Dear colleagues, dear friends,

On behalf of the European Association of Nuclear Medicine, it is my great honour to invite you to the 33rd Annual EANM Congress, which will take place virtually from 22 to 30 October 2020.

Nuclear Medicine keeps on growing in many clinical areas, from diagnostic imaging to therapy: our procedures are increasingly being incorporated into clinical practice, in a variety of settings and diseases. This success is mostly related to a peculiar characteristic of our specialty, namely the functional approach to medicine. PET imaging works so well because of the unique functional information provided to clinicians, and this feature is the key to the ongoing rapid diffusion of Nuclear Medicine.

In recent years, the status of the EANM Congress as the world-leading meeting in Nuclear Medicine has been firmly established. The number of attendees in 2019 exceeded that in any previous year, with more than 6950 participants, but we are working to make the 2020 event even bigger, more memorable, and virtual.

EANM cares for its members, participants and patients, with safety being our primary concern as COVID-19 continues to pose a major health threat worldwide. Therefore, it was decided that it is in the best interest of the entire NM community to go virtual only.

The Virtual EANM Congress will still have all the features that made the event successful in the past. The usual excellent tracks and sessions, from CME to joint sessions, have already been confirmed. A number of newer features are also being planned and we will have a new format for the plenary sessions, new top-rated oral presentation sessions and a new 'Top Trials' session.

A further characteristic of our Congress is its multidisciplinary nature, and this will be emphasised in 2020, with a number of sessions bringing together physicians from many specialties as well as specialists in radiochemistry and pharmacy, physicists and other professionals. In addition, a dedicated track for technologists will be provided.

If all of this still isn't enough to motivate you to attend the EANM'20 Congress virtually, we are working on providing some extra entertainment to make your virtual experience even more fun. This will include a daily nuclear quiz, daily programme highlights' announcements, games and social opportunities.

Stefano Fanti

EANM Congress Chair 2020–2022

THURSDAY | October 22, 2020

Time (EST)	Channel 1	Channel 2	Channel 3	Channel 4	Channel 5	Channel 6	Channel 7	Channel 8	Channel 9	Channel 10	Channel 11	Time (EST)

Phase I study of ^{99m}Tc-ADAPT6, a scaffold protein-based probe for visualization of HER2 expression in breast cancer

O. Bragina^{1,2}, E. von Witting³, J. Garousi⁴, R. Zelchan^{1,2}, M. Sandström⁴, A. Orlova^{1,4}, A. Medvedeva², A. Doroshenko², A. Vorobyeva^{1,4}, S. Lindbo³, J. Borin³, N. Tarabanovskaya², J. Sörensen⁴, S. Hober³, V. Chernov^{1,2}, V. Tolmachev^{1,4};

Aim/Introduction: Radionuclide molecular imaging of human epidermal growth factor (HER2) expression may be helpful to stratify breast and gastroesophageal cancer patients for HER2-targeting therapies. ADAPTs (albumin-binding domain derived affinity proteins) are a new type of small (5–2–7 kDa) proteins useful as probes for molecular imaging. ^{99m}Tc-ADAPT6 binds with high affinity to HER2. It demonstrated a high-contrast imaging of HER2-expressing human xenografts in mice in preclinical studies. The primary objective of this Phase I study was to evaluate biodistribution, dosimetry, and safety of the HER2-specific ^{99m}Tc-ADAPT6. The secondary objective was to compare the tumour imaging data with the data concerning HER2 expression obtained by immunohistochemistry (IHC) or fluorescent in situ hybridisation (FISH) analysis of biopsy samples. **Materials and Methods:** Twenty-nine breast cancer patients were included. Twenty-two patients with HER2-positive (n=11) or HER2-negative (n=11) histopathology were randomized to injection of either 500 µg (n=11) or 1000 µg (n=11) of ^{99m}Tc-ADAPT6. The injected activity was 385±125 MBq. Planar scintigraphy and SPECT imaging was performed after 2, 4, 6 and 24 h. An additional cohort of seven patients was injected with 165±29 MBq (injected protein mass 250 µg) and imaging was performed after 2 h only. **Results:** Injections of ^{99m}Tc-ADAPT6 at any injected mass were not associated with adverse effects. ^{99m}Tc-ADAPT6 had a rapid clearance from blood. The normal organs with the highest accumulation were kidney, liver and lung. Effective dose was 0.009±0.002 and 0.010±0.003 mSv/MBq for injected protein mass of 500 and 1000 µg, respectively. Injection of 500 µg resulted in an excellent discrimination between HER2-positive and HER2-negative tumors already 2 h after injection. The tumor-to-contralateral breast ratio was 37±19 for HER2-positive and 5±2 for HER2-negative tumors at this time point (p< 0.01). The tumor-to-contralateral

breast ratios for HER2-positive tumors were significantly (p <0.05) higher for injected mass of 500 µg than for both 250 and 1000 µg. In one patient, the imaging using ^{99m}Tc-ADAPT6 revealed three bone metastases, which were not found at the time of diagnosis by CT or ^{99m}Tc-pyrophosphate bone scan. MRI imaging confirmed this finding. **Conclusion:** Injections of ^{99m}Tc-ADAPT6 are safe, well tolerated and associated with low absorbed and effective doses. Protein dose of 500 µg provided the best discrimination between HER2-positive and HER2-negative tumors. ^{99m}Tc-ADAPT6 is a promising imaging probe for stratification of patients for HER2-targeting therapy. **References:** Garousi J, et al. Radiolabelling and Preliminary in vivo Study of a Small Molecule-based Ligand for CCK2 Receptors Targeting

M. Asti¹, M. Verona², S. Rubagotti¹, F. Mastrotto³, G. Marzaro², V. Di Marco², S. Corradetti³, N. Realdon³, A. Andrighetto³;

¹AUSL-IRCCS, Reggio Emilia, ITALY, ²University of Padua, Padua, ITALY, ³National Institute of Nuclear Physics, Legnaro (PD), ITALY.

Aim/Introduction: Receptors-specific targeting ligands were recently exploited to selectively deliver both imaging and therapeutic agents to cancer tissues in vivo. The cholecystokinin 2 receptor (CCK2R) is overexpressed in various human cancers (e.g. lung, medullary thyroid, pancreatic, colon, and gastrointestinal stromal tumors) but displays limited expression in normal tissues. For this reason, it is a suitable diagnostic and therapeutic target. In this study, a non-peptide-based ligand (namely IP2) functionalized with a DOTA chelator was synthesized and labelled with indium-111. **Materials and Methods:** The targeting agent Z-360, a benzodiazepine-derived CCK2R antagonist, was synthesized optimizing a previously published procedure. The synthesis pathway consists in a six steps reaction where the benzodiazepine structure was first formed and then functionalized with a di-ethylglycol spacer connecting the pharmacophore to a DOTA chelator (IP2). The ligand was radiolabeled in a pH 4 buffered environment with indium-111 and the reactions were optimized for precursor amount. Stability in human blood and lipophilicity by shake-flask method were evaluated as well. In vitro uptake and affinity of [¹¹¹In]In-IP2 were assessed at different time (2, 4, 8, 24 h) on a high CCK2R expressing tumor cell line (A549) and biodistribution, pharmacokinetic and specificity in vivo were evaluated on nude mice bearing A549 xenograft tumors. **Results:** The Z-360 core was obtained with an overall moderate yield (23%). IP2 was synthesized in good amounts and then purified with preparative HPLC. The radiolabeling process yields >95% with a molar activity of ca. 10 MBq/nmol and a radiochemical purity (assessed by RP-HPLC) >98%. Stability studies showed an amount of intact radiotracer higher than 93% after 2 hours of incubation. Computed

logP was 0.45. Cellular uptake showed a maximum after 4 hours of incubation. Tumors could be clearly visualized in vivo already after 2 hours although high amount of radiotracer was also found in the gastro-intestinal tract and other organs. Tumour retention persisted up to 24 hours and clearing was slow mainly by hepatobiliary excretion. Blocking experiments showed receptors mediated specific uptake. **Conclusion:** In this study a CCK2R antagonist ligands not based on a peptide sequence was synthesized and labelled with indium-111. In vitro and in vivo studies showed good potential but, due to the lipophilic nature of the targeting agent, a more hydrophilic spacer should be selected in order to improve biodistribution. Structural studies are on-going for enhancing receptor affinity as well. This study is a part of the so called "Isolpharm project". **References:** None

OP-018

Evaluation of Molecular Design of HER2-targeting Affibody-drug Conjugates for Drug Delivery to Ovarian Cancer

T. Xu¹, H. Ding², A. Vorobyeva^{1,3}, M. Oroujeni¹, T. Gräslund², A. Orlova^{4,5}, V. Tolmachev^{1,3};

¹Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, ²Department of Protein Science, KTH Royal Institute of Technology, Stockholm, SWEDEN, ³Research Centrum for Oncotheranostics, Research School of Chemistry and Applied Biomedical Sciences, Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, ⁴Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, ⁵Science for Life Laboratory, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Human epidermal growth factor receptor 2 (HER2) is overexpressed in ca. 30% of ovarian cancer patients, which offers an opportunity for HER2-targeting therapy. Antibody-drug conjugates (ADCs) permit specific delivery of cytotoxic drugs to antigen-expressing cancer cells. An alternative to ADCs are Affibody molecules. They are small engineered scaffold proteins that bind with high affinity and specificity to selected antigens. We previously demonstrated that the anti-HER2 Affibody-drug conjugates (AffiDCs) containing an albumin binding domain (ABD) for half-life extension and a cytotoxic drug DM1 prolonged survival of mice bearing HER2-expressing SKOV-3 xenografts. However, moderate hepatic uptake was observed that could pose a risk of hepatotoxicity. This study aimed to evaluate the influence of molecular design of AffiDCs on the biodistribution and drug delivery to tumors. **Materials and Methods:** Three monomer and dimer formats of anti-HER2 AffiDCs having a tri-glutamate or a tri-glycine linker $Z_{\text{HER2:2891}}-Z_{\text{HER2:2891}}\text{-ABD-EEE-DM1}$, $Z_{\text{HER2:2891}}\text{-ABD-EEE-DM1}$ and $Z_{\text{HER2:2891}}\text{-ABD-GGG-DM1}$ were labeled with $^{99m}\text{Tc}(\text{CO})_3^+$ via N-terminal (HE)₃-tag. Binding affinity to living SKOV-3 cells was measured using LigandTracer instrument. In vitro specificity of the labeled AffiDCs to HER2-overexpressing

SKOV-3 and BT474 cells was evaluated. The internalization rate during continuous incubation in SKOV-3 and BT474 was studied. Biodistribution was measured in Balb/c nu/nu mice bearing SKOV-3 xenografts at 4 h and 24 h after injection. **Results:** The radiochemical purity of conjugates after NAP-5 purification was $\geq 95\%$. All tested compounds were stable in the presence of large excess of histidine. Radiolabeled AffiDCs demonstrated specific HER2-mediated binding to SKOV-3 and BT474 cells. Affinity measurements showed dissociation equilibrium constants to SKOV-3 cells in the single digit nanomolar range. The cellular processing assay showed rapid binding of all conjugates to HER2-expressing cells and a similar internalization pattern with internalized activity increasing over time and reaching 40% of total cell-associated activity by 24 h. Biodistribution in SKOV-3 tumor-bearing mice demonstrated slow blood clearance for all tested compounds. Among the three compounds, $Z_{\text{HER2:2891}}\text{-ABD-EEE-DM1}$ had the lowest uptake in liver, spleen and large intestine while the tumor uptake was the same as the other compounds. Compared to tri-glycine linker, the tri-glutamate spacer provided 36% and 10% reduction in hepatic uptake by 4 h and 24 h, respectively. **Conclusion:** This study showed the importance of molecular design of AffiDCs for decreasing undesirable uptake in normal organs. Among all tested constructs, $Z_{\text{HER2:2891}}\text{-ABD-EEE-DM1}$ demonstrated equally high tumor uptake with the best tumor-to-liver ratio and is a promising candidate for HER2-targeted therapy of ovarian cancer. **References:** None

Optimization of the biodistribution of 1C1m-Fc anti TEM-1 antibody fusion protein in soft tissue sarcoma model in mice

J. Delage¹, A. Faivre-Chauvet², J. K. Fierle³, N. Schaefer⁴, G. Coukos⁵, S. M. Dunn³, D. Viertl⁴, J. O. Prior⁴;

¹Radiopharmacy Unit, Pharmacy Department, Lausanne University Hospital, Lausanne, SWITZERLAND, ²CRCINA, INSERM 1232-CNRS ERL 6001, University of Angers, University of Nantes, Nantes, FRANCE, ³LabCore, Ludwig Institute for Cancer Research, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND, ⁴Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND, ⁵Ludwig Institute for Cancer Research and Department of Oncology, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND.

Aim/Introduction: 1C1m-Fc is an anti TEM-1 scFv-Fc fusion antibody developed in Lausanne. Our previous study showed the interest of this new compound radiolabeled with ^{177}Lu for molecular imaging in soft tissue sarcoma. Even if the TEM-1 positive uptake was specific, we also observed an important liver uptake that was not saturation-dependent. Our hypothesis for this phenomenon was the influence of the number of DOTA on the biodistribution. The aim of this

study was to verify this hypothesis and find the best ratio of DOTA per antibody to develop an optimal radiolabeled 1C1m-Fc for theranostic applications. **Materials and Methods:** 1C1m was conjugated with six different concentrations of DOTA. The number of DOTA per antibody fusion protein was evaluated by mass spectrometry and was respectively 1.5; 2.5; 3; 6; 8.5 and 11. Tumors expressing huTEM-1 were established by subcutaneous injection of 3×10^6 SK-N-AS cells in mouse flank of 8-10-week-old female Balb/c nude mice. Tumors were allowed to grow to 5-10mm (largest diameter) before initiating studies. After radiolabeling, ^{177}Lu -1C1m-Fc conjugated with 1.5 to 11 DOTA was injected into the lateral tail vein of the mice. In each group, three animals were euthanized by CO_2 inhalation and exsanguinated at 24h after injection of the radiolabeled product. Blood was collected, organs and tumors were removed, weighed, and the activity was measured by gamma counter. **Results:** A significant decrease of the tumor uptake was observed with the antibodies conjugated with more than 3 DOTA (18%IA/g up to 3 DOTA to 7.5%IA/g for 11 DOTA). In parallel, the blood uptake at 24 h varied between 10.2 % for 1.5 DOTA per antibody to 2.5% for 11 DOTA per antibody. We observed an inverse correlation of the tumor/liver ratio with the increasing number of DOTA per antibody, from 2 with 1.5 DOTA per antibody to 0.17 with 11 DOTA per antibody ($\rho = -0.99$, $p < 0.0001$). **Conclusion:** The number of DOTA molecules attached per antibody moiety plays a significant role in determining successful tumor targeting with radiolabeled antibodies. 1.5 DOTA per antibody seems to be the best ratio to maintaining a balance between radiochemical yield, immunoreactivity and pharmacokinetic behavior. Our next step would be to measure immunoreactivity to gain more insight about the possible mechanism. **References:** None

⁶⁸Ga-NT-20.3 for imaging of neurotensin receptor: first human study

F. Wang¹, W. Wu¹, I. Virgolini², M. Hodlic³;

¹Nanjing Medical University, Nanjing, CHINA, ²Medical University Innsbruck, Innsbruck, AUSTRIA, ³Palacký University Olomouc, Olomouc, CZECH REPUBLIC.

Aim/Introduction: Over the last decades, multiple peptide receptors were recognized as potential diagnostic and therapeutic targets in nuclear medicine. The peptide neurotensin (NT) acts via seven-transmembrane, G-protein-coupled receptor called NT receptor (NTR). Three NTR subtypes have been cloned: NTR-1 (high-affinity NTR), NTR-2 (low-affinity NTR) and NTR-3 (Sortilin 1, a single transmembrane domain sorting receptor). NTR-1 is the most expressed NTR. High NTR-1 expression has been observed in various tumours, from pancreatic ductal adenocarcinoma (PDAC), mesothelioma and breast cancer to prostate cancer. With intention to quantitate NTR expression in various tumours,

⁶⁸Ga-NT-20.3 radiopharmaceutical has been developed. After demonstration of binding affinity to cell lines, ⁶⁸Ga labelled NT surrogate was successfully applied in animal model. The purpose of this study was to evaluate the safety and tolerability of ⁶⁸Ga-NT-20.3 radiopharmaceutical in the first human study.

Materials and Methods: This study was performed in accordance with Declaration of Helsinki and the Enforcement Decree of Pharmaceutical Affairs Good Clinical Practice after Ethical committee approval. DOTA-NT-20.3 was dissolved in sodium acetate buffer (0.25 M) and sent into the pre-heated reactor. ⁶⁸Ga eluting from the ⁶⁸Ge/⁶⁸Ga generator with 0.05 M HCl was added to the reaction vial. ⁶⁸Ga-DOTA-NT-20.3 was synthesized automatically with ITM module. Quality control was performed with HPLC, only radiolabeled ligand with 99% radiochemical purity was used in the clinical. Finally, the labeled product was eluted from the C18 cartridge with ethanol and collected in the product vial. 52 year old male with PDAC metastasised to liver was involved in this study. After 6 hours of fasting, 378 MBq (2.5 MBq/kg) of ⁶⁸Ga-NT-20.3 was administered intravenously. All subjective and physician's observations as well as vital parameters (systolic and diastolic blood pressure, heart rate, respiratory rate and body temperature) were checked before, immediately after and 3h after ⁶⁸Ga-NT-20.3 injection. **Results:** After intravenous injection of ⁶⁸Ga-NT-20.3, there was no side events neither from the perspective of patient neither from the perspective of nuclear medicine physician. No dizziness, shortness of breath, palpitations, nausea, vomiting or any gastrointestinal symptoms were registered. Vital parameters before injection, immediately after and 3h after injection were as follows: blood pressure (mmHg): 145/95, 146/101, 146/99; heart rate (beat/min): 89, 93, 92; respiratory rate (number of breaths/min): 20, 22, 22; body temperature (°C): 36.2, 36.2, 36.4. **Conclusion:** The first in human injection of ⁶⁸Ga-NT-20.3, PET radiopharmaceutical for imaging of neurotensin receptors, was performed without adverse events and seems to be tolerable in clinical work. **References:** None

Molecular imaging of monocarboxylate transporters with PET - development and biological evaluation of novel 2-fluoropyridinyl analogs of FACH

M. Sadeghzadeh¹, W. Deuther-Conrad¹, B. Wenzel¹, D. Gündel¹, M. Toussaint¹, R. P. Moldovan¹, S. Fischer¹, F. A. Ludwig¹, R. Teodoro¹, S. Jonnalagadda², S. K. Jonnalagadda², V. R. Mereddy², L. R. Drewes³, P. Brust¹;

¹Department of Neuroradiopharmaceuticals, Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf, Leipzig, GERMANY, ²Department of Chemistry and Biochemistry, Department of Pharmacy Practice & Pharmaceutical Sciences, University of Minnesota, Duluth, MN, UNITED STATES OF AMERICA, ³Department of Biomedical Sciences, University of Minnesota Medical School Duluth, Duluth, MN, UNITED STATES OF AMERICA.

Aim/Introduction: Monocarboxylate transporters 1-4 (MCT1-4) are involved in several metabolism-related diseases, especially cancer, providing the chance to be considered as relevant targets for diagnosis and therapy. Recently, we reported on [¹⁸F]FACH as a novel MCT-targeting imaging agent (1), whose limited blood-brain barrier permeability, however, excludes application in brain diseases. Accordingly, we aimed to develop a more lipophilic FACH-derived radiotracer possessing higher brain uptake. **Materials and Methods:** Two 2-fluoropyridinyl-substituted analogs of FACH (**1** and **2**) were obtained by Buchwald-Hartwig cross coupling reaction. The potency of **1** and **2** to inhibit MCT1 was measured by [¹⁴C]lactate uptake assay using rat brain endothelial-4 cells. Radiolabeling of [¹⁸F]**1** was proceeded using 1 mg nitro precursor and [¹⁸F]fluoride in the presence of Kryptofix and K₂CO₃ in dimethyl sulfoxide at 130 °C within 15 min. The logD_{7,4} value of [¹⁸F]**1** was experimentally determined in the n-octanol-PBS system. For biological evaluation of [¹⁸F]**1**, in vitro autoradiography on cryosections of mouse kidney and small animal PET-MRI studies in female CD-1 mice were performed. Target specificity was proven by using the sodium salt of the MCT inhibitor α-cyano-4-hydroxycinnamic acid (α-CCA-Na). **Results:** The analogs **1** and **2** inhibited MCT1 with IC₅₀ values of 118 and 274 nM, respectively. [¹⁸F]**1** was obtained by radiofluorination of the nitro precursor via nucleophilic aromatic substitution reaction with radiochemical yields of 73 ± 12% (n = 4, non-isolated, radio-HPLC), a high radiochemical purity of > 98% and molar activities in the range of 180-200 GBq/μmol (n = 3, end of synthesis) using starting activities of 2-3 GBq. The logD_{7,4} value of 0.82 achieved for [¹⁸F]**1** indicated 2-fold higher lipophilicity in comparison to [¹⁸F]FACH (**2**). In vivo and in vitro studies revealed high uptake of the new radiotracer in kidney and other peripheral MCT-expressing organs together with significant reduction by using α-CCA-Na (10 μM). The brain uptake of [¹⁸F]**1** was similar to [¹⁸F]FACH without significant washout and an almost unchanged SUV of 0.15 between 15 and 60 min p.i. **Conclusion:** Despite a higher lipophilicity of [¹⁸F]**1** compared to [¹⁸F]FACH, the brain uptake of [¹⁸F]**1** was in a similar low range, revealing the need for further structural modification. However, a high and specific uptake of the new radiotracer in the kidneys suggests suitability of [¹⁸F]**1** for investigations on the expression of MCT in vivo. **References:** (1) Sadeghzadeh M, et al. *J Label Compd Radiopharm.* 2019; 62: 411-424. 2-[¹⁸F]FDG metabolism: The role of alternative metabolic pathways

E. Klebermass^{1,2}, M. Mahmudi¹, A. Miller³, V. Pichler¹, C. Vranka¹, T. Balber⁴, A. Haschemi³, W. Wadsak^{1,5}, M. Hacker¹, H. Viernstein², M. Mitterhauser^{1,4};

¹Department of Biomedical Imaging and Image-guided

Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, ²Department of Pharmaceutical Technology and Biopharmaceutics, University of Vienna, Vienna, AUSTRIA, ³Department of Laboratory Medicine, Medical University of Vienna, Vienna, AUSTRIA, ⁴Ludwig Boltzmann Institute Applied Diagnostics, Vienna, AUSTRIA, ⁵CBmed GmbH - Center for Biomarker Research in Medicine, Graz, AUSTRIA.

Aim/Introduction: Studies show that the PET-tracer 2-[¹⁸F]FDG can be further metabolized via alternative metabolic pathways, such as the oxidative pentose phosphate pathway (oxPPP) after its phosphorylation (1), questioning the exact trapping mechanism and current PET-signal quantification. Recent discoveries further propose that 2-[¹⁸F]FDG accumulation in brain is largely independent of glucose consumption, but reflects the activation of a metabolic pathway in the endoplasmic reticulum, triggered by the oxPPP isoenzyme hexose-6-phosphate-dehydrogenase (H6PD) (2). The aim of this study is to examine 2-[¹⁸F]FDG metabolism in the light of these findings in order to better understand its influence on the tracer's accumulation and kinetics. **Materials and Methods:** Accumulation experiments and metabolism studies were performed using 3 different human cancer cell lines (HT29, Huh7, HT1080). Cells were pre-treated with oxPPP inhibitors (e.g. DHEA) and different media, incubated with 2-[¹⁸F]FDG, lysed and analyzed with a gamma counter or radio-HPLC. Previously characterized metabolites were produced as references following published procedures (3). OxPPP enzyme activities were determined spectrophotometrically in equally treated cell lysates by measuring NADPH. In addition, in vitro kinetics were analyzed with LigandTracer technology. **Results:** Up to 95% 2-[¹⁸F]FDG-6-phosphate conversion and 11 metabolites were detected, which was most pronounced in HT29 and enhanced by fasting or DHEA treatment. The combination led to a substantial formation of the oxPPP metabolite (up to 60%), deceleration of 2-[¹⁸F]FDG uptake and substantial decrease in total accumulation (down to 35%). HPLC measurements revealed that the oxPPP enzyme glucose-6-phosphate-dehydrogenase (G6PD) can also process 2-[¹⁸F]FDG-6-P. In enzyme activity measurements, G6PD/H6PD activity was shown to be lowered or unaffected by DHEA under starving when tested with glucose-6-phosphate, but enhanced using FDG-6-phosphate. **Conclusion:** Metabolism of 2-[¹⁸F]FDG can be substantial in vitro and enhanced by fasting or oxPPP manipulation. Our enzyme activity data support the hypothesis that 2-[¹⁸F]FDG may not be sweepingly seen as glucose surrogate. Contradicting Marini et al. (4), we found that 2-[¹⁸F]FDG is not only processed by H6PD, but also by G6PD, adding another layer of complexity to its intracellular fate. Enhanced metabolism via oxPPP enzymes correlates with a significant reduction of 2-[¹⁸F]FDG accumulation under glucose deprivation, however, further evaluations are needed to prove causality. **References:** (1) Bender D., et al. *J Nucl Med.* 2001 Nov, (2) Cossu V., et al. *Eur J Nucl Med Mol*

High-Contrast Radionuclide Imaging of EpCAM Expression in Ovarian Cancer Using DARPIn Labeled With a Non-Residualizing Label

A. Vorobyeva^{1,2}, E. Konovalova³, T. Xu¹, A. Schulga³, M. Altai¹, J. Garousi¹, S. S. Rinne¹, A. Orlova^{1,2}, S. M. Deyev^{3,2,4}, V. Tolmachev^{1,2}; ¹Uppsala University, Uppsala, SWEDEN, ²National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, ³Shemyakin & Ovchinnikov Institute of Bioorganic Chemistry, Moscow, RUSSIAN FEDERATION, ⁴Sechenov University, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Disseminated ovarian cancer is often diagnosed at late stages and requires effective and safe systemic treatment. Epithelial cell adhesion molecule (EpCAM) has intense overexpression in up to 75% of ovarian cancers and is a promising therapeutic target. To identify patients with high EpCAM expression for targeted treatment, radionuclide molecular imaging could be performed. Designed ankyrin repeat protein (DARPIn) Ec1 has high affinity to EpCAM (68 pM), small size (18 kDa) and was shown to be slowly internalized by pancreatic cancer cells. This provided preconditions for using a non-residualizing label in this study. The primary aim was to test a hypothesis that internalization of Ec1/EpCAM complex by ovarian cancer cells is slow to permit imaging hours after injection. The secondary aim was to evaluate what dose of Ec1 would permit DARPIn-mediated delivery of cytotoxic payload to ovarian cancer xenografts. **Materials and Methods:** Ec1 was indirectly radioiodinated using N-succinimidyl-3-methylstannyl-benzoate to provide non-residualizing [¹²⁵I]-PIB label. EpCAM-expressing OVCAR-3 and SKOV-3 ovarian cancer cells were used for characterisation of [¹²⁵I]-PIB-Ec1 in vitro and in vivo. Biodistribution was measured in BALB/C nu/nu mice bearing OVCAR-3, SKOV-3 and Ramos (negative control) xenografts 6 h after injection. MicroSPECT/CT imaging was used to confirm the biodistribution data. To investigate the effect of protein dose on tumor uptake, mice bearing SKOV-3 xenografts were injected with [¹²⁵I]-PIB-Ec1 at 0.8, 4, 40 and 640 µg total protein doses. **Results:** Ec1 was labeled with a radiochemical yield of 20±5%. Size exclusion purification provided radiochemical purity over 95%. Binding of [¹²⁵I]-PIB-Ec1 to ovarian cancer cells was specific and had picomolar affinity. Slow internalization of [¹²⁵I]-PIB-Ec1 by ovarian cancer cells confirmed utility of non-residualizing label for in vivo imaging. Six hours after injection [¹²⁵I]-PIB-Ec1 provided tumor-to-blood ratios of 30 ± 11 and 48 ± 12 for OVCAR-3 and SKOV-3 xenografts, respectively, and high contrast to other organs. Tumor targeting was highly specific. MicroSPECT/CT imaging confirmed high-contrast visualization of OVCAR-3 and SKOV-3 xenografts. High

doses of Ec1 can be administered to mice bearing SKOV-3 xenografts without saturating the tumor uptake. **Conclusion:** DARPIn [¹²⁵I]-PIB-Ec1 provided high-contrast imaging of EpCAM a few hours after injection in two models of ovarian cancer. This can be applied for clinical imaging of EpCAM using SPECT with ¹²³I label, as well as PET with ¹²⁴I and, potentially, with non-residualizing [¹⁸F]-fluorobenzaldehyde label. Dose-finding experiment provided a rationale for dose selection in further studies using therapeutic conjugates of Ec1 for targeted therapy. **References:** None

OP-024

Affibody-based Theranostics for HER3-expressing cancers: tumor growth inhibition, and PET-imaging of HER3 for therapy monitoring in a preclinical model

A. Orlova¹, S. S. Rinne¹, M. Altai¹, C. Dahlsson Leitao², S. Ståhl¹, J. Löfblom², V. Tolmachev¹; ¹Uppsala University, Uppsala, SWEDEN, ²Royal Institute of Technology, Stockholm, SWEDEN.

Aim/Introduction: } The human epidermal growth factor receptor type 3 (HER3) is involved in tumor progression and therapy resistance, and a potential therapeutic target in cancer. HER3-targeting affibody molecules (Z) are a promising theranostic approach for diagnostic imaging of HER3 expression and tumor growth inhibition. The aim of this study was to investigate the therapeutic efficacy of HER3-targeting affibody-conjugates fused to an albumin binding domain (ABD) (Z-ABD, Z-Z-ABD, Z-ABD-Z, ABD-Z-Z-, ABD-Z) and the potential of affibody-based imaging of HER3 expression for therapy monitoring in a preclinical model. **Materials and Methods:** The new conjugates were labeled with indium-111 via C-terminal maleimide DOTA and their biodistribution was studied in tumor bearing mice. Inhibition of cell proliferation and receptor phosphorylation was studied in vitro using HER3-expressing BxPC-3 cells. For the in vivo therapy BxPC-3 xenografted mice (n=10/group) with were treated (ip, three times/week) with Z-ABD, Z-Z-ABD, Z-ABD-Z, control groups were treated with seribantumab or PBS. Affibody [⁶⁸Ga]Ga-HE₃-Z-NODAGA was used to study receptor occupancy by microPET/CT imaging. **Results:** Residence time in blood was found the longest for Z-ABD and Z-ABD-Z and tumor accumulation the highest for Z-ABD, Z-Z-ABD, Z-ABD-Z. These conjugates inhibited cell proliferation and HER3 phosphorylation in vitro. In vivo, treatment was well tolerated without adverse effects. All treatment groups showed significantly inhibited tumor growth and significantly prolonged survival compared to PBS control. Treatment effect of Z-ABD and Z-ABD-Z (median survival 80.5 d), was significantly stronger than Z-Z-ABD (72 d), and comparable with seribantumab (83 d). microPET/CT imaging with [⁶⁸Ga]Ga-HE₃-Z-NODAGA showed uptake of the radiotracer in the tumor in PBS group, but not in the treated groups, due blocking of HER3 by the therapeutic agents.

