterile and endotoxin and are ready for human use. **Conclusion:** The study showed that MultiSom kit developed by Polatom can be effectively labelled with ^{177}Lu , ^{90}Y , ^{44}Sc and ^{47}Sc . When radioisotope is sterile, endotoxin free and of GMP grade, the radiolabelled DOTA-TATE radiopharmaceuticals can be prepared directly in the hospital radiopharmacies just before application to patients. **References:** This work was partly financed by grant No. POIR/01.02.00-00-0041/15 „Multivariate formulations of DOTATATE peptide as precursor for preparation of radiopharmaceuticals (MultiSom)” from the National Centre for Research and Development.

Aim/Introduction: Cancer-associated fibroblasts (CAFs) can contribute up to 90% of the gross tumor mass. CAFs have common properties distinct from normal fibroblasts like the expression of FAP (fibroblast activation protein), a type II transmembrane serine protease which plays multiple biologic roles in cancer and it is associated with a poor prognosis in a variety of tumors. FAP is considered a promising target for the development of diagnostic and therapeutic radiotracers. The quinoline-based FAP-inhibitor ^{68}Ga -FAPI-46 is a promising radiotracer for imaging of CAFs. Aim of this work was to perform the synthesis of this tracer for clinical use by using a fully automated synthesizer. **Materials and Methods:** ^{68}Ga -FAPI-46 synthesis was performed in a synthesis module equipped with single-use sterile cassettes (Modular-Lab PharmTracer) using the eluate of a GalliaPharm generator (1850 MBq). The eluate was purified with a cation exchange column and the labeling reaction with the precursor FAPI-46 was carried out at 95°C in acetate buffer. The crude product was then purified on C18 column, eluted with ethanol, diluted with saline and sterilized by 0.22 µm filter. Different labeling conditions were investigated by varying cation post processing purification methods, reaction times, precursor

amounts and the type of scavenger added to prevent radiolysis. **Results:** Labelling rate increased by time using both post processing purification methods and different precursor amounts. The use of ascorbic acid as scavenger provided better radiochemical purity than ethanol. The latter provided also an incomplete product trapping during purification step, even after dilution of the reaction mixture with saline. Better synthesis yield achieved was 82±1% corrected for the decay (n = 5) with 34 nmol of precursor in 35 minutes, including generator elution. Radiochemical purity was >97% (RP-HPLC) and colloids <3% (TLC), pH 5.5, ethanol and residual ^{68}Ge content complied with European Pharmacopoeia limits. The product was sterile and apyrogenic. **Conclusion:** ^{68}Ga -FAPI-46 synthesis and quality control were performed for studying oncological patients in a FAPI-based clinical trial. The labeling conditions found with Modular-Lab PharmTracer synthesizer allowed to obtain ^{68}Ga -FAPI-46 in good yield enough for multiple patients administration and in a good radiopharmaceutical quality with high radiochemical and radionuclidic purity. Further stability study of ^{68}Ga -FAPI-46 in higher radioactive concentrations, by using the eluate of 2 generators, is under evaluation in order to increase the number of patients studied for each synthesis. **References:** None

Impact of Synthesis Procedure, Patient and Procedure-related Parameters on Image Quality of ^{68}Ga -PSMA-11 PET/CT

L. Calderoni¹, A. Farolfi¹, F. Lodi², S. Telo¹, G. Ricci¹, D. Pianori³, E. Maietti³, V. Cabitza², M. Fantini³, P. Castellucci¹, S. Fanti¹;

¹Nuclear Medicine, Sant'Orsola University Hospital, Bologna, ITALY, ²PET Radiopharmacy Unit, Sant'Orsola University Hospital, Bologna, ITALY, ³Department of Biomedical and Neuromotor Sciences, Unit of Hygiene, Public Health and Biostatistics, Alma Mater Studiorum, University of Bologna, Bologna, ITALY.

Aim/Introduction: ^{68}Ga -labeled urea-based inhibitors of the prostate-specific membrane antigen (PSMA), such as ^{68}Ga -PSMA-11, are promising small molecules for targeting prostate cancer (Pca). Production of this radiopharmaceutical is generally performed by using an automated synthesis module, nevertheless recently a sterile cold kit for ^{68}Ga -PSMA-11 production was introduced and commercially available. Aim of our study was to evaluate the human imaging characteristics of ^{68}Ga -PSMA-11 PET/CT prepared with two different synthesis procedures: synthesis module and ANMI sterile cold kit using the eluate of a GalliaPharm generator (Eckert & Ziegler) in PCa patients population. Secondary aim was to assess among patients characteristics and technical features which ones most influence image quality. **Materials and Methods:** Two different groups of 100 consecutive PCa patients who underwent ^{68}Ga -PSMA-11 PET/CT and images were reviewed independently by two

experienced nuclear medicine physicians with at least two years of PSMA imaging practice and unaware of clinical history. The two reviewers rated quality of each ^{68}Ga -PSMA-11 PET/CT using a 3-point likert-type scale (excellent, good and moderate). The performance was evaluated on the basis of the expected biodistribution, lesion detection, physiologic background uptake and presence of artifacts. The first group of patients was studied with ^{68}Ga -PSMA-11 obtained with synthesis module while the second group underwent imaging with ANMI sterile cold kit synthesis based radiopharmaceutical. **Results:** Overall 97/200 (48.5%) ^{68}Ga -PSMA-11 PET/CT resulted positive. Patient indications were 7/200 (3.5%) primary staging, 168/200 (84.0%) biochemical recurrence and 25/200 (12.5%) castration-resistant PCa. No significant differences in image quality between cold kit and synthesis module were found ($p=0.176$) but a higher amount of excellent images was observed among kit examinations (35% vs. 26%). According to multivariable regression analysis patient age (OR=1.49; CI 95%=1.09-2.02; $p<0.05$), patient weight (OR=1.68; CI 95%=1.38-2.05; $p<0.05$) and ^{68}Ga -PSMA-11 uptake time (OR=1.38; CI 95%=1.11-1.71; $p<0.05$) were significantly associated with an excellent image quality. **Conclusion:** No significant differences were found on image quality between two groups of patients studied respectively with ^{68}Ga -PSMA-11 synthesized with cold kit or synthesis module. Patient age, patient weight and ^{68}Ga -PSMA-11 uptake time were significantly associated with image quality. **References:** Perera M, Papa N, Christidis D, et al. ²Zionexa, Paris, FRANCE, ³Cyclopharma, Tours,

FRANCE, ⁴Tours Hospital, Tours, FRANCE.

Aim/Introduction: Fluorine labelled 8-((E)-4-fluoro-but-2-enyl)-3 β -p-tolyl-8-aza-bicyclo[3.2.1]octane-2 β -carboxylic acid methyl ester ([^{18}F]LBT999) is a selective radioligand for in vivo neuroimaging and quantification of the dopamine transporter by Positron Emission Tomography (PET). (1-3) In regards with potent interest of this radiopharmaceutical in routine application, we report herein fully automated methodologies on two commercial modules, TRACERlab FX_{FN} (FXFN) and AllinOne (AIO) in accordance with criteria for human use. **Materials and Methods:** Automated production

of [^{18}F]LBT999 was first developed on FXFN module and then transferred on AIO synthesizer to comply with GMP. These automations were based on a previously reported radiosynthesis of [^{18}F]LBT999 in a one-step reaction strategy from a chlorinated precursor, with slight modifications.(1, 4) On AIO module, an optimization of various parameters was performed to get high reproducibility, repeatability as well as to shorten radiosynthesis process **Results:** Automation of [^{18}F]LBT999 radiosynthesis on FXFN was carried out in 35% yield (decay-corrected) in 65 min (n=16), with a radiochemical purity higher than 99 % and a molar activity of 158 GBq/ μmol at the end of synthesis. The transfer on the AIO platform followed by optimizations allowed the production of [^{18}F]LBT999 in 32.7% yield (decay-corrected) within 48 min (n=5), with a radiochemical purity better than 98% and a molar activity in average higher to 154 GBq/ μmol at the end of synthesis. Quality controls of both methods met the specification for clinical application. **Conclusion:** Both modules allow efficient and reproducible radiosynthesis of [^{18}F]LBT999 with good radiochemical yields and a reasonable synthesis time. The developments made on AIO as its ability to meet pharmaceutical criteria and to more easily comply with GMP requirements make this approach as the best for a potent industrial production of the [^{18}F]LBT999 and a future wider use **References:** (1) Serriere S et al. *Nucl Med Biol.* 2014;41(1):106-13; (2) Varrone A, et al. *JNM* 2011;52(8):1313-21.(3) Arlicot N et al. *Q J Nucl Med Mol Imaging.* 2019. under press. EP-348

Full quality control of ^{11}C - and ^{18}F -radioballeted compounds using compact and automated Quality Control device

B. Kuhnast¹, O. Carvalho¹, J. Witczak², R. Grugel², X. Franci²;

¹CEA, BioMaps, Orsay, FRANCE, ²TRASIS, Ans, BELGIUM.

Aim/Introduction: Quality control (QC) is a crucial step in the development of original radiotracers and in the pharmaceutical quality assurance of radiopharmaceuticals injected to Humans. In the clinical practice, QC meets requirements, which are laid down by the pharmaceutical authorities. Specifications in terms of organoleptic characteristics, purity, identity, concentration, molar activity and biological burden must be observed. QC1 is a compact and automated quality control device in development that allows for checking these quality parameters of a large array of radiotracers and radiopharmaceuticals, according to the European Pharmacopeia (EP) recommendations, as well as internal specifications depending on the tracer. **Materials and Methods:** Samples of [^{11}C]PIB, [^{18}F]DPA-714 and [^{18}F]JAV1451 have been submitted to radiophysical-chemical quality control using QC1 device. Chemical and radiochemical purity and identity have been evaluated by

analytical radioHPLC (according to “Liquid chromatography” monograph, 01/2019 :20229). Radionuclide purity and identity have been measured by gamma spectrometry (according to “Radiopharmaceutical preparations” monograph, 07/2016:0125). Residual solvent content has been determined by head-space gas chromatography (according to “Identification and control of residual solvents” monograph, 01/2017:20424). Kryptofix has been identified using spot-test and pH using pH paper-strip (according to “Approximative pH of solutions” monograph, 01/2016 :20204), both based on camera image analyses. Molar activity and radioactive concentration of the radiotracers have as well been calculated. This set of controls has been performed starting from a unique 200 µL sample of the radiotracer. **Results:** The entire QC process lasted between 20 and 25 min including three successive HPLC injections (in-house practice) from a unique sample of [¹¹C]PIB, [¹⁸F] DPA-714 or [¹⁸F]AV1451. On the same production-batch of these radiotracers, standard analyses using regular apparatus were conducted in parallel to the exception of the gas chromatography that is not adapted for radioactive samples in our laboratory. All measured parameters were in accordance with the EP or in-house specifications for each radiotracer e.g. radiochemical purity > 95%; half-life for fluorine-18 between 105 and 115 min and > 99% 511 keV photons.... A final report was automatically generated summarizing the nature of the tests, the specifications and the compliance of the measures. Graphs of the chromatographies and spectrometries were also included. Analyses (type and number) were fully customizable. **Conclusion:** The compact and automated device QC1 is fully adapted for the QC of radiotracers and radiopharmaceuticals in a time compatible with the half-life of the radioisotopes. The implementation of the QC of other radiopharmaceuticals is ongoing. **References:** None

EP-349

Fast, reliable and universal spot test for the detection of TBA⁺ in radiopharmaceutical preparations

F. Morelle, A. Vas;

Trasis, Liège, BELGIUM.

Aim/Introduction: Spot testing is a cheap method to determine the presence or absence of compounds in radio-pharmaceutical preparations. However, no separation of the analyte from other substances is performed in such tests. Therefore, the possibility of false positive or false negative results due to the presence of interfering substances in the product hampers the implementation of such test and can redirect to more time-consuming chromatography methods. The tetrabutylammonium cation (TBA⁺) is used as a phase-transfer catalyst for the labelling of ¹⁸F-radiopharmaceuticals and its presence in the final product is limited to 2.6 mg per dose according

to the European Pharmacopeia (EP). Its presence can be detected by a spot test on thin layer chromatography (TLC) silica plate using iodine or iodoplatinate as revealing agent. In the presence of sodium ascorbate (NaAsc), which is widely used as antioxidant for injectable solutions, iodine and iodoplatinate become ineffective at revealing the presence of TBA. This study aims at the development of a fast and reliable spot test method for TBA that remains valid for formulations containing NaAsc. **Materials and Methods:** The new method is based on the radial elution on a few mm scale of the initial spot. This is sufficient to separate the TBA from the interfering NaAsc. The detection limit was estimated and the specificity of the test was verified for several ¹⁸F-compounds matrices. **Results:** The detection limit of TBA with the new method was shown to be close to 0.1 µmol/ml. This value was not affected by the presence of NaAsc in the sample matrix. Considering a dose volume of 20 ml, this is 5 times below the accepted limit for TBA. The equipment required for the test is limited to a silica TLC plate, a reference solution of TBA, water for injection, iodoplatinate spray reagent and pipetting equipment. The method has been validated for manual and automated processes on systems such as QC1. **Conclusion:** The new spot test can be used for the quality control of radiochemical preparations using TBA in their preparation process regardless of the presence of sodium ascorbate in the final formulation. **References:** European Pharmacopeia 8.2 01/2015:1325

EP-350

Automation and High yield production of [¹⁸F] MK-6240, a promising PET Tracer for quantification of Human Neurofibrillary tangles in Alzheimer disease

C. Vriamont, C. Warnier, M. Otabashi;

Trasis, Ans, BELGIUM.

Aim/Introduction: Tau PET tracers are well known radioactive probes designed for imaging of the accumulation and regional spread of brain neurofibrillary tangles and characteristic of neurodegenerative disorders known as tauopathies. Second generation Tau tracers, such as [¹⁸F]-MK-6240, show an improvement in their binding properties and lower the off-target binding. First in human studies with [¹⁸F]-MK-6240 underlined it as a promising PET radioligand for in vivo imaging of neurofibrillary Tau aggregates in Alzheimer disease. Automation of the [¹⁸F]-MK-6240 radiotracer to ensure high and reproducible synthesis yields and to allow starting with multi-curies on a platform with disposable cassettes and reagent kits is therefore needed to allow production centers to produce and dispense this PET tracer. **Materials and Methods:** The production of [¹⁸F]-MK-6240 is performed along the synthesis method described hereafter and performed with an AllinOne-18 with HPLC. The resulting solution is clear, isotonic and can be used for quality control. The [¹⁸F] produced in the

cyclotron is separated from the aqueous solvent by trapping on an anion-exchange cartridge followed by elution with a solution of tetrabutylammonium hydrogen carbonate and evaporation to dryness. MK-6240 precursor is then added. The fluoride anion displaces the Nitro leaving group in a S_NAr reaction. Heating the reaction to 160°C in DMF allows a thermal deprotection of the Boc groups to afford the crude [^{18}F] MK-6240 radiotracer in one single step. The [^{18}F] MK-6240 is purified by a semi-preparative HPLC, followed by collection and trapping on a SPE cartridge. The [^{18}F] MK-6240 is eluted with ethanol and saline. The product is ready for QC and dispensing. **Results:** [^{18}F] MK-6240 was produced on the AllinOne unit- in 65 minutes- with an average yield of 30 +/- 5 % non-decay-corrected (NDC)- with a final volume of 20+- 1 ml The HPLC purification was performed on the embedded HPLC unit and allows to selectively collect the [^{18}F] MK-6240 peak, free from any radiochemical or chemical impurities. Stability studies were conducted during 8 hours with a product vial containing 750 mCi (28 GBq) at the end of synthesis time and showed a radiochemical purity higher than 98%. [^{18}F] MK-6240 Synthesis have been performed on different AllinOne units and at different facilities and showed consistent results, highlighting the reliability of the process. **Conclusion:** The automation of the [^{18}F] MK-6240 PET tracer synthesis on the AllinOne platform afford reliable cassette-based synthesis, providing high yields (30+-5% NDC) and stable product over time. **References:** None

EP-351

A Generic GC Protocol for the Residual Solvent Analysis of PET Radiopharmaceuticals

C. Marcolan, M. Glaser, F. Twyman, K. Sander, R. Awais, E. Årstad; University College London, London, UNITED KINGDOM.

Aim/Introduction: Testing for residual organic solvents is a regulatory requirement for quality control (QC) of PET radiopharmaceuticals prepared under Good Manufacturing Practice (GMP) for use in humans¹. As it is impractical and time consuming to use distinct GC methods for residual solvent analysis for each individual PET tracer produced in a GMP facility, we sought to develop a generic assay that allows robust identification and quantification of all solvents and volatile organic commonly used for PET tracer productions. **Materials and Methods:** A stock solution was prepared containing the following analytes; dimethylamine, dimethylaminoethanol, methanol, ethanol, acetonitrile, isopropanol, dichloromethane, acetic acid, dimethylformamide and dimethylsulfoxide. Selected diluents were then used to dilute the stock solution to concentrations ranging from 10-120% of the target value. Several GC columns and temperature gradients were evaluated and assessed for accuracy, repeatability, linearity, as well as resolution, peak tailing and sensitivity.

Results: Of the GC columns investigated, the CP-Volamine capillary column (PN: CP 7447, 30 m x 0.32 mm diameter) proved best suited for analysis of complex solvent mixtures. Dimethylacetamide gave optimal results when used as a diluent. 1-propanol was chosen as the internal standard as it readily could be resolved from the analytes investigated. The optimised GC system demonstrated satisfactory results for all analytes investigated. The accuracy ranged from 93-107%, with excellent linearity ($R^2 > 0.99$) and injection repeatability (RSD% in the range of 0.2-1.2). Resolution, peak tailing and sensitivity met ICH guidelines. The validated protocol was implemented for routine residual solvent analysis of a range of PET tracers, including ^{18}F -FDOPA, ^{18}F -D₄-FCholine, and ^{18}F -DPA-714. **Conclusion:** We have developed a generic GC assay that allows analysis of all solvents and volatile organic commonly used for PET tracer productions. The method overcomes the need for dedicated residual solvent analysis methods for individual PET tracers and can substantially simplify QC testing of residual solvents in PET GMP facilities. **References:** ¹ ICH Harmonised Guideline, Impurities: Guideline for residual solvents Q3C(R6). (2016).

Investigations on formulation of freeze dried kit for preparation of ^{99m}Tc -PSMA-peptid (Mepromostat)

S. Keresztes¹, T. Mándoki¹, Z. Kiss-Gombos¹, E. Szemenyei¹, M. Antalffy¹, J. Körmeyi¹, G. Trencsényi², L. Pávics³;

¹Institute Of Isotopes Co., Ltd., Budapest, HUNGARY,

²Department of Nuclear Medicine, University of

Debrecen, Debrecen, HUNGARY, ³Department of Nuclear

Medicine, University of Szeged, Szeged, HUNGARY.

Aim/Introduction: To formulate freeze dried cold kits for preparation of ^{99m}Tc -PSMA-peptid (Mepromostat) which is suitable for routine use in nuclear medicine laboratories for diagnostic imaging of prostata cancer. **Materials and Methods:** Systematic investigations were carried out on the impact of different excipient concentrations for the API content and on the radiolabeling efficiency of freeze dried cold kit. Three different compositions were tested in formulation by five batch preparation. Quality control tests were carried out to establish compliance of specifications: pH, tin(II) content, loss on drying, API assay and radiochemical purity of injection. In addition solubility studies were conducted in order to identify which buffer provides the highest solubility of API thus minimizing the API filtering loss. A Quality Control kit has been developed with a simple, end-user method for 'on-the-spot' testing of radiolabeling. Two radolabeling methods were compared in every batch. Finally, all formulas were tested regarding biodistribution in male Wistar rats. **Results:** All formulas were compliant to the predefined quality specifications and were successfully labeled with ^{99m}Tc . One specified phosphate buffer is proved to be a good candidate for ensuring high

solubility of API and robust manufacturing process. The different compositions showed similar biodistribution in male Wistar rats and two of them were successfully utilized for detection of prostate cancer in patients. Initial clinical trials demonstrated the high utility of ^{99m}Tc -PSMA (^{99m}Tc -mas3-y-nal-k(Sub-KuE)) in diagnostic imaging of prostate cancer. **Conclusion:** The formulated kits provide consistently high radiolabeling yields with ^{99m}Tc and appropriate API content. Quality tests are repeated in every six months to ensure compliance of cold kit specifications. **References:** None

Aim/Introduction: Sterility testing is used to assess the presence or absence of microorganisms in products made for human use. Most products can usually be tested directly after production, radiopharmaceuticals mostly with a significant time delay. Only few laboratories are equally authorized to handle radioactivity, and are also equipped to carry out sterility tests. According to the Radiation Protection Regulations, samples can only be sent from the manufacturing laboratory to a test laboratory without an authorization to handle radioactive materials after reaching the legal limit for unrestricted release of a particular nuclide. This value for the nuclide Lu-177 is 100 Bq/g. For the usual range of Lu-177-activities applied in the synthesis of radiopharmaceuticals as Lu-177-PSMA or Lu-177-DOTATOC this would correspond to a decay time of 20 to 22 weeks before a sample can be submitted for sterility testing. The aim of this project is to develop a concept for monitoring the sterility over the mentioned period of sample storage under varying storage conditions. **Materials and Methods:** Different sample compositions starting from the pure sample matrix to the manufactured Lu-177-DOTATOC sample are used. After the validation of methods for sterility testing and bioburden measurement, the recovery of microorganisms depending on the monitored sample volume, storage time and amount of inoculated microorganism have to be evaluated. According to USP and EP regulations, the inoculation of 7 different types of microorganisms in 3 different amounts varying from 10 to 100 CFU is used. Sterility tests are carried out for samples with varying activity concentrations between 0.26 GBq/mL

and 1.33 GBq/mL. Individual batches are stored at -20 °C, 4 °C and at room temperature, respectively, and tested at least 3 points in time. **Results:** A work flow has been developed to examine the impact of long term storage parameters on the detection of microbiological species, which could potentially contaminate the radiopharmaceutical during its manufacturing process. **Conclusion:** The proposed method of time-dependent sterility testing can be used to determine the impact of autosterilisation during long term storage of Lu-177-containing radiopharmaceuticals. It is transferable to other nuclides and radiopharmaceutical preparations. **References:** [1] StrSchV, 29.11.2018, p. 111. [2] EP, Chapter 2.6.1, Sterility, 8th edn, 2014. Study of Separation and Formulation Using Solid-Phase Extraction Method to Produce [^{11}C]DPA713 and [^{18}F]DPA714 as a Translocator Protein Ligands

S. Naka^{1,2}, K. Kurimoto¹, K. Matsunaga¹, T. Watabe¹, M. Tatsumi², E. Shimosegawa¹, H. Kato¹, J. Hatazawa¹;
¹Osaka University Graduate School of Medicine, Suita, Osaka, JAPAN, ²Osaka University Hospital, Suita, Osaka, JAPAN.

Aim/Introduction: [^{11}C]DPA713 and [^{18}F]DPA-714 have been developed to evaluate the relevance of expressed translocator protein (TSPO) and the activation of microglia in various neurodegenerative diseases. For the synthesis of both tracers, after labeling, HPLC separation and formulation with evaporation system were performed, however the cleaning validation of these device is required. We tried to establish a single-use system with solid-phase extraction (SPE) method. **Materials and Methods:** In the synthesis of [^{11}C]DPA713, [^{11}C]CH₃OTf as a labeling agent was adopted, and its production was performed by gas-phase method. On the other hand, for the [^{18}F]DPA714 synthesis, the precursor was used tosyl group and hydroxy group (same with [^{11}C]DPA713 precursor). The radiolabeling with tosyl group precursor was performed according to previous report (Michelle L. James, J Nucl Med 2008) and hydroxy group was labeled by [^{18}F]fluoroethyl bromide. After radiolabeling, reaction mixture was processed in SPE columns (reverse phase) and any concentration ethanol. **Results:** In the [^{11}C]DPA713 synthesis, 10-fold dilution solution of reaction mixture was passed through the tC2 column and then the column was washed with 20 mL of 25 % ethanol. [^{11}C]DPA713 eluted with 1 mL ethanol from tC2 column was obtained the high radioactivity (> 1.5 GBq) radiochemical purity (> 99%). [^{18}F]DPA714 synthesis with tosyl group could not be separated any chemical impurities using SPE column, however, good separation of radiochemical and chemical impurities were obtained by hydroxy group precursor and [^{18}F]fluoroethyl bromide. **Conclusion:** We could establish a single-use system

with SPE method for the synthesis of [^{11}C]DPA713 and [^{18}F]DPA714 using same precursor. **References:** None

Production of [^{18}F]PSMA-1007 using different starting activities of 18F-fluoride: yield and stability of the radioligand

C. Maisto, A. Morisco, E. Squame, L. D'Ambrosio, M. Aurilio, P. Gaballo, S. Lastoria;
Istituto Nazionale Tumori IRCCS Fondazione
G. Pascale, Naples, ITALY.

Aim/Introduction: Prostate-Specific Membrane Antigen (PSMA), overexpressed in prostate cancer (PC), is considered a good target for staging of this disease. Different ^{68}Ga -radiolabeled-PSMA ligands have been investigated as PET probes, showing excellent imaging properties. Unfortunately, they can be produced in small amounts because of the limited quantity of ^{68}Ga obtained from the generator with a limited number of studied patients. Recently, [^{18}F]PSMA-1007 has been introduced, matching the possibility of a large-scale production. Our aim was to evaluate the influence of different starting amounts of 18F-fluoride on radiochemical yield (RCY), radiochemical purity (RCP) and stability of the final product. **Materials and Methods:** [^{18}F]PSMA-1007 was produced under GMP-compliant conditions on a TRASIS AllinOne platform according to the manufacturing process. Briefly, [^{18}F]fluoride is trapped on QMA and then eluted with 75mM TBA; the PSMA-precursor in DMSO (1,6mg/2,2ml) is heated at 105°C for 10 min. The product was purified by C18ec cartridge and washed with 5.7% ethanol, then it was eluted with 30% ethanol on PS-H⁺ cartridge and buffered in PBS. The product was tested for RCP and stability by radio-HPLC using a Jupiter® 5 μm C18 300 Å, 250 x 4.6 mm column and a gradient method with solvent A (acetonitrile 0,1% TFA) and solvent B (water 0,1% TFA), flow 1ml/min. Starting [^{18}F]fluoride activities were: 58.2±5 GBq (A) and 88.4±3.9 GBq (B). **Results:** RCYs were determined as no decay corrected yields at end of synthesis (EOS). Four syntheses were performed with starting activity A with a final RCY of 49.2±3.8%; eight syntheses were performed with starting activity B with a final RCY of 51.9±3.6%. The [^{18}F]PSMA-1007 radiotracer was stable up to 8 h post synthesis with lack of degradation products due to radiolysis. **Conclusion:** The described method is very reliable and provides excellent RCYs in 35 min. The different activities did not affect the final RCY and the stability over a period of 8 hours, enabling to study up to 18 patients with PC by a single synthesis. **References:** None

CYP3A4 inhibitors affect the pharmacokinetics of the TSPO radioligand [^{18}F]DPA-714 in PET imaging studies in humans

M. Peyronneau¹, B. Jego¹, C. Letailandier², C. Leroy¹, S. Lavisse³, F. Caillé¹, B. Kuhnast¹, M. Bottlaender⁴;
¹CEA, BioMaps, Orsay, FRANCE, ²APHP, Hôpital Saint-Antoine, Paris, FRANCE, ³CEA, MIRcen, Fontenay-aux-Roses, FRANCE, ⁴CEA, Neurospin, UNIAc, Gif-sur-Yvette, FRANCE.

Aim/Introduction: [^{18}F]DPA-714, a known TSPO radioligand, has been recently evaluated by PET imaging in humans for investigating the role of neuroinflammation in the development and progression of neurodegenerative diseases like Alzheimer, Parkinson and multiple sclerosis [1,2]. During this study, we aimed to assess the effect of co-medications on the metabolism and pharmacokinetics of [^{18}F]DPA-714, in a large cohort of 192 subjects (genotyped for TSPO polymorphism) and consequently on the human brain input function that may be required for PET data analyses. **Materials and Methods:** Venous blood samples were collected from all subjects during PET (129 patients and 63 controls). Among them, arterial blood samples were also collected from 16 healthy controls free of any medication (HC). [^{18}F]DPA-714 and metabolites fractions were determined by a solid phase extraction method and used for the correction of individual input functions. The mean percentages of parent tracer in plasma at 70-90min ([^{18}F]DPA-714₇₀₋₉₀) and corresponding concentrations of [^{18}F]DPA-714 (AUC₀₋₉₀) in co-medicated patients were compared to HC. For statistical analyses, impact of endogenous factors such as age, gender, TSPO polymorphism was verified. **Results:** The metabolism of [^{18}F]DPA-714 was significantly lower in patients than HC ([^{18}F]DPA-714₇₀₋₉₀: 61.35±11.02 % vs 51.50±6.83 %, p<0.05). In order to investigate the potential source of variability, 38 subjects exhibiting a huge decrease of metabolites formation (parent radiotracer fraction higher than 70%) were analysed separately. Among the most common co-medications given, amlodipine, atorvastatine, metformin, nicardipine, sartans, verapamil were identified. All these drugs are known inhibitors of CYP3A4, the isoform mainly responsible for the metabolism of DPA-714 [3]. Considerable modifications of the plasma pharmacokinetics were observed, leading to an increase of the parent plasma concentration with AUC₀₋₉₀ values from 20.03±7.93 to 73.13±44.82 SUV·min in co-treated individuals

vs 15.57±5.24 SUV.min in HC. Finally, while [¹⁸F]DPA-714 is administrated at tracer dose, the toxicity of the radiotracer should be highly reduced as compared to pharmacological dose, co-medications may affect individual input functions. **Conclusion:** Thus any co-medication that inhibits CYP3A4 should be taken into account since it may lead to a decrease of [¹⁸F]DPA-714 metabolism that will likely produce an increase of the parent tracer in plasma and a potential increase of the brain uptake. Individual input functions should be preferred for the analysis of imaging patients data, instead of averaged input function derived from HC. **References:** ^[1]Hamelin et al. Brain. 2018;141(6):1855-1870. ^[2]Bodini et al., J Nucl Med. 2020 Jan 31. ^[3]Peyronneau et al., Drug Metab Dispos. 2013;41(1):122-31.

EP-357

A Physiologically Based Pharmacokinetic Model of ⁶⁸Ga-DOTATATE to Describe Organ Distribution

H. Siebinga^{1,2}, B. J. de Wit-van der Veen², J. H. Beijnen¹, M. P. M. Stokkel², T. P. C. Dorlo¹, A. D. R. Huitema^{1,3}, J. J. M. A. Hendriks^{1,2};

¹Department of Pharmacy & Pharmacology, The Netherlands Cancer Institute, Amsterdam, NETHERLANDS, ²Department of Nuclear Medicine, The Netherlands Cancer Institute, Amsterdam, NETHERLANDS, ³Department of Clinical Pharmacy, University Medical Center Utrecht, Utrecht, NETHERLANDS.

Aim/Introduction: Physiologically based pharmacokinetic (PBPK) models combine drug specific information with prior knowledge on the physiology and biology at the organism level (system specific information). Whole-body PBPK models contain an explicit representation of the organs and tissue and can be used as a tool to predict pharmacokinetic behavior of drugs. The aim of this study was to develop a PBPK model to describe organ distribution of ⁶⁸Ga-DOTATATE based on clinical PET/CT data. **Materials and Methods:** Clinical ⁶⁸Ga-DOTATATE PET/CT data from 41 patients without any visible somatostatin receptor (SSTR) overexpressing tumors were included. Scans were performed at 45 minutes (range 30-60 min) after intravenous bolus injection of approximately 100 MBq ⁶⁸Ga-DOTATATE (~10 µg peptide). Organ (spleen, liver, thyroid) and blood activity levels were derived from PET-scans and corresponding peptide concentrations were calculated. A whole-body PBPK model was developed using a standardized protein model in PK-Sim and MoBi (Open System Pharmacology, version 8.0). Organs were linked by blood compartments and each organ was further characterized by a specific blood-flow, volume, tissue-partition coefficient and permeability. The internalization reaction, enzymatic reaction for intracellular degradation and renal clearance were included in the model and SSTR2 expression was added to several organs (1). Input parameters were fixed or fitted using a built-in Monte Carlo algorithm for parameter identification. **Results:** ⁶⁸Ga-DOTATATE was administered with a median peptide

amount of 12.5 µg (range 8.0-16.9 µg) labeled with 92.7 MBq (range 43.4-129.9 MBq). SSTR2 expression for spleen, liver and thyroid were fitted at 24.3, 4.86 and 1.09 nmol/L, respectively. Variability in observed organ concentrations was described by variability in SSTR2 expression and differences in administered peptide amounts. Using this variability, the model predicted 78.0%, 90.2% and 94.1% of observed data for spleen, liver and thyroid, respectively. Fraction unbound in plasma was fitted at 0.28 and 13% of the peptide was excreted unchanged in the urine within 4 hours. **Conclusion:** To conclude, biodistribution of ⁶⁸Ga-DOTATATE can be described with a whole-body PBPK model, where tissue distribution is mainly determined by variability in SSTR2 organ expression. Besides, variability in observed concentrations was described by differences in administered peptide amounts. This PBPK model showed the feasibility to model concentration-time profiles for specific organs and, hereafter, can be used to predict distribution throughout other tissues. **References:** 1. Sandström M, et al. Comparative biodistribution and radiation dosimetry of ⁶⁸Ga-DOTATOC and ⁶⁸Ga-DOTATATE in patients with neuroendocrine tumors. J Nucl Med. 2013;54(10):1755-9.

Investigation of structure-affinity relationship of novel ¹⁸F-labeled norepinephrine analogue tracers

S. Mühlig^{1,2}, X. Chen^{1,2,3}, Y. Ohshima^{1,2,4}, Y. Yagi⁵, H. Kimura⁵, K. Koshino⁶, N. Nose⁷, C. Lapa³, A. Buck¹, T. Higuchi^{1,2,7};

¹Department of Nuclear Medicine, University Hospital of Würzburg, Würzburg, GERMANY, ²Comprehensive Heart Failure Center, University Hospital of Würzburg, Würzburg, GERMANY, ³Department of Nuclear Medicine, University Hospital of Augsburg, Augsburg, GERMANY, ⁴Department of Radiation-Applied Biology Research, Quantum Beam Science Research Directorate, National Institutes for Quantum and Radiological Science and Technology, Gunma, JAPAN, ⁵Department of Analytical and Bioinorganic Chemistry, Kyoto Pharmaceutical University, Kyoto, JAPAN, ⁶Department of Systems and Informatics, Hokkaido Information University, Ebetsu, Hokkaido, JAPAN, ⁷Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, JAPAN.