Accumulation of [^{68}Ga]Ga-HE₃-Z-NODAGA was observed in livers (mErbB3 expressing) in groups treated with PBS and non-cross-reactive seribantumab; in group treated with Z-ABD liver uptake was lower and no uptake was observed in groups treated with Z-Z-ABD, Z-ABD-Z. HER3 expression in tumors was confirmed in all groups at end-point by IHC. **Conclusion:** Combination of different HER3-affibody-constructs could be used for theranostic approaches in HER3-expressing cancer. The molecular design of the ABD-fused HER3 targeting agents affected their therapeutic efficacy. We have demonstrated that radiolabeling of therapeutic proteins helped to select the most promising candidates for further evaluation. The use of PET imaging with companion agent allowed therapy monitoring demonstrating receptor occupancy during HER3-targeted therapy. **References:** None

OP-025

In vitro receptor autoradiography utilising a novel ^{111}In -labeled GIP receptor antagonist reveal high signals in neuroendocrine tumours: A comparative study to ^{111}In -DOTATATE and ^{111}In -JR11

A. Schumann¹, C. Haase¹, U. Reineke¹, C. Smerling¹, J. C. Reubi², I. Eichhorn³, B. Wiedenmann³, C. Roderburg³; ¹3B Pharmaceuticals GmbH, Berlin, GERMANY, ²Institute of Pathology, University of Berne, Berne, SWITZERLAND, ³Charité-Universitätsmedizin, Berlin, GERMANY.

Aim/Introduction: The gastric inhibitory polypeptide receptor (GIPR) represents a promising structure for targeted radionuclide therapy. Autoradiography studies employing the agonistic peptide GIP(1-30) revealed substantial GIPR expression in numerous cancer types such as NETs and MTC and virtual absence in normal tissues [1]. We hypothesised that a GIPR antagonist might increase the detection of binding sites, as shown for the SSTR2 antagonist JR11 in comparison to the agonist DOTATATE [2]. 3B Pharmaceuticals has developed a high affinity GIPR antagonist (3BP-Tracer) for targeted radiotherapy of GIPR-positive tumours. In this study, we show a clear ranking of GEP-NETs visualising compounds based on autoradiographic signal intensity: ^{111}In -3BP-Tracer \sim ^{111}In -JR11 $>$ ^{111}In -DOTATATE $>$ ^{111}In -GIP(1-30). **Materials and Methods:** The novel 3BP-Tracer consists of a GIPR targeting moiety that is conjugated to DOTA enabling complexation of both diagnostic and therapeutic radionuclides. A human GIPR-transfected cell line was used for affinity assessment of the 3BP-Tracer by flow cytometry and radioligand binding assay. Antagonism was verified via Ca²⁺ signalling assay. In vitro receptor autoradiography was performed on GEP-NETs, their metastases, and corresponding normal tissues using the following tracers: ^{111}In -3BP-Tracer, ^{111}In -GIP(1-30), ^{111}In -DOTATATE, and ^{111}In -JR11. **Results:** Antagonism of the 3BP-Tracer was confirmed by the absence of Ca²⁺ release after binding of 3BP-Tracer with single digit nanomolar affinity to the hGIPR transfected cell line and by inhibition of

GIP(1-30) binding mediated Ca²⁺ signalling. In vitro receptor autoradiography in GEP-NETs revealed up to 6-fold higher signals of the ^{111}In -labelled GIPR antagonist, relative to the clinically relevant SSTR2 agonist DOTATATE. Binding signals of both GIPR and SSTR2 antagonists were equally strong in most GEP-NETs and all metastases. However, in contrast to ^{111}In -JR11, ^{111}In -3BP-Tracer showed no off-target binding to normal tissues. Signal strength of the GIPR agonist ^{111}In -GIP(1-30) was close to background in all investigated tumour samples. In SSTR2-positive tumours and liver metastases, ^{111}In -JR11 showed 3- to 6-fold increased uptake compared to ^{111}In -DOTATATE. However, ^{111}In -JR11 was found to bind non-specifically to normal tissues such as ileum and liver. **Conclusion:** The antagonist ^{111}In -3BP-Tracer was found to bind in a receptor-specific manner to GEP-NETs and corresponding metastases without unexpected off-target binding in normal tissues. Since ^{111}In -3BP-Tracer revealed substantially higher GIPR signals relative to previous autoradiography studies with GIP(1-30), our results strongly emphasise the clinical potential of the novel GIPR antagonist for targeted radiotherapy in NETs. **References:** [1] Waser, B., J Clin Endocrinol Metab, 2011. Multimodal In Ovo Imaging: The chicken embryo as an alternative model in preclinical research

T. Balber^{1,2}, J. Christl¹, J. Friske³, S. M. Bugayong², V. Fröhlich³, A. S. Zacher², L. Nics², W. Wadsak^{2,4}, M. Hacker², T. Helbich³, M. Mitterhauser^{1,2};

¹Ludwig Boltzmann Institute Applied Diagnostics, Vienna, AUSTRIA, ²Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA, ³Division of General Radiology, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA, ⁴Center for biomarker research in medicine, CBmed GmbH, Graz, AUSTRIA.

Aim/Introduction: The preclinical evaluation of novel PET diagnostics is time-consuming and costly, but many tracer candidates ultimately fail in vivo. We lack an adequate, but affordable model for preselecting high-potential candidates while reducing animal experimentation. This need has already been recognised by others and comparable in vivo distribution of several PET and SPECT tracers have been demonstrated in mice and chicken embryos post mortem.⁽¹⁾ In addition, the Chorion Allantois Membrane (CAM), as a highly vascularized membrane on the periphery of the embryo, in combination with the natural embryonic immunodeficiency makes xenotransplantation possible. Previously, in vivo PET/CT has been successfully performed in a human glioblastoma CAM model including dynamic imaging protocols.⁽²⁾ Thus, we aim to further explore the potential and possible limitations of this model in preclinical tracer development. **Materials and Methods:** To this, specific-pathogen free, fertilized chicken

eggs were incubated for 18 days to allow for embryonic development and formation of the CAM. Xenografts were generated by opening the eggshell and inoculating the CAM with human prostate cancer cells. PET-tracers (e.g. [^{18}F]FDG, [^{18}F]FEC, [^{18}F]PSMA-1007) were applied intravenously to a CAM-vessel. Immobilization of the embryo during imaging was achieved by applying volatile anesthetics or inducing hypothermia. Multimodal imaging was performed on a preclinical PET/CT scanner or using a PET Insert and a 9.4 Tesla micro-MRT. **Results:** Growth and vascularization of implanted tumor cells could be achieved within 5 to 7 days after inoculation depending on the cell line. Multimodal imaging (PET/MRI, contrast-enhanced PET/CT) enabled a clear delineation of tracer-accumulating tumor grafts. Due to the high soft tissue contrast, combined PET/ MRI significantly improved the accurate assessment of the organ-specific tracer distribution including brain uptake in the living chicken embryo. **Conclusion:** The in ovo model provides an affordable preclinical system of medium physiological complexity that has proven useful in tracer development, reducing the use of small animals in the future. The established workflow and imaging protocols demonstrate the resolution required for PET imaging of oncological models, and in ovo μ PET/MRI opens a new perspective in neurological imaging. **References:** (1) Haller S et al, Nucl Med Biol 42 (2015) 226-233, (2) Warnock G et al, J Nucl Med 2013; 54 (10)

OP-027

Reducing abdominal background in 4FMFES-PET using intestinal peristalsis inhibitors: a translational study

M. Paquette, E. Espinosa-Bentancourt, É. Lavallée, S. Phoenix, B. Guérin, É. E. Turcotte;

Université de Sherbrooke, Sherbrooke, QC, CANADA.

Aim/Introduction: Like every steroidal compounds, the Estrogen Receptor (ER) targeting PET tracer 4-fluoro-11 β -methoxy-16 α -[^{18}F]fluoroestradiol (4FMFES) is mainly eliminated via the hepatobiliary pathway. While 4FMFES allows unprecedentedly background-free assessment of thoracic ER+ lesions, gynaeco-oncological applications are more likely to be impaired by the overwhelming presence of radioactive intestinal content in the lower abdomen. In this project we sought to investigate the use of different pharmacological interventions, first in mice, then in uterine cancer patients, to slow down progression of the intestinal bolus sufficiently to reduce abdominal background at the time of imaging. **Materials and Methods:** Small cohorts (n = 4 each) of Balb-c mice received either 100 μ l saline (control) or 80 μ g loperamide per os 15 minutes prior injection of 4FMFES, or repeated intravenous administration of 10 μ g hyoscine butylbromide at 0, 20- and 40-minute post tracer injection. Mice were imaged on a small animal PET scanner for 90 minutes. Images were reconstructed using 1-minute time frames, and progression of the intestinal content was tracked.

In parallel, uterine cancer patients (n = 20) were recruited to evaluate 4FMFES-PET/CT for this new application. All patients were fasted for 5 hours before imaging, then were given either a 4 mg loperamide tablet 15 minutes prior 4FMFES injection or were injected with 20 mg hyoscine butylbromide at 0, 20 and 40 minutes after administration of the tracer. All patients also received furosemide after tracer injection to clear the bladder. Head-to-thigh acquisition occurred at 60 minutes post-injection. Abdominal background surrounding the uterine area was reported as SUVMean and intestinal progression was qualitatively evaluated. **Results:** While no differences could be observed for the distance traveled by the intestinal content between the control group and the hyoscine butylbromide treatment in mice (90.6 \pm 13.4 mm and 85.4 \pm 19.1 mm, respectively), loperamide pre-treatment had a significant effect (57.6 \pm 21.9 mm; p < 0.01). In contrast, no improvement in abdominal background was observed in patients receiving loperamide prior to 4FMFES, whereas repeated injection of hyoscine butylbromide allowed substantial reduction of abdominal uptake and improvement in image quality in most patients receiving this drug. **Conclusion:** It is possible to reduce abdominal background of 4FMFES-PET using drugs inhibiting intestinal peristalsis in combination with diuretic agents to clear the bladder. Other steroidal PET tracers might benefit from this protocol. Other pharmacological agents, such as low-dose opioids will be investigated in the near future. **References:** None

OP-028

An international quantitative SPECT/CT imaging exercise for Lu-177

J. Tran-Gia¹, A. P. Robinson², N. Calvert³, A. M. Denis-Bacelar², A. J. Fenwick^{2,4}, K. M. Ferreira², D. Finocchiaro^{5,6}, F. Fioroni⁵, E. Grassi⁵, W. Heetun², S. J. Jewitt⁷, T. Kalathas⁸, M. Kotzarslidou⁸, M. Ljungberg⁹, D. R. McGowan^{7,10}, J. Scuffham¹¹, K. Sjögreen Gleisner⁹, J. Tipping³, J. Wevrett¹¹, M. Lassmann¹;

¹Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY, ²National Physical Laboratory, Teddington, UNITED KINGDOM, ³The Christie NHS FT, Manchester, UNITED KINGDOM, ⁴Cardiff University, Cardiff, UNITED KINGDOM, ⁵Azienda Unità Sanitaria Locale di Reggio Emilia - IRCCS, Medical Physics Unit, Reggio Emilia, ITALY, ⁶Department of Physics and Astronomy, University of Bologna, Bologna, ITALY, ⁷Oxford University Hospitals NHS FT, Oxford, UNITED KINGDOM, ⁸"THEAGENIO" Anticancer Hospital, Thessaloniki, GREECE, ⁹Department of Medical Radiation Physics, Lund, SWEDEN, ¹⁰University of Oxford, Oxford, UNITED KINGDOM, ¹¹Royal Surrey NHS FT, Guildford, UNITED KINGDOM.

Aim/Introduction: Patient-specific dosimetry is required to ensure the safety of molecular radiotherapy treatments and to predict response. Dosimetry involves several steps, the first of which is the determination of the activity of the radiopharmaceutical taken up by an organ/lesion over time. As uncertainties propagate along each of the subsequent steps (integration of the time-activity curve, absorbed dose calculation), establishing a reliable activity quantification is essential. The MRTDosimetry project was a European initiative to bring together expertise in metrology and nuclear medicine research, with one main goal of standardising quantitative Lu-177 SPECT/CT imaging based on a calibration protocol developed and tested in a multicentre intercomparison.

Materials and Methods: The intercomparison included eight SPECT/CT systems (3×Siemens, 4×GE, 1×Mediso). Each site performed three measurements using the same acquisition (medium energy collimator, 2×60 projections of 60s, 208keV main energy windows) and reconstruction (OSEM with 25 iterations, 2 subsets, no postfiltering, attenuation correction [CT-based], triple-energy-window scatter correction [6%-20%-6% scatter-main-scatter], and resolution recovery [if available]): 1. Determination of image calibration factor (ICF): Counts (enlarged VOI around 216-mm Jaszczak cylinder filled with ~400MBq) divided by activity and scan duration (unit: cps/MBq). 2. Determination of recovery coefficients (RCs) for partial-volume correction (PVC) in IEC NEMA body phantom with 6 hot spheres (activity concentration ~2.0MBq/mL): Activity in CT-based VOI (counts/ICF/scan_duration) divided by each sphere's activity. Recovery curve: Comparison of weighted 3-parameter ($b1/(1+(b2/volume)^{b3})$) and 2-parameter fit ($b1:=1$) of RCs against sphere volumes. 3. Validation of quantitative imaging setup in 3D-printed kidney and spleen phantoms filled with different activity concentrations (kidney cortex & spleen: ~1.5 MBq/mL, kidney medulla: ~0.5 MBq/mL) assembled in Jaszczak cylinder (custom-made baseplate for repeatable positioning): Activity in CT-based VOI (counts/ICF/scan_duration) divided by volume-dependent recovery value. An uncertainty analysis was performed for all measurements. **Results:** Similar combinations of imaging system and reconstruction led to similar ICF values (Siemens 3/8": [21.5±1.6] cps/MBq, GE 3/8": [45.4±2.5] cps/MBq). In the anthropomorphic phantom validation, the mean ratios between SPECT-based and radionuclide calibrator-based activity were very close to the ideal value of 1 for the 3-parameter fit: 1.02±0.10 (kidney), 1.07±0.11 (spleen). Larger deviations were seen for the 2-parameter-fit: 0.89±0.06 (kidney), 0.94±0.06 (spleen). **Conclusion:** This comparison exercise shows that reliable quantitative SPECT/CT is feasible when following the very specific recommendations of the dedicated calibration protocol developed within MRTDosimetry. In addition, for an anthropomorphic phantom, the count loss due to spill-out was successfully compensated by using a standardized PVC based on sphere-based RCs. **References:** [http://mrtdosimetry-](http://mrtdosimetry-empir.eu/wp-content/uploads/2019/08/15HLT06_Publishable_Report_M36_Final.pdf)

OP-029

An in silico study on the influence of radiosensitivity and tumor growth on the total tumor volume in ¹⁷⁷Lu-PSMA therapy

P. Kletting¹, A. Gafita², H. Wang², A. Beer¹, W. Weber², M. Eiber², G. Glatting¹;

¹Universität Ulm, Ulm, GERMANY, ²Technische Universität München, München, GERMANY.

Aim/Introduction: Physiologically-based pharmacokinetic/dynamic modeling (PBPK/PD) allows to estimate important physiological and pathophysiological parameters using time activity data and tumor volume changes over time. The aim of this work was to 1) estimate tumor growth rates and radiosensitivities in patients with metastatic castration-resistant prostate cancer (mCRPC) and 2) to determine which combinations of tumor growth rate and radiosensitivity lead to a reduction of total tumor volume following ¹⁷⁷Lu-PSMA radioligand therapy (RLT) by model simulations. **Materials and Methods:** A PBPK/PD-model was developed describing the pharmacokinetics, tumor growth according to the power-law model and treatment effect in terms of the linear-quadratic model. The tumor is considered to be a sphere whose radius grows linearly, and the average size of the tumor lesions depends on the total tumor volume (TTV) of the patient. The radiosensitivity parameter α and the growth rate λ_g (tumor volume radius change per day) of the model were fitted to data derived from PSMA-targeted PET/CT prior to and following the first cycle of ¹⁷⁷Lu-PSMA-targeted therapy. The employed data were PSMA-positive TTV and total tumor activity concentration (TTA) determined semi-automatically in 30 patients using the qPSMA software. To obtain additional information on the global pharmacokinetics in the patient, the kidneys volume and activity were determined in the PET/CT prior and post treatment and in one peri-therapeutic SPECT/CT. Based on the estimated parameter values, simulations were performed for various combinations of radiosensitivity ($\alpha=0.001-0.1$ Gy⁻¹) and tumor growth rate ($\lambda_g=0.0004-0.04$ cm/day). For each combination, the TTV was simulated after 6 cycles of ¹⁷⁷Lu-PSMA RLT using a 6-week regimen of 7.4 GBq and 80 nmol amount of substance. **Results:** The growth rates ($\lambda_g=0.016\pm 0.010$ cm/day) and radiosensitivities ($\alpha=0.04\pm 0.03$ Gy⁻¹) of the PBPK/PD model were determined by fitting to the patients data. These parameter values compare favorably with literature values from radiotherapy and brachytherapy. The TTV simulations after 6 cycles show that for average tumor growth and radiosensitivity within this patient population, a ¹⁷⁷Lu-PSMA RLT 6-week regimen of 6 cycles leads to a TTV reduction in 8 out of 30 patients. **Conclusion:** This PBPK/PD modeling approach allowed to separately investigate the influence of radiosensitivity and

tumor growth on the total tumor volume after therapy. The identification of subpopulations with specific ranges of radiosensitivities or tumor growth values in a large patient population might improve patient selection for therapy.

OP-030

Impact of gamma camera uniformity calibration methods in SPECT Imaging

K. Ferreira, W. Heetun, A. P. Robinson;

National Physical Laboratory, Teddington, UNITED KINGDOM.

Aim/Introduction: The performance of conventional gamma cameras currently used in nuclear medicine is inherently non-uniform due to the underlying technology. The impact of non-uniformities in SPECT imaging has been widely recognised but more work is necessary to quantify the differences in corrections generated from different measurement techniques. In this work the impact of applying different uniformity calibration maps in SPECT imaging will be investigated. **Materials and Methods:** In this work, the uniformity of a Mediso AnyScan SPECT-CT camera was calibrated for Tc-99m imaging using a range of intrinsic and extrinsic methods. For intrinsic calibrations the following source geometries were used: ^{99m}Tc point Source, ^{57}Co point source and a ^{99m}Tc flood source. For extrinsic uniformity calibration a ^{99m}Tc and a ^{57}Co flood sources were used. To assess the impact of the choice of correction on SPECT/CT imaging data was acquired for: a cylindrical Jaszczak phantom, a NEMA phantom and a 3D-printed organ phantom filled with a known amount of ^{99m}Tc using the different uniformity calibration maps. The images were assessed visually to check for differences; and the Mean Squared Error (MSE) and respective uncertainties were calculated to estimate the possible differences between images. The percentage difference between total counts in the images was calculated to estimate the impact on quantitative imaging of using different uniformity calibration maps. **Results:** The use of intrinsic calibration maps was found to reduce the system sensitivity (total counts) compared to the corresponding extrinsic calibration. Changes in the sensitivity of the system were reported in terms of percentage when using different uniformity calibration maps, for the cylindrical phantom variations between -5.8 % and 5.2 % were estimated; for the NEMA phantom the differences ranged between -6.5 % and 6.3 % and for the 3D-printed organ differences between -3.4 % and 3.3 % were reported. **Conclusion:** This work showed that the method used for uniformity calibration has an impact in image quantification for SPECT. In molecular radiotherapy, these differences can be propagated to the absorbed dose calculations resulting in an underestimation or overestimation of the absorbed dose depending on the calibration map used. **References:** None

OP-031

Verification of xSPECT Quant for Quantitative ^{123}I -mIBG SPECT/CT Imaging

K. Baete, M. Sevenois, E. Pauwels, C. M. Deroose;
Nuclear Medicine, University Hospitals Leuven; Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, Leuven, BELGIUM.

Aim/Introduction: We have verified the accuracy of xSPECT Quant, a quantitative SPECT/CT imaging technique (Siemens Healthineers, Erlangen, Germany), for neuroendocrine tumor imaging using ^{123}I -meta-iodobenzylguanidine (^{123}I -mIBG). Image quantification in SPECT/CT is useful when comparing ^{123}I -mIBG with alternative PET/CT theranostics agents, such as ^{68}Ga -labeled somatostatin analogues or the recently introduced ^{18}F -meta-fluorobenzylguanidine. For that, SPECT/CT requires advanced QC and reliable activity determination. We assessed long-term stability of radionuclide calibrator and SPECT/CT cross-calibration accuracy using gamma spectrometry analysis. **Materials and Methods:** We verified the calibration factor settings of a radionuclide calibrator (IBC-LITE, VIK-202, Comcer) using the reported ^{123}I activity of an AdreView™ vial (GE Healthcare). We studied the influence of the used recipients (vial, syringe) with and without a copper filter insert. We transferred the ^{123}I activity uniformly in 1000 ml water in a plastic bottle. We weighed the recipients before and after activity transfer (analytical balance, Mettler), and corrected for residual syringe activity. From the ^{123}I solution, we pipetted and weighed three 1 ml samples for gamma spectrometry. Subsequently, we prepared a Symbia Intevo Bold (Siemens Healthineers, Erlangen, Germany) SPECT-CT camera for quantitative image analysis by performing standard maintenance and quality control procedures. We calibrated the SPECT camera for absolute ^{123}I quantification using the xSPECT Quant Calibration Source Kit, containing a NIST traceable ^{75}Se reference source. Using MELP collimators and factory based xSPECT acquisition and reconstruction settings, we performed a SPECT/CT acquisition of the bottle with the ^{123}I solution. We reconstructed the projection data using the xSPECT reconstruction method, and we analyzed the SPECT images, corrected for scatter, attenuation, decay, and expressed in Bq/ml, using MIM Encore (MIM Software, Cleveland, OH). We measured the samples using a 3-inch gamma counter (Wizard 1480, Perkin Elmer) with adjusted energy window settings to avoid the low-energy influence of possible ^{125}I contamination. We also verified the linearity of the gamma counter count-rate using the decaying samples. **Results:** At reference time, the prepared phantom activity concentration was 200.8 kBq/ml. In a central volume-of-interest in the bottle, the measured activity concentration of the xSPECT image measured 201.5 kBq/ml. Hence, the SUV deviation is 0.3 %. The gamma counter efficiency measured 0.778 ± 0.001 cps/Bq. The deviation from linearity between 400 Bq and 50 kBq ^{123}I was below 0.4%. **Conclusion:** We

established quantitative SPECT/CT imaging for ^{123}I , using a ^{75}Se reference source based calibration, and introduced quality assurance measures to perform follow-up analysis of the involved equipment. **References:** None

OP-032

Experimental validation of absolute SPECT/CT quantification for response monitoring in patients with coronary artery disease

A. van de Burgt¹, P. Dibbets-Schneider¹, C. H. Slump², A. J. H. A. Scholte¹, D. E. Atsma¹, L. F. de Geus-Oei^{1,2}, F. H. P. van Velden¹;

¹Leiden University Medical Center, Leiden, NETHERLANDS,

²University of Twente, Enschede, NETHERLANDS.

Aim/Introduction: Myocardial perfusion scintigraphy (MPS) is based on visual interpretation of relative myocardial perfusion and might underestimate the severity of ischemia due to global hypoperfusion. Quantification of SPECT imaging enables absolute measurement of perfusion defects. The aim of this experimental study is to assess quantitative accuracy and precision of a novel iterative reconstruction technique (Evolution; GE Healthcare, Milwaukee, USA) for the potential application of response monitoring using $^{99\text{m}}\text{Tc}$ -tetrofosmin SPECT/CT in patients with coronary artery disease (CAD). **Materials and Methods:** Acquisitions of an anthropomorphic torso phantom, with cardiac insert containing defects (with varying sizes) filled with $^{99\text{m}}\text{Tc}$ -pertechnetate, were performed on a SPECT/CT camera (Discovery 670 Pro, GE Healthcare). Subsequently, volumes-of-interest of the defects were manually drawn on CT to assess the recovery coefficient (RC). Bull's eye plots were composed to evaluate the uptake per segment. Finally, $^{99\text{m}}\text{Tc}$ -tetrofosmin SPECT/CT scans of 10 CAD patients were collected retrospectively before and after bone marrow cell (BMC) injection and used as a patient feasibility study to illustrate and test Evolution for clinical application. **Results:** The phantom study showed that the activity concentration converged after seven iterations (ten subsets). The average repeatability deviation of all configurations was 2.91% and 3.15% (%SD mean) for filtered (Butterworth) and unfiltered data, respectively. The accuracy after post-filtering was lower compared to the unfiltered data with a mean(SD) RC of 0.63(0.05) and 0.70(0.07), respectively ($p < 0.05$). More artificial defects were found on Bull's eye plots created with the unfiltered data compared to filtered data. Eight out of ten patients showed significant changes in uptake before and after BMC injection ($p < 0.05$). The median time between the SPECT/CT scans before and after BMC injection was 9 months. **Conclusion:** In a phantom study, it was demonstrated that absolute quantification of $^{99\text{m}}\text{Tc}$ -tetrofosmin SPECT/CT is feasible, when seven iterations (ten subsets), Butterworth post-filtering (cut off frequency 0.52 in cycles/cm, power 5) and manual delineation on CT images are applied. To show sufficient evidence for the use of Evolution in clinical practice for treatment response monitoring, validation should take place in a future clinical study. **References:** None

OP-033

Effect of Respiratory Motion on Dosimetric Measurements for $^{99\text{m}}\text{Tc}$ -MAA SPECT/CT

Z. Lu, G. Mok;

Biomedical Imaging Laboratory (BIG), Department of Electrical and Computer Engineering, Faculty of Science and Technology, University of Macau, Taipa, MACAO.

Aim/Introduction: Respiratory motion compromises $^{99\text{m}}\text{Tc}$ -MAA SPECT image quality and quantitation accuracy especially near the diaphragmatic region [1]. This study aims to systematically investigate the effect of breathing motion on lung shunt fraction (LSF), tumor-to-normal liver ratio (TNR), injected activity (IA) and absorbed dose estimation in $^{99\text{m}}\text{Tc}$ -MAA SPECT/CT for $^{90\text{Y}}$ microsphere radioembolization treatment planning. **Materials and Methods:** The 4D extended cardiac torso (XCAT) phantom was used to simulate a phantom population of 72 phantoms, modelling 6 different anatomies, 2 TNRs (8.2 and 13), 2 tumor sizes (3.0 and 4.5 cm diameter), 4 tumor locations and 3 axial/anterior-posterior motion amplitudes of 1/0.6, 2/1.2 and 3/1.8 (cm), mimicking $^{99\text{m}}\text{Tc}$ -MAA distribution with LSF of 5%, 10% and 15%. Phantoms with no motion were also generated for reference. An analytical projector for low energy high resolution parallel-hole collimator was used to simulate 128 projections over 360° for SPECT, modeling attenuation, scatter and geometric collimator-detector-response (GCDR). The OS-EM algorithm was employed for image reconstruction with 4 iterations and 16 subsets with attenuation correction using averaged attenuation map, effective source scatter estimation and GCDR modelling. The volumes-of-interest (VOIs) for liver, lungs and tumor were mapped out from the reconstructed images based on the original phantom organ maps. The LSF, TNR, IA, absorbed dose of normal liver, tumor and lungs were calculated based on the measured counts from different VOIs and the partition model [2]. **Results:** Generally, along with the increase of breathing motion amplitude, the absolute errors of LSF, TNR, IA and absorbed dose increase. The LSF and lung dose are overestimated while TNR and tumor dose are underestimated due to the respiratory motion. Larger LSF errors associate with tumors located closer to the lung-liver interface while larger TNR errors associate with smaller tumor size and higher TNR due to respiration. For axial respiratory motion of 2 cm and LSF of 10%, the mean errors of LSF, TNR, IA, absorbed dose of normal liver, tumor and lungs are $69.8 \pm 8.2\%$, $-27.0 \pm 7.1\%$, $-12.7 \pm 10.4\%$, $-2.3 \pm 2.5\%$, $-28.6 \pm 8.3\%$ and $69.8 \pm 8.2\%$, respectively. **Conclusion:** Respiration motion has a strong impact for $^{99\text{m}}\text{Tc}$ -MAA SPECT/CT based dosimetry and may change the patient management due to overestimation of LSF and underestimated IA may lead to under treatment. Further studies to minimize the impact of respiration on $^{99\text{m}}\text{Tc}$ -MAA SPECT/CT are warranted. **References:** [1] Bastiaannet R, et al. Medical Physics. 2017;44(10):5270-9. Aim/Introduction: The aim of the study was to compare relative quantitation accuracy of the routine whole-body imaging protocols in Finnish PET centers. **Materials and Methods:** To avoid re-filling the phantom in every center, a NEMA-2018-IQ phantom with Ge-68 was utilized, including six hot spheres with diameters of 10, 13, 17, 22, 28 and 37 mm with a concentration ratio of 4:1 to background. During five months period, the phantom was imaged in 11 PET centers with altogether 14 PET-CT scanners, including analog and digital systems from two major vendors. In every center, the local clinical imaging protocol for the whole body F-18-FDG studies was used. The imaging time was adjusted according to the average activity concentration of the phantom in the imaging day, varying from 3.2 to 2.1 MBq/kg, and the patient activity concentration as well as the patient resting and imaging times used in the particular center. In every scanning session, PET imaging was repeated 20 times, except for one scanner with 10 repetitions. In addition, for one scanner, the scanning sessions were repeated five times during 5.5 months. The peak, mean and max activity concentrations were measured from the 20 images and divided by the known activity concentration of the hot spheres. The results from the 20 repetitions were then averaged. The average values for different scanners were compared. Also, the standard deviations from the five scanning sessions of the

same scanner were compared to the standard deviations for the 14 different scanners. **Results:** Measurements from one scanner produced unexplainable high concentration values and were excluded from the further comparisons for now. The minimum-maximum results for the peak activity concentration ratios for hot spheres with radius of 10, 13, 17, 22, 28 and 37 mm were 0.35-0.48, 0.47-0.68, 0.58-0.89, 0.74-0.99, 0.85-1.02 and 0.93-1.04, respectively. The corresponding mean value ratios were 0.27-0.49, 0.39-0.68, 0.49-0.79, 0.59-0.85, 0.68-0.86 and 0.74-0.89, and max value ratios 0.43-0.77, 0.60-1.03, 0.76-1.22, 0.86-1.32, 0.99-1.36 and 1.08-1.43. The same scanner standard deviations for different spheres resulted in 0.02-0.06, 0.01-0.01 and 0.01-0.02 for the peak, mean and max value ratios. As expected, the different scanner standard deviations were clearly bigger, 0.03-0.09, 0.04-0.09 and 0.11-0.14. **Conclusion:** According to these results, 30 % difference in quantitation of activity concentrations of relatively small lesions can occur depending on the imaging site. The peak activity concentration value seemed to give more accurate concentration results than the mean and max values. **References:** None

OP-035**Application of a novel image-based partial volume correction method on a multi-reconstructed phantom**

N. Cole, *S. Lindler*, *K. Krawiec*, *P. Wilson*, *D. Nelson*, *J. Sunderland*, *A. S. Nelson*;
 MIM Software, Cleveland, OH, UNITED STATES OF AMERICA.