Aim/Introduction: The norepinephrine transporter (NET) is one of the major targets for radionuclide imaging of the cardiac sympathetic nerve condition and neuroendocrine tumors. Most radiotracers, which target NET-function, consist of derivatives of norepinephrine (NE). In this study two newly designed NE analogue ¹⁸F-labeled PET compounds, which have identical structure rather than meta-fluoride (compound **a**) or meta-iodide (compound **b**), were evaluated to understand the relationship with NET affinity. **Materials and Methods:** In vitro study with competitive uptake assay was performed with ³H-NE and human neuroblastoma SK-N-SH cell line to characterize

uptake via NET. Cells were treated with $^3\text{H-NE}$ (12 kBq/ml) in 0.1% BSA/DMEM containing non-radioactive compounds **a** or **b** in concentrations from 10^{-10} - 10^{-3} M. In the presence of 20 μM pyrogallol (catechol-O-methyl-transferase inhibitor) and 100 μM pargyline (monoamine oxidase inhibitor), cells were incubated for 60 min then washed with PBS, lysed in 0.1 M NaOH, followed by measurement of radioactivity. Cold hydroxyephedrine (HED), metaiodobenzylguanidine (MIBG) and NE were used as references for the target compounds. In vivo biodistribution study was performed on healthy male Wistar rats, whereby ^{18}F -labeled compound **a** or **b** were administered via tail vein. After 10 min tracer injection, heart, liver and blood were obtained for tissue counting study. **Results:** The in vitro study demonstrated that cold compound **a** had an IC_{50} value (3.4 μM) in a comparable range as the cold references NE (5.4 μM) and HED (2.1 μM). To be noted, these IC_{50} values are about 5 fold higher than clinical tracer MIBG (15.4 μM). In contrast, compound **b** greatly lost its NET affinity (IC_{50} value 98.1 μM). Animal study of both ^{18}F -labeled compound **a** and **b** showed homogeneous cardiac uptake, while higher cardiac uptake (heart-to-blood ratio) was seen with compound **a** than **b**: 12.0 and 13.1 ($n=2$) vs 5.8 ± 0.3 ($n=4$). **Conclusion:** In cell uptake studies, two ^{18}F -labeled compounds with an identical structure rather than meta-fluoride or -iodide greatly differ in NET affinity. The former has similar affinity as NE or HED and even better affinity than MIBG, whereas the latter showed a much lower affinity. In contrast, in vivo rat experiments revealed high cardiac uptake in both ^{18}F tracers. Considering the existence of an extra-neuronal cardiac uptake mechanism in rats, the uptake may be mediated by other transporters, such as organic cation transporters, which is currently under investigation. **References:** None

Can SPECT/CT lung shunt quantification improves dose optimisation with $^{99\text{m}}\text{Tc-MAA}$ study for ^{90}Y microsphere workup

A. Poon^{1,2}, J. Dal Santo¹, S. T. Lee^{1,3,4}, B. M. Chappell¹, K. Pathmaraj¹, A. M. Scott¹;

¹Austin Hospital, Heidelberg, AUSTRALIA, ²University of Melbourne, Parkville, AUSTRALIA, ³Olivia Newton-John Cancer Research Institute, Heidelberg, AUSTRALIA,

⁴La Trobe University, Heidelberg, AUSTRALIA.

Aim/Introduction: ^{90}Y microspheres radioembolisation

is a recognised treatment of inoperable liver cancer. Radioembolisation involves intrahepatic-arterial injection of ^{90}Y microspheres into tumour via the hepatic artery performed under angiogram guidance. To optimise risk/benefit for patients receiving ^{90}Y microspheres, a pretreatment $^{99\text{m}}\text{Tc-MAA}$ shunt study is required to assess lung shunting in order to minimise potential radiation pneumonitis. Current practice calculate percentage of lung shunt from planar imaging, however, implementation of software to quantify shunting from SPECT/CT may allow for more accurate assessment of lung shunt and therapeutic dose optimisation. To quantify and compare the percentage of $^{99\text{m}}\text{Tc-MAA}$ lung shunting calculated from planar and SPECT/CT imaging in patients being worked up for ^{90}Y microspheres radioembolisation and calculation of expected radiation dose to the lungs. **Materials and Methods:** A pilot study of patients with hepatic malignancies undergoing imaging workup for ^{90}Y microspheres radioembolisation was conducted. Planar and SPECT/CT imaging of chest and abdomen were acquired on a GE Discovery-670 system. $^{99\text{m}}\text{Tc-MAA}$ injected dose and patient demographics were collected. Percentage lung shunt was calculated using regions of interest drawn over the whole lungs and whole liver. The lung shunt is calculated by equation ($\text{lung shunt}\% = \frac{\text{geometric mean lung counts}}{\text{geometric mean liver counts} + \text{geometric mean lung counts}} \times 100$) and GE Q.Volumetrix software for planar and SPECT/CT imaging respectively. Lung radiation dose (Gy) was calculated by $49670 \times \text{Activity}(\text{lung})(\text{GBq}) / \text{Mass}(\text{lung})(\text{g})$ as per SIR-Spheres[®] product insert. Statistical analysis was performed. **Results:** Twenty patients were reviewed. Using planar analysis, the percentage lung shunt ranged from 2.5-38% (mean \pm SD = $11.61\% \pm 7.22\%$). Using SPECT/CT analysis, the percentage lung shunt ranged from 1.41-13.3% (mean \pm SD = $3.54\% \pm 2.64\%$); indicating a lower calculated lung shunt using SPECT/CT analysis. Two patients did not receive ^{90}Y microspheres therapy, one of which was due to lung shunt >20% on planar calculation but was only 13.3% on SPECT. Assuming a lung mass of 1000g, the estimated radiation dose to the lungs from the treated ^{90}Y microspheres dose ranged from 2.24-16.58Gy (mean \pm SD = 7.78 ± 4.06 Gy) from planar and 0.73-5.99Gy (mean \pm SD = 2.39 ± 1.55 Gy) from SPECT calculations. **Conclusion:** Quantification of lung shunting and hence radiation dose to the lungs calculated from SPECT/CT was lower when compared with planar imaging for patients undergoing workup for ^{90}Y microspheres radioembolisation, which may allow for better dose optimization in cases where lung shunting was the primary limiting factor. However, given the pilot study's small size, further investigation is needed to validate this technique for clinical practice. **References:** None

Neuroendocrine Tumours (NET) Quantitative SUV-SPECT/
CT Change during ¹⁷⁷Lu-DOTATATE MRTT. Alkahtani^{1,2}, L. Livieratos^{1,2}, V. Lewington^{1,2};¹King's College London, London, UNITED KINGDOM,²Guy's & St Thomas' Hospitals NHS Foundation

Trust, London, UNITED KINGDOM.

Aim/Introduction: Post-treatment imaging is routinely used to, verify radiopharmaceutical distribution in patients undergoing molecular radiotherapy (MRT). Beyond its role as a visual assessment tool, image quantification may have a role in monitoring changes induced by MRT. This project examines the role of quantitative SUV-SPECT during ¹⁷⁷Lu-DOTATATE MRT to determine whether Standardised Uptake Values (SUV) change in patients undergoing repeated radionuclide treatments. **Materials and Methods:** We retrospectively analysed serial SPECT/CT data for three patients undergoing ¹⁷⁷Lu-DOTATATE MRT for metastatic neuroendocrine tumours. 3D quantitative SUV-SPECT/CT data were reconstructed and analysed using Hybrid3D 3.01 software (HERMES Medical Solutions, Sweden). The SUV of normal and abnormal tissues was calculated following the first and fourth cycle of ¹⁷⁷Lu-DOTATATE. Seventeen lesions and healthy organs (liver, kidneys, and spleen) were assessed after both cycles to derive SUV_{max}, SUV_{mean}, SUV_{peak}, and SUV_{ratio}. Wilcoxon Signed-Rank test using SPSS (IBM SPSS Statistics 2019 v26.0; Armonk, NY) was applied testing of SUV changes. Paired sample t-test was used to evaluate differences for non-target organs. **Results:** SUV values changed significantly between the first and fourth PRRT cycles ($p < 0.05$). The mean overall SUV decrease in index tumour lesions was 70%. The mean total lesion: spleen SUV ratio decreased from 4:1 to 0.9:1 between PRRT cycles 1 and 4. The SUV of non-target organs such as liver, spleen and kidneys was stable between treatment cycles in all patients. **Conclusion:** Quantitative SPECT/CT appears feasible to evaluate changes in tumour and normal tissue uptake following MRT. SUV change has potential as a clinical marker to evaluate response between MRT cycles and might improve the optimisation and individualisation of MRT. **References:** None

Peptide Receptor Radionuclide Therapy With [¹⁷⁷Lu-DOTA⁰,Tyr³]octreotate. Experience At Our CenterM. Lara Martínez¹, M. De Sequera Rahola², A. Díaz Silván², O. Vilahomat Hernández², E. Martínez², D. Cabello García², M. López Acosta², A. Allende Riera²;¹Hospital Universitario de Canarias, Santa Cruz de Tenerife, SPAIN, ²Hospital Universitario Nuestra Señora de La Candelaria, Santa Cruz de Tenerife, SPAIN.

Aim/Introduction: There are limited therapeutic options for patients with advanced Neuroendocrine Tumors (NETs) progressing on first-line somatostatin analog therapy. Peptide receptor radionuclide therapy (PRRT) is an innovative technique that delivers cytotoxic radiation to tumor cells using a β^- emitting radionuclide such as [¹⁷⁷Lu-DOTA⁰,Tyr³]octreotate (¹⁷⁷Lu-DOTATATE) that is chelated to a somatostatin analog allowing targeted action on NETs which usually overexpress somatostatin receptors. PRRT is thus a new therapeutic option for NETs patients. Indicated for the treatment of unresectable or metastatic, progressive, well differentiated (G1 and G2), somatostatin receptor positive gastroenteropancreatic (GEP) and bronchial neuroendocrine tumours (NETs) in adults. **Materials and Methods:** Descriptive retrospective study of patients with GEP and bronchial NETs who were treated with ¹⁷⁷Lu-DOTATATE from 2018 to 2019. In this period, 15 patients were treated. In addition to demographic parameters, we analyzed NET type, stage, side effects and progression-free survival. **Results:** We analyzed 15 canarian patients treated with ¹⁷⁷Lu-DOTATATE who had previously progressed to somatostatin analogues and chemotherapy (11 men and 4 women), with a mean age of 58 years, with diagnoses of pancreatic NET (7 patients), ileal NET (6 patients), and pulmonar NET (2 patients), all of them in stage IV, 12 patients being G2 and 3 patients were G1. Three patients received 2 doses due to liver progression, both of them kept experiencing disease progression and only one patient received 3 doses due to severe thrombocytopenia, however this last one remains in stable disease until now with a mean progression-free survival of 12 months. The median progression-free survival after treatment of the 11 patients who completed all the 4 doses was 18 months, lower compared to the 28,5 months reported in the Netter study, probably because of the small sample and the scarce 2-year follow up since the first treatment was administered at our center. Of whom 7 remain in stable disease and 4 showed disease progression. Hematological toxicity was seen on 3 patients due to thrombocytopenia. **Conclusion:** PRRT with ¹⁷⁷Lu-DOTATATE is a favorable therapeutic option in patients with metastatic bronchial and GEP NETs that express somatostatin receptors that have progressed to other lines of treatment with few side-effects. **References:** None

EP-362**Tandem High-Dose ¹³¹I-MIBG Therapy For Paediatric Patients With Relapsed-Refractory High Risk Neuroblastoma: A Dosimetry Based Treatment**

C. Altini¹, M. Villani¹, B. Cassano², M. Pizzoferro¹, A. Serra³, A. Castellano³, V. Cannatà², M. Garganese¹;

¹IRCCS Bambino Gesù Children's Hospital, Nuclear Medicine Unit, Imaging Department, Rome, ITALY, ²IRCCS Bambino Gesù Children's Hospital, Medical Physics Unit, Rome, ITALY, ³IRCCS Bambino Gesù Children's Hospital, Paediatric Haematology/Oncology Department, Rome, ITALY.

Aim/Introduction: ¹³¹I-meta-iodobenzylguanidine (¹³¹I-MIBG) combined with myeloablative chemotherapy represents an useful modality of treatment in children affected by relapsed/refractory neuroblastoma (NB) for increasing palliation and progression-free survival. Aim of our study is to evaluate the feasibility, safety and response of tandem high-dose therapy based on two administrations of ¹³¹I-meta-iodobenzylguanidine (¹³¹I-MIBG) followed by Melphalan. **Materials and Methods:** 13 patients (age range: 3-17 years) affected by relapsed/refractory NB, (all previously subjected to several lines of treatment) were included. Each treatment included two administrations of ¹³¹I-MIBG (with a dosimetric approach); the WB absorbed dose resulting from the first administration was used to determine the second activity to be administered to reach a total WB absorbed dose of 4 Gy. 96 hours after second ¹³¹I-MIBG administration, a single dose of Melphalan (110 mg/m²) with peripheral blood stem cell (PBSC) rescue was given. In all patients, a ¹²³I-MIBG scintigraphy was performed before treatment and SIOPEN score was determined. **Results:** after first treatment no one experienced grade 4 of neutropenia; three patients needed an RBC transfusion. After second treatment twelve patients experienced grade 4 neutropenia and one grade 3, three patients presented fever and all needed a RBC and PTL transfusions; six patients showed mucositis. Cumulative WB absorbed doses ranged from 1.6 to 4.8 Gy (median: 3.6 Gy). Regarding treatment response, five patients showed progressive disease (they died after 6, 6, 10, 10 and 16 months respectively); four patients showed stable disease (FUP ranging from 14 to 24 months); two patient showed partial response (FUP: 12 and 14 months respectively) and 2 patients showed complete response (FUP of 9 and 30 months). **Conclusion:** in our experience, high-dose ¹³¹I-MIBG therapy combined with chemotherapy is a feasible and safe modality of treatment in heavily pre-treated patients affected by relapsed/refractory NB in order to achieve an effective myeloablation; dosimetric approach allows to prescribe a tailored treatment, administering activities as high as possible. Moreover it can be considered an effective therapy too, even though further studies with more patients and a longer FUP are mandatory. **References:** None

EP-363**Quantitative assessment of SUVs obtained in ⁶⁸Ga-labeled somatostatin analogue PET/CT for estimation of long term response to PRRT in patients with neuroendocrine tumors**

A. Sowa-Staszczak¹, M. Opalińska², A. Kania-Kuc², I. Al Maraih², M. Buziak-Bereza¹, A. Hubalewska-Dydejczyk¹;

¹Chair and Department of Endocrinology, Jagiellonian University CM, Krakow, POLAND, ²Nuclear Medicine Unit, Endocrinology Department, University Hospital in Krakow, Krakow, POLAND.

Aim/Introduction: PRRT is an effective treatment for disseminated NETs, especially for control of disease progression. Currently there is not known any effective predictors of the final response to PRRT. Aim: Quantification of SUVs obtain in ⁶⁸Ga-somatostatin analogue PET/CT in prediction of the long-term response to PRRT. **Materials and Methods:** Out of 20 people treated with PRRT using ¹⁷⁷Lu and ¹⁷⁷Lu/⁹⁰Y DOTA-TATE in 2017-2019 due to dissemination of G1 and G2 neuroendocrine neoplasm, 13 patients were eligible for study. In this group ⁶⁸Ga-DOTA-TATE PET/CT was performed in average 4.5 months before and 3.6 months after PRRT. A total of 83 metastatic lesions were evaluated and they were located in the liver, bones, lungs and lymph nodes of the neck, chest, abdominal and pelvic cavity. For every lesion in both PET/CTs (before and after PRRT) SUVmax, mean value of SUV, and ROI volume were measured. SUVmax in target lesion was compared to the mean value of SUV in the lesion volume to assess the homogeneity of the lesions. Further for all lesion corrected SUVmax was counted, taking into account individual for each patients SUV max of reference organs (normal liver and spleen). Finally corrected SUVmax change(before and after PRRT) was counted. Obtained results were assigned to three groups of variations: 1. SUV increase 2. SUV decrease 3. Insignificant variation. Those results were correlated with the progression, stabilization (SD) or regression of the disease seen in other imaging studies after mean 9 months of observation. **Results:** The mean follow-up was 8.9 months, during which progression was found in 3 patients, regression in 4 and disease stabilization in 6 patients. Among patients with regression, a decrease in the mean value of corrected SUVmax in comparison to the baseline study of 281% was observed. Among patients with SD, a mean of corrected SUVmax in comparison to the baseline study decreased by 190%. Stable values were observed among progressive patients, where change of corrected SUVmax was in average -1%. **Conclusion:** A decrease in the value of corrected SUVmax in metastatic lesions obtained from routine PET/CT tests with ⁶⁸Ga-DOTA-TATE may indicate a lower risk of neuroendocrine tumor progression within a 9 months from the end of PRRT and may constitute an additional independent parameter helping to estimate the risk of progression in this group of patients. **References:** None

EP-364**Complications During The Treatment Administration Of 177Lu-Oxodotreotide And Adverse Effect In The Patients**

S. Rodríguez Gadea, E. Cobreros Peña, A. Cuadra Plaza, M. Bravo Perez, D. Gimeno Gállego, M. Marín Ferrer, Á. Galiana Morón, M. Gonzalez Martín;
Hospital Universitario 12 Octubre, Madrid, SPAIN.