Aim/Introduction: Quantification of images can be heavily impacted by the resolution of the imaging system used. This is notably demonstrated with the partial volume effect (PVE) which causes an apparent decrease in activity in small regions of interest (ROI) due to a reduced system resolution. With resolution quality varying across cameras, reconstructions, institutions, and exam types, it is imperative to develop a partial volume correction (PVC) method that can correct PVE across a range of image resolutions. The aim of this study was to evaluate the performance of a novel image-based PVC method that uses system resolution to correct a phantom image reconstructed with multiple resolutions and varying degrees of PVE with known full-width-half-max (FWHM) values (Radial/Axial values ranging from 4.4/6 to 10.7/8.8 and 5/5 to 10/10). **Materials and Methods:** The SNMMI CTN oncology PET phantom containing twelve spheres of varying diameters (7 - 37mm) was acquired using a GE Discovery MI PET/CT system. Thirty reconstructions were created with various iterations, subsets, and smoothing filters. The image-based PVC method utilized known resolution values for each reconstruction parameter set to model the “spill-in” and “spill-out” of counts from each source and the background repeating over an optimized 4 iterations to correct the PVE. Spheres were segmented with the known sphere size (GS) and a clinically-used hybrid intensity and gradient-based

segmentation method (Hybrid). Mean activity (Bq/ml) was calculated for each ROI before and after PVC, then compared to measured activity. **Results:** Measured activity in each sphere was 25897 Bq/ml. Mean activity across all sphere sizes without PVC was 14818.9 ± 4966 Bq/ml and 15355.1 ± 4296 Bq/ml, yielding errors of 42.8% and 41.3% for the GS and Hybrid ROIs respectively. With PVC, mean activity was 20450.8 ± 3623 Bq/ml and 22584.7 ± 5235 Bq/ml reducing the error to 21.1% (GS) and 20.8% (Hybrid). This reflects an error reduction from 20% to 8.5% for 37mm spheres and 72.9% to 48.3% for 7mm spheres using the GS ROIs. Using Hybrid ROIs, the error was reduced from 22.8% to 12.1% for 37mm spheres and 71.7% to 47.1% for 7mm spheres. **Conclusion:** The image-based PVC method consistently improved activity quantification across a range of resolutions by iteratively modeling the PVE; accounting for a known resolution. This method significantly reduced errors for small volumes which can lead to improved accuracy in image analysis and treatment planning. **References:** Wan, H. et al. OP-036

Tracer effect on partial volume correction of Brain PET/MR imaging

E. Balci¹, Ü. Akdemir², L. Ö. Atay²,

¹Gazi University Medical Faculty Department of Nuclear Medicine, Ankara, TURKEY, ²Gazi University Medical Faculty Department of Nuclear Medicine, Ankara, TURKEY.

Aim/Introduction: Partial volume effect correction (PVEc) is very important in PET brain imaging in terms of getting regionally accurate tracer uptake values. In this study, regional tracer uptake values from metabolic and amyloid brain PET/MR imaging data that were obtained with/without PVEc (no-PVEc) were compared in the same group of patients with clinically suspected Alzheimer's disease (AD). **Materials and Methods:** Fourteen patients with clinically suspected AD were included in the neurodegenerative group (NG) and 44 subjects as control group (CG) in the study. The tracers used were (F¹⁸)fluorodeoxyglucose and (F¹⁸)flutemetamol, respectively, for the metabolic and amyloid PET/MR scans in the NG. Only metabolic PET/MR imaging was performed in the CG. Segmentation of T1-weighted brain MRI images and its co-registration with PET was done with the FreeSurfer software. PVEc was applied using the Müller-Gärtner method in the PetSurfer code. The total uptake values from PVEc/no-PVEc PET images were recorded using 93 anatomical regions covering the cortical-gray-matter (GM) regions, subcortical-GM structures, and white-matter (WM) regions. The percent change of values from no-PVEc to PVEc PET images were calculated by the formula: $(PVEc-(no-PVEc))/(no-PVEc)$. **Results:** Regional uptake values were increased by an average of 32% when PVEc was applied to the metabolic PET images in the NG patients. The highest increase was observed in the pericalcarine-transverse temporal in cortex-GM regions

and the putamen-caudate-nucleus-accumbens areas while WM uptake values decreased. The results observed in the CG were similar. For the amyloid PET images the change in regional uptake values were heterogenous: While the cortical GM regions showed an average increase of uptake by 10% when PVEc was applied in 11 subjects with visually positive amyloid PET scans; the cortical uptake of amyloid tracer was decreased with PVEc in three patients with visually negative amyloid PET scans. For amyloid PET imaging, the uptake in WM regions increased and the subcortical GM structures showed a similar trend with the cortex. **Conclusion:** The effects of PVEc on regional uptake values were higher in metabolic PET imaging than amyloid PET imaging. In the metabolic PET imaging, the total counts in cortical GM regions were increased with PVEc. However, the changes observed in the amyloid PET data were dependent on the amyloid positivity of the patients. While increasing the quantitative accuracy of data analysis, the opposite effects of PVEc observed in amyloid PET according to the amyloid positivity can be useful terms of classification of amyloid PET images. **References:** None

Effect of temporal sampling on myocardial blood flow measurements using Rubidium-82 PET

S. Koenders^{1,2}, J. D. van Dijk¹, P. L. Jager¹, M. Mouden³, C. H. Slump², A. G. Tegelaar¹, J. A. van Dalen⁴;

¹Isala Hospital, Department of Nuclear Medicine, Zwolle, NETHERLANDS, ²Technical Medical Center, University of Twente, Enschede, NETHERLANDS, ³Isala Hospital, Department of Cardiology, Zwolle, NETHERLANDS, ⁴Isala Hospital, Department of Medical Physics, Zwolle, NETHERLANDS.

Aim/Introduction: Myocardial blood flow (MBF) quantification is increasingly used when performing myocardial perfusion imaging (MPI) using Rubidium-82 (Rb-82) PET. This has resulted in a wide variety of temporal sampling protocols applied in dynamic imaging. Both the length and number of time-frames in the temporal sampling protocol may influence the time-activity curves and may therefore alter MBF and myocardial flow reserve (MFR) measurements. To be able to use and interpret MBF and MFR values interchangeably between different sites, it is important to know the effect of temporal sampling on MBF and MFR measurements. Our aim was to assess the effect of different clinically used temporal sampling protocols on MBF and MFR measurements. **Materials and Methods:** First, we performed a literature search to find all clinically applied Rb-82 temporal sampling protocols. Next, we retrospectively included 20 consecutive patients referred for rest and regadenoson-induced stress MPI using Rb-82 PET (Discovery 690, GE Healthcare). The Rb-82 PET data were acquired and then reconstructed with the different temporal sampling protocols. Using the one-tissue compartment model of Lortie et al., rest and stress MBF and

MFR were calculated for all protocols and compared to the reference protocol with 26 time-frames (24x5s, 2x120s). **Results:** After screening 103 articles with potential protocols, we included 14 different temporal sampling protocols using: 14 frames (9x10s, 3x30s, 1x60s, 1x120s), 16 frames (12x10s, 2x30s, 1x60s, 1x120s), 18 frames (1x10s, 8x5s, 3x10s, 2x20s, 4x60s), 20 frames (12x8s, 5x12s, 1x30s, 1x60s, 1x120s), 22 frames (18x10s, 4x60s), 23 frames (15x6s, 5x12s, 1x30s, 1x60s, 1x120s), 26 frames (A:12x5s, 6x10s, 4x20s, 4x40s and B:18x5s, 6x15s, 1x120s, 1x60s), 27 frames (A:20x6s, 4x30s, 3x60s and B:14x5s, 6x10s, 3x20s, 3x30s, 1x90s), 30 frames (16x5s, 6x10s, 3x20s, 4x30s, 1x80s), 31 frames (20x6s, 5x12s, 4x30s, 2x60s), 32 frames (24x5s, 8x30s) and 48 frames (36x5s, 8x15s, 4x30s). Rest and stress MBF measurements differed in six (43%) temporal sampling protocols as compared to the reference protocol ($p < 0.01$): the protocols using 22 frames, 27A, 30, 31, 32 and 48 frames. In addition, differences were found for rest MBF using 18 frames ($p = 0.007$) and for stress MBF using the 26A frames ($p = 0.006$). None of the tested protocols showed a significant difference in MFR. **Conclusion:** Different temporal sampling protocols result in different stress and rest MBF values. Therefore, temporal sampling protocols cannot be used interchangeably when considering MBF but can be used interchangeably when solely comparing MFR values. **References:** None

OP-038

Estimating Input Function with Incomplete Blood Samples for Quantification of Nonhuman Primate Dynamic F-18-FDG PET/CT Using a Patlak Plot-based Optimization Method

R. Wang^{1,2}, S. Zhang¹, X. Chen¹, J. Zhang¹, L. Chen¹, Y. Zhou³;

¹Peking University First Hospital, Beijing, CHINA, ²Peking University International Hospital, Beijing, CHINA, ³Washington University School of Medicine, St Louis, MO, UNITED STATES OF AMERICA.

Aim/Introduction: FDG uptake rate constant K_1 is a main physiology parameter measured by dynamic PET study. A model-independent graphical analysis using Patlak plot with plasma input function is a standard approach used to estimate K_1 . The plasma input function is the FDG time activity curve in plasma obtained by arterial blood sampling. The purpose of the study is to evaluate a Patlak plot-based optimization approach for noninvasive quantification of dynamic FDG PET. **Materials and Methods:** Eight 60-min monkey dynamic FDG PET studies with arterial blood samples were collected. The measured plasma input function (mPIF) was determined by arterial blood samples. Time activity curves of seven cerebral regions of interest were generated from each study. With a given number of blood samples, the estimated PIF (ePIF) was determined by either interpolation or extrapolation method using scale calibrated population mean of normalized PIF. The optimal time points for those blood samples to estimate PIF (ePIF) was determined by maximizing the correlations

between the K_1 estimated ePIF and ones estimated mPIF. A leave-two-out cross-validation method was used for evaluation. **Results:** The linear correlations between the K_1 estimates from ePIF with optimal sampling schemes and those from measured PIF were: K_1 (ePIF 1 sample) = 1.09 K_1 (mPIF) - 0.00, $R^2 = 0.95 \pm 0.08$; K_1 (ePIF 2 samples) = 1.09 K_1 (mPIF) - 0.00, $R^2 = 0.95 \pm 0.07$; K_1 (ePIF 3 samples) = 1.04 K_1 (mPIF) - 0.00, $R^2 = 0.96 \pm 0.05$; and K_1 (ePIF 4 samples) = 1.02 K_1 (mPIF) - 0.00, $R^2 = 0.97 \pm 0.04$. As sample size became greater or equal 4, the K_1 estimates from ePIF with optimal protocol were almost identical to those from mPIF. **Conclusion:** The Patlak plot-based optimization approach is a robust method to estimate plasma input function for noninvasive quantification of non-human primate dynamic FDG PET. **References:** None

OP-039

Investigation of Optimal Beta Value with Frame Duration for PET Bayesian Penalized-Likelihood Reconstructions

S. Jewitt¹, M. D. Walker¹, D. R. McGowan^{1,2};

¹Oxford University Hospitals NHS FT, Oxford, UNITED KINGDOM,

²University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: This research aims to assess how the optimal penalization factor (beta) in a Bayesian penalized-likelihood (BPL) PET reconstruction algorithm (Q.Clear) varies with frame duration. The results of the investigation will be used to determine the impact of gating on the optimal beta value. **Materials and Methods:** A solid Ge-68 phantom containing 7 hot spheres in a low activity concentration background was scanned in list-mode on a time-of-flight PET/CT scanner (GE Discovery 710) and reconstructed using ordered-subset expectation maximisation (OSEM) and BPL. The ratio of the activity concentration in the spheres to the background was approximately 4:1. The acquisition was retrospectively rebinned with frame durations from 10 seconds to 10 minutes. For each of these frame durations, 10 independent repeats were reconstructed. Contrast recovery (CR) and background variability (BV) were calculated for each dataset as per the NEMA 2001 protocol, but using volumes-of-interest rather than regions-of-interest. The contrast to noise ratio (CNR=CR/BV) for each hot sphere was calculated and compared as a function of beta value and frame duration. The average CNR was calculated from the 10 repeats. The beta value that resulted in the highest average CNR was taken to be the optimal beta value for a given frame duration. A paired t-test was used to determine if there was a significant difference ($p < 0.05$) in the optimal beta value for acquisitions with different frame durations. **Results:** A preliminary analysis of the BPL reconstructions with beta values of 500, 1000, 1500, 2000 and 3000; and frame durations of 30 seconds and 3 minutes, was performed. For the 3 minute and 30 second acquisitions the optimal beta was found to be around 1000 and 2000 respectively. For the 30 second acquisitions there was a significant difference in

CNR for all sphere sizes when comparing CNRs for beta of 2000 vs. 1000 ($p < 0.001$). This indicates that the optimal beta for a 30-second and a 3-minute acquisition is different. Work is ongoing to determine the optimal beta value for a range of frame durations from 10 seconds to 10 minutes. **Conclusion:** Preliminary results indicate that the optimal beta value varies with frame duration. Shorter frame durations produce noisier data and therefore require a higher beta value to maximize the CNR, providing better image quality and improved detection of small lesions. The results can be applied to gated PET acquisitions to optimise the image quality. **References:** None

Impact of PSMA PET/CT on SRT planning: Preliminary results from a randomized phase III trial

J. Calais, W. R. Armstrong, A. U. Kishan, K. M. Booker, J. Czernin, N.

G. Nickols;

UCLA, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: The purpose of this trial is to evaluate the success rate of salvage radiotherapy (SRT) for recurrent prostate cancer after prostatectomy with versus without planning based on PSMA PET. **Materials and Methods:** This is a Randomized, controlled, prospective, open label, phase 3 clinical trial with institutional funding. 193 patients are randomized to proceed with standard SRT allowing for any conventional imaging aside from PSMA PET/CT (control arm 1) or undergo a ^{68}Ga -PSMA-11 PET/CT scan prior to SRT planning (investigational arm 2). The primary endpoint is the success rate of SRT measured as biochemical progression-free survival (PFS) at 5 years. We hypothesized that the incorporation of PSMA PET to SRT planning will improve 5-year PFS survival by 20%: 60% in Arm 1 and 80% in Arm 2. We report here the preliminary results of the impact of PSMA PET on SRT planning by comparing the pre-randomization RT plans prospectively obtained on surveys to the actually delivered RT plans. **Results:** 153 patients were enrolled from 09.06.2018 to 01.24.2020. 7/75 patients (9%) in the control arm dropped-out the study to undergo a PSMA PET at another institution. After a median follow-up of 10.6 months delivered RT plans were obtained in 44/68(65%) and 50/78(64%) of patients of the control and the PSMA arms, respectively. In these, median PSA at enrollment was 0.42 ng/ml (IQR 0.20-1.75) in the control arm and 0.22 ng/ml (IQR 0.13-0.59) in the PSMA arm. PSMA PET was positive in 24/50(48%): 5/50(10%) showed prostate cancer outside of the pelvis, 12/50(24%) in pelvic nodes and 8/50(16%) in the prostate bed only. There was a change between the intended pre-randomization RT plan and the actually delivered RT plan in 28/50(56%) and 14/44(32%) of the patients in the PSMA arm and the control arm, respectively ($p=0.019$). SRT was aborted in favor of systemic therapy and/or metastasis directed RT for extra-pelvic M1 disease in 4/50(8%) of the PSMA arm vs. 1/44(2%) in the control arm ($p=0.21$). Dose prescription and/or target volume delineation was changed in 14/50(28%) in the PSMA arm vs. 3/44(7%) in the control arm ($p=0.008$). **Conclusion:** In this prospective randomized phase 3 study, PSMA PET had an impact on the RT plan in more than half of the patients. Notably, 8% of PSMA PET patients did not undergo SRT because the scan revealed extra-pelvic metastases. Long-term follow-up will show if the impact of PSMA PET on SRT planning improves PFS. **References:** None

OP-045**Urokinase Plasminogen Activator Receptor (uPAR) PET/ MRI of Prostate Cancer for Non-invasive Evaluation of Aggressiveness: a Prospective Phase II Clinical Trial Comparing with Gleason Score**

M. Fosbøl, S. Kurbegovic, H. H. Johannesen, M. A. Røder, A. E. Hansen, J. Mortensen, A. Loft, P. M. Petersen, J. Madsen, K. Brasso, A. Kjaer;
Rigshospitalet, Copenhagen, DENMARK.

Aim/Introduction: Overexpression of urokinase-type plasminogen activator receptor (uPAR) is an important biomarker for aggressiveness in prostate cancer. uPAR expression can now be imaged and non-invasively quantified by using the novel positron emission tomography (PET) ligand ^{68}Ga -NOTA-AE105. The aim of this study was to evaluate the correlation between uptake of uPAR ligand and Gleason score in patients undergoing prostate biopsy. **Materials and Methods:** Patients with clinical suspicion of prostate cancer (PCa) or previously diagnosed with PCa were prospectively enrolled in this phase II trial. A combined uPAR PET, multiparametric magnetic resonance imaging (mpMRI) was performed and standardized uptake value (SUV) from primary tumor, as delineated by mpMRI, was measured by two independent readers. Correlation between SUV_{max} and Gleason score obtained by biopsy was assessed. **Results:** A total of 27 patients had histologically verified PCa visible on mpMRI and constituted the study population. There was a positive correlation between SUV_{max} and Gleason score (Spearman's $\rho=0.55$; $p=0.003$). Receiver operating characteristics (ROC) analysis showed an area under the curve (AUC) of 0.88 (95%CI: 0.67-1.00) in discriminating Gleason score $\geq 3+4$ from $\leq 3+3$. A cut-off for tumor SUV_{max} could be established with a sensitivity of 96% (79-99%) and specificity of 75% (30-95%) in detecting Gleason Scores $\geq 3+4$. For discriminating Gleason score $\geq 4+3$ vs. $\leq 3+4$, a cut-off could be established for detecting Gleason score $\geq 4+3$ with a sensitivity of 93% (69-99%) and specificity of 62% (36-82%). **Conclusion:** SUV measurements from uPAR PET in primary tumors as delineated by mpMRI showed a significant correlation with Gleason score, and tumor SUV_{max} was able to discriminate between low-risk and intermediate risk Gleason score profiles with high diagnostic accuracy. Consequently, uPAR PET/MRI could be a promising method for non-invasive evaluation of PCa, which may in the future potentially reduce the need for repeated biopsies, e.g. in active surveillance. **References:** None

OP-046**Prospective study on PSMA flare phenomenon after androgen deprivation therapy evaluated with ^{18}F -PSMA-1007 PET/CT in treatment naïve metastatic prostate cancer: any link to glucose metabolism?**

S. Malaspina¹, O. Ettala², T. Tolvanen³, S. Forsback¹, P. J. Boström², J. Kemppainen¹;
¹Turku PET Centre, University of Turku and Turku University Hospital, Turku, FINLAND, ²Department of Urology, University of Turku and Turku University Hospital, Turku, FINLAND, ³Department of Medical Physics and Turku PET Centre, University of Turku and Turku University Hospital, Turku, FINLAND.

Aim/Introduction: Our previous clinical trial demonstrated that short-term androgen deprivation therapy (ADT) increases heterogeneously PSMA-uptake in hormone-sensitive prostate cancer (Pca). This PSMA-flare phenomenon needs validation, since possible factors associated with it remain unknown. We hypothesize that lesions having PSMA-flare might have a different potential to respond to ADT or progress. This prospective trial aims to validate our previous results and to observe whether FDG-PET might provide additional molecular imaging information, given that aggressive Pca tends to display FDG-uptake. **Materials and Methods:** This prospective, registered (NCT03876912), single-centre trial enrolls patients with newly diagnosed metastatic Pca, that undergo ^{18}F -PSMA-1007 PET/CT before and 3-4 weeks after the initiation of Degarelix. At baseline, ^{18}F -FDG PET/CT is also performed. SUV_{max} on primary tumor and metastatic lesions is calculated. The increase, decrease or no-change of PSMA-uptake after ADT is represented as $\Delta\text{SUV}_{\text{max}}\%$. **Results:** To date, 8 patients (mean age: 71 years, median PSA: 59 ng/ml, range 8-130) completed all PET/CT scans. All patients reached castration levels (s-testo $<1.7\text{nmol/L}$) before the second PSMA PET/CT scan, performed with a 21-days median interval (range 17-31) after initiation of ADT. One patient had bone-only, one nodal-only and six bone and nodal metastases. In total 159 bone metastases, 53 lymph nodes (LN) and 12 prostate lesions were analysed. Out of the total, 116/224 (52%) lesions were FDG-positive. After ADT, 90/159 (57%) bone, 10/53 (19%) LN and 2/12 (17%) prostate lesions showed an increase of PSMA-uptake, with a median $\Delta\text{SUV}_{\text{max}}\%$ of 47% (range 11-136), 33% (range 14-172) and 28% (range 14-43), respectively. The remaining lesions showed either a decrease or no-change ($\Delta\text{SUV}_{\text{max}} \pm 10\%$) of PSMA-uptake. According to lesions presenting PSMA-flare, 50/90 (56%) bone, 4/10 (40%) LN and 1/2 (50%) prostate lesions were FDG-positive (median FDG- SUV_{max} : 4.8). Out of the lesions presenting decrease of PSMA-uptake, 30/54 (56%) bone, 16/41 (39%) LN and 5/9 (56%) prostate lesions showed FDG-uptake (median FDG- SUV_{max} : 9.8). **Conclusion:** These preliminary results confirmed a heterogeneous increase of PSMA-uptake after ADT, most evidently seen in bone metastases. It appears that this phenomenon is not associated with glucose metabolism.

Nevertheless, the lowest FDG-uptake was observed in lesions that presented with PSMA-flare, suggesting that these lesions might potentially be less aggressive and have a better response to ADT. **References:** Ettala et al. Prospective study on the effect of short-term androgen deprivation therapy on PSMA uptake evaluated with ^{68}Ga -PSMA-11 PET/MRI in men with treatment-naïve prostate cancer. *Eur J Nucl Med Mol Imaging*. 2020; 47(3): 665-673.

OP-047

Predictors of Intertumoral Heterogeneity of ^{18}F -FDG and ^{68}Ga -PSMA Uptake in Patients with Prostate Cancer

T. Telli, M. Tuncel, M. Caglar;

Hacettepe University Faculty of Medicine, Ankara, TURKEY.

Aim/Introduction: ^{68}Ga -PSMA PET/CT plays a pivotal role in patients with prostate cancer. It changes treatment plans and guides new therapy options. Although the sensitivity of PSMA PET is higher than other PET tracers, FDG PET/CT may detect PSMA-negative disease, in patients with metastatic castration-resistant prostate cancer (mCRPC) and change treatment decisions. The study aims, to evaluate baseline clinical, biochemical, ^{68}Ga -PSMA PET-related parameters that can predict patients in whom FDG PET showed additional lesions when compared to ^{68}Ga -PSMA PET/CT (FDG > ^{68}Ga -PSMA). **Materials and Methods:** Sixty-three patients with mCRPCa who underwent both FDG and ^{68}Ga -PSMA PET/CT within two months were evaluated. The number and SUVmax of metastatic foci, total lesion-PSMA (TL-PSMA), total tumor volume-PSMA (TV-PSMA) were calculated. Patients' clinical parameters, sites of metastases, performance status, and bone pain score (VAS) were recorded. Baseline laboratory tests including PSA kinetics, complete blood counts, serum liver and kidney function tests, neuron-specific enolase (NSE), carcinoembryonic-antigen (CEA), lactate dehydrogenase (LDH), alkaline phosphatase (ALP), C-reactive-protein (CRP), and erythrocyte sedimentation rate (ESR) results were correlated with PET results. Based on FDG and ^{68}Ga -PSMA PET/CT images, patients were grouped into two categories: patients who had FDG PET/CT avid but ^{68}Ga -PSMA negative lesion (FDG > ^{68}Ga -PSMA) and patients who had same or more number of lesions on PSMA PET compared to FDG PET (^{68}Ga -PSMA \geq FDG). Variables associated with FDG > ^{68}Ga -PSMA disease were investigated using logistic regression analysis. **Results:** 25/63 (39,7%) patients had FDG > ^{68}Ga -PSMA disease. Discordant lesions were present in the bones (20/25), lymph nodes (12/25), liver (11/25), lung (2/25), pancreas (1/25). Five patients showed discordance in the local disease of the prostate, bladder wall, or seminal vesicles. Univariate analysis revealed that stage at the diagnosis (stage4b), higher ECOG, lower Karnofsky PS, higher pain score, not using 2nd generation anti-androgen therapy, higher baseline LDH, ESR, AST, GGT values, lower baseline hemoglobin (Hb) and visceral metastases were potential predictive factors for FDG > ^{68}Ga -

PSMA disease. On multivariate analysis, elevated AST (p: 0,012, RR: 1,145, CI: 1,056-1,26) and presence of visceral metastases (p: 0,02, RR: 33,479, CI: 1,833-611,5) were significant for predicting FDG > ^{68}Ga -PSMA disease. **Conclusion:** In patients with mCRPC, increased incidence of PSMA negative disease may have both diagnostic and therapeutic consequences. Our findings showed that patients with poor health performance and advanced disease on PSMA PET, especially with visceral metastases, may benefit from additional imaging like FDG PET. **References:** None

¹IRCCS Ospedale Policlinico San Martino, Genova, ITALY, ²Spedali Civili of Brescia and University of Brescia, Brescia, ITALY, ³Nuclear Medicine, AUSL-IRCCS of Reggio Emilia, Reggio Emilia, ITALY, ⁴Department of Biomedical and Dental Sciences and of Morpho-functional Imaging, University of Messina, Messina, ITALY.

Aim/Introduction: In the last years, the therapeutic strategy for metastatic castration-resistant prostate cancer (mCRPC) radically changed due to improved knowledge of PC biology and progression mechanisms. However, clinicians presently face critical therapeutic challenges mainly related to the choice of the best treatment sequencing for each specific patient. In this scenario, there is an urgent need for the identification of reliable biomarkers to early and non-invasively determine treatment efficacy (possibly improving patients' selection). ^{18}F -Fluorodeoxyglucose (FDG)-avidity is low in naïve prostate cancer, but it is enhanced in advanced mCRPC, providing prognostic insights. We thus aimed to verify whether the prognostic power of FDG PET/CT extends to the estimation of systemic treatment response duration in mCRPC. **Materials and Methods:** We conducted a retrospective review of mCRPC patients who were submitted to FDG PET/CT for prognostic purposes in four Italian centers from 2005 to 2020. Patient's age, Gleason Score (GS), prostate-specific antigen (PSA), Lactate dehydrogenase (LDH), and Alkaline Phosphatase (AP) at the time of imaging were collected. From PET/CT images SUVmax of the hottest lesion, total metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were computed. The correlation between PET- and biochemical-derived parameters with Overall Survival (OS) was calculated by Kaplan-Meier, univariate and multivariate analyses. The prediction of duration of treatment response was also assessed in the subgroup submitted to FDG imaging before systemic therapy administration. **Results:** We enrolled 116 mCRPC patients clinically followed-up for a median

interval lasting seven months. PSA, MTV, and TLG significantly predicted long term OS in this cohort ($p < 0.01$). Moreover, PSA and TLG evaluation of baseline metabolically active disease were able to predict OS with an additive independent value, as documented by multivariate Cox regression analysis, even after adjusting for patient's age, GS, LDH, and AP. When FDG imaging was performed at baseline before systemic treatment administration (40 patients), only MTV and TLG were able to significantly and independently predict therapy response duration ($p < 0.01$ in either chemotherapy or Androgen Receptor-Targeted Agents treatment subgroups). **Conclusion:** FDG PET/CT imaging provides robust prognostic insights in hormone-refractory prostate cancer. This prognostic power may predict treatment response duration when FDG imaging is performed before systemic treatment administration. Prospective studies are needed to verify whether PET-derived parameters may also improve the selection of systemic treatment. **References:** None

⁶⁸Ga- PSMA PET/CT on Local Disease Detection: The Added Value of Early Dynamic Imaging After Radical Prostatectomy

M. Monteiro¹, R. Silva^{1,2}, T. Saraiva¹, G. Costa^{1,3}, J. Pedroso de Lima^{1,2,3};

¹Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL, ²Instituto de Ciências Nucleares Aplicadas à Saúde (ICNAS), Coimbra, PORTUGAL, ³Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: ⁶⁸Ga-labelled prostate-specific membrane antigen positron emission tomography/computed tomography (⁶⁸Ga-PSMA PET/CT) is a non-invasive diagnostic technique to image prostate cancer with increased PSMA expression. Bladder activity may hinder local disease detection, particularly in patients submitted to prostatectomy. To overcome this limitation, some authors recommend early dynamic imaging of the pelvis. In this retrospective work, we aim to assess the added value of early dynamic imaging on local disease detection, when compared to whole body PET/CT only. **Materials and Methods:** A total of 229 ⁶⁸Ga-PSMA PET/CT scans, performed between April 2019 and March 2020, were reviewed. All prostate cancer patients submitted to radical prostatectomy who performed early dynamic imaging of the pelvis (4 min dynamic acquisition starting immediately after injection) and whole body PET/CT were selected and two databases were created after anonymization. Database A: including only whole body PET/CT scans; Database B: including dynamic images of the pelvis and whole body PET/CT scans. All scans were reviewed and patients were categorized in each database as: 1-negative for local disease; 2-positive for local disease; 3-doubtful for local disease. All relevant demographic and clinical data was recorded (when available), such as PSA values and tumor characteristics.