Aim/Introduction: The present study aims to describe the complications and adverse effects observed during the administration of 177Lu-oxodotreotide in the treatment of neuroendocrine tumours (NET), according to the technical specifications sheet of the radiopharmaceutical. **Materials and Methods:** Nineteen patients (average age 60.4± 12.65) including 9 women were treated with 177Lu-oxodotreotide (4 doses/7400MBq every 8 weeks) between March 2016 and November 2019. Fourteen patients had a primary lesion in the digestive system and 5 in the lungs. A total of 67 doses were administered, 13 patients completed the treatment, in 4 patients the treatment was discontinued because progression disease or toxicity and 2 patients were pending completion of the treatment. The procedure was carried out by a nurse of our department, supervised by Nuclear Medicine physician or a third-year internal resident. During each patient procedure we collected the following data: percentage of radiopharmaceutical injected, injection instruments malfunctions, changes in pump injection pressure or flow rate to the patient, radioactive contaminations, problems with urine incontinence requiring bladder catheterization and stopping the treatment. And finally any adverse symptoms referred by the patient during the procedure or the following days. **Results:** According to our data, the average dose injected to the patients was 98.40%±2.23 of the total amount in the vial. The problems observed during the procedures were: instrument malfunctions 8 (11.94%); changes in pressure/flow rate of perfusion pump 13 (19.24%); radioactive contaminations: floor 2 (2.98%), bed and sheets 2 (2.98%), staff skin 3 (4.17%); 3 patients (4.47%) required bladder catheter due to urinary incontinence (4.47%). Adverse reactions: nausea 13 patients (G1- 42.1%, G2 21.1%, G3 5.2%); vomits 6 patients (G1 26.3%, G2 5.2%), diarrhoea 3 patients (G1 10.5%, G2 5.2%), abdominal pain 4 patients (G1 10.5), headache 2 patients (10.52%). **Conclusion:** The perfusion technique employed in our department allows for a 98.4% administration of the total dose prescribed. All the problems occurred during the procedure were successfully resolved. The adverse effects observed are few and similar to the published data. **References:** Nuclear Medicine Service, Hospital 12 de Octubre

EP-365**¹³¹I-MIBG treatment in patients with metastatic paraganglioma and pheochromocytoma**

J. Bernal, S. Prado, M. Agudelo, A. Utrera, J. Cañón, P. Bello;
Hospital Universitario y Politécnico La Fe, Valencia, SPAIN.

Aim/Introduction: To describe our experience with ¹³¹I-MIBG in patients with metastatic paraganglioma and pheochromocytoma during the last decade. **Materials and Methods:** Descriptive, retrospective study of 7 patients (4 men, one of them child), with an age range between 5-77 years (mean: 45.14), diagnosed with metastatic paraganglioma/pheochromocytoma and treated with ¹³¹I-MIBG from 01-01-2010 until 01-17-2020. All of them were previously studied with ¹²³I-MIBG scintigraphy, somatostatin receptor scintigraphy and/or PET-CT (¹⁸F-FDG or ⁶⁸Ga-DOTATOC). **Results:** 4/7 pheochromocytomas and 3/7 paragangliomas were treated. 2/7 patients presented SDHB mutation. In 2/7 cases a second cycle of ¹³¹I-MIBG was administered and one cycle in the remaining patients. The average activity administered was 165.37mCi (83-222.5mCi). The treatment was clinically well tolerated by all patients. The most frequent adverse event was hypertensive crisis (2/7 patients) despite premedication, with improvement after adjusting the supportive treatment. The mean follow-up after treatment was 23.42 months. During the first year: 1/7 patient had a partial response, 3/7 stable disease, 2/7 progression of disease, and 1/7 died due to advanced disease. Clinical improvement was reported in 5/7 cases and laboratory parameters normalization in 3/7. In the long-term follow-up 2/3 patients are with stable disease, and do not have any clinical change and 1/3 patients have progressed in 22 months. The pediatric patient is into partial response and remains asymptomatic after 62 months follow-up. **Conclusion:** Treatment with ¹³¹I-MIBG has shown excellent tolerance and improves the life quality in most of the patients, with bearable short-term adverse events. Although larger series are necessary, about half of the patients remain free of disease progression, and it could be advisable to assess the use of this treatment in earlier stages of the disease. **References:** None

EP-366**Assessment of early cardiotoxicity following the use of radiotheranostics agents 177Lu-PSMA for prostate cancer and 177Lu-DOTATATE for neuroendocrine tumors**

M. Assadi¹, A. Amini¹, E. Jafari¹, H. Ahmadzadehfard², D. Bagheri³;
¹Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, ²Klinikum Westfalen, Knappschaft Hospital, Dortmund, GERMANY, ³Persian Gulf University, Bushehr, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Cardiovascular diseases and cancer are the most common causes of morbidity and mortality around the world. Nowadays, with progression in technology

and patient care procedures, the survival rate of cancer patients is improved significantly. Nevertheless, all of the therapy procedures lead to short and late-term adverse side effects which can decrease the clinical efficacy such as cardiovascular toxicity (CVT). Therefore, evaluation of novel cancer treatment procedures associated CVT is necessary for its efficiency. Aim of this study was evaluation of early cardiotoxicity following radionuclide therapy (RNT) including peptide receptor radionuclide therapy (PRRT) with ^{177}Lu -DOTATATE for treatment of patients with neuroendocrine tumors (NETs) and radioligand therapy (RLT) with ^{177}Lu -PSMA by measurement of serum troponin as a cardiac injury indicator. **Materials and Methods:** From December 2018 to October 2019, patients with prostate cancer and NET referred for PRRT and RLT, respectively, were enrolled to this study. To measure troponin, blood samples were taken immediately before treatment and 48 hours after treatment for each patient and the serums were separated and frozen. **Results:** 42 RNT cycles were evaluated in 26 patients with mean age of 60.08 ± 17.55 years from 27 - 99) including 13 NET patients (23 cycles) and 13 prostate cancer patients (19 cycles) underwent PRRT and RLT, respectively. The NET patients included five females and eight male. The median administered dose was 6.6 with range of 3.7 to 7.4 GBq. The serum values of troponin before and after treatment were 0.61 ± 0.49 and 0.47 ± 0.54 ng/ml, respectively ($p=0.12$). In prostate cancer patients, the serum values of troponin before and after treatment were 0.59 ± 0.42 and 0.53 ± 0.38 ng/ml, respectively ($p=0.4$). In NET patients, the serum values of troponin before and after treatment were 0.62 ± 0.47 and 0.42 ± 0.51 ng/ml, respectively ($p=0.39$). **Conclusion:** In this study, it has been shown that PRRT and RLT as novel cancer treatment have no significant effect of the early values of serum troponin as a cardiac injury indicator, therefore, these procedures have no significant cardiotoxicity. **References:** None

EP-367

Peptide receptor radionuclide therapy for glioma tumors: An extended report on a pilot study

M. Assadi¹, R. Nemati¹, A. Amini¹, H. Ahmadzadehfar², H. Shooli¹, S. Rekabpour¹, E. Jafari¹;

¹Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, ²Klinikum Westfalen, Knappschaft Hospital, Dortmund, GERMANY.

Aim/Introduction: The prognosis for high-grade glioma is

impoverished yet despite application of optimal available treatment (surgery, radiation, and chemotherapy). We aim to report our ongoing pilot study in which we assess the therapeutic effectiveness of intravenous (iv) ^{177}Lu -DOTATATE in glioma tumors. **Materials and Methods:** Between January 2017 and April 2020, eighteen patients with glioma tumors were included. Inclusion criteria are defined as tissue-based confirmation of glioma tumors, blood brain barrier (BBB) interruption, and sufficient expression of somatostatin receptors (SSTRs) by the tumor tissue. In all patients, ^{99m}Tc -octreotide SPECT or ^{68}Ga -DOTATATE PET-CT scan was acquired as a screening evaluation for confirming high level of SSTR expression. Our interdisciplinary group, consist of oncologist, neurologist, neurosurgeon, nuclear medicine specialist, and cardiologist, visited each patient and discussed him/her individually. Accordingly, if no other alternative therapeutic option was available (failed state-of-the-art treatment, inoperable tumors, or patient refusal to available treatment), every patient was individually treated on a compassionate basis. We planned to treat all cases with 1 to 4 cycles of iv ^{177}Lu -DOTATATE (50-200 mCi for each cycle). After each cycle, ^{177}Lu -DOTATATE brain and whole-body scan (24-hr, 48-hr, and if needed 72-hr after treatment) were obtained to evaluate drug delivery and SSTR-binding capacity. Tumor response was assessed using response assessment in neuro-oncology (RANO) criteria. Eastern Cooperative Oncology Group (ECOG) (score: 0-5) and Karnofsky Performance Score (KPS) (score: 0-100) were used to assess Patients' quality of life (QOL) before and after treatment. **Results:** Sixteen adults (m/f=9/7) and two children (2 girls) with a mean age of 54.75 and 6.5 years, respectively, were included in our study. The mean ECOG and KPS score (pre-/post-treatment) were respectively (2.3/2.1) and (57.5/60.6) for adults and (2/2) and (65/65) for children. Of note, the pattern of radionuclide uptake on post-therapy imaging (^{177}Lu -DOTATATE scans) was spatially corresponded to enhancing-areas on MRI. ^{177}Lu -DOTATATE effectively bound to SSTR receptor-positive regions and it was also able to identify new brain masses. The participants' response to the treatment were observed as complete remission (n=1), partial remission (n=6), stable disease (n=3), progressive disease (n=8). Nonetheless of the promising radiologic response, QOL was not significantly improved ($p<0.05$). These clinical and radiological inconsistency can be attributed to the well-established injury to the critical structures in the brain. **Conclusion:** PRRT approach using ^{177}Lu -DOTATATE seems promising option in treating brain tumors and warrant further well-designed trials to solidify current evidence. **References:** None

EP-368**Initial practice with Gallium-68 DOTATATE PET/CT and peptide receptor radionuclide therapy for pediatric patients with relapsed or refractory metastatic neuroblastoma: A promising point-of-care after failure 131I- MIBG therapy**

M. Assadi¹, G. Fathpour¹, E. Jafari¹, H. Dadgar²;

¹Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, ²Cancer Research Center, Razavi Hospital, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: There are limited therapeutic methods for pediatric patients with refractory neuroblastoma. Since somatostatin receptors (SSTRs) expression had been shown in neuroblastoma lesions, we aimed to evaluate STTR expression in these patients for imaging and therapeutic purpose with 68Ga-DOTATATE PET/CT and peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE, respectively. **Materials and Methods:** 13 pediatric patients with refractory neuroblastoma were enrolled in this study with mean age of 5.18±.188 from 2-8 years old including 6 (46.2%) males and 7 (53.8%) females. Among them 4 patients were underwent PRRT. Treatment response, survival and therapy related toxicity were assessed in these patients. **Results:** Of 13 patients underwent 68Ga-DOTATATE PET/CT, 9 (69.2%) patients were referred for restaging and 4 (30.8%) were referred for staging. 68Ga-DOTATATE was positive in 9 (69.2%) of patients and median number of detected lesions was 2 (1-13) in patients with positive 68Ga-DOTATATE. Of 4 patients who were refractory or relapsed after 131I-MIBG therapy and showed significant 68Ga-DOTATATE uptake underwent PRRT, 1 showed partial response following 7 PRRT cycles (24.8 GBq) and has 19 months overall survival. One of the patients with complete response following 4 cycles PRRT (13.69 Gbq) has no sign of disease and overall survival of 16 months. Another patient with complete response following 4 PRRT cycles (19.95 GBq) has overall survival of 18 months. One patient showed progressive disease following 2 PRRT cycles (7.4 GBq) and died 2 months after PRRT begins. No significant PRRT associated toxicity was observed. **Conclusion:** 68Ga-DOTATATE was positive in a high proportion of neuroblastoma patients, therefore, it can be used as imaging modality for management of primary or relapsed neuroblastoma patients and identifying suitable candidates for PRRT with 177Lu-DOTATATE. In addition, safety and feasibility of PRRT for refractory neuroblastoma pediatric patients were proved. **References:** None

EP-369**Technical and procedural aspects of high dose-personalized brachytherapy using a not sealed ¹⁸⁸Rhenium-resin in patients with non-melanoma skin cancer**

A. Farina¹, F. Savoia², G. Lima¹, A. Patrizi³, F. Zagni⁴, S. Vichi⁴, G.

Argalia¹, E. Dika³, L. Strigari⁴, A. Morganti⁵, S. Fanti¹, P. Castellucci¹;
¹Nuclear Medicine Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, ²Dermatology Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, ³Dermatology Medicine Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, ⁴Medical Physics Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, ⁵Radiation Oncology Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY.

Aim/Introduction: High dose-personalized brachytherapy with a non-sealed ¹⁸⁸Rhenium-resin (OncoBeta®GmbH for Rhenium-SCT®) is a new option for the treatment of non-melanoma skin cancer (NMSC) especially in patients where surgical approach would be sub-optimal as concerns the features of the lesion or the aesthetic outcome after surgery. The aim of this study is to describe the technical and procedural aspects and the times required for the treatment of NMSC with ¹⁸⁸Rhenium-resin. **Materials and Methods:** From September 2017 to February 2020, we performed 57 treatments in 48 patients (15F, 33M, age 56-97, mean 81) showing 57 histologically proven NMSC (40BCC; 14SCC; 2Spino-CC; 1BCC&SCC). Lesions were located on face, ears, nose or scalp (45/57), extremities (8/57), trunk (4/57). Mean surface areas 6,4cm² (range 1-36cm²); mean thickness invasion 1,1mm (range 0.2-2.5mm). The procedure consists in three consecutive steps: Preparation, Treatment, Discharge. **Results:** Preparation: 1) lesion curettage; delineation of tumor margins and application of plastic foil over the lesion avoiding any direct contact of the resin with the skin; 2) loading of ¹⁸⁸Re-cartridge in the applicator. This phase takes approximately 15-20 minutes and it is the most critical since the application of the protective foil in non-planar surfaces may result difficult to perform. Treatment: 1) measure the initial ¹⁸⁸Re-activity; 2) apply the ¹⁸⁸Re-resin over the foil following the lesions margins; 3) measure the remaining ¹⁸⁸Re-activity in the applicator; 4) calculate the treatment time using the simulation software (WARSKIN5.2). This phase usually does not present significant problems and it takes usually less than 10 minutes, however the effective treatment time vary a lot depending on lesion size, lesion thickness and the required effective dose delivered to the lesion. In our population the mean dose delivered to the lesions was 62Gy (range 18-126Gy), the mean treatment time was 78 minutes (range 21-285 minutes). In this phase, we have never observed any discomfort or pain during or soon after the treatment. Discharge: 1) removing the foil from the lesion 2) performing contamination control 3) clean the lesion and 4) provide the information to the patient for home care and follow up checkpoint. This phase takes about 10 minutes. We have never observed any contamination after removing the protective foil. In conclusion, the whole procedure takes approximately 35-40 minutes to be added to effective treatment time. **Conclusion:** In our experience

high dose brachytherapy with a not-sealed ¹⁸⁸Rhenium-resin in NMSC is easy to perform, quick and patient friendly. It may offers many advantages over surgery, in particular no pain and simple patient care during and after treatment. **References:** None

EP-370

Initial experience with ¹⁷⁷Lu-PSMA therapy for patients with advanced liver cancer

M. Assadi¹, S. Rekabpour¹, E. Jafari¹, N. Shakibazad¹, H.

Ahmadzadehfar², Z. Alipour¹, A. Amini¹;

¹Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, ²Klinikum Westfalen, Knappschaft Hospital, Dortmund, GERMANY.

Aim/Introduction: Patients with advanced liver cancer typically have poor survival outcomes. Until recently, few agents especially sorafenib were the systemic therapy options available. The aim of this study was evaluation of clinical efficacy of radioligand therapy (RLT) with ¹⁷⁷Lu-PSMA on liver cancer patients. **Materials and Methods:** We enrolled 3 liver cancer patients showed intensive PSMA uptake on pre-therapy diagnostic scan with ⁶⁸Ga-PSMA PET/CT and/or ^{99m}Tc-PSMA scintigraphy in this study. The patients underwent RLT and for evaluation of response to therapy, follow up conventional imaging had been performed. In addition, for evaluation of therapy associated toxicity, laboratory tests were obtained. The interval time between RLT cycles was 4 weeks. **Results:** In this study 3 males patients included 2 hepatocellular carcinoma (HCC) patients (61 and 56 years old) and one 12 years old child with hepatoblastoma were underwent RLT. HCC cases had local involvement but hepatoblastoma case in addition to local involvements, had multiple pulmonary involvements. Of two HCC patients, one who had portal vein thrombosis (PVT) and cirrhosis received 2 cycles of RLT (8 GBq) and another one took 4 cycles (14 GBq) till now. The hepatoblastoma case underwent 3 cycles of RLT (7 GBq) till now. Stable disease was observed in all patients according to the imaging analysis. The patient with HCC, PVT and cirrhosis showed stable lesions with some evidence in thrombosis resolution. One HCC patient died after 3 months from RLT beginning due to complications of cirrhosis. The two other patients are alive since from starting of RLT in 4 months ago. No significant therapy associated toxicity was observed in all patients. **Conclusion:** The therapy of advanced liver cancer remains challenging and complex. RLT with ¹⁷⁷Lu-PSMA might take in consideration in therapy of liver cancer patients with progression despite multimodality treatment. These data support ongoing clinical trials in such challenging patients. **References:** None

EP-371

Molecular Imaging in the selection and evaluation of response in patients treated with Radium-223 in six different solid tumors: A single center experience

S. Medina-Ornelas, F. García-Perez, M. Alvarez-Avitia, N. Sobrevilla-Moreno, D. Garcia-Ortega, F. Barron-Barron, M. Jimenez-Rios, O. Arrieta-Rodriguez;

Instituto Nacional de Cancerologia, Mexico City, MEXICO.

Aim/Introduction: Evaluate impact after ²²³Ra therapy and ¹⁸F-NaF (sodium fluoride) PET/CT in the selection and evaluation of response in patients treated with ²²³Ra in six different solid tumors. **Materials and Methods:** Twenty patients with metastatic castration-resistant prostate cancer (mCRPC), seven metastatic castration-sensitive prostate cancer (mCSPC), three osteosarcoma, two breast cancer, two non-small cell lung cancer (NSCLC), one chondrosarcoma, one chordoma and one patient lung neuroendocrine carcinoma. Three groups of study were defined according total skeletal tumor-burden obtained by ¹⁸F-NaF PET/CT, group 1 <1000cm³, group 2 1001-2999cm³ and group 3 >3000cm³ VOI's. A semi-quantitative comparison was performed measuring the SUVmax values of VOIs values in all bone metastases in each patient previous to receive the first cycle of ²²³Ra, after 3 and 6 cycles. **Results:** 30 patients non-progress disease was documented after 24±4 weeks. 8 patients progress disease was presented after three cycles of ²²³Ra, two patients with osteosarcoma, four patients with mCRPC, one patient with chondrosarcoma and one patient with NSCLC. Group 1 patients showed better response rates compared to group 3 (p<0.05). Group 2 patients who showed improvement clinical and radiological, had prostate malignancies compared to those in the same group, but non-prostatic malignancies (p<0.05). No significant difference in group 2 patients compared to group 3 (p<0.67). Symptomatic skeletal-related event was observed in 7 patients. **Conclusion:** ¹⁸F-NaF PET/CT allows to identify patients who show osteoblastic bone activity and discard or confirm progression in the interval PET/CT image, allowing change of treatment, reducing costs. High tumor-burden strongly suggests a poor response to treatment. **References:** None

EP-372

Complex treatment of bone metastases of tumors of different origin

O. Solodyannikova¹, Solodyannikova OI, Danilenko VV, Stolyarova OY, V. Danilenko²;

¹Institute of Oncology AMS of Ukraine, Kiev, UKRAINE,

²National Institute of Cancer, Kiev, UKRAINE.

Aim/Introduction: Radionuclide therapy is quite widely used in developed countries in the treatment of multiple bone metastases, as "last-line" therapy. The aim is to perform

a comparative analysis of radionuclide, radiation and accompanying treatment of bone metastases of malignant tumors **Materials and Methods:** Radionuclide therapy was performed in accordance with standardized treatment protocols by radiopharmaceutical (European Nuclear Medicine Guide, 2018). Among the treated patients, 58 were with breast cancer, 30 - prostate cancer, 6 - lung cancer, 4 - kidney cancer, 1 - cervical cancer and 1 - rectal sigmoid angle of the colon. Of these, 64 are women and 36 are men. The age of those treated is 32 to 78 years. Mean age (55.0 ± 11.6) years. In 94 patients (90%) the presence of bone metastases was determined by osteoscintigraphy with ^{99m}Tc -MDP. In 6 patients, the diagnosis of bone lesion was verified by other methods of radiodiagnosis. Radiation therapy was performed for 30 patients, 20 of them with prostate cancer and 10 with breast cancer. During treatment, patients received a total dose of 30 Gy, 3 Gy for 10 fractions. All patients were treated with bisphosphonate as an accompaniment therapy. **Results:** It was found that the intensity of pain before and after treatment with different radiopharmaceutical varied as follows: ^{32}P - before treatment 7.1 ± 1.5 , after treatment $- 5.0 \pm 3.1$ * ($p < 0.05$); ^{89}Sr - before treatment 8.0 ± 2.2 , after treatment $- 4.8 \pm 1.5$ * ($p < 0.05$); ^{153}Sm - before treatment 8.4 ± 1.3 , after treatment $- 3.5 \pm 1.8$ * ($p < 0.05$). Thus, under the influence of radionuclide therapy, pain levels were reduced to 3-5 points, averaging 47%. The effectiveness of the analgesic influence of radiation therapy averaged $52.2\% \pm 4.1\%$, i.e., before treatment on the LACOMED scale the level of pain syndrome fluctuated within 7.2 ± 3.6 points, and after treatment 3.7 ± 4.4 , respectively ($p < 0.05$). **Conclusion:** 1. Complex treatment of metastatic damage of the bone system in malignant tumors of different localization is as effective as possible when using both radionuclide therapy and remote radiation. 2. The most effective compared to ^{32}P and ^{89}Sr in the treatment of bone metastases for analgesic influence and tolerability is ^{153}Sm oxabiphor ($p < 0.05$). 3. The effectiveness of the analgesic action of radiation therapy is significantly higher in the treatment of single but larger metastatic bone lesions, it achieves high reliability. **References:** None

Prognostic implications of dual tracer PET/CT: additional FDg PET/CT in patients undergoing [^{177}Lu]PSMA radioligand therapy

K. Michalski¹, J. Ruf¹, P. Meyer¹, A. Buck², C. Lapa³, P. Hartrampf²;

¹University hospital Freiburg, Freiburg, GERMANY,

²University hospital Würzburg, Würzburg, GERMANY,

³University hospital Augsburg, Augsburg, GERMANY.

Aim/Introduction: A recent study has shown poor survival of patients with metastatic castration-resistant prostate cancer (mCRPC) scheduled for [^{177}Lu]PSMA radioligand therapy (RLT) who presented with lesions positive on FDG PET/CT but without relevant concordant uptake on PSMA PET/CT [1]. These patients were subsequently not treated with RLT, and the overall survival (OS) in this group was 3.9 months [1]. In contrast, patients without any discordant FDG-positive lesions underwent RLT with a distinct higher OS of 12.0 months [2]. The aim of the following analysis was to investigate the prognostic value of the combination of PSMA PET/CT with FDG PET/CT for outcome prediction in patients undergoing RLT. **Materials and Methods:** This bicentric, preliminary analysis included 54 patients with mCRPC who underwent both FDG and PSMA PET/CT prior to RLT. In all patients, the pattern of PSMA-ligand and FDG uptake was visually assessed. Patients with lesions positive on FDG PET but without relevant concordant uptake on PSMA PET were compared to patients without any discordant FDG-positive lesions. A log-rank analysis was used to assess the difference in OS between groups. **Results:** A significant lower OS was found for patients with lesions positive on FDG PET but without relevant concordant uptake on PSMA PET ($n=17$) with a median OS of 6.0 ± 0.8 months (95% CI 4.4 - 7.6) vs. the patients without any discordant FDG-avid disease ($n=37$) with a median OS of 13.0 ± 0.9 months (95% CI 11.3 - 14.7; $p = 0.000$). **Conclusion:** This preliminary analysis demonstrates a significantly poorer response to treatment with RLT in patients with mCRPC and discordant FDG-positive lesions. In how far this patient population still (partially) benefits from RLT remains to be elucidated. **References:** [1] Thang, SP et al. ¹Nuclear Medicine, University Hospital Frankfurt,

Frankfurt, GERMANY, ²Urology, University Hospital

Frankfurt, Frankfurt, GERMANY, ³Radiation Oncology,

University Hospital Frankfurt, Frankfurt, GERMANY.

Aim/Introduction: Repeated cycles of radioligand therapy (RLT)

may be associated with an increased risk of myelosuppression. This study aims to investigate the incidence, severity and reversibility of hematotoxicity in a large patient cohort with progressive metastatic prostate cancer undergoing RLT with ^{177}Lu -PSMA-617. The impact of pre-existing risk factors and the cumulative administered activity were of particular interest. **Materials and Methods:** RLT was performed in 156 patients. Previous treatments included second-generation antiandrogens (enzalutamide, abiraterone) in 116, at least one line of chemotherapy in 79, and ^{223}Ra -dichloride in 66 patients. A mean activity of 6.7 ± 1.3 GBq ^{177}Lu -PSMA-617 per cycle was administered in a median of 4 treatment cycles (IQR 2 to 5) at intervals of 6 to 8 weeks. Median cumulative activity was 19.3 GBq (IQR 11.5 to 35.6). Hematological parameters were measured at baseline, prior to each treatment course, 2 to 4 weeks thereafter and throughout follow-up. Toxicity was classified using Common Terminology Criteria for Adverse Events v5.0. **Results:** Significant treatment-induced hematotoxicity (grade 3 or 4) occurred in 18 patients (12%), with anemia in 9%, leukopenia in 4% and thrombocytopenia in 5%. Bone marrow impairment was reversible throughout a median follow-up of 8 months (IQR 9 months) in all but two patients who died from disease progression within less than 3 months after RLT. Severe myelosuppression was significantly more frequent in patients with pre-existing grade 2 cytopenias ($p=0.04$) or high bone tumor burden (disseminated pattern based on PROMISE mITNM criteria, $p<0.001$). A history of chemotherapy, treatment with ^{223}Ra -dichloride and cumulative RLT treatment activity were not associated with an increased incidence or higher degree of hematotoxicity ($p=0.20, 0.15, 0.11$). **Conclusion:** Hematotoxicity after RLT is frequently reversible and has an acceptable overall incidence. High bone tumor burden and pre-existing moderate cytopenia (grade 2) were identified as risk factors for developing relevant hematotoxicity (grade 3 to 4). Previous chemotherapy, ^{223}Ra -dichloride treatment or cumulative RLT activity have no impact on the incidence of significant hematotoxicity. **References:** None

EP-375

Whole-Body Dosimetry in Therapy of Metastatic Prostate Cancer with ^{177}Lu -PSMA-617

C. Happel, L. Völler, W. T. Kranert, D. Gröner, B. Bockisch, N. Mader, F. Grünwald, A. Sabet;

University Medical Center Frankfurt, Department of Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: Molecular radiotherapy with ^{177}Lu -labelled prostate specific membrane antigen (PSMA) is being increasingly implemented as therapeutic option for patients with metastatic prostate cancer. However, accumulation in metastases as well as physiologic uptake in several organs necessitate dosimetric considerations. Aim of this study was therefore to calculate the mean whole body dose of

patients undergoing ^{177}Lu -PSMA-617 treatment. **Materials and Methods:** In this study the course of 672 ^{177}Lu -PSMA-617 therapy cycles in 198 consecutive patients was analyzed retrospectively. The median age of the patient cohort was 72.9 years (41 - 89.6 years) at administration of ^{177}Lu -PSMA-617. Median administered activity per cycle was 6.96 GBq (1.08 - 11.2 GBq) depending on tumor burden, physiological condition, blood parameters and kidney function. Whole body dosimetry was performed by measuring the geometric mean of the remaining activity in the whole body at three timepoints per day over the complete in-patient stay of 72h with an individually calibrated collimated gamma probe with attached multi-channel analyzer (2"x2" NaI(Tl)-detector scintiSPECT; SCINTRONIX). The individual calibration resulted from an initial measurement of the remaining activity directly after administration of the ^{177}Lu -PSMA-617 prior to micturition. Mean whole-body doses were calculated with Microsoft Excel 2010 using a bi-exponential fit to the measurements as time activity curve. **Results:** The effective doses to the whole-body ranged from 27.7 to 1,794 mGy per cycle (median: 226 mGy). Related to the administered ^{177}Lu -PSMA-617 activity the whole body dose ranged from 9.62 to 251 mGy/GBq (median: 33.1 mGy/GBq). The primary exponential rapid declining phase of ^{177}Lu in the whole-body which is mainly caused by renal elimination, varied from 1.43 to 97.8 h (median: 7.32 h). In contrast, the effective half-life during the secondary exponential slow phase which is mainly influenced by metastatic burden and physiological accumulation ranged from 4.75 - 160h (median: 51.5 h). **Conclusion:** The course of ^{177}Lu -PSMA-617 in the whole body can be subdivided into a first rapid phase which is mainly influenced by renal elimination and a second slow phase mainly influenced by metastatic tumor burden. Individual doses vary for a huge range and may reflect tumor accumulation and changes of it during fractionated treatment of one patient. The calculated median whole-body dose of 226 mGy is comparable to the whole body doses known from radioiodine-131 therapy. Due to multiple influences to the time course it gives only limited information to organ doses and tolerability to further applications. **References:** None

EP-376

Brazilian Profile of Ra-223 Therapy - a Multicenter Study

E. Etchebehere¹, F. P. P. Lopes², S. A. L. Matedi², R. Fockink³, D. A. Anjos³, G. V. Gomes⁴, L. R. Silva⁴, A. O. Santos⁵, T. Minekawa¹, V. M. Araújo⁶, A. B. M. J. Teixeira⁶, R. Martins⁷, G. E. Bier⁷, A. Sanches⁸, N. Hanaoka⁹, R. M. Tavares², F. Mourato¹⁰, M. C. L. Lima¹, P. Almeida¹⁰, A. E. T. Brito¹⁰;

¹The University of Campinas, Campinas, BRAZIL, ²Clinica de Medicina Nuclear Villela Pedras, Rio de Janeiro, BRAZIL, ³Hospital Santa Paula, São Paulo, BRAZIL, ⁴Núcleos, Brasília, BRAZIL, ⁵Medicina Nuclear de Campinas, Campinas, BRAZIL, ⁶Centro de Diagnósticos por Imagem de Goiânia, Goiás, BRAZIL, ⁷Centro

de Tomografia e Medicina Nuclear (CETAC), Curitiba, BRAZIL, ⁸Santa Casa de Misericórdia da Bahia, Salvador, BRAZIL, ⁹Dimen, Campinas, BRAZIL, ¹⁰Real Hospital Português, Recife, BRAZIL.

Aim/Introduction: Although Ra-223 therapy has been available since 2013 for metastatic castrate-resistant prostate cancer (mCRPC), only in 2017 was Ra-223 approved by the National Health Surveillance Agency in Brazil. Purpose: To perform a multicenter analysis of the profile of mCRPC submitted to Ra-223 in the Brazilian Nuclear Medicine institutions and to describe their clinical outcomes. **Materials and Methods:** A retrospective analytical study of mCRPC patients who underwent Ra-223 treatment was undertaken. All clinical and laboratory data (age, previous treatments, previous imaging and laboratory tests, pain scale and performance status, number of Ra-223 cycles, reasons for discontinuation, possible adverse effects) as well as follow-up data (time to death, progression or bone event) was evaluated. **Results:** A total of 303 submitted to 1,402 Ra-223 cycles between August/2017 and March/2020 from 9 centers were studied. The mean age of the patients was 74 years (43 - 100 years). 229 patients underwent previous treatments (mean 3.4 months) prior to Ra-223 as follows: chemotherapy (44%), radiation therapy (42%), hormone therapy (70%). Ra-223 was used as first line treatment in 3%, 25% as second line, 35% as third line and 37% fourth or more. The mean number of Ra-223 cycles was 4.6, 51% of patients completed all six cycles and 15% interrupted Ra-223 due progression. Association of Ra-223 with other treatments occurred in 34% of patients, 62% due to secondary hormone therapy. Major hematologic toxicity causing interruption of Ra-223 occurred in 6%. After the 1st Ra-223 cycle 33.6% patients progressed (median 3.4 months) and 13.5% had bone events. The most common bone event was intractable bone pain (20.3%). The median overall survival was 8 months. **Conclusion:** The survival benefit of Ra-223 was not satisfactory most likely because >70% of the patients were submitted to Ra-223 as third or more-line therapy. This data is an important and clear demonstration of the necessity to educate the referring physician as to the proper timing for Ra-223 in order to have maximum benefit. **References:** None

EP-377

Bone scintigraphy to evaluate response to therapy with Radium-223 for castration-resistant prostate cancer patients with bone metastases: a single-center experience

E. Martínez Albero, A. Gómez Grande, A. Saviatto Nardi, Á. Galiana Morón, D. Vega Pérez, V. Godigna Guilloteau, J. Pilkington Woll, S. Ruiz Solís, P. Sarandeses Fernández, M. Tabuenca Mateo, J. Estenoz Alfaro;
Hospital Universitario 12 de octubre, Madrid, SPAIN.