Statistical analysis was performed using SPSS version 25.0. **Results:** Seventy-nine patients were included (age: 71.3 ± 6.4 years, 53–85). Median PSA was 0.66 (interquartile amplitude = 1.66; 0.00–5060.60). In database A 62 patients (78.5%) were categorized as negative, 9 (11.4%) as positive and 8 (10.1%) as doubtful for local disease. While in database B 58 patients (73.4%) were categorized as negative, 19 (24.1%) as positive and 2 (2.5%) as doubtful for local disease. Thus, with dynamic imaging 9 patients previously categorized as negative were re-categorized either as positive (7) or doubtful (2) for local disease, and all 8 patients previously categorized as doubtful were re-categorized either as negative (5) or as positive (3) for local disease. No change was recorded for patients categorized as positive for local disease in Database A. A statistically significant difference in patient categorization between databases was found (McNemar, $p < 0.01$). **Conclusion:** Early dynamic imaging altered local disease detection in ⁶⁸Ga-PSMA PET/CT, in a statistically significant manner, by increasing positive findings and decreasing doubtful results. Remarkably, dynamic imaging had no effect on positive whole body ⁶⁸Ga-PSMA PET/CT results. **References:** None

Bone marrow expansion in patients with prostate cancer bone metastases: prognostic role and correlation with tumour load, based on ¹⁸F-FDG PET/CT segmentation analysis

F. Fizz¹, M. Bauckneht², S. Morbelli², A. Miceli³, I. Donegani³, C. Campi⁴, M. Piana⁵, G. Sambucetti²;

¹Humanitas Clinical and Research Center - IRCCS, Milan, ITALY, ²IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, ³University of Genoa, Genoa, ITALY, ⁴Dipartimento di Matematica "Tullio Levi-Civita", Università di Padova, Padua, ITALY, ⁵Department of Mathematics, University of Genoa, Genoa, ITALY.

Aim/Introduction: Bone marrow (BM) failure is a major cause of morbidity and mortality in patients affected by metastatic, castration-resistant prostate cancer (mCRPC). Bone metastases from mCRPC seed into the axial skeleton preferentially, thus reducing the space available for normal BM. We hypothesized that this phenomenon could cause an increase of active BM in the peripheral skeleton and that BM relocation has a prognostic role for patients' survival. **Materials and Methods:** Thirty-seven mCRPC, with evidence of bone metastases in the axial skeleton, underwent a whole-body PET/CT with ¹⁸F-FDG before treatment with ²²³RaCl₂. Each PET/CT was analysed by a semi-automated segmentation software, which identifies the skeletal tissue on the CT images and automatically separates the cortical bone volume, the trabecular bone volume (IBV) and the bone metastases (MBV). From IBV, it extracts the FDG PET information, to calculate the volume of active BM and its SUV, based on a published statistical criterion. Axial (spine

and sternum) and appendicular (humeral, femoral, and tibial bone shafts) values were computed separately. The results were compared with age- and sex-matched controls from a published normalcy database. The mCRPC patients were followed up, and overall survival (OS) was calculated. **Results:** Appendicular active BM volume and SUV were both greater in mCRPC patients than in controls (35.8 ± 15.9 ml Vs. 9.9 ± 13.9 ml, $p < 0.01$ and 1.3 ± 0.1 Vs. 1.1 ± 0.2 , $p < 0.05$, respectively). Axial active BM volume and SUV were not significantly different between cases and controls. Appendicular active BM volume directly correlated with haemoglobin levels at the time of PET/CT ($R = 0.68$, $p < 0.01$). MBV directly correlated with appendicular BM volume ($R = 0.49$, $p < 0.05$) and SUV ($R = 0.65$, $p < 0.01$); it inversely correlates with OS ($R = -0.71$, $p < 0.001$). **Conclusion:** The presence of metastases in the axial skeleton causes a measurable increase in BM metabolic activity in the appendicular bones. This phenomenon is linked with BM haematopoietic capability, as well as overall survival. **References:** Sambuceti G et al. Estimating the whole bone-marrow asset in humans by a computational approach to integrated PET/CT imaging. *Eur J Nucl Med Mol Imaging*. 2012 Aug;39(8):1326-38.

Clinical significance of 68Ga-DOTATOC prostatic uptake on PET/CT: A ten-year review

F. Gossili¹, C. E. Almasi¹, H. D. Zacho^{1,2}, L. J. Petersen^{1,2};
¹Department of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, ²Department of Clinical Medicine, Aalborg University, Aalborg, DENMARK.

Aim/Introduction: Gallium68 DOTATyr3octreotide (68Ga-DOTATOC) is a radiolabeled somatostatin receptor (SSTR) analogue that is widely used in positron emission tomography/computed tomography (PET/CT), especially in the imaging of neuroendocrine tumors (NETs). Benign and malignant prostate tumors have been observed to express SSTR. Diffuse symmetric DOTATOC uptake in prostate is a normal PET-finding. The aim of this study was to evaluate the frequency and clinical significance of incidental atypical prostatic uptake in men undergoing 68Ga-DOTATOC PET/CT. **Materials and Methods:** A retrospective review of male patients who underwent 68Ga-DOTATOC PET/CT studies at our department from November, 2010 to April, 2020 was performed. PET/CT reports were searched for text words or phrases indicating incidental atypical prostatic uptake. The DOTATOC uptake in the prostate gland was categorized as focal, diffuse or mixed. The intensity of the uptake was visually graded by comparing the prostatic uptake to the background uptake in the liver and the spleen uptake (Krenning visual score). Follow up was based on available clinical, biochemical, imaging, and pathology follow up. **Results:** 188 male patients underwent 68Ga-DOTATOC PET/CT. Incidental atypical uptake of 68Ga-DOTATOC on PET/CT in the prostatic bed was

observed in eight patients (4%) (mean age 68 years, range 58-77 years). Four patients (50%) had diffuse uptake, four (50%) patients had mixed uptake. One patient (13%) had low uptake (Kenning grade 1), four patients (50%) had moderate uptake (grade 2) and three patients (37%) showed grade 3 uptake. Follow up was conducted in all patients (median follow up of 29 months (range 56-7 months)). All patients had measurements of prostate-specific antigen and were referred for urological evaluation. Five patients (62%) underwent a transrectal, ultrasound-guided biopsy. No cases of prostate malignancy (including prostatic cancer) were diagnosed. **Conclusion:** During a 10-year period, we found that 4% of men exhibited prostate incidentalomas on 68Ga-DOTATOC PET/CT. No malignancy was found in the prostate in this population despite thorough examination and long-follow up. Our preliminary data indicate low or absent malignancy among incidental 68Ga-DOTATOC findings in the prostate. **References:** None

Radiolabeled PSMA And Choline PET/MRI In Prostate Cancer: A Systematic Review And Meta-Analysis

L. Evangelista¹, F. Zattoni², G. Cassarino¹, P. Artioli¹, D. Cecchin¹, P. Zucchetta¹;

¹University of Padua, Padua, ITALY, ²Hospital of Udine, Udine, ITALY.

Aim/Introduction: In prostate cancer (PCa) patients, large experiences have been conducted by using PET/computed tomography (CT). However, the implementation of magnetic resonance imaging (MRI) in the hybrid systems with PET has conjugated the "real" potential of metabolic/receptorial imaging to functional parameters. The aim of the current systematic review and meta-analysis is to summarize the diagnostic information provided by PET/MRI in PCa patients. **Materials and Methods:** A bibliographic search was performed by including the following databases: Pubmed, Scopus and Web of Science. The terms used were "Choline" or "prostate specific antigen membrane-PSMA" AND "prostate cancer" or "prostate" AND "PET/MRI" or "positron emission tomography/magnetic resonance imaging". All recognized records were combined and the full texts were retrieved. Full texts were further evaluated, by also checking the references in order to improve the eligibility. Reports were excluded if they did not 1-consider hybrid PET/MRI scanners or 2-a sample size <10 patients, or 3-sufficient raw data was provided for completion of a 2x2 contingency table; 4-the performances' outcomes. **Results:** 50 articles were eligible for the systematic revision and 23 for meta-analysis. Overall, the number of included patients was 2313 of which 2104 (91%) underwent hybrid PET/MRI. Initial staging of disease was the most common indication (n=23 studies). Radiolabeled PSMA was used in the majority of case. In primary tumor, the pooled sensitivity was 94.9% (95% confidence interval-CI: 87.5-98.6%), at patient-based analysis. In restaging, the pooled detection rate was 80.9%

(95%CI: 73.0-86.9%), being higher for radiolabeled PSMA than radiolabeled Choline (81.8% vs. 77.3%, respectively). **Conclusion:** PET/MRI has a high sensitivity for the detection of primary PCa and a high detection rate for recurrent disease, particularly with radiolabeled PSMA. It would be of great importance for the detection of primary tumor and early recurrence of disease. **References:** 1. Kranzbuhler et al. J Nucl Med 2020; 61:194-201

OP-053

Evaluation of ^{68}Ga -PSMA PET/CT Images Acquired with a Reduced Scan Time Duration in Prostate Cancer Patients using a Digital PET/CT Scanner

M. Weber¹, R. Hofferber¹, K. Herrmann¹, W. P. Fendler¹, M. Conti², A. Wetter³, D. Kersting¹, C. Rischpler¹, W. Jentzen¹, P. Costa¹;

¹Department of Nuclear Medicine, University of Duisburg-Essen and German Cancer Consortium (DKTK)-University Hospital Essen, Essen, GERMANY, ²Siemens Medical Solutions USA, INC, Essen, GERMANY, ³Institute for Diagnostic and Interventional Radiology and Neuroradiology University Hospital Essen, Essen, GERMANY.

Aim/Introduction: PET/CT with ^{68}Ga -PSMA allows for a superior detection of prostate cancer tissue, especially in context of a low tumor burden. Digital PET/CT bears the potential of reducing scan time duration or administered tracer activity due to, for instance, its higher sensitivity and improved time coincidence resolution. It might thereby expand ^{68}Ga -PSMA PET/CT availability currently limited by $^{68}\text{Ge}/^{68}\text{Ga}$ -generator yield. Our aim was to clinically evaluate the influence of a reduced scan time duration in combination with different image reconstruction algorithms on the diagnostic performance. **Materials and Methods:** Twenty prostate cancer patients (11 for biochemical recurrence, 5 for initial staging, and 4 for metastatic disease) sequentially underwent ^{68}Ga -PSMA PET/CT examination on a digital Siemens Biograph Vision. In 11 of these PET data were collected in continuous-bed-motion mode with a scan time duration of approximately 15 min (reference acquisition protocol) and 5 min (reduced acquisition protocol). For both protocols, 4 iterative reconstruction algorithms were applied using a time-of-flight (TOF) approach alone or combined with point-spread-function (PSF) correction, each with 2 or 4 iterations. To evaluate the diagnostic performance, the following metrics were chosen: (a) per-region detectability, (b) the tumor maximum and peak standardized uptake values (SUV_{max} and SUV_{peak}) and (c) image noise using the liver's activity distribution. **Results:** Overall, 98% of regions (91% of affected regions) were correctly classified in the reduced acquisition protocol independent of the image reconstruction algorithm. Two pelvic nodal lesions (each ≤ 4 mm in size) were not identified at 5 min vs 15 min scan duration leading to downstaging in 1 of 20 cases. Mean absolute percentage deviation of SUV_{max} and SUV_{peak} was approximately 9% and 6% respectively for each

reconstruction algorithm. The mean image noise increased approximately from 13% to 21% (4 iterations) and from 10% to 15% (2 iterations) for both PSF+TOF and TOF images. **Conclusion:** Using a digital PET/CT, three-fold reduction of scan time resulted in near equal per-tumor region detection (98 % of regions) and image quantification (mean deviation ≤ 10 %); however, small lesions can be missed in about 5% of patients. Our results suggest that a reduction of scan time duration or administered ^{68}Ga -PSMA activities can be considered in patients with more advanced or extra-pelvic disease. **References:** None

TROP Session: Therapeutic Options in Thyroid Cancer - Radioiodine and Beyond

Thursday, October 22, 2020, 13:30 - 15:00

Channel 9

OP-054

The effectiveness of ^{177}Lu -DOTATATE in patients with metastatic medullary thyroid cancer

S. Bilgic, M. S. Sağer, M. F. Beytur, A. Nazari, R. L. Uslu Beşli, S. Asa, L. Kabasakal, H. B. Sayman, K. Sönmezoğlu; Istanbul University - Cerrahpasa, Istanbul, TURKEY.

Aim/Introduction: The current therapeutic options in metastatic medullary cancer (mMTC) are limited. Although tyrosine kinase inhibitors are recommended as a first-line therapy, these treatments have considerable side effects, which often limit the therapy effect. Peptide receptor radionuclide therapy (PRRT) is another possible treatment modality in patients with mMTC. The purpose of this study is to investigate the effectiveness of ^{177}Lu -DOTATATE in patients with mMTC. **Materials and Methods:** 19 mMTC patients (6 female and 13 male) treated by ^{177}Lu -DOTATATE in our institution between the years of 2012 and 2018 were retrospectively analyzed. Pretreatment ^{68}Ga -DOTATATE-PET-CT imaging was performed. Pretreatment serum calcitonin (Ctn) values were assessed. The primary endpoints are: 1) increase in Ctn value more than 50% 2) post-therapy progression confirmed via ^{68}Ga -DOTATATE PET/CT scan. **Results:** 19 patients (aged: 32 - 87 years) with mMTC were enrolled. Only 1 patient (5.3%) had familial MTC (MEN2A). All patients underwent total thyroidectomy and bilateral central and lateral neck dissection. The median Ctn values before treatment were 1723 pg/ml (60 - 4840). 15 patients had no previous treatments, 4 patients were previously treated with other systemic agents (1 vandetanib, 1 sorafenib, 2 somatostatin analogs). Local recurrence was present in 8 patients. The most frequent sites of metastases were cervical lymph nodes (15), bone (12), mediastinum (5), liver (4), and lungs (3). Four patients were in stage IVB, and 15 patients were in stage IVC. The median of administered activity was

177 mCi (11–214) in a median of 3 cycles with a range of 1 to 8 cycles with 2 months and longer intervals. The median Ctn values after treatment were 1291 pg/ml (20 - 9855). No patient had a complete response at the Ctn level. 8 patients had a partial response, 7 patients a disease stabilization, and 4 patients a disease progression. The biochemical disease control rate was 79%. Post-therapy ^{68}Ga -DOTATATE-PET-CT results and post-therapy Ctn levels were discordant. Based on ^{68}Ga -DOTATATE-PET-CT, no patient had a complete response, 2 patients had a partial response, while 15 patients had a disease stabilization, and 2 patients had a disease progression. The disease control rate was 89%. There was no grade 3/4 toxicity. **Conclusion:** In patients with mMTC, ^{177}Lu -DOTATATE therapy appears to be effective in disease control. **References:** Makis W, McCann K, McEwan AJ. Medullary thyroid carcinoma (MTC) treated with ^{177}Lu -DOTATATE PRRT: a report of two cases. *Clinical nuclear medicine*. 2015;40:408-12. doi:10.1097/rln.0000000000000706

OP-055

The Effectiveness of ^{177}Lu -DOTA TATE in Radioiodine-Refractory Differentiated Thyroid Cancer

A. Nazari, M. S. Sağer, S. Bilgiç, F. Beytur, R. L. Uslu Beşli, S. Asa, L. Kabasakal, H. B. Sayman, K. Sönmezoğlu;
Department of Medicine, Istanbul University
Cerrahpasa, Istanbul, TURKEY.

Aim/Introduction: Differentiated thyroid carcinomas (DTC) are cancers that develop from thyroid follicle epithelial cells and makeup 90% of all thyroid carcinomas. Radioiodine-Refractory (RAIR) DTC has a poor prognosis and fewer treatment options. In this study, we aimed to investigate the effectiveness of ^{177}Lu -DOTATATE treatment in patients with RAIR DTC. **Materials and Methods:** 28 patients who underwent ^{177}Lu -DOTATATE treatment in our institution between 2011–2020 were examined retrospectively. The study includes patients with total thyroidectomy (TT), followed by RIT but considered RAIR, biochemically progressive, and a positive somatostatin receptor in ^{68}Ga -DOTATATE PET/CT. **Results:** 28 patients, 17 women (60.7%), and 11 men (39.3%) with a mean age of 62.8 (42–81) were included in the study. Papillary thyroid carcinoma (PTC) in 21 patients (53.8%), follicular thyroid carcinoma (FTC) in 5 patients (12.8%), Hürthle cell carcinoma (HCC) in 1 patient (2.6%), poorly differentiated thyroid carcinoma (PDTC) in 1 patient (2.6%). Patients were classified according to TNM classification before treatment; 27 patients (96.4%) evaluated as stage 4C, one patient as stage 4A. Median 2 cycles (1–12) of ^{177}Lu -DOTATATE treatment was applied with an average dose of 454 mCi (149–1376) at intervals of 2 months and longer. Patients had a history of TT before treatment and received a median of 500 mCi (100–1100) RIT therapy. 11 patients (39.3%) received lymph node dissection (LND), 5 patients (17.9%) tyrosine kinase inhibitor (TKI), 3 patients (10.7%) Radiotherapy (RT). Prior treatment

median thyroglobulin (Tg) value was measured as 238.5 ng/mL (2.12–1804). 12 patients (42.9%) had metastatic lesions in the thyroid region, 9 patients (32.1%) in the cervical lymphatic stations, 18 patients (64.3%) in the lungs, 10 patients (35.7%) in the skeletal system, and 2 patients (7.1%) in the muscles. **Conclusion:** No hepatotoxicity/nephrotoxicity was observed in patients during and after treatment. The median Tg values measured after treatment were as 300 ng/mL (7–5000). None of the patients had complete Tg response, a partial response in 4 patients (16%), and progressive Tg response in 21 patients (84%). No complete morphological response was observed in any patient; Partial response was detected in 1 patient (4.8%), stable disease in 3 patients (14.3%), and progressive disease in 17 patients (81%). ^{177}Lu -DOTATATE treatment is an alternative treatment method in patients with RAIR DTC. **References:** 1. PRRT with the CCK-2 receptor Agonist ^{177}Lu -PP-F11N - First results of a Phase 1 “LUMED” Study

C. Rottenburger¹, G. Nicolas¹, L. McDougall¹, M. Fürstner², M. Hentsche², F. Kaul¹, E. R. Christ³, M. Cachovan⁴, H. A. Vija⁵, R. Schibli⁶, S. Geistlich⁶, M. Béhé⁶, D. Wild¹;

¹University Hospital Basel, Division of Nuclear Medicine, Basel, SWITZERLAND, ²Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, ³Division of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, SWITZERLAND, ⁴Siemens Healthcare GmbH, Forchheim, GERMANY, ⁵Molecular Imaging, Siemens Medical Solutions USA, Inc., Hoffman Estates, IL, UNITED STATES OF AMERICA, ⁶Center for Radiopharmaceutical Sciences, Paul Scherrer Institute, Villigen, SWITZERLAND.

Aim/Introduction: Despite the introduction of new molecular targeted therapies, there is still an unmet need for an effective systemic therapy for advanced medullary thyroid carcinoma (MTC). Recently, we demonstrated that the administration of the novel CCK-2 receptor agonist [^{177}Lu -DOTA-(DGlu)₆-Ala-Tyr-Gly-Trp-Nleu-Asp-PheNH₂] (^{177}Lu -PP-F11N) is safe and enables for visualization of metastasized disease in patients with MTC. This subsequent phase 1 study aims to determine the maximum tolerated dose of ^{177}Lu -PP-F11N (ClinicalTrials.gov: NCT02088645). Here we present the preliminary results of the first activity escalation step. **Materials and Methods:** Two patients received three injections of 6 GBq ^{177}Lu -PP-F11N in an interval of 8 weeks and one patient received the first injection. Planar scintigraphy and SPECT/CT scans were performed at several time points for up to 72 h post injection in order to calculate tumour and organ radiation doses using 3D voxel- and MIRD based dosimetry (Dosimetry Research Tool v5.2, Siemens Medical Solutions, USA). Blood

samples were taken for bone marrow dose calculations as well as measurement of blood count and blood chemistry. **Results:** Adverse reactions (mainly hot flashes, nausea and hyperhidrosis) after injection of 3 x 6 GBq ¹⁷⁷Lu-PP-F11N were comparable to the phase 0 study and not higher than grade 2 according to CTCAE version 4.03. Follow up visits at 9 and 6 months after the last injection did not reveal any dose limiting toxicity in patient #1 and #2. Dosimetry results are available for patient #1. The median (range) radiation dose for lymph node metastases (n=4) was 0.96 Gy/GBq (0.88-1.46), resulting in a median cumulative dose of 18.3 Gy (16.8-27.9). Median radiation doses in Gy/GBq (range) for stomach, kidneys and bone marrow were 0.29 (0.25-0.32); 0.04 (0.04-0.05) and 0.04 (0.03-0.04). In patient #1, maximum reduction of calcitonin was 12% 4 months after the first injection and calcitonin remained below initial levels for further 3 months before increasing again above baseline. In patient #2, calcitonin was not reliable because of intermittent PPI therapy, but maximum CEA reduction was 36% 5 months after first application. At present, CEA still remains below baseline, despite stopping vandetanib therapy after enrolment. **Conclusion:** The administration of the novel CCK-2 receptor ligand ¹⁷⁷Lu-PP-F11N at a potentially therapeutic dose was observed to be safe in all patients. The first results of tumour and organ dosimetry suggests that the cumulative administered activity dose (18 GBq) can be further increased without exceeding the threshold radiation dose for potential organs of risk. **References:** None

Aim/Introduction: Advanced differentiated thyroid carcinoma (aDTC) - herein defined as locally unresectable or metastatic disease - is one of the most common late-stage endocrine neoplasias. However, available data about its natural history is limited. ERUDIT is a multicenter, observational, retrospective study of patients diagnosed with aDTC in Spain and Portugal. The study describes its natural history from the initial diagnosis until the advanced stages of disease, focusing on specific characteristics of this subpopulation of DTC, as well as its treatment, response patterns and medical specialties involved in its management. The aim of this communication is to describe the patterns of use and efficacy of RAI as first intervention (RAI ± surgery) and at its relapse in patients with aDTC diagnosed in Spain and Portugal. **Materials and Methods:** Clinical records from patients ≥18 y-o diagnosed with aDTC (including poorly differentiated DTC) with first evidence of advanced disease documented between January 2007 and August 2017 were retrospectively reviewed until death or lost to follow-up. **Results:** 213 patients were identified in 23 centres. The median age at initial diagnosis was 63 years and 59% were women. 52% had metastatic disease at debut (de novo). Following surgery, patients received mostly one (34%) or two (28%) ablative RAI doses, with a median (Q1-Q3) of 150 (100-170) mCi per dose and total cumulative activity of 750 (600-800) mCi after 5 doses. Persistent structural disease was the most frequent response, seen on average in 50% of the patients after two doses. The median (95% CI) progression-free and overall survival (OS) after the first RAI were 1.5 (0.7-1.9) and 10.1 (8.2-17.5) years, respectively. After a first intervention, 46% of the patients relapsed to advanced disease and, of these, 33% received RAI with a medium dose (Q1-Q3) of 150 (140-180) mCi. In this context, the accumulated activity was 620 (560-700) mCi after 3 doses with the result of persistent structural disease in 49% of the cases. Although 99% of the patients were RAI-avid at diagnosis, 68% of them became RAI-refractory after 27.6 (9.7-50.6) months. The median (95% CI) of OS in RAI-refractory patients was 4.7 (3.4-8.0) years. **Conclusion:** Regardless of the initial type of diagnosis (de novo vs localized), in this DTC series, half of the cases maintained persistent disease after 620 mCi and two thirds became RAI-refractory after 27.6 months. **References:** None

OP-058**Radioiodine therapy (RAIT) guided by 124I-PET/CT imaging in metastatic differentiated thyroid cancer (DTC): long-term follow-up of patients recruited in a prospective trial**

E. Lodi Rizzini¹, C. Pettinato², L. Zanon¹, V. Allegri¹, E. Tabacchi¹, A. Repaci³, A. G. Morganti⁴, S. Fanti¹, F. Monari⁴;

¹Nuclear Medicine Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, ²Medical Physics Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, ³Endocrinology Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, ⁴Radiation Oncology Center, S.Orsola-Malpighi Hospital, Bologna, ITALY.

Aim/Introduction: Although RAIT was used for over 80 years in the metastatic-DTC management, number, frequency and optimal administered 131I activity remain matter of debate. 124I-PET/CT can be a useful tool to identify lesions still iodine-avid with higher detection rate than post-treatment I-131 scan (RxWBS) and to perform personalized dosimetry to the lesions, particularly in the case of potentially curative RAIT. The aim of this study is to confirm with long-term follow-up (FU) data the utility of 124I-PET/CT in RAIT planning of metastatic-DTC. **Materials and Methods:** We collected long-term FU data of 30 patients (pts) affected by metastatic DTC and recruited in a prospective trial from July 2011 to July 2013, who underwent to a personalized RAIT after performing 124I-PET/CT imaging. Clinical/Laboratory data were collected every 6/12 months from February 2012 to March 2020. In the case of strong suspect of relapse, contrast-enhanced-TC and/or 18FDG-PET/CT were also performed. Response to therapy was assessed according to ATA2015 guidelines. **Results:** Mean FU was 73.5 months (range: 17–108 months). All pts received prior RAIT, with an average administered 131I activity of 9195.5 MBq (range: 1110–25900 MBq). 15/30 (50%) pts had negative 124I-PET/CT and RxWBS scans; 11/15 pts received 3700 MBq while 4/15 pts refused treatment. At last FU, 4/15 pts had indeterminate response (IR), one pt had biochemical persistence (BP), 7/15 pts had structural persistence (SP), one pt died for disease not-related causes and 2/15 were lost at FU. 15/30 (50%) pts had positive 124I-PET/CT and RxWBS scans but in 2/15 pts dosimetry was not performed because of the influence of intestinal activity. All those pts received an 131I activity of at least 7400 MBq. Overall, dosimetry was performed to 34 lesions. In 5/13 (38%) pts lesions received less than the target dose of 80 Gy (average dose: 14.25 Gy; range: 1.47–60.50 Gy); at last FU 2/5 pts had SP and 3/5 pts died for progression disease. In 2/15 (15%) pts the majority of lesions received less than 80 Gy and at last FU one pt had SP and one had IR. In 6/13 (46%) pts lesions received more than 80 Gy (average dose: 393 Gy; range: 163.73–1283.12 Gy); at last FU 2/5 pts had SP, 2/5 pts had an excellent response, one pt died for disease not-related causes and one pt was lost at FU. **Conclusion:** 124I-PET/CT imaging guided us to choose the optimal 131I administered activity; long-

term FU data confirmed that pts who received more than 80 Gy to the lesions have a better response disease than those who received lower activities. **References:** Pretherapeutic dosimetry in patients affected by metastatic thyroid cancer using 124I PET/CT sequential scans for 131I treatment planning. OP-059**Variations in Radioiodine Therapy in Europe- Decision Making after total Thyroidectomy**

F. Forrer¹, G. Fischer¹, M. Putora¹, L. Giannelou², M. Hoffmann³, I. Iakovou⁴, M. Luster⁵, J. Mihailovic⁶, P. Petranovic⁷, A. Vrachimis⁸, S. Zerdoud⁹, O. Maas¹;

¹Kantonsspital St. Gallen, St. Gallen, SWITZERLAND, ²Ospedale Regionale di Lugano, Lugano, SWITZERLAND, ³University Vienna, Vienna, AUSTRIA, ⁴Aristotle University AHEPA Academic Hospital, Thessaloniki, GREECE, ⁵Universitätsklinikum Marburg, Marburg, GERMANY, ⁶Oncology Institute of Vojvodina, Novi Sad, SERBIA, ⁷University Hospital Center, Zagreb, CROATIA, ⁸German Oncology Center, Limassol, CYPRUS, ⁹Institut Universitaire du Cancer Toulouse, Toulouse, FRANCE.

Aim/Introduction: The role of radioiodine therapy (RIT) (used as ablation therapy or adjuvant therapy) following total thyroidectomy for differentiated thyroid cancer (DTC) changed over the last decade. Major revisions of the American Thyroid Association Guidelines in 2015 resulted in significant differences in treatment recommendations in comparison to the European Association of Nuclear Medicine (EANM) 2008 guidelines. Recently, we presented the effects on daily practice for RIT among Swiss Nuclear Medicine centers [1]. We now performed a project at the European level and hypothesized that there is also considerable variability regarding the use of RIT among recognized European experts. **Materials and Methods:** We performed a decision-tree based analysis of management strategies from all members of the EANM thyroid committee to map current practice among experts. Within this analysis, we collected data on whether or not RIT is administered, on which criteria these decisions are based, and collected details on treatment activities and patient preparation. **Results:** Our survey shows discrepancies for low risk DTC after thyroidectomy, where “follow-up only” is recommended by some experts while RIT with significant doses is used by other experts in the same situation. E.g. for pT1b tumors without evidence of metastases the level of agreement for the use of RIT, depending on histologic features, is as low as 50%. If RIT is administered in this setting, activities of I-131 range from 1.1 GBq to 3.0 GBq. In other constellations (e.g. pT1a) experts diverge from current clinical guidelines as up to 75% administer RIT in certain cases. For intermediate and high-risk patients, RIT is generally recommended. However, dosing and treatment preparation (rTSH vs. THW) vary distinctly. In comparison to the Swiss study, the general level of agreement

is higher among European experts. **Conclusion:** Currently, existing variety in the use of RIT after total thyroidectomy by European experts reflects differences in clinical guidelines as well as the lack of high level evidence. The recently proposed approach on the use of RIT, based on integrated post-surgery assessment (Martinique paper)[2] and results of ongoing prospective randomized studies are likely to reduce uncertainty in approaching RIT treatment in DTC patients. In certain constellations, consensus identified among European experts might be helpful in formulating future guidelines. **References:** 1. Maas et al. OP-060

Prognostic Factors and Disease-Specific Survival of Recurrent Differentiated Thyroid Carcinoma Patients

J. Mihailovic, V. Cimbalevic, J. Roganovic, N. Prvulovic Bunovic;
Institute of Oncology, Sremska Kamenica, SERBIA.

Aim/Introduction: Differentiated thyroid carcinoma (DTC) patients with recurrent disease (RD) have worse prognosis than patients without recurrence. However, they usually get cured if RD is detected and treated on time. The aim of this study was to analyze prognostic factors and disease-specific survival (DSS) in recurrent DTC patients. **Materials and Methods:** Among 680 DTC patients treated in our institution between 2007 and 2019, 67 patients had recurrent disease (RD): 39 females, 28 males; 23 patients <45 years, 44 patients ≥45 years; median follow-up of 3,3 years; 5 follicular, 56 papillary carcinomas and 6 unfavourable types; T stage 1, 2, 3 and 4 included 16, 5, 37 and 9 patients, respectively. Initial nodal-(N1) and distant metastases (M1) and combined metastases (N1M1) were detected in: 34, 2 and 6 patients, retrospectively. DSS was analyzed by Kaplan-Meier method/Log-rank test. **Results:** RD appeared in 67/680 (9.9%) patients. The probability of recurrence was 8.4% at 5 y, 14.2% at 10 y, 32.1% at 15 y, and 49.7% at 19 years after the initial treatment. Strong predictors of RD were: gender, T stage, N stage, M stage, and initial treatment ($p=0.0001$). No significant difference was associated with the following prognostic factors: age, histologic type of the tumor, and presence of second primary neoplasm ($p=0.208$, $p=0.531$, and $p=0.993$, respectively). The 5-, 10-, 15-, 20- and 26-year DSS was: 0.966 ± 0.24 , 0.804 ± 0.064 , 0.76 ± 0.074 , 0.608 ± 0.148 , and 0.228 ± 0.183 , respectively. Patients with RD were treated with surgery, followed by radioiodine therapy (several courses if necessary). Additionally, in patients with advanced disease and iodine non-avid DTC, external radiation, chemotherapy and Lu-177 DOTATATE treatment were performed (in 12, 1, and 2 patients, respectively). At last check up, there were 14 (20.9%) deaths: [12 (17.9%) of disease-related

deaths, while 2 (3%) patients have died from other causes], and 53 (79%) patients were alive [complete remission was achieved in 18 (26.9%) patients, partial remission in 11 (16.4%) patients, stable disease in 7 (10.4%) patients while 17 (25.4%) patients had progressive disease]. **Conclusion:** Since recurrent disease may appear at any time, life-long monitoring of DTC patients is necessary. Recurrent disease should be treated until remission (surgery followed by RAI, and radiation therapy if necessary). **References:** Leboulleux S, Rubino C, Baudin E, et al. Prognostic factors for persistent or recurrent disease of papillary thyroid carcinoma with neck lymph node metastases and/or tumor extension beyond the thyroid capsule at initial diagnosis. *J Clin Endocrinol Metab* 2005;90:5723-5729.

CRISPR/Cas9-mediated knockout of ESRRG gene (Estrogen-related Receptor gamma) restore the radioiodine avidity in poorly differentiated thyroid cancer

Y. Jeon¹, H. Ji², S. Kim¹, J. Lee¹, S. Lee³;

¹Laboratory Animal Center, Daegu-Gyeongbuk Medical Innovation Foundation, Daegu, KOREA, REPUBLIC OF, ²Department of Nuclear Medicine, School of Medicine, Kyungpook National University Hospital, Daegu, KOREA, REPUBLIC OF, ³Kyungpook National University, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: The resistance of radioiodine therapy in poorly differentiated thyroid cancer (PDC) is associated with insufficient function of the sodium iodide symporter (NIS). Recently, we have reported the important role of estrogen-related receptor gamma (ESRRG; also known as ERRγ) as a member of the orphan nuclear receptors on the regulation of NIS function in poorly differentiated thyroid cancer. Herein, we evaluated the effects of silencing of ERRγ on NIS function in poorly differentiated thyroid cancer cells using CRISPR/Cas9 gene editing system. **Materials and Methods:** Stable cell lines were generated by transducing CAL62 cells of human poorly differentiated thyroid cancer cells with the lentiviral CRISPR/Cas9 ERRγ or mock gRNA vectors, which was referred to as CAL62/ERRγ KO and CAL62/Mock cells, respectively. Iodine uptake was conducted to evaluate the NIS function in the presence or absence of $KClO_4$, a specific inhibitor of NIS using two cell lines. The mRNA and protein level of crucial gene expression related to iodine metabolism (NIS, TPO, TG, and TSHR) was determined in CAL62/Mock cells and CAL62/ERRγ KO by Q-PCR and western blotting assay. Finally, the cytotoxic effect of I-131 was determined by clonogenic assay. **Results:** Radioiodine avidity was increased in CAL62/ERRγ KO cells but not in CAL62/Mock cells. The increased radioiodine uptake of CAL62/ERRγ KO cells was completely inhibited by $KClO_4$. Q-PCR and western blotting assay revealed the up-regulation of NIS, TPO, TG, and TSHR genes in CAL62/ERRγ KO cells but not in CAL62/Mock cells. In vitro clonogenic assay demonstrated drastic reduction in the colony formation of

CAL62/ERRy KO cells. **Conclusion:** These findings suggest that CRISPR/Cas9-mediated ERRy gene editing may serve as novel therapeutic approach for enhancing the responsiveness of radioiodine therapy by modulating NIS function in poorly differentiated thyroid cancer. **References:** None

Dosimetric study for refractory metastatic differentiated thyroid with RAS or BRAFV600 mutation treated with MEK +/- BRAF inhibitors followed by radioactive iodine treatment

N. Anizan¹, G. Lion², Y. Godbert³, C. Bournaud⁴, D. Taieb⁵, S. Bardet⁶, D. Benisvy⁷, S. Zerdoud⁸, I. Borget⁹, S. Leboulleux⁹;

¹Gustave Roussy, Villejuif, FRANCE, ²CHRU de Lille - Hôpital Claude Huriez, Lille, FRANCE, ³CLCC Institut Bergonié, Bordeaux, FRANCE, ⁴CHU Lyon - Groupement Hospitalier Est, Lyon, FRANCE, ⁵CHU de Marseille - Hôpital de la Timone, Marseille, FRANCE, ⁶CLCC François Baclesse, Caen, FRANCE, ⁷CLCC Antoine Lacassagne, Nice, FRANCE, ⁸IUCT Oncopole - CLCC Institut Claudius Regaud, Toulouse, FRANCE, ⁹Gustave Roussy, Villejuif, FRANCE.

Aim/Introduction: The MERAIODE study is a prospective multicentric study evaluating the efficacy of selective MEK (trametinib) and BRAFV600E (dabrafenib) inhibitors associated with radioactive iodine (RAI) for the treatment of refractory metastatic differentiated thyroid cancer (DTC) with RAS or BRAFV600E mutation. A dosimetric evaluation was planned as an additional index to understand response to treatment. Results of the first available data on dosimetry of the BRAF cohort are presented. **Materials and Methods:** Following 5 weeks of trametinib plus dabrafenib, patients were given 5500 MBq of RAI after recombinant human TSH stimulation. Whole-body scans were performed 1, 2, 3 and 4 days after RAI administration and a SPECT/CT acquisition was done on day 4. To quantify I-131 uptake, SPECT/CT images were calibrated using a phantom acquisition with a I-131 source. The present work shows the dosimetric evaluation of patients treated in one center where whole-body retention was measured using NaI counter positioned in the room. Whole-body absorbed dose was estimated using S factor function of patient mass. Time activity curves in lesions and lungs were extracted from images using PLANET® Dose then corrected for deadtime. Absorbed doses were calculated using IDAC_DOSE 2.1. **Results:** Dosimetric evaluation was performed for 5 patients with BRAFV600E mutation. None of them disclosed RAI uptake on a diagnostic whole-body scan performed prior to treatment initiation and all did after MEK and BRAF inhibitors. Absorbed doses were calculated for 18 metastases with a median diameter of 10 mm (range: 4-24). Median whole-body absorbed dose was 322 mGy (range: 172-571 mGy). Median absorbed dose to the lungs was 10.8 Gy (range: 0.62-19.1 Gy) with 3 patients with an absorbed dose greater than 10 Gy. Mono-exponential fit was used for lesions and the median effective half-life of RAI was 53 hours

(range: 21-81 h) with a median calculated absorbed dose of 211 Gy (range: 17-2764 Gy). **Conclusion:** Dosimetric evaluation is under investigation for all patients included in the study. First patients treated in one center show encouraging results regarding RAI uptake with some patients showing high absorbed dose in the lesions. RECIST evaluation is ongoing and correlation between tumor response and absorbed dose calculation remains to be evaluated. In the light of the high lungs absorbed dose, toxicity to the lungs should be evaluated. Funded by InCA, ClinicalTrials.gov number, NCT NCT03244956 **References:** None

OP-063

Value of interim F-18 FDG PET/CT imaging in patients with metastatic radioiodine-refractory thyroid carcinoma undergoing tyrosine-kinase inhibition therapy

G. Rendl¹, B. Sipos¹, L. Hehenwarter¹, G. Schweighofer-Zwink¹, H. Gallowitsch², C. Pirich¹;

¹Department of Nuclear Medicine and Endocrinology, University Hospital Salzburg, Paracelsus Medical University Salzburg, Salzburg, AUSTRIA, ²Department of Nuclear Medicine and Endocrinology, PET/CT Centre, Klinikum Klagenfurt am Wörthersee, Klagenfurt, AUSTRIA.

Aim/Introduction: This retrospective study aimed to analyse the predictive value of interim F-18 fluorodesoxyglucose (FDG) PET/CT in patients with radioiodine (RAI)-refractory thyroid carcinoma (TC) and treated with the tyrosine-kinase inhibitor therapy lenvatinib. **Materials and Methods:** Metabolic data from F-18 FDG PET/CT imaging were obtained from 21 patients with metastatic RAI-refractory TC (11 males, 10 females) with a median age of 67 years (range 39 - 80 years). The interval between PET/CT and start of lenvatinib therapy was 16 ± 30 days and the first interim PET/CT was performed 4 ± 1 months later. Compartmental analysis (locoregional uptake, lymph node, visceral and bone metastasis) was performed using an index lesion in the respective lesion. PERCIST was used to categorize the metabolic response in patients. **Results:** Mean survival was 29 months (4 - 56 months) in all patients. Five out of 21 patients died (24 %) and 4 patients discontinued lenvatinib (19 %). Overall, mean locoregional SUV was 12.23 ± 11.42 versus (vs) 11.36 ± 13.94 , in lymph nodes 12.64 ± 11.90 vs 14.18 ± 15.72 , in visceral metastases 10.98 ± 13.76 vs 5.87 ± 7.35 and 8.23 ± 4.51 vs 9.38 ± 7.58 in bone metastases in PET/CT at beginning and interim, respectively. Patients with complete metabolic response (CMR, n=2, 10 %) showed a mean survival of 45 months (36 - 53 months), patients with partial metabolic response (PMR, n=11, 52 %) of 28 months (4 - 53 months) and patients with progressive metabolic disease (PMD, n=8, 38 %) 26 months (7 - 56 months), respectively. **Conclusion:** In our patient cohort, complete metabolic response as defined by interim PET was rare but associated with a trend towards longer disease control with lenvatinib. However, the absence

of metabolic response at first interim PET indicated no worse prognosis when compared to patients with PMR, possibly due to timely treatment changes. **References:** None

OP-064

Prediction of treatment response to Lenvatinib with ¹⁸F-FDG-PET/CT in patients with advanced thyroid cancer

F. Ahmaddy, L. Beyer, V. Wenter, P. Bartenstein, A. Todica;
LMU, München, GERMANY.

Aim/Introduction: In patients with advanced thyroid cancer, Lenvatinib is a promising treatment option for prolonged progression free survival (PFS). We aimed to assess the role of ¹⁸F-FDG-PET/CT in monitoring treatment response and predict prognosis using quantitative PET-parameters. **Materials and Methods:** Patients with advanced thyroid carcinoma who underwent baseline FDG-PET/CT shortly before and 3, 6, 9, 12 months after initiation of the treatment were included. PET-parameters (SUV_{peak}, TV=tumor volume, TLG=total lesion glycolysis) as well as clinical parameters (age, sex, tumour stage) were assessed. Treatment response was evaluated according to PET Response Criteria in Solid Tumors (PERCIST) as well as Response Evaluation Criteria in Solid Tumors 1.1 (RECIST) and correlated with clinical outcome (disease-specific survival (DSS) and PFS) and PET-parameters using Kaplan-Meier-Survival analysis. **Results:** 21 patients met the inclusion criteria. Within a median follow up time of 2.5±1.0 years, 11 patients died (DSS 2.5±0.2 years). DSS could be predicted using treatment response by RECIST (p=0.001) and PERCIST (p=0.026) in PET/CT after 12 months; PFS only by RECIST (p=0.027) after 9 months. Evaluating single PET-parameters, DSS and PFS could be predicted even earlier at 6 months after treatment start (DSS: pSUV_{peak}=0.007, pTV=0.001, pTLG=0.004; PFS: pSUV_{peak}=0.009, pTV=0.012, pTLG=0.012). **Conclusion:** Response evaluation with ¹⁸F-FDG-PET/CT prior and after initiation of Lenvatinib treatment can predict the DSS and PFS in patients with advanced thyroid cancer. PET-parameters can be used for early (6 months) prediction of DSS and PFS. **References:** None

OP-065

¹⁸F-FDG PET/CT whole body volumetric evaluation in iodine-refractory differentiated thyroid cancer as predictors of Lenvatinib response

E. Califaretti¹, P. Thuillier^{1,2}, V. Liberini¹, A. Ragni³, A. Nervo³, M. Gallo³, A. Piovesan³, E. Arvat³, S. Grimaldi¹, D. Deandrei¹;
¹Division of Nuclear Medicine, Department of Medical Sciences, University of Turin, Turin, ITALY, ²Department of Endocrinology, University Hospital of Brest, Brest, FRANCE, ³Oncological Endocrinology Unit, Department of Medical Sciences, University of Turin, Turin, ITALY.

Aim/Introduction: Tyrosine kinase inhibitors (TKI) improve progression free survival in patients with metastatic

iodine-refractory differentiated thyroid cancer (RDT) but considering TKI frequent side effects and high costs, a careful selection of patients is necessary. Currently, there is no consensus on the selection of patients and the role of ¹⁸F-FDG PET/CT. The main objective of this retrospective study was to evaluate pre-therapy ¹⁸F-FDG-PET/CT quantitative volumetric and metabolic parameters in order to identify prognostic indices of clinical benefit. **Materials and Methods:** Ten patients with metastatic RDT treated with Lenvatinib and with a pre-treatment ¹⁸F-FDG PET/CT were retrospectively analyzed. Lesions contouring was performed by one operator with an isocounting method with a SUV_{max} fixed threshold of 41% using LifeX v5.1. For each lesion, semi-quantitative parameters were evaluated: standard uptake value (SUV_{max}), metabolic tumor volume (MTV) and total lesion glycolysis (TLG). Moreover, whole-body and total-bone MTV (MTV_{wb} and MTV_{bone}) and TLG (TLG_{wb} and TLG_{bone}) were assessed. Bone-to-total MTV and bone-to-total TLG ratios (%MTV_{wb}/wb and %TLG_{wb}/wb respectively) were calculated. Therapy response was assessed according to RECIST 1.1 criteria on CT scan. Patients were divided in two groups according to the best RECIST 1.1 response: complete/partial response (group A) and stable disease/progression (group B). PET parameters were compared between the 2 groups with Mann-Whitney test. Results are expressed as median [range]. **Results:** Ten patients (F:M=5:5; median age=68y) with metastatic RDT (3 follicular, 4 papillary and 3 poorly differentiated) were included; 8/10 patients had bone metastases. Contouring was performed on 121 lesions: 46 bone (38%), 36 lung (30%), 20 lymph nodes (16%), 7 thyroid bed (6%) and 12 other sites (10%). Group A included 3 patients with partial response, group B included 5 patients with stable disease and 2 with progressive disease. In group B, 65.4% [20-83] of analyzed lesions were bone metastases compared to 0% [0-6] in group A. Group B showed higher median values of %MTV_{wb}/wb (49% [18-89] vs 0% [0-7]) and %TLG_{wb}/wb (53% [17-92] vs 0% [0-9]) compared to group A (p=0.016). A similar trend was observed for MTV_{bone} and TLG_{bone}, but the difference did not reach statistical significance. All other PET parameters (SUV_{max}, MTV_{wb} and TLG_{wb}) were not significantly different between the two groups. **Conclusion:** In RDT patients treated by Lenvatinib, ¹⁸F-FDG PET/CT performed before starting treatment might be an important tool to predict response to treatment. Bone tumor burden might be one of the main predictive factors in these patients. **References:** None

Quantification of MBF with PET - How Can Technology Improve Accuracy?

M. Lubberink; Uppsala University Hospital, PET Center, Uppsala, SWEDEN.

OP-067

Patient motion influence on the quantitative accuracy of cardiac ^{15}O -water PET

J. Nordström¹, H. J. Harms², T. Kero¹, J. Sörensen¹, M. Lubberink¹;
¹PET Center Uppsala Akademiska sjukhuset, Uppsala, SWEDEN, ²Medtrace Pharma A/S, Lyngby, DENMARK.

Aim/Introduction: Cardiac PET is increasingly being used in the clinical assessment of coronary artery disease (CAD). ^{15}O -water PET is considered gold standard for non-invasive quantification of myocardial blood flow (MBF), which has been shown to improve detection of CAD over qualitative assessments. Cardiac PET is, though, prone to motion artefacts arising from the cardiac and respiratory cycle, or from patient motion. Therefore, the purpose of the present study was to investigate to what extent motion influences quantitative MBF from ^{15}O -water PET/CT. **Materials and Methods:** Clinical stress scans from 10 patients referred for assessment of ischemia with ^{15}O -water PET/CT were included. Motion in the original scan was ruled out by visual assessment. A total of 17 different types of motion were simulated, divided into 3 different types of patient body motion and cardiac creep. The 3 body motions simulated 1) a stress agent reaction, 2) a caudal linear slide and 3) a cough at first pass and after 1 min. Maximum displacement for all motions relative to the original scan position ranged between 5–20 mm. All simulated motions and the original scan were quantitatively analyzed in aQuant (MedTrace Pharma A/S, Lyngby, Denmark). MBF and transmural MBF (MBFt) were studied for all three coronary territories. **Results:** MBF and MBFt was generally shown to be decreased in the region of myocardium in which direction the motion occurred (e.g. in inferior wall for motion in inferior direction). PTF trended in the opposite direction. However, even if a clear pattern for each simulated motion type could be seen, the effect of motion is not completely predictable even when the exact same motions were simulated for each patient. A high inter-patient variance was seen in the deviation of the simulated motions from the original scan for all parameters, probably explained by different patient anatomy. On the global level MBF was significantly affected in 8 motions with average deviation $6.3\% \pm 5.6\%$ and non-significantly affected in 9 motions with average deviation

$2.8\% \pm 4.0\%$. MBFt was significantly affected in 4 motions with average deviation $8.0\% \pm 5.5\%$ and non-significantly affected in 13 motions with average deviation $1.8\% \pm 5.0\%$. **Conclusion:** Patient motion can impair the quantitative accuracy of ^{15}O -water cardiac PET and may induce false positive or false negative results in the most severe cases. Understanding how motion affects the quantification and knowledge on how to detect motion artifacts is important in the clinical evaluation. **References:** None

OP-068

Clinical use of a Rb-82 simplified myocardial flow reserve model using myocardial activity ratio: Comparison to full-kinetics myocardial flow reserve quantitation

C. Kamani, M. Jreige, M. Pappon, P. Genoud, G. Allenbach, J. Prior; University Hospital Lausanne, Lausanne, SWITZERLAND.

Aim/Introduction: Myocardial flow reserve (MFR) measurement is a well-validated independent predictor of major adverse cardiovascular events and can be used to guide myocardial revascularization. Due to non-linear radiotracer extraction, its estimation requires kinetic modeling with specialized software packages. We aimed to investigate the correlation between a simplified model using only the stress/rest myocardial activity ratio (MAR) and the MFR corrected for partial volume effect (MFR_{rc}) in patients undergoing rest/stress perfusion study using Rubidium-82 chloride (Rb-82) PET/CT. **Materials and Methods:** In total, 439 patients referred to our institution underwent rest and pharmaceutical (adenosine or regadenoson) stress dynamic PET imaging. Stress/rest myocardial activity ratio (MAR) was obtained using the left ventricular (LV) mean count activity from the 2–6-minute post-injection images. Simplified estimates of MFR (MFR_{est}) was obtained from MAR, and compared with the gold standard reference MFR_{rc}, obtained from a one-tissue compartment model. The correlation between MFR_{est} and MFR_{rc} has been further assessed. Using the Receiver Operator characteristic (ROC) analysis, the accuracy of the MFR_{est} was assessed for diagnosing impaired MFR_{rc}<2. **Results:** There was significant correlation between MFR_{est} and MFR_{rc} ($R=0.57$, $p<0.001$). The overall diagnostic performance of MFR_{est} to identify an impaired MFR_{rc}<2 was good, with AUC=0.76. There were fair sensitivity (75%) and specificity (78%), with a good negative predictive value (87%). However, the corresponding positive predictive value was poor (60%). **Conclusion:** Using a simplified method based on the MAR following a stress/rest Rb-82 perfusion PET, an impaired MFR_{rc}<2 can be estimated with a good sensibility and specificity, as well as a good negative predictive value without the need for kinetic flow modeling. **References:** None

Aim/Introduction: The quantification of myocardial blood flow (MBF) and myocardial flow reserve (MFR) utilizing ¹³N-ammonia regadenoson low dose rest/high dose stress MPI provides additional diagnostic value for detection of CAD. Patients are typically instructed to avoid caffeinated beverages for at least 12 hours prior to the study. The impact of persistently measurable caffeine in the blood on MBF and MFR quantification with ¹³N-ammonia, despite this period of supervised abstinence, remains uncertain. **Materials and Methods:** 76 consecutive inpatient subjects who were admitted with chest pain (64% female, age 66 ± 11 years, BMI 30.2 ± 8) underwent a low-dose rest/ high-dose regadenoson stress MPI protocol with a fully digital PET/CT hybrid scanner having had their blood caffeine level checked immediately prior to the study. Per standardized MPI protocol, all had been placed on a caffeine free diet for at least 12 hours prior to the exam in a supervised inpatient setting. MBF and MFR were calculated using proprietary software and adjusted to the resting heart rate x systolic blood pressure product and motion correction methodology. Intention to treat methodology was utilized for analysis. The study readers were blinded to caffeine levels and were interpreted by consensus between two qualified physicians from both Cardiology and Radiology. **Results:** Eight (6 female) of 76 inpatients (10.5%) had significant blood levels of caffeine in samples drawn just before the PET/CT exam (mean caffeine blood level = 2.6 ± 2.1 $\mu\text{g/mL}$, range: 1-7 $\mu\text{g/mL}$). In the caffeinated group, the average age was 70 ± 9 years (range: 55-84 years), mean global MFR = 3.0 ± 0.7 , mean resting global MBF = 0.86 ± 0.1 ml/min/gram and stress global MBF was 2.95 ± 0.86 ml/min/gram. Four of the eight patient studies with residual blood caffeine were read as ischemic by standard MPI qualitative and quantitative imaging criteria. **Conclusion:** A significant percentage of inpatients that are supervised regarding caffeine abstinence for at least 12 hours prior to a MPI exam still have detectable blood caffeine levels. At these levels, however, global MBF metrics are not meaningfully impeded when using ¹³N-ammonia low-dose rest/high-dose regadenoson stress protocols. More vigorous dietary control is needed to prevent unrecognized persistent caffeine blood levels due to surreptitious or accidental intake by inpatients. It is likely that this phenomenon is more prevalent in the unsupervised outpatient population. **References:** None

OP-070**Effect of PET CT misalignment on the quantitative accuracy of cardiac ¹⁵O-water PET**

J. Nordström¹, H. J. Harms², T. Kero¹, M. Ebrahimi¹, J. Sörensen¹, M. Lubberink¹;

¹PET Center Uppsala Academic Hospital, Uppsala, SWEDEN, ²Medtrace, Lynby, DENMARK.

Aim/Introduction: Cardiac PET is increasingly being used in the clinical evaluation of coronary artery disease and ¹⁵O-water PET is considered gold standard for non-invasive quantification of myocardial blood flow (MBF). For all PET tracers except ¹⁵O-water, MBF is determined based on the uptake rate of the tracer. For accurate estimation of tracer uptake, accurate attenuation correction and consequently correct alignment between PET and the attenuation CT is critical. Misalignment is a common problem and may induce artifacts in uptake rates. With ¹⁵O-water, MBF is determined based on washout rather than uptake rate. Since attenuation correction mainly affects the amplitude of tissue time-activity curves, but not its shape, we hypothesize that misalignment has minimal effect on washout-based MBF estimates of ¹⁵O-water. This study aims to investigate the impact of misalignment on the quantitative accuracy of cardiac ¹⁵O-water PET. **Materials and Methods:** Clinical adenosine-induced stress scans from 10 randomly selected patients referred for evaluation of ischemia were included in the study. Misalignment between PET and CT was ruled out by visual assessments. Eleven different misalignments were induced in six different directions with 10 and 20 mm amplitudes: caudal (-Z), cranial (+Z), lateral ($\pm X$), anterior (+Y), and anterior combined with cranial (+Y+Z). All scans were analyzed in aQuant software (MedTrace Pharma A/S, Lyngby, Denmark) for calculation of MBF, uptake-based MBF (MBFt) and perfusable tissue fraction (PTF), and the results were compared with the original, non-misaligned data. **Results:** On the global level, washout-based MBF was not significantly different for misalignments +X, +Y, +Y+Z, and -Z with average deviation of $0.9\% \pm 1.7\%$ and significantly different for -X and +Z with average deviation of $2.0\% \pm 1.7\%$. Uptake-based MBFt, however, was significantly affected by all misalignment directions with average deviation of $7.4\% \pm 3.0\%$ and not significantly affected in 20 mm +X and 10 mm +Z with average deviation $6.5\% \pm 4.2\%$. Larger effects were seen in LAD- and LCX-regions compared with the RCA-region. **Conclusion:** Misalignment between PET and CT has only margin effects in the quantitative accuracy of ¹⁵O-water PET using washout-based MBF estimates. Uptake rate (MBFt) on the other hand was more affected by misalignment. Overall, however, additional co-registration between PET and CT images is not necessary. **References:** None

OP-071**Identification of predictors for myocardial blood flow using Rubidium-82 PET**

R. Metselaar^{1,2}, J. A. van Dalen³, B. N. Vendel¹, J. R. Timmer⁴, M. Mouden⁴, J. D. van Dijk¹;

¹Isala Hospital, department of Nuclear Medicine, Zwolle, NETHERLANDS, ²University of Twente, Enschede, NETHERLANDS, ³Isala Hospital, department of Medical Physics, Zwolle, NETHERLANDS, ⁴Isala Hospital, department of Cardiology, Zwolle, NETHERLANDS.

Aim/Introduction: Myocardial blood flow (MBF) measurements using Rubidium-82 PET provides incremental diagnostic and prognostic information in the evaluation of coronary artery disease (CAD). In particular, high myocardial flow reserve (MFR) values have a high negative predictive value for obstructive CAD. Understanding which features are characteristic for normal MBF and MFR values can aid in the risk stratification of patients with suspected obstructive CAD. The aim of this study was to identify these features for developing a clinical decision tool. **Materials and Methods:** We retrospectively included 997 patients with suspected CAD (50,7% Male, age 65,99 ± 10.43 years), who were referred for rest and regadenoson-induced stress Rubidium-82 PET/CT (Discovery 690, GE Healthcare). Cardiac risk factors; cigarette smoking, hypertension, hypercholesterolemia, diabetes, positive family history of CAD; prior medical history; age; gender; body mass index (BMI); creatinine serum values; coronary artery calcification (CAC) score and medication usage were registered at time of the PET/CT examination. All variables except CAC score, age, resting heart rate and BMI were transformed to categorical variables. Multiple linear regression with forward stepwise selection (F-to-enter < 0.050) was calculated to correlate variables with rest and stress MBF and MFR. The importance of significant predictors was determined by ranking using the incremental increase in adjusted R². **Results:** Significant predictors for high rest MBF were, in order of importance, high heart rate, female sex, calcium-channel blocker usage, low BMI, calcium-channel blocker usage, hypertension, no acenocoumerol usage and older age. The adjusted R² was 0.34. Furthermore, the significant predictors for high stress MBF were, in order of importance, female sex, high heart rate, low CAC score, low BMI, younger age, clopidogrel usage, no beta blocker usage, COPD. (Adjusted R²: 0.23). The predictors for high MFR were younger age, low heart rate, low CAC score, no calcium-channel blocker usage, no underlying diabetes mellitus, positive family history of CAD normal creatinine serum levels and male. (Adjusted R²: 0.19). **Conclusion:** We identified several features that correlate with MBF and MFR measurements using Rubidium-82 PET. These features can be used in a clinical decision tool for risk stratification of patients with CAD. Further studies are needed to determine the prognostic value of the identified features in combination with MBF and MFR. **References:** None

OP-072**Myocardial flow reserve could predict major adverse cardio and cerebrovascular event in the dialysis dependent end stage renal disease patients even without myocardial perfusion abnormality**

S. Ohshima;

Nagoya Kyoritsu Hospital, Nagoya, JAPAN.

Aim/Introduction: Advanced atherosclerosis in dialysis dependent end stage renal disease (dd-ESRD) patient is critical issue to be solved. In prior studies, we reported a clinical usefulness of myocardial flow reserve (MFR) evaluated with ¹³N-ammonia positron emission tomography (¹³NH₃-PET) in prediction of poor prognosis in dd-ESRD population. However, no data were shown about the significance of MFR in the patients without myocardial perfusion abnormality. In this study, we investigated the relations between MFR and clinical events in the dd-ESRD patients without myocardial perfusion abnormality. **Materials and Methods:** We investigated 182 patients without myocardial perfusion abnormality (SSS≤3), of consecutive 438 dd-ESRD patients for suspected ischemic heart disease. The patients undergone any revascularization within 60 days after ¹³NH₃-PET were excluded. Patients were divided into two groups according to MFR=2.0: MFR<2.0 as the lower MFR(LM) group (n=56), and others as the higher MFR(HM) group(n=126). We followed up 1,509 days (median=900) and analyzed for major adverse cardio cerebrovascular event (MACCE), all-cause death and cardiovascular (CV) death. **Results:** There were significant differences in age, myocardial blood flow and MFR. There were no differences in SSS, SRS and SDS. Kaplan-Meyer analysis showed that LM group had significantly poorer prognosis than HM group (log rank p= 0.03) in MACCE. On the other hand, there were no difference in all-cause mortality (log rank p= 0.22) and CV death (log rank p= 0.30). Cox regression model showed relative risk ratio 2.29 (95% confidential interval 1.05 -4.99, p=0.04). Furthermore, multivariate cox regression model showed the continuous value of MFR was an independent risk factor for MACCE (risk ratio 0.56, 95% CI 0.31-0.98, p=0.04), considering risk factors that showed univariate assessment p value under 0.10. **Conclusion:** In the patients without myocardial perfusion abnormality, MFR would have predictability for MACCE in dd-ESRD population. **References:** None

OP-073**Coronary microvascular dysfunction as early marker of cardiac involvement in patients with Anderson-Fabry Disease**

T. Mannarino¹, R. Assante¹, C. Nappi¹, V. Gaudieri¹, A. Ponsiglione¹, E. Zampella¹, A. D'Antonio¹, A. Giordano¹, P. Buongiorno¹, A. Pisani², M. Imbriaco¹, W. Acampa¹, A. Cuocolo¹;

¹Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, ²Department of Public Health, University Federico II, Naples, ITALY.