Aim/Introduction: We aimed to assess treatment-related changes on conventional bone scans (BS) in metastatic

castration-resistant prostate cancer (mCRPC) patients treated with Radium-223 (²²³Ra). **Materials and Methods:** We included 62p (median age 77y; range: 56-93 years) with mCRPC and bone metastases treated with ²²³Ra from March 2013 to December 2019. Radium-223 therapy was given intravenously every 4 weeks, at a dose of 50 kBq/kg body weight for up to six cycles. Fifty-six patients had undergone conventional bone scintigraphy (^{99m}Tc-HDP) before the start of treatment and 4 weeks from last cycle. Pre and post-treatment bone scans were evaluated visually. Patients were classified according to extent of bone disease (EOD) in four groups: EOD1 (<6 metastatic lesions), EOD2 (6-20), EOD3 (>20) and EOD4 (superscan). Changes with each scan pair were assessed as one of three response patterns: Partial Response (PR), defined as decrease and/or disappearance of HDP uptake in metastatic foci; Stable Disease (SD) and Progression Disease (PD), if at least two new foci of HDP uptake are seen. We also evaluated the correlation between the response pattern observed in the bone scan and the number of cycles administered, Gleason score, the levels of prostatic-specific antigen [PSA] and alkaline phosphatase [ALP]. Changes in PSA and ALP, were defined as an increase or a decrease of ≥ 30% from baseline. **Results:** Thirty-six patients (64,3%) had high risk prostate cancer (Gleason score >7; range 8-10). Most of them, 35/56p (62,5%) were treated with ²²³Ra post-docetaxel. The mean of bone lesions observed in baseline bone scintigraphy was 15,5 (range 1-68): 22p (EOD1), 13p (EOD2), 15p (EOD3) and 6p (EOD4). Among the patients who received 6 and 5 cycles, 71% showed PR or SD in bone images. Significant differences between Gleason score and response (PR+SD) were not found: Gleason 7 (10p), Gleason 8 (10p), Gleason 9 (11p). Increase in PSA level was similar in patients who presented PR+SD (71%) and those who presented PD (76%), while ALP levels decrease in 55% of patients included in the PD/SD groups. No correlation was observed between the extent of metastatic bone disease and the response patterns shown on BS. **Conclusion:** BS is useful to evaluate the response of metastatic bone disease in the follow-up of patients with mCRPC treated with ²²³Ra. No progression of bone disease was observed in most of the patients during treatment. PSA levels showed no correlation with the response pattern on BS. **References:** None

EP-378

Initial experience with somatostatin receptor (SSTR) imaging and peptide receptor radionuclide therapy for patients with neuroendocrine differentiation (NED) of prostate cancer

M. Assadi¹, S. Rekabpour¹, H. Ahmadzadehfar², E. Jafari¹, A. Amini¹;
¹Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, ²Klinikum Westfalen, Knappschaft Hospital, Dortmund, GERMANY.

Aim/Introduction: Nowadays, neuroendocrine differentiation

(NED) of prostate cancer has increasing attention due to its limited and challenge for treatment modalities. The aims of this study were, first, evaluation of somatostatin receptor (SSTR) expression in castrate resistant prostate cancer (CRPC) patients who is refractory or progressive to radioligand therapy (RLT) with ^{177}Lu -PSMA. As second aim, we evaluated the clinical efficacy of peptide receptor radionuclide therapy with ^{177}Lu -DOTATATE for CRPC patients with NED. **Materials and Methods:** In this study, the patients who are refractory to multiple cycles of RLT were asked to perform ^{68}Ga -DOTATATE PET/CT or $^{99\text{mTc}}$ -octreotide for evaluation of SSTR expression and NED. The patients who showed positive SSTR, underwent PRRT. For evaluation of treatment response, in addition to post therapy imaging, chromogranin A (Cg-A) had been measured before and 2 months after PRRT. For evaluation likely toxicity, periodically laboratory tests were taken after therapy. **Results:** In this study, we evaluated 5 CRPC patients with mean age of 67.6 ± 10.73 ranged from 55–80 years old. For evaluation of SSTR expression, 4 patients underwent $^{99\text{mTc}}$ -octreotide and one of them underwent ^{68}Ga -PET/CT. One of them, despite had widespread metastases on $^{99\text{mTc}}$ -MDP bone scan showed no abnormal uptake on $^{99\text{mTc}}$ -PSMA scintigraphy suspected for NED but interestingly octreotide scan was normal as well. 4 other patients, showed progressive or stable response to several cycles of ^{177}Lu -PSMA, therefore they underwent evaluation of SSTR expression. 2 of them showed negative SSTR expression and 2 showed significant uptake of radiotracer. Pre-PRRT Cg-A in both patients was several times more than normal value. Therefore, these two patients underwent 2 cycles of PRRT with ^{177}Lu -DOTATATE (3.7 GBq per cycles with time interval of 6–8 weeks). Interestingly, in addition to reduction in number and size of metastases and improvement in quality of life in both patients, the value of Cg-A significantly decreased after 2 cycles of PRRT (in one patient, the Cg-A reached to normal value). There was no significant toxicity observed after PRRT. **Conclusion:** Our results suggested that in CRPC patients showed refractory or progressive disease following several cycles of RLT, the SSTR expression has been checked for NED. In CRPC patients with positive SSTR expression, PRRT can be considered as a valuable therapeutic option. **References:** None

Fractionated ^{177}Lu -PSMA-617 therapy with 101 GBq in a patient with metastatic prostate cancer

C. Happel, J. Wichert, W. T. Kranert, L. Völler, B. Bockisch, D. Gröner, F. Grünwald, A. Sabet;

University Medical Center Frankfurt, Department of Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: ^{177}Lu -labelled prostate-specific membrane antigen (^{177}Lu -PSMA-617) has evolved as promising therapeutic target for patients with castration resistant

prostate cancer (CRPC). The German consensus-protocol is based on therapeutic cycles with standard activities of 6 GBq up to a recommended cumulated maximum activity of 18 GBq and a kidney dose of 23 Gy. **Materials and Methods:** A 73-years-old patient with CRPC and osseous metastases (Gleason 8) was treated over a period of 2.6 years with all in all 14 cycles of ^{177}Lu -PSMA-617. Previous therapy included ADT, local radiation, chemotherapy and $^{223}\text{RaCl}_2$. During each in-patient-stay dosimetric monitoring was performed including measurements with an individually calibrated gamma-probe (SCINTRONIX), whole-body scintigraphy and SPECT (Mediso AnyScan). Therapeutic monitoring was ensured by frequent ^{68}Ga -PSMA-11-PET/CT and functional scintigraphy of the kidneys. Mean whole-body dose (MWBD) was calculated from integrating the bi-exponential activity course. Kidney dosimetry was performed using a combination of planar scintigraphy, SPECT and gamma-probe. **Results:** Mean administered activity was 7.5 GBq per cycle (5.6–9.2 GBq) taking into account the tumor burden, PSA and kidney function. In total, 101 GBq ^{177}Lu -PSMA-617 were administered. Treatment was continued after exceeding the cut-off of 18 GBq even after the 8th and 12th therapy due to scintigraphic detection of tumor tissue and biochemical response in accordance with the recommendation of an interdisciplinary tumor-board to avoid further metastatic progression and disease specific complications. The cumulative MWBD was 5.1 Gy. Median MWBD was 354 mGy per treatment cycle (48 mGy/GBq) decreasing dependent on the time after initial treatment. Mean calculated kidney dose was 1.4 Gy per treatment corresponding to a median activity-related dose of 0.19 Gy/GBq. The cumulative kidney dose was 19 Gy. Therefore, the cut-off value for the kidneys was not exceeded. Blood parameters (leucocytes and thrombocytes) did not change significantly over the treatment. Hemoglobin stayed stable up to the 12th cycle and showed a slight drop afterwards. Kidney function parameters (GFR, creatinine) stayed stable throughout the therapy. After the 14th cycle, the patient showed an overall improvement of symptoms compared to the 1st cycle with good general condition. PSA continuously decreased during ^{177}Lu -PSMA-617-therapy from 50 to less than 1 ng/ml. **Conclusion:** A cumulative activity beyond 100 GBq ^{177}Lu -PSMA-617 during a treatment course of 2.6 years was well tolerated without relevant complications. Depending on kidney and MWBD, considering the good therapeutic response and state of health, an escalation of the cumulative activity to up to 100 GBq seems to be feasible and effective in selected cases. **References:** None

Gallium-68 DOTATATE PET/CT and peptide receptor radionuclide therapy for patients with refractory/recurrence metastatic medullary carcinoma of thyroid

M. Assadi¹, H. Dadgar², S. Rekabpour¹, E. Jafari¹, H.

Ahmadzadehfar³, A. Amini¹;

¹Bushehr University of Medical Sciences (BUMS), Bushehr, IRAN, ISLAMIC REPUBLIC OF, ²Razavi Cancer Research Center, Razavi Hospital, Mashhad, IRAN, ISLAMIC REPUBLIC OF, ³Klinikum Westfalen, Knappschaft Hospital, Dortmund, GERMANY.

Aim/Introduction: Medullary thyroid carcinoma (MTC) is a kind of thyroid malignancies originated from the parafollicular cells (C cells) which are responsible for the hormone calcitonin production. Accurate detection of MTC has great impact on management of MTC patients. Since it has been proved that MTC tumors express somatostatin receptors (SSTR), the aim of this study was the clinical efficacy of 68Ga-DOTATATE PET/CT on detection of MTC. As a secondary aim we evaluated the treatment efficacy of 177Lu-DOTATATE for MTC patients. **Materials and Methods:** We retrospectively evaluated 15 MTC patients referred for evaluation of staging, workup for metastasis, recurrence disease and response evaluation. 68Ga-DOTATATE PET/CT was performed following injection of 70-180 MBq radiotracer. Images were interpreted with two blind nuclear medicine specialists. Patients who showed intensive 68Ga-DOTATATE uptake according to our clinical team consideration underwent peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE. **Results:** We evaluated 15 MTC patients with mean age of 52.2±13.44 (27-71) years old included 8 (53.3%) males and 7 (46.7%) females. Of 15 patients, 5, 7, 2, 1 were referred for evaluation of staging, recurrence, workup of metastasis and response evaluation, respectively. Thyroidectomy was performed for 12 (80%) of patients. 68Ga-DOTATATE was positive on 13 (86.7%) of patients. Of 13 positive scans, 3, 5, 5 scans showed locoregional, distant and locoregional/distant involvement, respectively. The total number of detected lesions in patients with positive scan were 46 in all patients with median of 2 (range: 1-16). Of these patients, 5 patients underwent PRRT included 3 females and 2 males with mean age of 50.2±13.36 (34-70) years old. Patients totally underwent 13 cycles of PRRT with median of 2 cycles (1-4) and median of injected dose of radiotracer was 14 GBq (6-29 GBq). All patients showed partial response with improvement in quality of life. Overall survival was 12.2±7.79 months (4-21). Of 5 patients, only one of them died duo to GI bleeding after 11 months from the beginning of PRRT. **Conclusion:** Our results reveal that

SSTR agents are clinically suitable for management of MTC patients as a diagnostic procedure using 68Ga-DOTATATE PET/CT or therapeutic option as PRRT with 177Lu-DOTATATE.

¹³¹I-SPECT/CT after radioiodine therapy in patients with differentiated thyroid carcinoma (DTC)

S. Nuvoli, A. Marongiu, I. Gelo, L. Mele, M. Rondini, M. L. Stazza, G.

Madeddu, A. Spanu;

University of Sassari, Sassari, ITALY.

Aim/Introduction: We further investigated ¹³¹I-SPECT/CT usefulness after radioiodine therapy in DTC patients to achieve the best strategy in the affected patient management during follow-up. **Materials and Methods:** We retrospectively enrolled 89 DTC patients, 81 with papillary carcinoma, 3 with follicular and 5 with Hürthle cell carcinomas. In 36 patients, papillary carcinoma was multifocal; in 17 cases extra-thyroid tumor extension was present and in 10 neck cervical lymph node (LN) metastases were ascertained. Moreover, 16 patients were at high risk (H), 55 at low risk (L) and 18 at very low risk (VL). All patients underwent ¹³¹I-whole body scan (WBS) followed by SPECT/CT 5-7 days after 1.85-5.66 GBq radioiodine therapeutic dose using a hybrid dual head gamma camera with high energy, parallel hole collimators. **Results:** SPECT/CT detected 206 radioiodine-avid foci in the 89 patients, while WBS identified 194 foci, all positive at SPECT/CT. Both procedures concordantly classified 153 foci (139 residues, 8 lung metastases, 5 soft tissue metastases, 1 cutaneous contamination). SPECT/CT also characterized 39 foci unclear at WBS (24 residues, 8 neck LN metastases and 5 LN outside neck, 1 bone metastasis and 1 physiologic uptake). Moreover, SPECT/CT identified 12 foci occult at WBS (9 residues, 2 neck LN metastases and 1 LN metastasis outside neck). SPECT/CT also changed WBS classification of 2 foci in neck LN metastasis and muscle metastasis in the thorax, wrongly classified as residue and lung metastasis, respectively. Globally, SPECT/CT correctly classified 32 malignant foci in 12/89 patients (6H, 4L, 2VL). WBS evidenced 29/32 foci; however, it classified as unclear 14/29 foci, wrongly classified 2 foci and missed 3 further foci. At surgery, 6 of the 12 metastatic patients had carcinomas with extra-thyroid extension and 5/6 also with loco-regional LN metastases and one with multifocal disease, too; of the remaining 6/12 patients, 2 had multifocal papillary carcinoma and 4 unifocal intracapsular carcinomas. Thyroglobulin was >10 ng/dl in 8/12 patients, between 2.5 to 5 ng/dl in 1 patient, < 2.5 ng/dl

in 1 patient and undetectable in the remaining 2 patients (1L, 1VL). SPECT/CT had an incremental value over WBS in 23.6% of patients and changed the classification and therapeutic management in 12.3 % of cases. **Conclusion:** ^{131}I -SPECT/CT with therapeutic dose improved loco-regional and distant metastasis identification and characterization than WBS with more correct disease staging and more appropriate patient management in DTC follow-up. Thus, SPECT/CT complementary use of WBS is routinely suggested after radioiodine therapy. **References:** None

EP-382

FDG PET/CT versus Somatostatin Receptor PET/CT in TENIS Syndrome: a systematic review and meta-analysis

E. Etchebehere¹, F. Mourato², A. Maria², A. Brito², A. Leal³, P. Almeida Filho²;

¹The University of Campinas, Campinas, BRAZIL, ²Real Hospital Português de Beneficência em Pernambuco, Recife, BRAZIL, ³Real Hospital Português de Beneficência em Pernambuco, Re, BRAZIL.

Aim/Introduction: In patients with de-differentiated thyroid cancer (or TENIS Syndrome - Thyroglobulin-Elevated Negative Iodine Scintigraphy), radiotracers that are specific for PET/CT imaging may be used to identify metastases, such as FDG PET/CT and somatostatin analogs (SSTR PET/CT). Objective: This study aims to compare capability and current diagnostic performance of identifying metastatic lesions in patients with TENIS syndrome using FDG PET/CT and SSTR PET/CT through a systematic review of the literature and meta-analysis. **Materials and Methods:** A literature search was performed in electronic databases (Medline / Pubmed, Scopus, Web of Science, Scielo, and LILACS) until February 2020 to identify relevant studies on ^{18}F -FDG and ^{68}Ga -somatostatin analogs tracers in patients with TENIS Syndrome. The search terms used were: "Thyroid cancer", "somatostatin analog", "Positron emission tomography" and "FDG". **Results:** A total of 3551 abstracts were obtained from electronic databases and bibliographic references. The initial review of these articles identified 13 candidates for full-text analysis. Of these, six articles were included in qualitative and quantitative analyses and a total of 179 patients that were submitted to both SSTR PET/CT and FDG PET/CT to evaluate performance of these radiotracers were analyzed. FDG PET/CT images identified significantly ($p = 0.006$) more patients with metastases when compared to SSTR PET/CT (143 vs 103, respectively). Even though FDG PET/CT outperformed SSTR PET/CT, in FDG PET/CT- negative cases, SSTR PET/CT was able to detect metastases in approximately 17% of them. **Conclusion:** FDG PET/CT has a higher capability to detect metastases than SSTR PET/CT in patients with TENIS Syndrome. However, when an FDG PET/CT study is negative, SSTR PET/CT can still help by detecting metastases in approximately 1 out of every 5 patients. **References:** None

EP-383

Comparison between [^{11}C]-acetate and [^{18}F]-FDG positron emission tomography (PET) in radioactive-iodine-refractory (RAIR) differentiated thyroid cancer (DTC)

S. Li, E. Kretschmer-Chott, M. Wibbe, E. Rainer, S. Rasul, R. Dudczak, M. Hacker;

Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: The purpose of this study is to evaluate the diagnostic value of [^{11}C]-acetate PET in patients with radioactive-iodine-refractory differentiated thyroid cancer (RAIR-DTC) as compared with [^{18}F]-FDG PET. **Materials and Methods:** The study population comprised 7 patients with RAI-DTC who underwent both [^{18}F]-FDG PET and [^{11}C]-acetate PET. The presence of recurrent cancer was evaluated on a patient-related and lesion-related basis. Histology, elevated thyroglobulin and prior as well as follow-up examinations (such as CT, sonography) served as the standard of reference. **Results:** Recurrent or metastatic tumour lesions were confirmed in all 7 patients. [^{18}F]-FDG PET correctly identified the tumour lesions in 6 of 7 (86 %) patients. In 3 patients tumour lesions were missed by [^{11}C]-acetate PET (57%). In the lesion-related analysis, overall lesion detection rates were 33/44 (68 %) and 15/44 (34 %) for [^{18}F]-FDG PET and [^{11}C]-acetate PET, respectively. [^{18}F]-FDG PET was significantly ($p < 0.05$) superior to [^{11}C]-acetate PET in the overall lesion evaluation. Whereas, no significant difference was found in the detection of pulmonary metastases between [^{18}F]-FDG PET and [^{11}C]-acetate PET. **Conclusion:** This study demonstrated that [^{18}F]-FDG PET has significantly higher lesion-related sensitivity as compared with [^{11}C]-acetate PET in the detection of overall DTC lesions. No significant difference between these two tracers was found in the detection of pulmonary lesions. Therefore, [^{11}C]-acetate cannot replace [^{18}F]-FDG PET for evaluation of patients with RAIR-DTC. **References:** None

EP-384

The diagnostic value of stimulated serum thyroglobulin in the follow-up of low and intermediate-risk patients with differentiated thyroid cancer

I. Mihaljevic^{1,2,3}, V. Wagenhofer^{1,2}, T. Kraljić², D. Vrdoljak¹, T. Kizivat^{1,2}, D. Mudrić^{1,2}, M. Franceschi^{4,2,3}, T. Jukić^{4,2};

¹Clinical Institute of Nuclear Medicine and Radiation Protection, University Hospital Osijek, Osijek, CROATIA, ²Faculty of Medicine Osijek, Josip Juraj Strossmayer University of Osijek, Osijek, CROATIA, ³Academy of Medical Sciences of Croatia, Zagreb, CROATIA, ⁴Department of Oncology and Nuclear Medicine, Sestre milosrdnice University Hospital Centre, Zagreb, CROATIA.

Aim/Introduction: The aim of this study was to evaluate the diagnostic value of stimulated serum thyroglobulin (sTg) in the follow-up of patients with differentiated thyroid cancer (DTC) with respect to new classification criteria for risk groups

(American Thyroid Association, ATA 2015) and to determine whether repeated measurement of sTg had an additional clinical benefit for detecting structural recurrent or persistent disease if the first sTg was negative. **Materials and Methods:** The negative predictive value (NPV) of the first sTg for detecting structural persistent or recurrent disease obtained 12 months after the initial therapy has been compared with NPV of sTg performed during 3 consecutive examinations in the follow-up of patients with DTC. The retrospective study included 388 consecutive patients with DTC treated and followed-up between 2004 and 2018 in the Clinical Institute of Nuclear Medicine and Radiation Protection, Osijek University Hospital. Patients were categorised based on risk group according to the classification criteria for risk groups of the American Thyroid Association (ATA, 2015). **Results:** NPV of the first sTg, measured 12 months after initial treatment, amounted to 99.5 % in the group of low-risk patients and 96.1 % in the group of intermediate-risk patients. In both groups (low- and intermediate-risk) there were no differences between NPV of the first sTg and NPV of sTg performed in 3 consecutive tests during a minimum of a 3 year monitoring period. **Conclusion:** Repeating the measurement of the stimulated serum thyroglobulin after negative result of the first stimulated thyroglobulin had a limited clinical value for detecting structural recurrent or persistent disease, and is not recommended for routine use in the group of low- and intermediate-risk patients with DTC. **References:** Prpic M, Franceschi M, Romic M, Jukic T, Kusic Z. EP-385

Standardised uptake value (SUV) of iodine-131 at post-treatment SPECT/CT in patients with differentiated thyroid cancer

A. Trukhin, P. Romyantsev, A. Bubnov, E. Kolpakova, K. Slaschuck, Y. Sirota, M. Degtyarev, S. Serzhenko;

Endocrinology Research Center, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Standardized uptake value of ¹³¹I accumulation in tumor foci at whole body scintigraphy of patients after radioiodine therapy of differentiated thyroid cancer (DTC) is strongly required by clinical practice. **Materials and Methods:** Study included 148 patients (f-105,

m-43) with DTC treated with ¹³¹I-iodine. Administered treatment activities of ¹³¹I calculated according to clinical features including tumor recurrence risk group. Patients were divided into three groups using ATA 2018 recommendations. Absolute risk groups: low risk (L), medium risk (M), high risk (H). Administered ¹³¹I activity [MBq]: <A_L> = 3223±729, <A_M> = 3696±456, <A_H> = 4589±1078; Tg [ng/ml]: <Tg_L> = 7,4±1.7 ng/ml, <Tg_M> = 14,8 ±5,9, <Tg_H> = 68,3 ±18,5; TgAb [IU/ml]: <TgAb_L> = 124,3 ± 81,7, <TgAb_M> = 29,2 ±15,9, <TgAb_H> = 85,7 ±28,9. All null hypothesis was checked using paired Mann-Whitney U-test. Calibration of system SPECT/CT and evaluation SUVs completed according to protocols designed using Jaszczak phantom Deluxe. Model development based on logistic regression with ROC-analysis, regularization and cross-validation. **Results:** Reference intervals of SUV_{peak} and SUV_{max} calculated for all groups of risk. SUV_{peak}: low risk >155, medium risk 105-155, high risk 0-105 pL-M=0.069 pL-H=0.0037 pM-H=0.7514; SUV_{max}: low risk >38, medium risk 29-38, high risk 0-29 pL-M=0.052 pL-H=0.0033 pM-H=0.949. Logit model based on SUV_{peak} without regularization has: AUC = 0.67 (95%CI 0.33-1.00); Accuracy = 0.82; SE = 0.89; SP = 0.4; PPV = 0.41; NPV = 0.89, cross-validated AUC = 0.67 (0.4-0.88), regression coefficients: B₀=0.037, B₁=0.001. Regularization (SUV_{peak}<100) lead to AUC = 0.75, (95%CI 0.44-1.00); accuracy = 0.89; SE = 0.98; SP = 0.4; PPV = 0.76; NPV = 0.87, cross-validated AUC = 0.513 (0.36-0.71) regression coefficients: B₀=0.473, B₁=0.003. **Conclusion:** Study shows that SUV has wide range of values and can be matched with existed model of risk assessment of DTC. Algorithm of image segmentation and evaluation of SUV_{peak} and SUV_{max} for SPECT/CT systems was developed. According to the ROC analysis, developed predictive model shows an acceptable performance for further clinical investigation and advancement focused on refining model parameters and introducing additional predictors. **References:** None

Rare sites of metastasis in differentiated thyroid carcinoma: case series study

N. Bashank¹, H. Farghally², S. Hassanein³, M. Abdeltawab³, M. Wahman⁴;

¹Assuit university, AUH, clinical oncology and nuclear medicine department, Assuit, EGYPT, ²Assuit university, clinical oncology and nuclear medicine department, Assuit, EGYPT, ³Assuit University Hospitals, Diagnostic Radiology department, Assuit, EGYPT, ⁴South Vally University, Clinical Oncology and Nuclear Medicine Department, Qena, EGYPT.

Aim/Introduction: The most common sites of metastasis in differentiated thyroid cancer are the neck lymph nodes with distant metastasis to lungs and bone. The liver, brain, adrenal gland, kidney, pancreas, eye, muscle and skin can be sites for rare metastasis. Rare metastases can be missed resulting in diagnostic pitfalls and inappropriate treatment

Identification of such cases has a great impact on patients management . There is lack of knowledge about dealing with such patients and what treatment they should receive and response of therapy due to rarity of such cases. More studies are needed to establish a therapeutic algorithm with an accurate and definitive treatment for these patients. Our study aims to study and report these rare cases of distant metastasis in patients with differentiated thyroid cancer (DTC) increasing the awareness about these cases and their methods of treatment and response to therapy. **Materials and Methods:** A retrospective review of 1,200 cases of thyroid cancer cases was performed. A total of 9 cases of DTC that had a rare distant metastasis were recognized . **Results:** 9 patients were included in this study (7 females ,2 males) with median age 57 years (range:32-79). 6 patients had follicular carcinoma ,2 patients had papillary carcinoma & 1 patient had insular carcinoma. 4 cases (44.4%) had multi-organs distant metastasis. the metastases were as following:, kidney and pancreas metastases (1), sella-turcica metastasis(1) muscle metastasis(1) paralaryngeal metastasis(1) , solitary brain metastasis (1),solitary bone metastasis(1)papillary carcinoma with bone metastasis(1)liver metastasis (1)and Malignant jugular vein thrombus (1).All patients received the initial therapy (total thyroidectomy with lymph node dissection & radioactive iodine therapy) in addition to external beam radiotherapy in 4 cases & tumour excision with vertebral fixation in one patient.5 patients showed disease regression while progression in 3 patients with disease stability in one patient. **Conclusion:** Rare metastases Identification has a significant impact on patients management . However, distant metastasis in DTC patients carries a bad prognosis, disease remission can occur especially if they are iodine avid or surgically resectable. More studies are needed to establish a therapeutic algorithm promoting an accurate and definitive treatment for such rare cases **References:** 1. 18F-FDG PET-CT: impact in the diagnosis and management of a population of thyroid cancer patients

C. Varela Pinto, B. Martins, D. Calado, D. Macedo, A. Martins, F. Sobral do Rosário, C. Loewenthal;
Hospital da Luz Lisboa, Lisbon, PORTUGAL.

Aim/Introduction: To evaluate the impact of 18F-FDG PET-CT results on the therapeutic management of patients with thyroid cancer. **Materials and Methods:** Retrospective analysis of clinical electronic records of 44 patients (mean age 52 years, range 30-86) who underwent 18F-FDG PET-CT at the time of diagnosis or follow-up of thyroid cancer between January 2008 and April 2020. Biochemical, clinical, imaging and

pathological findings were reviewed. We compared results of all other imaging modalities combined, with PET-CT results, and evaluated clinical impact of PET-CT on management. **Results:** Forty-four patients (25 women, 19 men) underwent 18F-FDG PET-CT, 11 for initial staging and 33 for re-staging of thyroid cancer. The most common histological subtypes was papillary (28), followed by medullary (8), follicular (4) and anaplastic (4). On PET-CT, 3 patients had disease confined to the thyroid gland, 10 had locoregional disease, 17 had metastatic disease (10 lung lesions, 5 bone lesions, 1 liver lesion and 1 bone plus liver lesions) and 14 patients had no detectable lesions. PET-CT and other imaging modalities results were similar in the diagnosis and management of the disease in 38 patients (86%). In the remaining 6 patients (14%), PET-CT results detected unknown disease and determined a change in strategy. PET-CT detected hypermetabolic lesions in cervical lymph nodes in 2 patients, lung lesions in another 2 and bone lesions in 2. In 4/6 patients, PET-CT results were confirmed pathologically. In the other 2/6 patients, PET-CT results were confirmed during follow-up, with reduction of serum thyroglobulin after radioactive iodine therapy in one patient and stereotactic body radiation therapy on the other. **Conclusion:** PET-CT with 18F-FDG appears to bring added value in the diagnosis and management of patients with thyroid cancer. A percentage of patients seem to benefit from the additional information provided, altering the therapeutic management at least in 14% of the patients, all of them in the follow-up of papillary thyroid cancer. **References:** None

EP-388

A critical review of the contact restrictions following radioiodine (I-131) therapy in the UK

E. Stamou, D. Morgan, A. Hallam;

Oxford University Hospitals NHS Trust, Oxford, UNITED KINGDOM.

Aim/Introduction: Radioiodine therapy is particularly effective in managing differentiated thyroid cancers. Upon therapy completion, patients are given restrictions to minimize doses to the public, family and friends. IRR17[1] established the 1 mSv/year limit for keeping doses ALARP, whereas IRMER[2] yields for differentiated doses for the latter if justified as “comforters and carers”, where employers establish constraints, those being 5mSv in 5yrs in our hospital. Following MDGN[3] guidelines, the UK release criterion is the retained activity, with 800MBq threshold. Given restrictions are currently calculated based on radioiodine’s biological half-life. This study assessed this model against a proposed one and investigated their effectiveness in complying with legislation. **Materials and Methods:** Data from 32 patients (16 Female, 16 Male) (69% papillary carcinoma, 31% follicular carcinoma) with age range 25-77yrs, over a period of 2yrs (2018 to 2020) were analysed. 77% of patients underwent a single treatment (Activity_{average} =3.7GBq) while 22% (13% within a year, 9% within 4 years) received a second treatment

(Activity_{average} = 5.6 GBq). Restrictions were generated using the proposed bi-phasic model based on the physiological kinetics, utilising a slow and fast clearance component. **Results:** For 41% of the patients (68% males, 32% females) the current dose to bedsharing adults exceeded the 1mSv/yr limit by 31% ($D_{\text{mean}} = 1305 \mu\text{Sv}$; $D_{\text{max}} = 9353 \mu\text{Sv}$), while for children <5yrs it was $D_{\text{mean}} = 620 \mu\text{Sv}$; $D_{\text{max}} = 2913 \mu\text{Sv}$. According to the proposed model, doses to bedsharing adults could be brought to 1mSv with 2 additional days and significantly optimised with 4 extra days (we currently instruct for 2 days on average, following the 3-day hospital isolation). With up to 30% recurrence probability [1], a second treatment with 3.7GBq could result in high doses to close contact adults, with 20% of cases approaching the 5mSv in 5 yrs limit. Interestingly, positive correlations were found between the doses to adults and children, and the % of tumour uptake ($r_{\text{Pearson's_children}<5\text{yrs}} = 0.77$; $r_{\text{Pearson's_Adults}(\text{bedshare})} = 0.82$) while no correlation was shown between whole-body counts and doses to adults and children, respectively ($p_{\text{adults}(\text{bedshare})} = 0.04$; $p_{\text{children}<5\text{yrs}} = 0.01$). **Conclusion:** Notwithstanding minimising children's exposure to radioiodine patients due to greater radiosensitivity, we highlight that prolonged close contact to patients, occurring mainly with adults, could result in higher total dose potentially exceeding the dose constraints, especially with repeat treatment. It is, therefore, vital to carefully consider the outcomes of the study and review the current guidelines to avoid underestimating the restrictions given to patients. **References:** [1]Legislation.gov.uk.Available from:http://www.legislation.gov.uk/ukxi/2017/1075/pdfs/ukxi_20171075_en.pdf [2]Ionising_Radiation_(Medical_Exposure)_Regulations_(IR(ME)R)_Available from:<https://www.cqc.org.uk/guidance-providers/ionising-radiation/ionising-radiation-medical-exposure-regulations-irmer> [3][Internet].Available from: http://files.site_fusion.co.uk/webfusion117640/file/medicalguidancenotes_1.pdf [4]Shaha_A.Recurrent_differentiated_thyroid_cancer. *Endocrine_Practice*.2012_Jul_1.18(4):600-3.

The Diagnostic Contribution and Clinical Impact of ¹³¹I SPECT/CT in the Evaluation of Extrathyroidal Uptake in Patients with Differentiated Thyroid Carcinoma after Radioiodine Therapy

T. Bahceci, E. Özdemir;

Ankara City Hospital, Ankara, TURKEY.

Aim/Introduction: The purpose of this study was to determine the diagnostic contribution and clinical impact of adding SPECT/CT to posttherapy ¹³¹I whole body scan (WBS) in the evaluation of equivocal extrathyroidal ¹³¹I uptake in patients with differentiated thyroid cancer (DTC). **Materials and Methods:** We retrospectively reviewed ¹³¹I-WBS imaging findings in 280 patients (March 2019-January 2020) who were operated for DTC and treated with RAI. A total of

116 patients (93F, 23M; mean age:48.34±13.41) who had extrathyroidal uptake on WBS and who underwent SPECT/CT imaging were included in the study. We assigned an incremental value to SPECT/CT when it provided better interpretation and identification of the foci of radioiodine, more correct anatomic localization and characterization, and precise differentiation between malignant lesions and physiologic uptake. The contribution of SPECT/CT imaging was evaluated in both lesion-based analysis and on patient-based analysis. Changes in staging and patient management were investigated after SPECT/CT evaluation. Serum thyroglobulin level, histopathology, other imaging modalities and clinical follow-up served as the gold standard. **Results:** The contribution of SPECT/CT to distinguish various causes of false-positive uptake images showed that the most common I-131 uptake site, except the thyroid bed, was observed in the thyroglossal duct (n:64(55%)) and thyroglossal duct uptake was correctly localized by SPECT/CT in all cases. The physiological uptake was most frequently observed in the salivary glands (n: 10 (9%)) and most commonly detected benign nonthyroidal pathology was the dental pathology (n: 25 (21%)). In 60 patients (51.7%) with doubtful findings in planar imaging, SPECT/CT was excluded pathological uptake. Overall, SPECT/CT changed therapy management for 17 patients (14.6%), by upstaging nodal staging (n: 12) and distant metastasis staging (lung metastasis n: 5, bone metastasis n: 1). **Conclusion:** SPECT/CT imaging after RAI therapy in patients with DTC improves diagnostic accuracy of WBS imaging by identification of physiological uptake and the differentiation of benign pathologies from malignancy and accurate localization and diagnosis of lymph node/distant metastases; It contributes significantly to the clinical impact and patient management. **References:** None

EP-390

Six-Year Experience With The ROLL Technique In The Detection And Treatment Of Loco-Regional Recurrence In Thyroid Cancer

J. Villena Salinas, E. Ramos Moreno, J. Alors Ruiz, A. Montellano

Fenoy, T. Amrani Raissouni, S. Ortega Lozano;

Hospital Universitario Virgen de la Victoria, Malaga, SPAIN.