Aim/Introduction: Cardiac involvement in Anderson-Fabry disease (AFD) is characterized by left ventricular hypertrophy, cardiomyopathy and heart failure. ^{18}F -fluorodeoxyglucose (FDG) metabolic activity by positron emission tomography (PET)/computed tomography (CT) and late gadolinium enhancement (LGE) by magnetic resonance imaging (MRI) are able to identify different patterns of cardiac involvement in AFD. ^{82}Rb PET/CT allows non-invasive measurement of stress myocardial perfusion and myocardial perfusion reserve (MPR). We investigated the relationship among metabolic activity, coronary microvascular function and LGE to define the progression of the pathophysiological patterns in AFD. **Materials and Methods:** We studied 31 asymptomatic AFD patients (14 men, mean age 49 ± 11 years) without overt coronary artery disease. Eight patients were receiving enzyme replacement therapy (ERT) at the time of the study. All patients underwent cardiac imaging by ^{18}F -FDG and rest/stress ^{82}Rb PET/CT. Sixteen (52%) patients also underwent cardiac MRI. A focal increase of FDG uptake was considered as positive finding for presence of active inflammation. Myocardial perfusion was considered normal in presence of a summed stress score < 3 . Absolute myocardial blood flow (MBF) was computed from dynamic rest and stress imaging. MPR was defined as ratio of hyperemic to baseline MBF and considered reduced when < 2 . Focal LGE on MRI indicated intramyocardial fibrosis. **Results:** Myocardial perfusion imaging was normal in all 31 patients, while 11 (35%) patients had a reduced MPR. A significant relationship between reduced MPR and focal FDG uptake was found (chi-square=9.85, $p < 0.01$). Among 14 patients with focal FDG uptake 10 (71%) had reduced MPR and 4 (29%) preserved MPR. In 17 patients with homogenous FDG uptake, only 1 patient (6%) had reduced MPR. Reduced MPR was not significantly related to ERT (chi square=0.08, $p = 0.7$). Among the 16 patients undergoing MRI, 5 (31%) had left ventricular hypertrophy associated with focal FDG uptake and focal LGE in corresponding regions. Among these 5 patients, 3 had preserved MPR and 2 reduced MPR. Among 11 (69%) patients without LGE, 2 showed both focal FDG uptake and reduced MPR while 9 patients had homogeneous uptake of FDG, and 8 (82%) of them had preserved MPR. **Conclusion:** In patients with AFD, reduction of MPR may represent not only an evidence of coronary microvascular dysfunction, but also a very early sign of cardiac involvement anticipating active inflammation and more severe fibrosis. Evidence of different pathophysiological patterns in AFD would help in customization of therapeutic strategy to prevent progression of cardiac involvement. **References:** None

OP-074

Prognostic value of peri-coronary adipose tissue and coronary vascular function by cardiac ^{82}Rb PET/CT imaging in patients with suspected coronary artery disease and normal perfusion imaging

V. Gaudieri¹, E. Zampella¹, C. Nappi¹, R. Assante¹, T. Mannarino¹, A. D'Antonio¹, A. Giordano¹, P. Buongiorno¹, M. Petretta², P. Arumugam³, W. Acampa¹, A. Cuocolo¹;

¹Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY; ²Department of Translational Medical Sciences, University Federico II, Naples, ITALY; ³Department of Nuclear Medicine, Central Manchester University Hospitals, Manchester, UNITED KINGDOM.

Aim/Introduction: Peri-coronary fat thickness (PCFT), by releasing inflammatory mediators, demonstrated a local pro-atherosclerotic effect. We evaluated the prognostic value of PCFT, coronary artery calcium (CAC), and myocardial perfusion reserve (MPR), in patients with suspected coronary artery disease (CAD) and normal myocardial perfusion imaging (MPI). **Materials and Methods:** A total of 640 patients without overt CAD and with normal ^{82}Rb PET/CT MPI were studied. PCFT was calculated on CT images as the maximum fat thickness (mm) between heart surface and visceral epicardium surrounding the main coronary arteries. CAC score was categorized as < 400 or ≥ 400 . MPR was considered reduced when < 2 . Endpoints were cardiac death, nonfatal myocardial infarction and coronary revascularization. **Results:** During a follow-up of 42 ± 13 months, 29 events occurred (cumulative event rate 5%). Patients with events were older (66 ± 13 vs. 60 ± 13 years, $p < 0.01$), had higher PCFT (13 ± 2 vs. 11 ± 2 mm, $p < 0.001$), higher prevalence of CAC score ≥ 400 (48% vs. 21%, $p < 0.01$), and lower MPR (2.1 ± 0.7 vs. 2.7 ± 0.7 , $p < 0.001$) compared to those without. A higher prevalence of MPR < 2 was observed in patients with events (48% vs. 18%, $p < 0.001$) compared to those without. Patients with reduced MPR had higher PCFT compared to those with normal MPR (12 ± 2 vs. 11 ± 1 mm, $p < 0.01$). A PCFT value of 11.2 mm was the best trade-off between sensitivity and specificity to detect reduced MPR. Event rate was higher in patients above this threshold compared to those below (8% vs. 1.5%, $p < 0.001$). At Cox univariate analysis, age ($p < 0.05$), PCFT > 11.2 mm ($p < 0.001$), CAC score ≥ 400 ($p < 0.01$), and MPR < 2 ($p < 0.001$) were predictors of events. At multivariate analysis, only PCFT > 11.2 mm and MPR < 2 were independent predictors of events (both $p < 0.01$). At incremental analysis, adding PCFT > 11.2 to a model including clinical data and MPR < 2 increased the global chi-square from 26 to 35 ($p < 0.01$). Classification tree analysis produced 3 terminal groups. For patients with MPR < 2 , no further split was needed (event rate 12% vs. 3%, $p < 0.001$). On the contrary, patients with MPR ≥ 2 were further stratified by PCFT (event rate 7% in patients with and 0.3% in those without ($p < 0.001$)) PCFT > 11.2 . **Conclusion:** In patients with suspected CAD and normal stress MPI, coronary

vascular dysfunction and high PCFT are associated with increased cardiac risk. PCFT could help in identifying patients at higher risk of events. Combined evaluation of anatomical and functional vascular abnormalities by ^{82}Rb PET/CT might allow a better risk stratification. **References:** None

OP-075

Does a Clinical Risk Score Improve the Negative Diagnostic Utility of a Zero Calcium Score?

C. Nappi¹, R. Megna², V. Gaudieri^{1,2}, T. Mannarino¹, R. Assante¹, E. Zampella¹, R. Green¹, V. Cantoni¹, A. D'Antonio¹, P. Arumugam³, W. Acampa¹, M. Petretta⁴, A. Cuocolo¹;

¹Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, ²Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY, ³Department of Nuclear Medicine, Central Manchester Foundation Trust, Manchester, UNITED KINGDOM, ⁴Department of Translational Medical Sciences, University Federico II, Naples, ITALY.

Aim/Introduction: Coronary artery calcium (CAC) score is a useful diagnostic and prognostic marker of coronary artery disease (CAD). The probability of obstructive CAD based on clinical variables and CAC score was first determined by Genders et al.¹. More recently, Alshahrani et al.² proposed and validated a scoring system including clinical variables in patients with zero CAC score (ZCS) to drive the obstructive CAD ruling out. We evaluated if these risk scores may be also useful to predict a normal stress myocardial perfusion imaging (MPI) study in patients with ZCS. **Materials and Methods:** Our cohort included a total of 1,422 consecutive patients with ZCS who underwent rest-stress ^{82}Rb PET/CT for evaluation of suspected CAD. Predictive models were constructed as reported by Genders et al.¹ and Alshahrani et al.² and the probability of abnormal (>3) summed stress score (SSS) and of reduced (<2) myocardial perfusion reserve (MPR) based on these risk scores was assessed. **Results:** In the overall population, the prevalence of abnormal SSS was 0.10 and the prevalence of reduced MPR was 0.17 (both $P < 0.001$). The observed frequencies of abnormal SSS and reduced MPR versus the probabilities predicted by the Genders and Alshahrani models were above the diagonal identity line, highlighting an underestimation of the observed occurrence by these models. The areas under the receiving operating characteristic curve of the Genders and Alshahrani models were fail, indicating lack of discriminative ability for predicting abnormal SSS (0.547 and 0.527) and reduced MPR (0.509 and 0.538). The Hosmer-Lemeshow test indicated that both models underestimated the observed occurrence of abnormal SSS and reduced MPR. **Conclusion:** Available models were unable to identify among patients with ZCS those with a low probability of a normal stress MPI study. Even using a low probability threshold, many positive MPI tests would have been missed. Thus, an optimal approach to rule out from MPI patients without detectable coronary calcium still needs to be

improved. **References:** 1. Genders TS, Steyerberg EW, Hunink MG, Nieman K, Galema TW, Mollet NR, et al. OP-076

Ultra-low-dose coronary artery calcium scoring yields equivalent results compared to standard protocol: a study on 919 consecutive patients

F. Caobelli¹, I. Allio¹, C. E. Popescu², M. Zellweger¹;

¹Universitätsspital Basel, Basel, SWITZERLAND, ²Kantonsspital Baden, Baden, SWITZERLAND.

Aim/Introduction: Recent studies featuring small patients' populations suggest that the assessment of coronary artery calcium (CAC) scoring with computed tomography (CT) with 80 kilovolt-peak (kVp) tube voltage yields comparable results to the standard 120-kVp protocol. However, these preliminary findings still need to be validated in larger patients' populations. **Materials and Methods:** We included consecutive patients undergoing myocardial perfusion scintigraphy as part of clinical care. All underwent standard CT scanning with 120-kVp tube voltage and an additional scan with 80 kVp, which was also used for attenuation correction purpose. All patients had suspected but no prior coronary artery disease. Mean body mass index (BMI) was $28.3 \pm 6.1 \text{ kg/m}^2$. CAC score was calculated on both CT images using the Agatston score, thus generating two datasets (low-dose and standard protocol), which were compared with linear regression and Bland-Altman analysis. Furthermore, risk-class (0-25, 25-50, 50-75, 75-90 and >90 percentiles according to data of the literature [1]) were recorded. **Results:** 919 patients were included (443 females, age 67.3 ± 11.5). Estimated mean radiation doses were 0.6 mSv for standard CT and 0.2 mSv for the ultra low-dose CT, respectively. Median CAC score from 120 kVp scans was 104 (inter-quartile range 5-551). 179 (19.5%) patients had CAC score=0. Median CAC score from 80 kVp scans was 39 (inter-quartile range 0-330). 273 (29.7%) patients had CAC score=0. Scores calculated with 80 kVp scans showed a very good correlation with those calculated with standard 120 kVp scans ($r = 0.947$, $r^2 = 0.867$, $p < 0.001$), with Bland-Altman limits of agreement of -495.9 to 739.4 and a bias of -121.7. The correlation across percentiles classes was also good ($r = 0.857$, $r^2 = 0.74$, $p < 0.001$). **Conclusion:** In a large consecutive patient population, CAC scores calculated with ultra low-dose CT scan and those assessed with standard protocol correlated well regarding numeric CAC scores and CAC score classes. Thus, a substantial further radiation dose reduction (about 0.6 mSv) can be pursued by omitting

a standard scan for CAC assessment, while preserving diagnostic and prognostic accuracy. **References:** [1] Hoff JA et al. *Am J Cardiol.* 2001;87:1335-9

Role of FDG-PET/CT in patients with Non-Hodgkin Lymphoma treated with Chimeric Antigen Receptor T Cells

C. Bailly, B. Tessoulin, T. Eugene, T. Gastinne, F. Kraeber-Bodere, S. Le Guillou, C. Bodet-Milin;
CHU Nantes, Nantes, FRANCE.

Aim/Introduction: CD19-targeting chimeric-antigen-receptor (CAR)-T-cells has changed the landscape of immunotherapy in relapsed or refractory B-cell non-Hodgkin's lymphoma (NHL). Given the role that FDG-PET/CT already plays in the management of lymphoma, this study explored the potential prognostic or predictive values of this imaging modality in CAR-T-cells therapy. **Materials and Methods:** We retrospectively reviewed patients with NHL who received CD19-targeting CAR-T-cells therapy at our hospital between November 2018 and December 2019 and who underwent FDG-PET/CT imaging at the time of enrolment, showing relapsed or refractory disease (FDG-PET/CT_{baseline}), before CAR-T-cells injection (FDG-PET/CT_{pre-infusion}) and at 1 month after treatment (FDG-PET/CT_{post-infusion}). Most patients had repeated FDG-PET/CT scans during follow-up at 2, 3 or 4 months after CAR-T-cells injection. SUVmax, whole-body functional volume (MTV) and whole-body total lesion glycolysis (TLG) were extracted. Lugano criteria (LC) were used to evaluate therapeutic response. **Results:** Thirteen patients were enrolled. All patients had FDG-PET/CT_{baseline} with active disease. Most patients received salvage chemotherapy before leukapheresis (92.7%;12 patients) and 8 patients (61.5 %) bridging chemotherapy before CAR-T-cells infusion. After a median follow-up of 9.9 months [range 3.2-15.9], overall response rate to CAR-T-cells therapy was 46.1%. Only the six patients (41.6 %) who presented objective response (complete or partial response) according to LC on FDG-PET/CT_{pre-infusion} remained disease-free after CAR-T-cells infusion. On FDG-PET/CT_{pre-infusion} SUVmax (medianSUVmax: 15.06 [range 4.08-23.19] vs 25.15 [range 9.33-32.58]; p = 0.23), MTV (medianMTV: 42.72 cm³ [range 6.29-407.68] vs 111.95 cm³ [range 10.09-877.53]; p=0.35) and TLG (medianTLG: 111.66 [range 32.62-1147.78] vs 1968.25 [range 45.39-8696.18]; p=0.11) seemed to be higher in non-responding patients but with no significant difference. At 1 month after treatment, changes in SUVmax or volumetric measures were

not correlated to improved survival. All patients achieving a complete response according to LC on follow-up FDG-PET/CT scans (41.6%; 6 patients) between 1 and 4 months post-CAR-T-cells infusion remain disease-free >10 months post-therapy. Supplementary early FDG-PET/CT 15-days post-infusion showed one pseudoprogression with no predictive or prognostic value. Development of Cytokine Release Syndrome was not correlated to FDG-PET/CT findings. **Conclusion:** These preliminary results show the importance of the "dynamic" of response on FDG-PET/CT_{pre-infusion}, as all patients presenting a semblance of response using LC, consolidate this latter. Quantitative metrics determined on FDG-PET/CT_{pre-infusion} seemed to be higher in non-responding patients with no significant difference at this time of analysis. LC allowed good prediction of response during follow-up. The study is ongoing and supplementary data including more patients will be presented at the congress. **References:** None

EPS-002

Chimeric Antigen Receptors T Cell Therapy in the Treatment of Non-Hodgkin Lymphoma. Assessment of Response and Side Effects using¹⁸F-FDG-PET / CT

J. Ardila Mantilla, I. Gómez Fernández, A. Rotger Regí, M. Kwon, J. Orcajo Rincón, M. Baquero Oliveros, C. Durán Barquero, D. Zamudio Rodríguez, A. Marí Hualde, Y. Henao Celada, J. Atance García de la Santa, J. C. Alonso Farto;
Hospital General Universitario Gregorio Marañón, Madrid, SPAIN.

Aim/Introduction: CD19-targeting chimeric antigen receptor (CAR)-T cell therapy has shown great efficacy in patients with relapsed/refractory non-Hodgkin lymphoma (NHL) but has been associated with serious adverse effects, such as cytokine release syndrome (CRS), making necessary to search metabolic parameters that apart from predicting the response to treatment can also identify those patients with a higher risk of presenting CRS, who can benefit from cytoreductive therapy before CAR-T injection. Our aim is to assess the usefulness of ¹⁸F-FDG-PET / CT in response evaluation to CAR-T therapy and to determine the value of metabolic tumor volume (MTV) and total lesion glycolysis (TLG) as a prognostic factor in development of CRS. **Materials and Methods:** Retrospective, descriptive, observational study; we included 13 patients with CAR-T therapy. Multiple variables were extracted (age, sex, Ann Arbor, histological type, previous treatment lines and dose). We performed baseline ¹⁸F-FDG-PET / CT (prior to therapy), at 30, 100, and 180 days. In baseline PET / CT, the tumor burden was evaluated, classifying it as high (MTV> 1781.19 cm³ and TLG> 16254) and intermediate-low (MTV <1781.19 cm³ and TLG <16254) and correlated it with clinical and analytical data after treatment (severe SLC grade 3-4 and mild-moderate SLC grade 1-2). The response to CAR-T therapy was evaluated using the Deauville scale classifying them as stable disease, pseudoprogression, progression and

hyperprogression. **Results:** We included 13 patients treated with CAR-T therapy, 7 women and 6 men, the mean age was 50.7 years; 10 NHL BDCG and 3 follicular lymphoma. 1 patient was assessed on PET / CT + 30 + 100 + 180 days, 2 PET / CT +30 +100 and 9 PET / CT on day +30. 10 patients showed baseline PET / CT (76%) with low tumor load, presenting no serious later complications and 3 high tumor load (24%) of which 1 died from SLC and in 2, the CAR-T infusion was delayed, administering cytoreductive treatment prior to the CAR-T infusion. **Conclusion:** Baseline ^{18}F -FDG-PET / CT prior to CAR-T therapy can predict the appearance of serious adverse effects and we can identify those patients with high tumor load that can benefit from cytoreductive treatments prior to the therapy administration. **References:** None

EPS-003

Possibility of ^{18}F -FDG activity reduction for Hodgkin lymphoma patients performed on high sensitivity PET/CT camera

M. Dziuk^{1,2}, E. Witkowska-Patena², A. Gizewska¹, A. Mazurek², M. Kozal¹, A. Pieczonka³, M. Chojnowska², Z. Podgajny³;
¹Affidea, PET-CT, Warsaw, POLAND, ²Military Institute of Medicine, Warsaw, POLAND, ³Affidea, PET-CT, Wrocław, POLAND.

Aim/Introduction: We aimed to investigate the dose reduction of fluorodeoxyglucose (^{18}F -FDG) in positron emission tomography/computed tomography (PET/CT) of Hodgkin lymphoma patients performed on a camera with bismuth germanate (BGO) crystals. **Materials and Methods:** Ninety-one ^{18}F -FDG PET/CT scans (each in seven Bayesian Penalised Likelihood [BPL] reconstructions with varying acquisition time per bed position - 2 min, 1.5 min, 1 min, 50 sec, 40 sec, 30 sec and 20 sec) were independently assessed by three physicians to evaluate image quality. Mean administered dose was 3.0 ± 0.1 MBq/kg and mean uptake time was 54.0 ± 8.7 min. Each time series quality was subjectively marked in 1-10 scale and then ranked 1-7 basing on the mean mark. Series with mean mark ≥ 7 were regarded as good quality appropriate for assessment, mean mark 5-6 was mediocre quality and mean < 5 was poor quality (inappropriate for assessment). Interobserver rank correlation and intraclass correlation within each time series for the three observers were calculated. Phantom studies were also performed to find a correlation between reduced acquisition time and dose reduction. **Results:** Time series were marked and ranked unanimously - the longer the time of acquisition the higher the mark and rank. The interobserver agreement in ranking was excellent (100%) with kappa coefficient of 1.00 (95% CI [0.83-1.0]). The general intraclass correlation coefficient (agreement between the marks observers gave each time series) was very high (0.952, 95% CI [0.946-0.958]) and was the higher the shorter the time per bed. According to all three observers only the series with 2 min and 1.5 min acquisition time were appropriate for assessment (mean mark

≥ 7). In phantom studies the time of acquisition was strongly linked with the tracer activity. A reduction of acquisition time of 25% (from 2 min to 1.5 min) corresponded to a 25% dose reduction (with 1,64% error). Further reduction (to 1 min and less) resulted in an error of $\geq 16\%$. **Conclusion:** In a BGO crystal camera, ^{18}F -FDG dose can be reduced by up to 25% without substantial compromising PET/CT image quality in patients with Hodgkin lymphoma. **References:** None

EPS-004

Influence of digital PET/CT and Q.Clear algorithm on determination of response to chemotherapy in patients with diffuse large B-cell lymphoma

C. Arede¹, J. M. Riedinger¹, J. M. Vrigneaud^{1,2}, C. Tabouret-Viaud¹, J. L. Alberini^{1,2}, C. Drouet¹, Y. E Silva¹, R. Popoff^{1,2}, C. Rossi³, O. Casasnovas³, A. Berriolo-Riedinger¹, A. Cochet^{1,2};
¹Department of Nuclear Medicine, Centre Georges-François Leclerc, Dijon, FRANCE, ²ImVIA, EA 7535, University of Burgundy, Dijon, FRANCE, ³Department of Haematology, University Hospital, Dijon, FRANCE.

Aim/Introduction: Baseline and interim ^{18}F -FDG PET/CT are performed to monitor the early response to chemotherapy in diffuse large B-cell lymphoma (DLBCL) patients, using residual tumor metabolism compared to liver metabolism with the Deauville 5-point scale (DS), but also metabolic response using ΔSUV . However, the impact of digital PET/CT coupled with iterative Bayesian penalized-likelihood algorithm (Q.Clear), which improves signal-to-background ratio, has yet to be determined. **Materials and Methods:** Forty-four patients (23 men, 21 women, mean age= 64 ± 15 y) with newly diagnosed DLBCL were prospectively included between February 2018 and February 2020. Each patient had interim ^{18}F -FDG PET/CT after two cycles of chemotherapy (PET2). Among them, 29 had previously baseline ^{18}F -FDG PET/CT (PET0). All acquisitions were performed on the same digital PET/CT (Discovery MI 4, GEHC, injected dose 3MBq/kg). PET images were all reconstructed using two algorithms: one optimized for harmonized quantification (EARL; OSEM with 2 iterations and 34 subsets) and one optimized for lesion detection (Q.Clear, beta=800). PET images (EARL and Q.Clear) were visually and semi-quantitatively analysed. SUVmax of the tumor and the liver were determined to calculate a Tumor to Liver ratio (T/L). Moreover, ΔSUV was calculated for patients who had PET0 and PET2. T/L ratios and ΔSUV determined with EARL and Q.Clear algorithms were compared using Bland-Altman plots. Finally, tumor response was determined based on both reconstruction algorithms using DS, and ΔSUV (cut-off -66%). **Results:** T/L ratio was significantly higher with Q.Clear reconstruction than with EARL, both at PET0 (8.5 ± 4.9 vs 6.7 ± 4.0 , bias=+1.8, $p < 0.0001$) and PET2 (1.7 ± 1.5 vs 1.4 ± 1.1 , bias=+0.4, $p < 0.0001$). However, there was no significant difference concerning ΔSUV (-69.2% vs -68.9%, bias=-0.3%, $p = \text{NS}$). Concerning response evaluated

with DS based on Q.Clear reconstructions, 29 patients were responders (DS 1-3) and 15 were non-responders (DS 4-5), including 3 with progression. Only one non-responder (DS 4) was found to be responder (DS 3) on EARL reconstructions. Concerning response evaluated with Δ SUV, 24 patients were responders on Q.Clear reconstructions (Δ SUV<-66%) and 5 were non-responders. Only 2 responders were classified as non-responders on EARL reconstructions; these patients had a low baseline tumor metabolism on EARL reconstructions ($SUV_{max} < 10$) which is a well-known limitation of Δ SUV. **Conclusion:** In patients with diffuse large B-cell lymphoma, the use of digital PET/CT and Q.Clear algorithm improve tumor-to-background ratio, with a limited impact on the interpretation of tumor response to chemotherapy, based on Deauville score and Δ SUV. **References:** None

EPS-005

Is visual residual lymphoma on FDG PET concordant with its quantitative assessment?

A. Al-Busaidi^{1,2}, Z. Al-Bimani^{1,2}, A. Miglietta¹, W. Zeng¹;

¹Division of Nuclear Medicine, Department of Medicine, University of Ottawa, Ottawa, ON, CANADA, ²Ministry of Health, Muscat, OMAN.

Aim/Introduction: ¹⁸F-FDG PET/CT is the current standard of care for aggressive lymphoma. Based on the NCCN guidelines (2018) and Consensus of the International Conference on Malignant Lymphomas Imaging Working Group (2014) the FDG PET assessment is visual. However, in clinical practice, SUV_{max} is often used to derive the Deauville score as it is considered less subjective. The aim of this study is to compare the visual and quantitative assessment for residual or resolved lymphoma. **Materials and Methods:** Consecutive patients with Hodgkin's lymphoma or diffuse large B-cell lymphoma following chemotherapy referred for FDG PET/CT from January, 2016 to October, 2019 with a Deauville score of 3 and 4 based on SUV_{max} (3=above mediastinal blood pool and below liver, 4=above liver) were included. All lesions with a Deauville score other than 3 and 4 or small size (<1.0 cm) were excluded. Visual assessment was performed by experienced radiologist (Reader 1) and technologist (Reader 2) independently for Deauville score. Both were blinded to clinical and other imaging results including SUV_{max} of the lesions. SUV_{max} of tumor lesions, liver and mediastinal blood pool was measured by an experienced nuclear medicine physician. Both the visual and quantitative Deauville score as well as the score between two readers were compared with Cohen's Kappa. **Results:** 120 lesions from 100 patients (age: 58.0± 19.2, F:M=36:64) were analyzed. The mean tumor and liver SUV_{max} was 3.65 ±1.0 and 3.1±0.5 respectively, with 56 lesions (47%) at the Deauville score 4 category. The percentage agreement between quantitative and visual assessment was 73% for both readers. The agreement by taking into account the chance agreement was 43% for Reader 1 and 52% for

Reader 2 with Cohen's Kappa calculation. Of note there were 32 lesions (27%) scored 3 by Reader 1 but scored 4 by SUV_{max} . There agreement between readers was fair with a Cohen's Kappa at 0.38 (38% of agreement). **Conclusion:** A lesion with a Deauville score of 4 following chemotherapy is usually considered residual lymphoma while a score of 3 is resolved or borderline lymphoma. There appears to be suboptimal agreement between the visual and quantitative methods. The difference in approaches should receive more attention as this could lead to changes in patient's management and continues to be a challenge to all reporting and referring physicians. **References:** None

EPS-006

Comparison of ⁶⁸Ga-PSMA and ¹⁸F-FDG PET/CT Uptake in Different Lymphoma Subtypes: Preliminary Results

C. Ramos¹, S. Souza¹, N. Tobar¹, V. Castro¹, F. Frasson¹, B. Amorim¹, E. Etchebehere¹, M. Lima¹, J. Mengatti², E. Araujo², E. Perini², C. Souza¹, I. Lorand-Metze¹, A. Santos¹, M. Delamain¹;

¹University of Campinas, Campinas, BRAZIL, ²Nuclear and Energy Research Institute (IPEN), Sao Paulo, BRAZIL.

Aim/Introduction: Few reports have documented the uptake of radiolabeled Prostate-Specific Membrane Antigen (PSMA) in lymphomas [1,2]. It is not known how PSMA uptake varies among various histological subtypes and how it correlates with ¹⁸F-FDG uptake in lymphomas. This study aimed to compare ⁶⁸Ga-PSMA and ¹⁸F-FDG in different lymphoma subtypes. **Materials and Methods:** Nine randomly selected patients with biopsy-proven lymphoma -median age 43 (32-70) years, 5 female - were submitted to whole-body ¹⁸F-FDG and ⁶⁸Ga- PSMA PET/CT (time interval: 1-6 days between procedures). Lymphoma subtypes included: nodular-sclerosis Hodgkin's lymphoma (HL; 2 patients); diffuse large B-cell lymphoma (DLBCL; 1); marginal-zone lymphoma (2); MALT lymphoma (ML; 1); follicular lymphoma (FL; 1); lymphoplasmacytic lymphoma (1); and B-cell non-Hodgkin's lymphoma, unspecified (BCNHL-U; 1). Eight patients were under initial staging, and 1 (HL) with disease relapse after treatment. Two experienced nuclear physicians analyzed the images by consensus. The intensity of tracer uptake was visually classified as marked, moderate or mild. The affected sites (lymph node chains, spleen, diffuse bone marrow involvement and non-lymphatic focal lesions) were counted in both sets of images and their respective maximum SUV (SUV_{max}) were measured. **Results:** PSMA PET/CT was positive in all patients except for one with ML. FDG PET/CT was positive in all patients. At visual analyses, FDG uptake was higher than PSMA uptake in all patients, except for one patient with BCNHL-U (both tracers with similar low-intensity uptake). The intensity of FDG and PSMA uptake was respectively classified as marked in 3/9 and 0/8 patients, moderate in 4/9 and 1/8 and mild in 2/9 and 7/8. One patient (FL) presented a "mismatch" uptake pattern with different

parts of an extensive lesion presenting predominant uptake of PSMA or FDG. Brain infiltration in one patient (DLBCL) was more easily identified on PSMA than on FDG images. FDG detected a total of 58/58 and PSMA 43/58 affected sites in all patients with a median SUVmax of respectively 5.4 (2.0–31.1) and 2.8 (1.3–5.4), $p < 0.0001$. The median SUVs of the 43 lesions with uptake of both tracers was respectively 5.5 (2.0–28.9) and 2.8 (1.3–5.4) for FDG and PSMA, $p < 0.0001$. **Conclusion:** Distinct lymphoma subtypes present PSMA uptake, with less intensity than FDG uptake. Although PSMA uptake is usually mild, several lymphoma subtypes might cause false-positive results in PSMA PET/CT performed to assess prostate cancer. **References:** [1] Kanthan GL, et al. Clin Nucl Med.2016;41(6):500–501. [2] Vamadevan S, et al. Clin Nucl Med.2016;41(12):980–981.

EPS-007

Artificial intelligence can warn for focal skeleton/bone marrow uptake in Hodgkin lymphoma patients staged with FDG-PET/CT

M. Sadik¹, J. Lopes-Urdaneta¹, J. Ullén², O. Enqvist³, A. Krupic¹, R. Kumar⁴, P. Andersson⁵, E. Trägårdh⁶, L. Edenbrandt⁷;

¹Nuclear Medicine, Gothenburg, SWEDEN, ²Eigenvision AB, Malmö, SWEDEN, ³Image Analysis and Computer Vision, Gothenburg, SWEDEN, ⁴Nuclear Medicine, Chandigarh, INDIA, ⁵Hematology and Medicine, Borås and Gothenburg, SWEDEN, ⁶Nuclear Medicine, Malmö, SWEDEN, ⁷Nuclear Medicine, Malmö and Gothenburg, SWEDEN.