Aim/Introduction: Describing the experience gained in radioguided surgery with ROLL technique (Radioguided Occult Lesion Localization), in order to detect and excise loco-regional recurrences in patients diagnosed with thyroid cancer. **Materials and Methods:** It is a prospective study with 39 patients: 19 men and 20 women, with suspected tumoral recurrence, previously treated with surgery. The differentiated carcinomas received complementary therapy with 131I. 0.4-0.6mCi of MAA-99mTc was administered in 0,07ml of saline solution by ultrasound-guided intralesional injection. The Navigator2.0 (Dilon technologies Inc®) radiation detector probe was used to localize on skin the highest radioactivity

point, in order to guide the surgeon towards the suspicious lesion. After its excision, lack of activity in the surgical field and its presence in the ex-vivo piece were proven and the piece was sent to conventional histopathological study. **Results:** The patient's average age was 56.6±13.1 years old. The histological types of the primary tumor were: papillary (30/39, 76.92%), medular (4/39, 10.26%), follicular (1/39, 2.56%) and Hurtle (1/39, 2.56%). The performed surgical treatment was total thyroidectomy with radical lymphadenectomy (23/39, 85.97%) and total thyroidectomy without lymphadenectomy (16/39, 41.03%). From all the patients, 33/39 (84.62%) received complementary therapy with ¹³¹I, average dose of 115±24mCi. The average preoperative values of thyroglobulin were 12.02±18.62 ng/ml and 58.28±150 ng/ml of antithyroglobulin antibodies. The average size of the recurrences was of 2.6±1.6cm, with 21 of them (53.85%) being tumor recurrence, and 18 (46.15%) lymph nodes recurrence. The lesion was localized in 100% of the cases, and in 33 cases (82.62%) it was positive in the histopathological analysis, and negative in 6 cases (15.38%). **Conclusion:** Radioguided surgery with ROLL technique in thyroid cancer can be established as a reliable procedure which has allowed, since the beginning of its use in 2013, the localization of the suspected recurrence. **References:** None

EP-391

The influences of TSH stimulation level, stimulated Tg level and Tg/TSH ratio on the prognosis of ¹³¹I treatment in DTC patients

W. Zheng, Z. Rui, X. Wang, N. Li, Z. Meng, J. Tan, Q. Jia;
Department of Nuclear Medicine, Tianjin Medical University General Hospital, Tianjin, CHINA.

Aim/Introduction: To study the influences of preablation TSH stimulation level, sTg and sTg/TSH ratio on the prognosis of ¹³¹I treatment in DTC patients. **Materials and Methods:** According to the TSH levels (mU/l), all the 479 patients were divided into two groups: TSH < 30 and TSH ≥ 30. And then, the TSH ≥ 30 group was divided into three subgroups: 30 ≤ TSH < 60, 60 ≤ TSH < 90 and TSH ≥ 90. The clinical features and the prognosis were analyzed. The cutoffs of sTg and sTg/TSH were calculated to predict the prognosis of DTC. **Results:** The TSH ≥ 90 subgroup was younger and less possible with LNM. The postoperative L-T4 dose in the 30 ≤ TSH < 60 subgroup was higher than 60 ≤ TSH < 90 subgroup. In the TSH < 30 group, the postoperative L-T4 dose was higher and THW (d) was longer. The response rate six months after the first ¹³¹I treatment among the three subgroups and between the two groups were no statistical significances. The distribution of different TSH stimulation levels among each response group was similar. The cutoffs for good prognosis in sTg and sTg/TSH were < 9.51 ng/ml and < 0.11, respectively. Both univariate and multivariate logistic regressions showed that LNM, distant metastasis and higher sTg, sTg/TSH predicted

poor prognosis. **Conclusion:** There was no significant effect of TSH stimulation level before the first ¹³¹I treatment on the prognosis of DTC. Both preablation sTg and sTg/TSH can be considered as predictors of ¹³¹I treatment outcome. **References:** None

EP-392

Outcome related to changes of stimulated and suppressed thyroglobulin

C. Hong, S. Lee, J. Lee, S. Jeong, B. Ahn;
Kyungpook National University Hospital,
Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: Stimulated thyroglobulin (off-Tg) and suppressed thyroglobulin (on-Tg) are widely used for risk assessment of thyroid cancer patients. However, there is only few studies about outcome related to changes of off-Tg and on-Tg. **Materials and Methods:** We retrospectively reviewed DTC patients who underwent total thyroidectomy and radioactive iodine (RAI) ablation between Jan-2000 and Feb-2002. Response to therapy risk (RTT) assessment using both off-Tg and on-Tg were performed 6-15 months after high-dose RAI therapy. All the patients were under TSH suppression. Median follow-up period after RAI ablation was 15.6 ± 5.4 years. **Results:** Finally, 411 patients were included in this study. 80 patients were low risk, 165 were intermediate and 166 were high-risk according to ATA risk stratification. At initial RTT (off-Tg/on-Tg), 176/156 patients were excellent response (ER), 130/159 were indeterminate response (IR), 62/53 were biochemical incomplete response (BIR), and 43/43 were structural incomplete response (SIR) and. Progression rates of DRS using off-Tg/on-Tg were 1.7%/5.8% in ER, 15.4%/12.6% in IR, 43.5%/39.6% in BI, 69.8%/69.8% in SI. During the follow-up, 41 patients were down-staged to ER (from IR/BI) or IR (from BI) using off-Tg without any kind of procedures, and only 1 patient (2.4%) showed progression. And 30 patients were down-staged using on-Tg during follow-up and only 1 patient (3.3%) showed progression. **Conclusion:** Off-Tg shows better prognostic value than on-Tg on DRS. The patients who down-staged without any procedure showed excellent prognosis. **References:** None

EP-393

¹³¹I Effective Half-life in Children and Adolescents with Thyroid Cancer Patients

X. Zhang, B. Liu;
Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: The kinetics of ¹³¹I in therapy of children and adolescents with thyroid cancer is poorly studied. The goal was to investigate the effective half-life of ¹³¹I in children and adolescents with thyroid cancer treated in our center in relation to clinical parameters. **Materials and Methods:** Fifty-

two thyroid cancer patients <20 years of age at diagnosis were included. Probe measurement of whole-body dose rate was serially performed after ingestion of ^{131}I . **Results:** The median age was 16 years, and the majority were female (73.1%). All patients underwent total thyroidectomy and received ^{131}I therapy after thyroid hormone withdrawal. The mean effective half-life was 10.9 hours, ranging from 6.4 to 26.0 hours. Significant correlation coefficient was only found between effective half-life and body surface area ($r=0.349$; $p=0.11$). **Conclusion:** Effective ^{131}I half-life in children and adolescents with thyroid cancer is shorter than that in adult populations reported previously, suggesting that age may be an affecting factor. Body surface area should be included in specific recommendations regarding ^{131}I activity retention during ^{131}I therapy in children and adolescents with thyroid cancer. **References:** None

EP-395

Impact of 18F-FDG PET/CT on the management of well differentiated thyroid cancer (DTC) persistence/recurrence in the suspect of radio-iodine refractory disease (RAI-R-DTC)

E. Lodi Rizzini¹, L. Zanoni¹, E. Tabacchi¹, A. Repaci², A. G. Morganti³, S. Fanti¹, F. Monari³;

¹Nuclear Medicine Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, ²Endocrinology Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, ³Radiation Oncology Center, S.Orsola-Malpighi Hospital, Bologna, ITALY.

Aim/Introduction: Prognostic role of 18FDG-PET/CT imaging in advanced DTC has already been reported in literature. However, there is still lack of data about the real impact of 18FDG-PET/CT on treatment management in the case of advanced and aggressive disease, so the first aim of our study was to retrospectively assess the impact of 18F-FDG PET/CT and secondly to confirm the prognostic role of clinical and semi-quantitative metabolic 18F-FDG PET/CT parameters in comparison with scientific literature. **Materials and Methods:** A monocentric retrospective/observational study was performed from a database of 208 pts treated, from January 2011 to July 2019, for local/metastatic DTC with several RAI courses in our Radiation Oncology Center. 53 pts who started to perform 18FDG-PET/CT scan after the second RAI course because of strong suspect of RAI-R-DTC (negative Rx-WBS scan and/or high thyroglobulin levels) were included. Clinical, laboratory and imaging data were collected. Metabolic response was defined according to PERCIST criteria. SUVmax, SUVmean, MTV, TLG were calculated. Kruskal-

Wallis, Chi-Square-Pearson tests and Cox regression were used to compare metabolic/clinical parameters and PFS. **Results:** In our sample (mean age: 52 ± 19.9 years; 31F-22M) 20/53(38%) pts had a negative RxWBS and a positive PET/CT scan, 7/53(13%) pts had positive RxWBS and PET/CT scans, 24/53 (45%) pts had negative RxWBS and PET/CT scan and 2/53(4%) pts had a positive RxWBS and a negative PET/CT scan. Therapeutic approaches addressed after PET/CT positivity were external-beam-radiation therapy in 4/27(15%) pts, surgery in 4/27(15%), further RAI course in 2/27(7.4%), surgery+EBRT in 1/27(4%) and observation in 16/27(59%) pts. PERCIST response was evaluated in 14/27 FDG/PET positive scans. Median FU and median PFS were 5.8 ± 3.9 years and 38 ± 21.8 months respectively. At the last FU, 13/53(24.5%) pts had persistence of structural disease, 25/53(47%) persistence of biochemical disease and 15/53(28%) excellent response. Significant associations were found between clinical response assessment and therapeutic approach ($p=0.01$) and between PFS and metabolic response ($p=0.02$). Linear correlation between MTV and TLG and suppressed-Tg was found. At Cox-Regression multivariate analysis only MTV ($p=0.034$ HR 1.100 CI95% 1.007-1.202) and PERCIST response ($p=0.004$ HR 2.434 CI95% 1.322-4.481) were independently associated to persistent disease. **Conclusion:** In our analysis 18F-FDG-PET/CT turned out to be a guide for clinical management of RAI-R-DTC, particularly to avoid further ineffective/toxic RAI administrations. Randomized trials are needed to confirm our results and the real impact of 18F-FDG-PET/CT on therapy choice. **References:** Prognostic value of 18F-FDG PET/CT metabolic parameters in metastatic differentiated thyroid cancers. EP-396

To compare high turnover and normal turnover Graves' disease outcomes after ^{131}I -Radioiodine therapy and determine prognostic factors

S. Arora, D. Chakraborty, K. S. Reddy, M. Prabhu, A. Behera, A. Tupalli, A. Passah, B. S. Mangu, A. Hemrom, C. Bal; All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: To compare the outcomes after ^{131}I -Radioiodine therapy in high turnover and normal turnover Graves' disease patients. **Materials and Methods:** High turnover (HTO), was defined as 2h RAIU/24h RAIU ratio ≥ 1 and normal turnover (NTO) as 2h RAIU/24h RAIU ratio < 1 (1,2). These two cohorts of Graves' disease (GD) patients were selected for a retrospective cohort design study (1:2 ratio, $n=104$: $n=208$) and then matched using propensity score matching (PSM) (1:1, 77:77). ^{131}I cure rate (euthyroid plus hypothyroid) at 12 months was compared. Univariate and multivariate analysis were done to determine prognostic factors. The binary logistic regression model was used to predict the factors responsible for the failure of RIT. **Results:**

There was a significant difference in cure rates, 28% vs 66% (unadjusted) and 31% vs 61% (adjusted for covariates using PSM) in HTO and NTO groups, respectively noted ($P < 0.001$). The median number of RIT (2 vs 1) and median cumulative activity (15 vs 7 mCi) was required to achieve cure in two groups respectively. The variables associated with the failure after 131 RIT (at 12 months) were; age >44 years (odds ratio-2.6, $p < 0.001$), grade 2 goitre (odds ratio-2.8, $p < 0.029$), high turnover group (odds ratio-2.6, $P < 0.007$) and 2h RAIU $>37\%$ (odds ratio 2.7, p -value 0.005). **Conclusion:** High turnover Graves' disease patients differ significantly from normal turnover in outcome (failing after routine lower activities of 131 I). Factors predicting high failure rate are higher age (>44 years), higher grade of goiter, high turnover of the gland and higher 2h RAIU ($>37\%$). **References:** 1. Aktay R, Rezai K, Seabold JE, Bar RS, Kirchner PT. Four- to twenty-four-hour uptake ratio: an index of rapid iodine-131 turnover in hyperthyroidism. *J Nucl Med.* 1996; 37(11):1815-9. 2. EP-397

Dynamic risk stratification to evaluate prognostic factors (PrFs) for differentiated thyroid cancer (DTC): A retrospective cohort study

E. Giannoula¹, N. Papadopoulou², C. Sachpekidis³, A. Doumas¹, G. Gerasimou¹, F. Spyroglou¹, V. Chatzipavlidou⁴, I. Iakovou¹;

¹Nuclear Medicine dpt of Aristotle University AHEPA Academic hsp, Thessaloniki, GREECE, ²G.Gennimatas hsp, Thessaloniki, GREECE, ³Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY, ⁴Nuclear Medicine dpt of THEAGENEIO Anticancer hsp, Thessaloniki, GREECE.

Aim/Introduction: Despite excellent prognosis, small cohorts of DTC-patients experience a more aggressive form of disease often associated with certain poor PrFs. Identifying these patients at an early stage and dynamically evaluating them is imperative for guiding treatment decisions. Risk stratification should be a dynamic process to predict the appropriateness for minimalistic initial therapy, disease-specific-mortality, risk of recurrence, and the most likely response to initial therapy. In this respect, the objective of our study is to investigate the factors (demographic, clinical, pathologic, treatment administrated characteristics) influencing treatment response. **Materials and Methods:** Our cohort comprised all 551 patients (47.2 ± 14 yrs) with DTC, who underwent a first radioiodine ablation procedure or follow-up-WBS at our institutions from June_2016 to June_2018. All demographic and pathologic characteristics were recorded. TSH, Tg, TgAb and AntiTPO levels were measured after TSH stimulation. Thyroid remnant in post-therapy and follow-up 131 I-WBScan was retrospectively given classification scores based on visual assessment of the number of foci of thyroid bed uptake and

their overall intensity on 131 I-WBScan. Response to therapy was assessed according to the ATA2015-guidelines response to therapy re-classification. **Results:** Cohort overwhelmingly comprised patients with papillary type (76.8%). Despite favorable histotypes, a large proportion of patients had characteristics suggested higher risk or uncertainty regarding risk, or both: Almost, half of the cohort (46.25%) was diagnosed with primary tumors ≥ 2 cm. Multifocality was detected in 53.95% patients. Invasiveness was documented for 40.5% of the patients. Lymph node metastases were detected in 39.4% and distant metastases in less than 5% of the patients. Virtually, all patients had evidence of postsurgical thyroid remnant (thyroid-bed uptake was absent in only 7.75% of cases). Response to treatment evaluation showed 37.7% Excellent Response-ER, 14.7% Biochemical Incomplete Response-BIR, 21.7% Structural Incomplete Response-SIR and 26% Indeterminate Response-IR which were significantly correlated with histological type ($p = 0.001$), stage ($p = 0.039$), preablation Tg ($p = 0.001$) and remnant scoring ($p < 0.001$). **Conclusion:** Several PrFs (clinical, pathologic, treatment administrated characteristics) for DTC have emerged and should be addressed. However, their role has yet to be determined not only for achieving an adequate therapeutic approach, but also for avoiding overtreatment of low-risk patients. Dynamic-risk-assessment should be used to guide all aspects of DTC management, beginning before a definitive diagnosis is made and continuing through the final follow-up visit. **References:** -Frangos_S, Iakovou_IP, Marlowe_RJ et al. Difficulties in deciding whether to ablate patients with putatively "low-intermediate-risk" DTC: do guidelines mainly apply in the centres that produce them? **WORLD
LEADING
MEETING**

34th ANNUAL CONGRESS OF THE
EUROPEAN ASSOCIATION OF
NUCLEAR MEDICINE

HAMBURG

Oct 23 - 27, 2021

— eanm21.eanm.org —

ESMIT Live Webinar series - to be continued!

Place:

Nuclear Imaging Technology: Where we came from, where we are and where we are heading

Speakers:

Ian Armstrong, John Dickson,
Stephan Nekolla, Dimitris Visvikis

Moderator:

Michel Koole

PHYSICS

Place:

PET MPI: Tracers, Equipment, Protocols, Flow Quantification, Viability

Speakers:

Mark Lubberink,
Roberto Sciagra

Moderator:

Christoph Rischpler

CARDIOLOGY

For more information visit the ESMIT Booth of EANM'20

**Stay tuned for more
ESMIT Live Webinars coming up in 2021!**

Course Programme 2021

Dosimetry	Practical Implementation of Clinical Dosimetry in NM Therapy	Feb 2021
Oncology I	Therapy Assessment	Mar 2021
Physics	Advanced Features of Quantification	Apr 2021
Neurology	Quantification in Neurology	Apr 2021
Bone & Joint	Post-Operative Skeleton	Jun 2021
Oncology II	Prostate Cancer (advanced)	Sep 2021
Thyroid	Management of Thyroid Cancer (advanced)	Nov 2021
Tba	Theranostics	Dec 2021

Please note that the information given above is subject to change.
For regular updates, please visit the EANM website or
subscribe to the ESMIT vNewsletter.

Acknowledgement

The ESMIT leadership likes to thank all contributors of this initiative.
Special thanks to the EANM Committees and the ESMIT Project
Groups for their continuing support.

POSTPONED
DUE TO COVID-19

SEVILLE, SPAIN

NEW DATES: FEBRUARY 3-5, 2022

4 EANM
FOCUS

MOLECULAR IMAGING
AND THERAPY IN
HAEMATOLOGICAL TUMOURS

EARL RELEASED

¹⁸F STANDARD 2 ACCREDITATION,

Allowing sites to benefit from state-of-the-art PET/CT technology while still ensuring harmonized scanners performance,

UNIQUE ⁸⁹Zr PET/CT ACCREDITATION

Based on and derived from the procedures performed for the ¹⁸F-FDG PET/CT accreditation which is a prerequisite for ⁸⁹Zr accreditation

**EANM
RESEARCH
LTD (EARL)**

EARL is a 100% subsidiary of the EANM, which aims to enhance the quality of nuclear medicine practice for the benefit of public health.