Aim/Introduction: To develop an artificial intelligence (AI) method for the detection of focal skeleton/bone marrow uptake and quantification of diffuse bone marrow uptake (BMU) in patients with Hodgkin lymphoma undergoing staging with FDG-PET/CT. The results of the AI-method were compared to image interpretations of a group of physicians from different hospitals. **Materials and Methods:** Forty-eight non-treated patients who had undergone a staging FDG-PET/CT between 2017–2018, with biopsy proven Hodgkin lymphoma, were retrospectively included. The skeleton and bone marrow were segmented using a convolutional neural network [1]. To detect focal uptake, bone uptake significantly higher than the mean bone marrow uptake was marked as abnormal and an index, based on the total squared abnormal uptake, was computed. Patients with an index above a predefined threshold was interpreted as having focal uptake. Diffuse BMU was classified as high if the patient had a SUVmedian spine bone marrow uptake larger than the liver (> 1.0). Ten physicians, with 2–12 years of PET/CT-experience, working in three different hospitals classified the cases regarding focal skeleton/bone marrow uptake and diffuse BMU. **Results:** AI agreed with the majority of the readers in 39 of the 48 cases (81%) regarding focal skeleton/bone marrow involvement. While for diffuse BMU AI agreed in 33 (69%) cases with the majority of the physicians, in 1

case half of the physicians agreed with AI and in 14 cases most physicians disagreed with AI. Inter-observer agreement between the physicians, both regarding focal and diffuse BMU was moderate, Kappa 0,53 (range 0,25–0,80) and Kappa 0,41 (range 0,03–0,68), respectively. **Conclusion:** An AI-method can be developed to highlight suspicious focal skeleton/bone marrow uptake in Hodgkin lymphoma patients staged with FDG-PET/CT. This AI-method can also objectively present high versus low BMU by calculating median SUV-values in the whole spine marrow and the liver. We have demonstrated that inter-observer agreement regarding both focal and diffuse BMU are moderate among nuclear medicine physicians. **References:** 1. Bone Marrow 18F-FDG Uptake Patterns to Evaluate Infiltration in Mantle Cell Lymphoma

A. Sabaté-Llobera¹, M. Cortés-Romera¹, A. Palomar-Muñoz¹, E. Llinares-Tello¹, C. Soldevila-Lozano¹, L. Rodríguez-Bel¹, M. Martínez de Bourio-Allona¹, F. Climent-Esteller², E. M. González-Barca³;

¹IDI - Hospital Universitari de Bellvitge - IDIBELL, L'Hospitalet de Llobregat, SPAIN, ²Hospital Universitari de Bellvitge - IDIBELL, L'Hospitalet de Llobregat, SPAIN, ³ICO - Hospital Duran i Reynals - IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: To determine the utility of establishing patterns of 18F-FDG uptake in the bone marrow to evaluate bone marrow infiltration (BMI) in mantle cell lymphoma (MCL). **Materials and Methods:** Retrospective review of PET/CT of 42 patients with MCL (3 women, average age 62.5 years), treatment-naïve and with bone marrow biopsy (BMB) as part of the diagnostic work-up study. PET/CT images were visually evaluated, defining five patterns of 18F-FDG uptake in the bone marrow: A-focal (uni or multifocal), B-diffuse homogeneous similar to liver activity, C-diffuse homogeneous above liver activity, D-heterogeneous, E-no uptake/below liver activity. All the patterns except the last one were considered as BMI. Results of image evaluation were compared with BMB. **Results:** PET/CT considered BMI in 30 cases (71.4%), most of them with pattern B (40.5%), while BMB revealed involvement in 35 patients (83.3%). There were 17 discordant results (40.5%), 11 of which were interpreted as no-BMI by PET/CT but BMB proved as infiltrated by lymphoma. At least 75% of the cases with uptake pattern C and 88.9% of those with pattern D showed disease at the BMB. No cases with pattern A were identified. **Conclusion:** Establishing patterns of FDG uptake in the bone marrow helps standardizing the visual evaluation of PET/CT to determine BMI in MCL, obtaining concordant results with the

BMB in most of the cases with diffuse homogeneous uptake of activity similar or above the liver, or with heterogeneous uptake. However, many cases with no uptake/below liver activity are misinterpreted as no-BMI, so BMB is still mandatory, especially in these patients. **References:** None

EPS-009

Assessment of the Predictive Capacity of Pretreatment 18F-FDG PET/CT in Gastric Mucosa-associated Lymphoid Tissue (MALT) Lymphoma

C. Jiang¹, C. Ding², Z. Zhou¹;

¹Department of Nuclear Medicine, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing Unive, Nanjing, CHINA, ²Department of Nuclear Medicine, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, CHINA.

Aim/Introduction: The predictive capacity of positron emission tomography/computed tomography (PET/CT) using [18F]-fluorodeoxyglucose (18F-FDG) for gastric mucosa-associated lymphoid tissue (MALT) lymphoma (GML) remains still not determined. Therefore, we evaluated the predictive capacity of pretreatment 18F-FDG PET/CT in GML patients. **Materials and Methods:** Thirty-six patients with newly diagnosed GML were enrolled in this retrospective study. Each patient underwent 18F-FDG PET/CT scans before treatment. 18F-FDG PET/CT results were analyzed visually, and the lesion with the highest maximum standardized uptake value (SUVmax) was recorded. The predictive capacity of PET positivity, SUVmax and other clinical parameters were assessed. **Results:** Over a median follow-up of 38.2 months, PET positivity, SUVmax as well as large B cell transformation were the significant predictors of PFS. Multivariate analysis showed that SUVmax was the only independent predictor of PFS (P=0.027). SUVmax can independently predict the treatment response (P=0.016). Patients who presented with SUV \geq 6.5 had a higher rate of large cell transformation. **Conclusion:** A high 18F-FDG uptakes prior to treatment can predict unfavorable outcomes and are associated with large cell transformation in GML patients. **References:** None

EPS-011

Impact of Gender on Metabolic Response in Patients with Head and Neck Cancers using End of Treatment ¹⁸F-FDG PET/CT

M. Zaman¹, N. Fatima¹, U. Zaman², A. Zaman³, S. Zaman⁴, R. Tahseen⁵;

¹AKUH, Karachi, PAKISTAN, ²Dept of Medicine Suny Downstate Hospital, New York, NY, UNITED STATES OF AMERICA, ³Department of Medicine, Dr Ruth Hospital, Karachi, PAKISTAN, ⁴Dow Medical College, Dow University of Health Sciences (DUHS), Karachi, PAKISTAN, ⁵Department of Radiation Oncology, Aga Khan University Hospital (AKUH), Karachi, PAKISTAN.

Aim/Introduction: The purpose of this study was to determine the impact of gender on response in patients with head and neck cancers (HNC) based on end of treatment (EoT) 18-fluorodeoxyglucose (¹⁸F-FDG) positron-emission tomography/computed tomography (PET/CT). **Materials and Methods:** This retrospective study was conducted at PET/CT section of a JCI-accredited healthcare facility from January 2017 to February 2020. Patients with baseline (pretreatment) and EoT ¹⁸F-FDG PET/CT (12 week post-treatment) scans were selected. Based on EoT scans findings patients were categorized as responders and non-responders. Study population was divided on the basis of gender and various demographic factors were compared among them. Furthermore, Kaplan Meier analysis was used to see the impact of age, BMI, nodal status, size and SUVmax of primary tumor in non-responders. **Results:** Total 323 patients with HNC (oral cavity cancers: 201/323; larynx cancers: 97/323; sinonasal cancers: 12/323; submandibular cancers: 13/323) were categorized on the basis of gender into male (236/323; 73%) and female (87/323; 27%; P<0.05) cohorts. Female group was significantly obese (Body Mass Index \geq 30 kg/m²) and elder. Rest of demographic factors (age, fasting blood level, ¹⁸F-FDG dose, uptake time, mean liver uptake, baseline highest SUVmax and primary tumor size) show no significant difference. Males had significantly higher incidence of throat cancers while no significant gender predisposition seen in oral, sinonasal and submandibular cancers. Left sided cancers were significantly higher in both genders than right side and mid line disease. No significant gender based difference was seen for cervical or extra-cervical nodal disease and intracranial extension. Male had significantly higher advanced disease with local bony destruction and stage IV disease as well. EoT PET/CT revealed metabolic response in 59% female and 51% of male participants (non-significant p-value). Kaplan Meier curves showed negative correlation between age, nodal status, primary tumor size and SUVmax for metabolic response without gender biasness. However, obesity was found a predictor in non-responder females (Log rank value: 6.336; F:M odd ratio: 1.61; p <0.05). **Conclusion:** We conclude that prevalence of HNC is higher in males with a higher tendency of local bony destruction and stage IV disease on baseline ¹⁸F-FDG PET/CT. Male had significantly higher laryngeal cancers with left laterality in both genders. EoT ¹⁸F-FDG PET/CT revealed no significant gender biasness on metabolic response. In non-responders, no significant impact of age, nodal status, primary tumor size and SUVmax in either gender noted. However, obesity was found a significant predictor in female non-responders. **References:** None

EPS-012

Image quality and interpretation of [¹⁸F]-FES-PET: is there any effect of food intake?

J. Boers¹, K. Giatagana¹, G. A. P. Hospers¹, C. P. Schröder¹, E. F. J. de Vries², A. W. J. M. Glaudemans²;

¹Department of Medical Oncology, University Medical Center Groningen, Groningen, NETHERLANDS, ²Department of Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Whole-body estrogen receptor (ER) expression can be visualized with 16 α -[¹⁸F]-fluoro-17 β -estradiol ([¹⁸F]-FES) positron emission tomography (PET). This imaging technique may improve diagnostic understanding and help in therapy decision-making. However, high physiological [¹⁸F]-FES uptake in the liver, gall bladder and gastrointestinal tract may limit scan interpretation in these regions. We hypothesized that eating a (fatty) meal before [¹⁸F]-FES-PET imaging would lead to lower [¹⁸F]-FES uptake in the upper abdomen due to faster gall excretion, thereby improving scan interpretation of the upper abdomen. Therefore, in this exploratory study we investigated the effect of food intake prior to PET acquisition on abdominal background activity in [¹⁸F]-FES-PET scans. **Materials and Methods:** Breast cancer patients referred to the UMCG for [¹⁸F]-FES-PET due to a clinical dilemma between February 2012 and August 2019 were included. Three groups were designed: 1) patients who consumed a chocolate bar (fatty meal) between tracer injection and [¹⁸F]-FES-PET acquisition (n=20), 2) patients without diet restrictions before tracer injection (control group, n=20), and 3) patients that fasted for 4–6 h before tracer injection (n=20). We compared the physiological [¹⁸F]-FES uptake, expressed as mean standardized uptake value (SUV_{mean}), in the gall bladder and gastrointestinal tract between groups. **Results:** After chocolate, the median [¹⁸F]-FES uptake (SUV_{mean}) in the gall bladder was 71 [interquartile range 38–91], compared to 85 [62–128] for the control group, and 102 [68–140] for the fasting group (P=0.015). This [¹⁸F]-FES uptake pattern was similar in the lumen of the stomach, with the lowest values for the chocolate group: 0.55 [0.19–0.80], compared to 0.65 [0.48–0.92], and 0.90 [0.67–1.11] for the control and fasting group, respectively (P=0.011). [¹⁸F]-FES uptake in other abdominal regions was not different between groups. Post hoc analysis showed significant differences in gall bladder and stomach lumen [¹⁸F]-FES uptake between the fasting and chocolate group, but not between the chocolate and control group. **Conclusion:** In this exploratory study we showed that, compared to fasting, eating chocolate decreases physiological [¹⁸F]-FES uptake in the upper abdomen. Eating a fatty meal (chocolate) does not significantly decrease [¹⁸F]-FES uptake further compared to a normal diet. Therefore, eating before the scan may increase passage of the tracer. We suggest, particularly for

patients suspected of metastases in the upper abdomen, that fasting is not recommended and eating (chocolate) prior to [¹⁸F]-FES-PET could help to lower the physiological uptake in gall bladder and stomach. **References:** None

EPS-013

¹⁸F-FLT PET/CT in locally advanced breast cancer: texture analysis and image quantification

A. Capozza¹, B. Padovano¹, G. Serafini¹, A. Lorenzoni¹, G. Infante², R. Agresti², R. Miceli², E. Seregni¹, A. Alessi¹;

¹Nuclear Medicine Unit, IRCCS Istituto Nazionale dei Tumori di Milano, Milan, ITALY, ²IRCCS Istituto Nazionale dei Tumori di Milano, Milan, ITALY.

Aim/Introduction: Radiomics studies intratumoral heterogeneity, relying on the assumption that quantitative data are expression of molecular mechanisms determining cancer behavior. Breast cancer (BC) is a highly heterogeneous disease, with severely different outcomes based on biological subtypes and molecular profile. Our pilot study[1] showed that the uptake of ¹⁸F-FLT, a tracer of proliferation, in BC, identifies patients that will achieve a complete response on final histology, after neoadjuvant chemotherapy (NCT). Aim of this study is to deepen the potentiality of ¹⁸F-FLT PET/CT advanced image analysis in BC. **Materials and Methods:** Enrolled patients underwent NCT and performed ¹⁸F-FLT PET/CT at baseline (PET0) and after first (PET1) and last (PET2) NCT cycles. Semi-quantitative analysis of ¹⁸F-FLT uptake of breast and nodal lesions was performed using semi-automatic segmentation method with fixed threshold (SUVmax 40%). Standard parameters and advanced imaging features were derived using statistic based method (LifeX software). Overtime variation of radiomic parameters (delta-features) were analyzed among PET0, PET1 and PET2. Hierarchical clustering analysis was performed to evaluate correlations between baseline- and delta-radiomic features, pathological response (RCB), histo-pathological data. Pathological analysis was performed on pre-treatment biopsy or surgical histological specimen. Pathological response was assessed using Anderson Residual Cancer Burden (RCB). **Results:** Fifteen female patients, with locally advanced T2–3–4 N0–1 BC, were evaluated. Median age at diagnosis was 42 years (range 29–63y); median follow-up 7 years. At time of our analysis, 27% patients had died for disease progression, 11/15 patients were progression-free. Histopathological analysis showed median Ki67 index= 50 (range 12–90). A significant correlation was found between a cluster of features, from texture analysis on PET0 images, and Ki67 expression, evaluated according to the standard cut-off Ki67 \geq 20. Patients' population was then classified according to pathological response in two groups: responders (RCB 0+I) vs non-responders (RCB II+III). Cluster analysis, with heatmap designed on delta-features, showed a correlation between a group of specific radiomic

parameters (entropy and correlation derived from grey-level co-occurrence matrix, and histogram-based entropy) and pathological response. **Conclusion:** Whilst confirming previously reported data, on the potentiality of FLT in BC[1], texture-analysis may have a complementary role and offer adjunctive informations to in-vivo characterize BC lesions. Of the over 90 features analyzed, only a cluster of parameters (related to texture and homogeneity) has been found to correlate with pathological response and histopathological characteristics, thus allowing early prediction of NCT response and outcome. **References:** 1.Crippa F, et al. Eur J Nucl Med Mol Imaging. 2015 May;42:818-30.

Multiple bone scintigraphy metastatic lesions in correlation with breast carcinoma human epidermal growth factor receptor 2 neu and hormone receptor expression

S. Stojanoski^{1,2}, A. Jankulovska¹, E. Lazareva¹, T. Makazlieva¹, M. Iljovska¹, N. Manevska¹, M. Jovanovski Srceva¹, S. Smichkoska¹, D. Miladinova¹;

¹Medical Faculty, Skopje, NORTH MACEDONIA, ²Medical Faculty, Lazarski University, Warsaw, POLAND.

Aim/Introduction: Bone scintigraphy is a useful tool for the accurate diagnosis of skeletal metastatic lesions among oncological patients. Several factors have been proposed for the prediction of osseous and/or visceral metastatic disease onset in breast cancer patients. The aim of our study was to determine the correlation between multiple bone metastatic lesions initially diagnosed with bone scintigraphy and tumor receptor characteristics of breast cancer patients. **Materials and Methods:** We performed a monocentric (University Clinic "Mother Theresa"), retrospective, observational study at the Institute of Pathophysiology and Nuclear Medicine and the Institute for Radiotherapy and Oncology in Skopje. Between January 2013 and December 2018, 66 female breast cancer patients (mean age $52,51 \pm 10,64$ years) who underwent initial ^{99m}Tc-MDP bone scintigraphy procedure and were diagnosed with multiple skeletal metastatic lesions were included in the study. Primary tumor characteristics regarding the human epidermal growth factor receptor 2 neu - HER2neu and hormone receptor - HR (estrogen receptor - ER and/or progesterone receptor - PR) expression of each patient were evaluated for association with multifocal osseous metastasis. **Results:** Bone metastatic lesions were initially detected $5,59 \pm 2,72$ years after the breast cancer diagnosis confirmation. The axial skeleton was affected in 29% of patients and in 71% the affection was both axial and appendicular. In our study cohort, the spine (predominantly the thoracic segment), the ribs and the pelvis were the most common sites of metastatic involvement ($p = 0.013$). ER+ were 86% (57/66) of the patients, PR+ were 74% (49/66) and HER2neu+ were 35% (23/66). HR+/HER2neu- were 65% (43/66) of the patients,

HR+/HER2neu+ were 29% (19/66) and HR-/HE2neu+ were 6% (4/66). Multiple bone scintigraphy metastatic lesions significantly correlated with HR+ status of breast cancer patients ($p = 0.021$). **Conclusion:** Breast cancer patients with hormone receptor-positive status present significant predilection for skeletal metastatic patterns. **References:** None

EPS-016

¹⁸F-FDG PET/CT Volume-based Metabolic Parameters in Advanced Non-Small-Cell Lung Cancer Patients Treated with anti PD-1 Immunotherapy: A Potential Biomarker for Predicting Prognosis

M. Rashki¹, E. Triviño-Ibañez¹, V. Amezcua Hernández², J. Valdivia Bautista², T. Rudolphi Solero¹, J. Fernández Fernández¹, J. Llamas-Elvira¹, A. Rodríguez-Fernández¹;

¹Servicio de Medicina Nuclear, Hospital Virgen de las Nieves, Granada, SPAIN, ²Servicio de Oncología Médica, Hospital Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: Pembrolizumab and Nivolumab are anti-programmed death-1 (PD-1) antibodies, that are used as treatment for previously treated non-small-cell lung carcinoma (NSCLC). We evaluated the potential predictive value of metabolic parameters of ¹⁸F-FDG PET/CT before treatment with anti-PD 1 immunotherapy, in patients with NSCLC and the association with therapeutic response and survival. **Materials and Methods:** We retrospectively analyzed the data from stage IV, NSCLC patients who underwent a PET scan before treatment with anti-PD 1 immunotherapy. Images were qualitatively and semiquantitative analyzed by measuring the volumetric parameters: total metabolic tumor volume (TMTV), total lesion glycolysis (TLGt), and SUVmax, SUVmean, SUVpeak, SUVmin, MTV and TLG of the lesion with the highest SUVmax value. Treatment response was evaluated at 3 months (RECISTv1.1). The correlation between metabolic parameters and early treatment response, progression-free survival (PFS), and overall survival (OS) were analyzed. **Results:** 54 patients were enrolled (mean age: 66.26 ± 8.73 , 68.5% male), followed until last observation or death (mean 23.9 months). The most frequent histological type was adenocarcinoma 64.8% followed by squamous cell carcinoma 24.1%. 66,7% were treated with Pembrolizumab and 33,3% with Nivolumab. 39/54 patients (72.2%) relapsed or progressed and 30/54 (55.6%) died. Response assessment, 3 months after immunotherapy showed two groups: responders (including patients with complete/partial response or stable disease) and non-responders. The expression of PD-L1 was higher in the responders' group (74.7 vs 54.7, $p=0.038$). TMTV and TLG were higher in the nonrespondents group. We found a low-moderate correlation between SUVmax, SUVpeak, SUVmean, and SUVmin and PDL1 expression (kappa coefficient 0.32-0.35; $p<0.05$). The median OS and PFS were 17.15 and 4.8 months, respectively. The mean TMTV was significantly higher in the patients who died (165.81 ± 159.07 vs. $87.92 \pm$

95.08, $p=0.039$). The baseline PET/CT metabolic parameters (TMTV, TLGt, and also MTV and TLG of the main lesion) were associated with a shorter OS and FPS ($p < 0.05$). ROC curves analysis showed an optimal cut-off point of 80cm³ for TMTV and 478cm³ for TLG. These values were associated with shorter OS (HR: 2.47 y 2.75; $p=0.021$ y $p=0.012$ respectively). **Conclusion:** In this study, a higher tumor burden assessed by PET MTV and TLG showed a significant association with overall and progression-free survival in patients with NSCLC treated with anti-PD1 immunotherapy. **References:** None

EPS-017

Low-activity digital PET emulation from decimated statistics applied to lung nodules detection

M. Jreige¹, S. Gnesin¹, P. Schleyer², M. Conti³, J. O. Prior¹;

¹Lausanne University Hospital, Lausanne, SWITZERLAND, ²Siemens Healthineers UK, Frimley, Camberley, UNITED KINGDOM, ³Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Functional imaging by F-18-fluorodeoxyglucose (FDG) SiPM PET/CT can potentially be used as a stand-alone modality in lung cancer screening, allowing nodule characterization for malignancy and staging. Recent studies have shown that statistical decimation of standard dose scans can generate new emulated scans from identical radiotracer spatial distributions, even when simulating extremely low-count conditions [1]. We present the first results of low-dose simulated PET/CT derived from decimated reconstruction (up to 10% of the original activity) applied to malignant lung nodule detection. **Materials and Methods:** Six patients investigated for lung nodules were enrolled in this study and underwent a standard-activity (2 MBq/kg) PET/CT (Siemens Biograph Vision 600) with standard free-breathing trunk acquisition (FB, continuous bed motion 1.4mm/s equivalent to 90-s per bed position). Low-activity emulations were reconstructed to simulate scans with 75%, 50%, 25% and 10% of the standard injected activity (2MBq/kg). SUV_{max} and SUV_{mean} were measured for malignant nodules, in addition to lung background SUV_{mean} allowing to calculate a Signal-to-Background-Ratio (SBR) across scans. **Results:** Six malignant lung nodules, measuring 15.3±7.6 mm, showed increased FDG uptake with SUV_{max}, SUV_{mean} (g/mL) of 8±3.6 and 4.7±2.2, respectively. Low-activity simulation scans of 75%, 50%, 25% and 10% the injected activity led to a mean variation (%) of 1.3, 1.1, 10.8 and 42.4 of SUV_{max} and 1.8, 4, 9.6 and -16.6 of SUV_{mean} in lung nodules, respectively. SBR was 17±6, 17±7, 17±6, 18±7 and 22±9, respectively for the standard dose, 75%, 50%, 25% and 10% emulations. **Conclusion:** This study shows that low-activity (10%) PET/CT is feasible for lung nodule evaluation, allowing for a potential application in lung cancer screening. Lower emulated dose PET/CT showed a slightly higher FDG uptake in nodule with good SBR, allowing the identification of the malignant lesions. **References:** [1] Schaefferkoetter J, Nai YH1, Reilhac A, et al. Synthesis and Characterization of ¹⁸F-Labeled 4-Thia-oleic Acid Derivatives for Fatty Acid Beta-Oxidation Imaging

Y. Murakami, Y. Fujita, H. Fushiki;

Astellas Pharma Inc., Tsukuba, JAPAN.

Aim/Introduction: To develop novel PET tracers for fatty acid oxidation, we have tried to modify 18-¹⁸F-fluoro-4-thia-oleate (¹⁸F]FTO) which was reported by DeGrado et al (1). [¹⁸F] AS3504073-00 (7-¹⁸F-fluoro-4-thia-oleate) was successfully discovered as an excellent PET tracer for beta-oxidation imaging as previously reported (2) (3) (4). [¹⁸F]AS3504073-00 has an ideal characteristics, high accumulation in heart and no bone accumulation by defluorination, even though only the ¹⁸F labeling position is different from that on [¹⁸F]FTO. In the present study, more several analogs of [¹⁸F]FTO were synthesized and evaluated in monkey PET studies to clarify the relationship between the ¹⁸F-position on 4-thia-oleate and the imaging characteristics as a PET tracer. **Materials and Methods:** Several secondary ¹⁸F-fluorinated analogs, 17-fluoro-4-thia-oleate (17-FTO), 15-fluoro-4-thia-oleate (15-FTO), 12-fluoro-4-thia-oleate (12-FTO), 7-fluoro-4-thia-oleate, (7-FTO, AS3504073-00) and 6-fluoro-4-thia-oleate (6-FTO) were prepared from each tosylate or bromide-precursor in a similar manner. Nucleophilic ¹⁸F fluorination on each precursor using [¹⁸F]TBAF/TBAHCO₃, and then hydrolysis of methylester was performed. The obtained all ¹⁸F-labeled compounds were administered to cynomolgus monkeys and PET measurements were performed. **Results:** All five compounds were successfully synthesized with enough quality and stability for animal experiment, although the radiochemical yield of 6-¹⁸F]FTO was lower than those of other compounds. In monkey PET studies, 12-¹⁸F]FTO, 7-¹⁸F]FTO ([¹⁸F]AS3504073-00) and 6-¹⁸F]FTO showed higher accumulation in heart than [¹⁸F]FTO. However, only [¹⁸F]AS3504073-00 showed no significant accumulation of radioactivity in the bone. The SUV values of 12-¹⁸F]FTO, 7-¹⁸F]FTO ([¹⁸F]AS3504073-00) and 6-¹⁸F]FTO in the heart and bone were 9.77 (heart), 3.17 (bone), 9.26, n.d. and 7.25, 1.96 at 60 min after administration, respectively. **Conclusion:** In the present study, we clarified the relationship between the ¹⁸F position on 4-thia-oleate and the characteristics as a PET tracer. The only 7-position of ¹⁸F on 4-thia oleate was metabolically stable. With regard to the accumulation in heart, compounds in which the closer position of ¹⁸F to the olefin showed higher uptake. Taken together, we concluded [¹⁸F]AS3504073-00 was the best tracer among [¹⁸F]fluoro-

4-thia oleates. **References:** (1) DeGrado TR et al., J Nucl Med. 2010;51:1310-1317., (2) Murakami Y et al, SNMMI 2020 Annual meeting in New Orleans., (3) Fushiki H et al, SNMMI 2020 Annual meeting in New Orleans., (4) Ohshima Y et al, SNMMI 2020 Annual meeting in New Orleans.

OP-099

Production of [¹⁸F]AS3504073-00 for Investigational PET Imaging of Fatty Acid Beta-Oxidation in Human Subjects

Y. Murakami, H. Fushiki;

Astellas Pharma Inc., Tsukuba, JAPAN.

Aim/Introduction: Fatty acid beta-oxidation is a complex process involving several enzymes and transport proteins, and several SPECT and PET tracers have been developed. 3-[[[(3RS,5Z)-3-¹⁸F]Fluorotetradec-5-en-1-yl]sulfanyl]propanoic acid ([¹⁸F]AS3504073-00) was discovered as a novel PET tracer for fatty acid beta-oxidation, and showed high accumulation in heart and metabolically stable character. Preclinical toxicity studies of AS3504073-00 was already conducted, and the safety of [¹⁸F]AS3504073-00 for human administration was verified. In the present study, our goal is to establish the synthetic method of [¹⁸F]AS3504073-00 which meets the requirement of cGMP regulation. **Materials and Methods:** [¹⁸F]AS3504073-00 was prepared by two subsequent reactions, (i) a nucleophilic fluorination of the corresponding tosylate precursor with [¹⁸F]fluoride in the presence of tetrabutylammonium hydrogen carbonate in acetonitrile at 120 °C, for 10 min; (ii) hydrolysis of methyl ester with KOH at 110 °C, for 4 min. Product purification was done by semi-prep HPLC (Waters XBridge C18 column, 0.1 M HCl/CH₃CN=30/70), followed by solid phase extraction eluted with ethanol and saline dilution including ascorbic acid. The resulting solution is passed through a sterilizing 0.2 μm membrane filter into a sterile vial. **Results:** Progress with process validation demonstrated that 78.3 ± 3.7 mCi (EOS; 11.4 ± 0.6% RCY (DC)) of formulated [¹⁸F] AS3504073-00 could be made. Full QC was performed on these preparations to show that they met or exceeded the acceptance specifications required for the release of the drug product. The radiochemical purity was more than 97%, and the specific activity was over 5.1 Ci/micromol. Stability of the radiopharmaceutical was evaluated after storage in the final dosage form. The radiochemical purity of the product remained higher level, >95% up to at least 8 h after EOS at room temperature. **Conclusion:** An automated radiosynthesis of [¹⁸F]AS3504073-00 has been developed, and the procedure intended for clinical use meets the requirements of cGMP regulatory bodies. **References:** None

Longitudinal evaluation of myocardial fatty acid metabolism post-myocardial ischemia/reperfusion injury in the border and remote myocardium using ¹⁸F-fluoro-6-

thia-heptadecanoic acid PET imaging in swine model

F. Zhang^{1,2}, Y. Wang^{1,2};

¹The Third Affiliated Hospital of Soochow University, Changzhou, CHINA, ²Changzhou Key Laboratory of Molecular Imaging, Changzhou, Jiangsu Province, CHINA.

Aim/Introduction: Myocardial ischemia/reperfusion injury (MI/RI) is a pivotal therapeutic target to optimize revascularization therapy for acute coronary syndrome. Previous studies have found that reduced myocardial fatty acid (FA) uptake in ischemic myocardium, to date there have been no reports focusing on the myocardial substrate metabolism in the border and remote areas and its longitudinal changes. Thus, we used PET imaging to noninvasively evaluate the longitudinal uptake of 14(R,S)-¹⁸F-fluoro-6-thiaheptadecanoic acid (¹⁸F-FTHA) as analogs of FA to quantify myocardial metabolic substrate change in a swine model of MI/RI. **Materials and Methods:** Five male Bama miniature swine (weight 30–35 kg) were modeled by catheter-based 30 mins occlusion of left anterior descending coronary artery followed by reperfusion. ¹⁸F-FTHA PET, ^{99m}Tc-sestamibi (^{99m}Tc-MIBI) SPECT myocardial perfusion imaging (MPI), and echocardiography were performed simultaneously at baseline and 2h, 1, 5, 21, and 30 days post-MI/RI. The left ventricular myocardium was divided into the infarct, border, and remote areas. FA metabolism in different regions were assessed as ¹⁸F-FTHA uptake ratio (calculated as the ratio of Myocardium_{SUVmean} to Mediastinal Blood Pool_{SUVmean}) on PET imaging. The longitudinal changes of FA metabolism and differences between ischemic, border and remote areas were analyzed by repeated measurement ANOVA and generalized estimating equations. **Results:** ¹⁸F-FTHA uptake ratio in the three regions significantly decreased at 2h post MI/RI, reached the lowest point at 1 day, partially recovered at 5 days (All P < 0.05), and no significant differences were observed during the following 30-day follow-up period (All P > 0.05). FA metabolism in the ischemic area was significantly less than the border and remote areas at every time point post MI/RI. The ischemic area was the lowest, the border area was the second, and then was the remote area (All P < 0.05). Interestingly, reduced ¹⁸F-FTHA uptake ratio in the border and remote areas revealed very similar trends when compared with ischemic area in the progression of FA metabolism disorder following MI/RI. **Conclusion:** ¹⁸F-FTHA PET metabolism imaging, as a noninvasive molecular imaging, is a useful tool to monitor myocardial metabolism in vivo. FA metabolism in the LV myocardium decreased and changed dynamically after MI/RI. In addition to the ischemic region, myocardium FA metabolism was also impaired to varying degrees even in the border and remote regions after the onset of MI/RI, although the three showed a similar trend. This finding may suggest the mechanism underlying MI/RI and has important implications from the viewpoint of myocardial substrate metabolism. **References:** None

OP-101

Predicting post-ischemic angiogenesis with an APJ-specific PET radiotracer

B. Louis¹, A. Moyon², A. Bouhlef¹, L. Balasse¹, S. Fernandez¹, S. Simoncini³, G. Hache², F. Dignat-George⁴, P. Garrigue², B. Guillet²;

¹C2VN INSERM 1263 INRA 1260 CERIMED Aix-Marseille Université, Marseille, FRANCE, ²C2VN INSERM 1263 INRA 1260 CERIMED, APHM, Aix-Marseille Université, Marseille, FRANCE, ³C2VN INSERM 1263 INRA 1260 Aix-Marseille Université, Marseille, FRANCE, ⁴C2VN INSERM 1263 INRA 1260, APHM, Aix-Marseille Université, Marseille, FRANCE.

Aim/Introduction: APJ receptor, expressed in various tissues has recently been identified as a key player in angiogenesis and as an innovative pharmacological target to promote angiogenesis. Thereby, we aimed to evaluate an innovative PET imaging agent specific of APJ, [⁶⁸Ga]Ga-AP747, in two preclinical models of angiogenesis. **Materials and Methods:** AP747 was designed, synthesized, radiolabeled with gallium-68 and specificity was setup. Radiochemical stability in NaCl 0.9% and in human serum was validated up to 2h after synthesis by TLC. Swiss mice were subcutaneously implanted behind their neck with 400µL of Matrigel supplemented with 10% fetal bovine serum, described as a simple hypoxic model (n=7). Unilateral hindlimb ischemia (HLI) mouse model was initiated by femoral artery resection (n=8). LASER-Doppler perfusion imaging was performed up to day 21 after surgery and expressed as ischemic to non-ischemic limb blood flow ratio (i/c). On days 1, 3, 7, 10, 13 and 21 post-surgery, mice were IV injected with 5–10 MBq (50µL, 0.17µg) of [⁶⁸Ga]Ga-AP747. PET images were acquired 60 min after IV injection on a Mediso Nanoscan PET/CT and compared to PET images obtained after IV injection of 5–10 MBq (50µL, 0.17µg) of [⁶⁸Ga]Ga-NODAGA-RGD₂. **Results:** [⁶⁸Ga]Ga-AP747 was produced with a radiochemical purity of 96.7%±2.0 and radiochemical stability in serum evaluated at 2h (95.0±1.5%). In a simple hypoxic model, [⁶⁸Ga]Ga-AP747 accumulated in Matrigel and this accumulation was significantly higher than that of [⁶⁸Ga]Ga-NODAGA-RGD₂ from day 10 (*P=0.036), to day 21 (**P=0.002). In the ischemic model, we observed an intense, earlier and higher [⁶⁸Ga]Ga-AP747 PET signal in the ischemic hindlimb (peaking on day 7, i/c=5.49±5.98) than with [⁶⁸Ga]Ga-NODAGA-RGD₂ (peaking on Day 10, i/c=2.51±1.29; *P=0.066). Day 7 [⁶⁸Ga]Ga-AP747 PET signal in ischemic hindlimb was negatively correlated to LASER-Doppler signal at day of surgery (R²=0.6291; P=0.02), seeming to highlight that [⁶⁸Ga]Ga-AP747 PET signal within ischemic limb increased with tissue ischemia intensity. [⁶⁸Ga]Ga-AP747 PET signal in ischemic limb is more important when reperfusion is longer: signal at Day 7 (peak) is correlated to late reperfusion index (Day 21/ Day 1) (R²= 0.6245; P=0.02). **Conclusion:** We initially developed AP747 as a companion tool for APJ-modulating therapeutic strategies. We additionally postulate that PET imaging of APJ using AP747 could be a potential tool to

evaluate tissue angiogenesis. [⁶⁸Ga]Ga-AP747 PET imaging in two angiogenesis models: simple hypoxic model (Matrigel) and hypoxo-ischemic model (hindlimb ischemia), not only outbroke [⁶⁸Ga]Ga-RGD-based PET imaging, the actual reference in angiogenesis molecular imaging, but also was positively correlated with late reperfusion. **References:** None

OP-102

Dynamic evaluation of diastolic dyssynchrony by SPECT gated myocardial perfusion imaging early after acute myocardial infarction and the relationship with progression of left ventricular remodeling in swine model

F. Zhang^{1,2}, J. Wang³, X. Shao³, Y. Wang^{1,2};

¹The Third Affiliated Hospital of Soochow University, Changzhou, CHINA, ²Changzhou Key Laboratory of Molecular Imaging, Changzhou, Jiangsu Province, CHINA,

³The Third Affiliated Hospital of Soochow University, Changzhou, China Changzhou Key Laboratory of Molecular Imaging, Changzhou, Jiangsu Province, CHINA.

Aim/Introduction: Left ventricular diastolic asynchrony (LVDD), a dyssynchronous relaxation pattern, was known to develop after myocardial damage. We aimed to evaluate the dynamic changes of LVDD in the early stage of acute myocardial infarction (AMI) by phase analysis of ^{99m}Tc-sestamibi (^{99m}Tc-MIBI) SPECT gated myocardial perfusion imaging (GMPI) and its relationship with the progression of left ventricular remodeling (LVR). **Materials and Methods:** The left anterior descending coronary artery of 16 Bama miniature swine were occluded by balloon to build AMI models. Animals were imaged before AMI and at 1 day, 1 week and 4 weeks after AMI by SPECT GMPI, and quantitative analysis was performed to obtain the extent of myocardial perfusion defect (Extent), and LVDD parameters: phase histogram bandwidth (PBW) and phase standard deviation (PSD). Echocardiography was simultaneously applied to evaluate left ventricular end-diastolic volume (LVEDV), left ventricular end-systolic volume (LVESV) and left ventricular ejection fraction (LVEF). Both myocardial injury markers and 12-lead ECG were measured. The degree of LVR progression was defined as $LVEF_{AMI4\ weeks} - LVEF_{AMI1\ day} / LVEF_{AMI1\ day}$. Generalized estimating equations and Pearson linear correlation analysis were mainly used for data analysis. **Results:** Thirteen swine were successfully completed the study. LVDD changes dynamically at different time points after AMI. LVDD occurred as early as 1 day after AMI, peaked at 1 week, and there was a partial recovery trend in 4 weeks. PBW, PSD on 1 day after AMI were associated with LVRP, respectively ($r = 0.662, 0.617$, both $P < 0.05$). After adjusted for QRS duration and Extent, PBW, PSD on 1 day after AMI were independently associated with progression of LVR (PBW, OR=1.004, 95%CI: 1.001-1.007, $P=0.017$; PSD, OR=1.008, 95%CI: 1.000-1.017, $P=0.049$). In addition, the repeatability and reproducibility of LVDD by phase analysis of SPECT GMPI were all excellent

(ICCs: PBW: 0.948, 0.921; PSD: 0.977, 0.914, all $P < 0.001$). **Conclusion:** LVDD occurred on the first day of AMI, reaches its peak in 1 week and partly recovered in 4 weeks after AMI. LVDD evaluated by phase analysis of SPECT GMPI early after AMI could independently predict progression of LVR after adjusted for QRS duration and Extent. The early assessment of LVDD after AMI may provide helpful information for predicting the progression of LVR in the future. **References:** None

OP-103

[¹⁸F]AS3504073-00, Reflects Mitochondrial Fatty-Acid Oxidation in Physiological Alterations and Cardiac Disfunctions

H. Fushiki, Y. Murakami;

Astellas Pharma Inc., Tsukuba, Ibaraki, JAPAN.

Aim/Introduction: Myocardial energy metabolism is mainly dependent on Fatty Acid Oxidation (FAO) in ATP production, however, FAO alteration in cardiac dysfunction is still unclear. We reported [¹⁸F]AS3504073-00 as a novel PET probe for FAO with good property on higher uptake in heart and no defluorination in vivo. Here we report further evaluation of the accumulation in mitochondria and the character of [¹⁸F]AS3504073-00 in physiological alterations and cardiac disfunctions. **Materials and Methods:** [¹⁸F]AS3504073-00 was synthesized in house. DBA2 mice were used for biodistribution study of [¹⁸F]AS3504073-00 with or without etomoxir, an inhibitor for CPT-1, to understand specificity of accumulation of [¹⁸F]AS3504073-00 inside mitochondria. To understand the alteration of FAO in several physiological properties, uptake studies of [¹⁸F]AS3504073-00 were performed under starvation or exercising burden in DBA2 mice. Longitudinal PET imaging with [¹⁸F]AS3504073-00 was demonstrated to monitor the FAO status in both animals. Heart infarction model in monkey was established by occluding left anterior descending coronary artery (LAD). Head-to-head comparison of PET imaging with [¹⁸F]AS3504073-00 in acute (1-week) and subchronic (1-month) phase was conducted in ischemic heart disease monkey models. **Results:** [¹⁸F]AS3504073-00 was successfully synthesized with enough quality and purity. In the biodistribution study with etomoxir in mice, [¹⁸F]AS3504073-00 was mainly accumulated into brown adipose tissue, heart and diaphragm and these accumulations were inhibited with etomoxir. Food-restricting starvation and running burden, which induce upregulation of FAO, increased [¹⁸F]AS3504073-00 accumulation in several organs, including heart, diaphragm and skeletal muscle. In monkey LAD occlusion model, [¹⁸F]AS3504073-00 was visualized ischemic region at acute and subchronic phase. The higher uptake of [¹⁸F]AS3504073-00 was observed in non-ischemic heart region at subchronic phase rather than that at acute phase. These observations might reflect the metabolic dysfunction and the remodeling in ischemic heart disease.

Conclusion: [^{18}F]AS3504073-00 is shown to be a potential tool of mitochondrial FAO specific PET probe. The character of [^{18}F]AS3504073-00 warrants the usefulness with good specificity and imaging efficacious window in clarifying the several heart disease mechanism and region from FAO point of view.

Multitracer PET imaging for characterization of the IDH mutation in glioma: a translational in vitro and in vivo study

A. Clement¹, T. Zaragori¹, M. Doyen¹, R. Filosa¹, O. Ovdichuk¹, G. Hossu², C. Collet¹, F. Maskali¹, J. Pierson³, E. Roeder¹, G. Karcher⁴, A. Verger⁴;

¹Nancyclotep, Vandoeuvre-Les-Nancy, FRANCE, ²IADI UMR 1254, Vandoeuvre-Les-Nancy, FRANCE, ³CRAN UMR 7039, Vandoeuvre-Les-Nancy, FRANCE, ⁴Nuclear Medicine, Vandoeuvre-Les-Nancy, FRANCE.

Aim/Introduction: PET imaging is currently proposed as an adjunct to MRI for brain tumor characterization. This translational research project proposes to explore multi-tracer PET imaging for the non-invasive characterization of the mutation IDH1 in glioma, a factor of good prognosis.

Materials and Methods: U87 high-grade glioma isogenic cell lines with (CRISP/Cas9 method) or without IDH1 mutation (IDH1 +/-) were studied in vitro and in vivo after stereotactic grafts into brain rats through a 4 consecutive days protocol with static and dynamic PET imaging of glycolytic metabolism ([^{18}F]FDG), amino acid metabolism ([^{18}F]FDopa, [^{11}C]MET and [^{18}F]FET), angiogenesis ([^{68}Ga]NODAGA-(RGD)₂) and inflammation ([^{18}F]DPA-714), in association with anatomical MRI. In vitro, the radiotracer uptake was expressed as a percentage per million cells. In vivo, maximal and mean tumor-to-background ratios (TBR_{max} and TBR_{mean}) for static analysis, time-to-peak and slope curve parameters for dynamic analysis were calculated for each radiotracer.

Results: In vitro, IDH1+ cells showed significant lower levels of [^{68}Ga]NODAGA-(RGD)₂ and [^{18}F]DPA-714 uptake at all times of concentration measurements ($p \leq 0.04$ for all), in comparison to the IDH1- cells. These results were confirmed by in vivo analyses where lower uptake with [^{68}Ga]NODAGA-(RGD)₂ (7.19 vs. 9.70 for TBR_{max} , $p=0.01$) but significantly higher decreasing curves for [^{68}Ga]NODAGA-(RGD)₂ and [^{18}F]DPA-714 (respectively, -0.15 vs. 0.02 and -0.18 vs. 0.23, $p=0.04$) were observed in IDH1+ tumors. In univariate analysis, no other significant result was obtained in vitro and in vivo for the other tracers. In multivariate analysis, the combination of TBR_{max} and slope of [^{68}Ga]NODAGA-(RGD)₂ and slope of [^{18}F]DPA-714 provided the best diagnostic performances

to discriminate between the two isogenic cell lines (AUC of 0.87, $p < 0.01$). **Conclusion:** [^{68}Ga]NODAGA-(RGD)₂ and [^{18}F]DPA-714, reflecting lower angiogenesis and inflammation in IDH1+ tumors, are two independent tracers of choice for characterizing the IDH1 mutation in high-grade gliomas and should be translationally studied for clinical applications in patients. **References:** None

Towards simultaneous extracorporeal recordings of PET and MRI arterial input functions in mice

P. Backhaus^{1,2,3}, F. Büther^{1,2}, L. Wachsmuth³, S. Hermann², K. Schäfers², C. Faber³, M. Schäfers^{1,2};

¹University Hospital Münster, Department of Nuclear Medicine, Münster, GERMANY, ²University of Münster, European Institute for Molecular Imaging (EIMI), Münster, GERMANY, ³University of Münster, Translational Research Imaging Center (TRIC), Münster, GERMANY.

Aim/Introduction: Compartmental modeling in small animal PET and MRI can serve to better judge the performance of radiotracer candidates and the translational potential of contrast agent-driven perfusion studies. Precise recording of the arterial input function (AIF) is a key prerequisite for modeling, but its acquisition is very challenging in small animals. So far, no method for simultaneous recordings of PET radiotracers and MR contrast agent AIFs has been reported in mice. We recently introduced a novel experimental setup allowing to record perfusion MRI AIFs in mice using an extracorporeal circulation. The shunted blood perfuses two reservoirs that reside in the field of view of a 9.4 T Bruker MRI for dynamic recording of the arterial contrast agent concentration (Backhaus et al. 2020). This study aims to explore simultaneous recordings of the radiotracer AIF using MR compatible measuring units. **Materials and Methods:** We performed recordings of the extracorporeal radiotracer AIF with two MR-compatible measurement systems: (1) a Polyether ether ketone (PEEK) measuring chamber equipped with a plastic scintillator (beta microprobe, Biospace Lab) and (2) the Twilight blood sampler (SwissTrace, Zurich). The validity of the extracorporeal measurements and different approaches of dispersion correction were tested by comparison to the undispersed recorded AIF using a pair of beta microprobes inside the aortic arch and the mediastinum. **Results:** We could perform simultaneous measurements of PET and DCE-MRI AIF in mice using the beta microprobe measuring chamber after intravenous co-injection of Gadobutrol (Gadovist®) and ^{18}F -PSMA-1007 (14 - 38 MBq). The blood concentration peaks of the 2 agents showed very good quantitative agreement. In the validation experiments, the height of the dispersion corrected AIF peaks inside the measuring chamber were significantly smaller than simultaneously measured in vivo signals using the infraaortal and mediastinal microprobes in some animals.

Numerical simulations show that this may be explained by small accumulations of radioactivity within the chamber over the duration of the measurement. The two extracorporeal measurement systems showed comparable sensitivities. **Conclusion:** We demonstrate that recordings of the PET radiotracer AIFs can be simultaneously combined with the novel perfusion MRI extracorporeal circulation model using the two tested systems. This allows to firstly explore the potential synergistic effects for dual AIF recordings and integrated modeling in PET/MRI imaging in mice. **References:** Backhaus P, Büther F, Wachsmuth L, et al. Toward precise arterial input functions derived from DCE-MRI through a novel extracorporeal circulation approach in mice. *Magn Reson Med.* 2020;:1–12. doi:10.1002/mrm.28214

OP-106

Succinate promotes neovascularization in a peripheral ischemia rodent model: a microPET/CT study

A. Moyon, L. Balasse, S. Fernandez, G. Hache, F. Dignat-George, P. Garrigue, D. Taïeb, B. Guillet;
APHM, Marseille, FRANCE.

Aim/Introduction: Beyond its role in carbohydrate metabolism as a tricarboxylic acid cycle intermediate, succinate has a hormone-like function acting in various tissues and in tumors (1). GPR91 is a G protein-coupled receptor activated by specific binding with extracellular succinate. In recent years, it has been described that activation of the GPR91-ERK1/2-C/EBP- β signaling pathway played an important role in regulating angiogenesis through VEGF transcription (2) and was associated with neovascularization notably in diabetic retinopathies (3) and rheumatoid arthritis (4). Therefore, we hypothesized that succinate could be a simple and original key promoter of therapeutic angiogenesis and vascular regeneration in peripheral ischemia. **Materials and Methods:** Swiss mice (n=18) were subjected to right hindlimb ischemia induced by ligation and partial resection of the right femoral artery. Ischemic mice were daily injected with succinate solution (1mM in PBS pH7.4, 10 μ L, n=10) or with PBS (10 μ L, n=8) in the gastrocnemius muscle up to day 23 post-ischemia. Hindlimb perfusion was measured in vivo by LASER Doppler on days 1, 3, 8, 15, and 24 after ischemia, and results were expressed as mean \pm s_d ipsi- to contralateral ratios (i/c). To assess in vivo angiogenesis, mice were injected in the caudal vein with 5.8 \pm 1.5 MBq/50 μ L [⁶⁸Ga]Ga-RGD₂ allowed to rest for 60 min then underwent a 20min-long microPET/CT scan on days 4, 7, 10 and 14 after ischemia. Quantifications from [⁶⁸Ga]Ga-RGD₂ microPET/CT in ischemic hindlimb were expressed as percentage of the injected dose per gram of tissue (%ID/g). Statistical analysis was performed with Prism v8.4.2 (Graphpad software). **Results:** Over the 24-day follow-up by LASER-Doppler, succinate treatment enabled an earlier and more intense reperfusion of the ischemic hindlimb compared to PBS treatment (*P=0.0189)

and especially on day 8 (i/c succinate: 72.3 \pm 18.5%; i/c PBS: 49.3 \pm 20.8%; *P=0.0110) and on day 15 (i/c succinate: 75.8 \pm 8.9%; i/c PBS: 50.6 \pm 23.4%; **P=0.0040). Interestingly, [⁶⁸Ga]Ga-RGD₂ microPET quantifications on day 4 (succinate: 0.32 \pm 0.17%ID/g; PBS: 0.10 \pm 0.07%ID/g; *P=0.0295) translating an earlier angiogenic activation maintained up to day 10 post-ischemia enabled by succinate treatment, corroborating with the clinical benefits on hindlimb perfusion. **Conclusion:** The present study shows that intramuscular injections of succinate promote earlier angiogenesis resulting in earlier and more intense revascularization in a hindlimb ischemia mouse model. This microPET/CT study provides an impetus to better characterize the determinants of post-ischemic vascular regeneration through GPR91 and downstream signaling pathways. **References:** (1) [https://doi.org/10.2967/jnumed.117.192674\(2\)](https://doi.org/10.2967/jnumed.117.192674(2)) [https://doi.org/10.18632/oncotarget.14485\(3\)](https://doi.org/10.18632/oncotarget.14485(3)) [https://doi.org/10.1038/srep45807\(4\)](https://doi.org/10.1038/srep45807(4)) <https://doi.org/10.1016/j.freeradbiomed.2018.07.009>

Modeling DNA damage induced by targeted radionuclide therapy

G. Tamborino^{1,2}, M. De Saint-Hubert¹, L. Struelens¹, J. Nonnekens^{2,3}, M. W. Konijnenberg², M. De Jong², Y. Perrot⁴, C. Villagrasa⁴;
¹Research in Dosimetric Applications, Belgian Nuclear Research Centre (SCK-CEN), Mol, BELGIUM, ²Department of Radiology & Nuclear Medicine, Erasmus MC, University Medical Center Rotterdam, Rotterdam, NETHERLANDS, ³Department of Molecular Genetics, Erasmus MC, University Medical Center Rotterdam, Rotterdam, NETHERLANDS, ⁴Institut de Radioprotection et de Sécurité Nucléaire (IRSN), Fontenay aux Roses, FRANCE.

Aim/Introduction: The aim of this study is to build a simulation framework to evaluate the number of DNA double strand breaks (DSBs) occurring during in vitro targeted radionuclide therapy (TRNT), adapting a simulation chain that has been benchmarked against external beam radiotherapy. This work represents the first step towards modeling DSBs during TRNT with the ultimate goal of exploring underlying biological mechanisms and influence of physical/chemical parameters to enable a better response prediction in patients. This tool characterized early DSB induction by [¹⁷⁷Lu]Lu-DOTA-[Tyr³] octreotate (¹⁷⁷Lu-DOTATATE), a commonly used TRNT for neuroendocrine tumors. **Materials and Methods:** A multiscale approach is implemented to simulate the number of DSBs produced by the cumulated decays of ¹⁷⁷Lu-DOTATATE, preliminary assumed as purely beta emitter, without

including any repair. The approach involves 2 sequential simulations performed with Geant4/Geant4-DNA and accounts for a realistic geometry of the cell population and detailed sampling of the activity distribution within it. In order to reproduce the exposure conditions of cells incubated 4h with ^{177}Lu -DOTATATE(2.5MBq/ml), a phase space is scored by recording particles that enter the nucleus of a cell belonging to a population modelled by realistic polygonal mesh structures. The radioactive source is sampled according to previous uptake experiments on the distribution of activities within medium and cells, assuming instant and permanent internalization. Following, the particles recorded in the phase space file are released within an ellipsoidal nucleus geometry, including a multi-scale description of the DNA. DnaFabric software is used to model the entire human genome with a continuous chromatin fiber per chromosome. This geometry is used to simulate the physical, physicochemical and chemical stages in Geant4-DNA in order to score the number of DSB/decay. **Results:** Our results reveal induction of 6-10 DSBs/cell, depending on the confluence level of the cell population, compared to on average 11 ± 2 DSBs/cell which were experimentally measured. This slight difference may arise from neglected or simplified contributions dealing with physics (i.e. ^{177}Lu spectrum, radionuclide localization, morphological variation within a cell population, chromatin compaction, nuclear size), chemistry (i.e. extended chemical stage simulation time) or biology (i.e. other pathways for DSB formation) that are currently under investigation. **Conclusion:** Monte Carlo Track Structure codes, such as Geant4-DNA, are considered as suitable tools for the study of biological responses to ionizing radiation. Overall a better understanding of the mechanisms and biophysical parameters characterizing biological damage will allow to improve our ability to predict responses on a clinical scale. **References:** None

OP-108

Understanding the LET dependence of the RBE observed in cell assays irradiation

S. Walrand, M. Hesse, R. Lhommel, F. Jamar;

Université Catholique de Louvain, Brussels, BELGIUM.

Aim/Introduction: to derive an analytical expression for the RBE in term of the particle track structure properties which can be computed in water using Geant4-DNA. **Materials and Methods:** the DSB probability resulting from n SSB produced in n_{bp} base-pairs by a particle track is $n(n-1)/4n_{\text{bp}}$ (1). The probability distribution and geometric considerations governing the SSB induction by a free radical, the production of a free radical by a particle track and the number of track corresponding to a given nucleus dose were identified. These processes were successively mathematically applied to eq. 1 an resulted in a simple mathematical expression for the DSB probability. **Results:** The radiosensitivity was found to be

$\alpha(\text{LET}) = N_{\text{bp}} F f(\text{LET})^2 Y(\text{LET})$, where N_{bp} is the total genome length in base-pair units, F is a form factor depending on the nucleus and on the DNA compaction geometry, f is the particle track structure radius FWHM and Y is the free radicals yields. Both parameters f and Y were computed for various particles and LET values using Geant4-DNA. Using a single fitted F value for all, the RBE was rightly predicted for hamster V79 cells irradiated with proton, deuteron, He3 and alpha particle for LET ranging from 10 up to 150 keV/ μm . **Conclusion:** The RBE is simply the product of 4 distinct quantities: the genome length, a form factor F depending on the spatial DNA compaction, the particle track FWHM and the free radicals yield in water. **References:** None

OP-109

Strand DNA break non-linear dynamics equations perfectly predict the asymptotic high dose behaviour of log cells survival fraction post irradiation

S. Walrand, M. Hesse, R. Lhommel, F. Jamar;

Université Catholique de Louvain, Brussels, BELGIUM.

Aim/Introduction: the multiple-target model (MTM) requires an additional empiric term to explain the non-null slope of the log-survival curve at low dose, while the linear-quadratic model (LQM) requires an additional one to reproduce the linear asymptotical behaviour of the log-survival fraction at high dose. Our aim is to solve the full DNA SSB dynamics equations system including all non linear effects to overcome these models drawbacks. **Materials and Methods:** The equation governing the number N of viable cells is: $dN = -(Y N_{\text{bp}} N dD) (n/(2 N_{\text{bp}} N)) - \alpha N dD (1)$, the first term is the SSB production (Y is the free radicals yield) and the second one is the probability that the SSB occurs in the mirror base of an already existing SSB in order to produce a DSB. The last term is the probability of a direct DSB production. The total number n of SSB inside these viable cells is governed by: $dn = (Y N_{\text{bp}} N dD) P + n/N dN (2)$, the second term takes into account that when a cell is condemned its SSB leaves the pool N of viable cells. $P = (1 - n/(N_{\text{bp}} N)) (3)$ takes into account that a new SSB is produced only if the free radical hits an intact base-pair. **Results:** Taking into account that $Y \ll \alpha$, the analytical integration of eq. 1-3 shows that the LQM β term is simply multiplied by: $\text{eff}(D) = (\alpha D + e^{-\alpha D} - 1) / (\alpha^2 D^2 / 2)$. At low dose this efficacy term tends to unity giving back the conventional LQM β term, at high dose it tends to $2/(\alpha D)$ explaining the linear asymptotical behaviour. Assuming n proportional to $N D$ in eq. 1 gives back the conventional LQM at any dose. Confrontation with cell assay survival curves proves $\text{eff}(D)$ quantitatively predicting the linear asymptotic position. **Conclusion:** Linear asymptotic behaviour of the log-survival curve simply results from the non-linear feature of the SSB dynamics equations. **References:** McParland BJ. Nuclear medicine radiation dosimetry: advanced theoretical principles. Springer Science & Business Media; 2010 Jul 3.

OP-110**Radiobiology of Auger Electron-emitter Technetium-99m: In Vitro Toxicity in Triple Negative Breast Cancer Cells Expressing Human Sodium Iodide Symporter**

I. Costa¹, N. Siksek¹, K. Osytek¹, A. Volpe¹, F. Man¹, E. Verger¹, G. Schettino^{2,3}, G. O. Fruhwirth¹, S. Y. A. Terry¹;

¹King's College London, London, UNITED KINGDOM, ²National Physical Laboratory, Teddington, UNITED KINGDOM,

³University of Surrey, Guilford, UNITED KINGDOM.

Aim/Introduction: Gamma-emitting technetium-99m is widely used in nuclear medicine diagnostic scans. It also emits on average 4 Auger electrons and 1.1 internal conversion electrons per decay⁽¹⁾. Despite increasing use of Auger electrons for molecular radionuclide therapy (MRT)⁽¹⁾, technetium-99m derived Auger electrons remain unexplored. This study explores the potential of technetium-99m for MRT and its imaging safety in triple negative breast cancer cells. **Materials and Methods:** MDA-MB-231 cells expressing human sodium iodide symporter (hNIS) were incubated with [^{99m}Tc]TcO₄ at activities up to 4 MBq/mL and for up to 24 hours. Efflux and intracellular location of [^{99m}Tc]TcO₄ using fractionation methods were determined and absorbed dose to the nucleus calculated. Toxicity in both parental and hNIS-expressing cells of [^{99m}Tc]TcO₄ was determined using clonogenic assays and compared to untreated cells, [⁹⁹Tc]TcO₄ and Caesium-137. Direct and indirect formation of DNA damage was determined using the γ-H2AX assay and radical scavenger Dimethyl sulfoxide (DMSO). A preliminary in vivo study was carried out by establishing orthotopic breast cancer models using hNIS-expressing cells and the biodistribution of [^{99m}Tc]TcO₄ determined at 30 minutes and 24 hours post-intravenous administration of [^{99m}Tc]TcO₄ by SPECT/CT imaging. **Results:** Intracellular uptake of [^{99m}Tc]TcO₄ peaked at 30 minutes, reaching a maximum intracellular activity of 1.9 ± 0.2 Bq/cell, with 50% efflux observed after 35.6 ± 0.2 minutes post-incubation, contributing to a maximum nuclear absorbed dose of 1.85 Gy at 24 hours. Following 30 minutes and 24 hours incubation with 4 MBq/mL, the average foci/nucleus increased by 13.4 ± 3.1 and 18.7 ± 3.1 compared to untreated cells, respectively. No decrease in average foci/nucleus was observed with DMSO and 24 hours post-incubation values were still greater than control. No DNA damage was observed in parental cells nor with [⁹⁹Tc]TcO₄. Survival fraction was reduced only in hNIS-expressing cells at 24 hours (A₅₀=0.76 Bq added/cell). In vivo, [^{99m}Tc]TcO₄ was taken up by endogenously hNIS-expressing organs and tumours at 30 minutes and at 24 hours post-administration [^{99m}Tc]TcO₄ was retained only in the hNIS-expressing tumours (28 ± 2.3%ID/g). **Conclusion:** In vitro toxicity, direct and partially repaired DNA damage following intracellular uptake of [^{99m}Tc]TcO₄ and its in vivo retention in hNIS-expressing tumours at 24 hours show that technetium-99m derived Auger electrons must not be neglected in

dosimetry calculations. Further research is needed to determine the potential and limitations of technetium-99m for MRT/theragnostics and the appropriate doses for use in imaging without safety concerns. **References:** (1)Ku, A. et al. EJNMMI radiopharm (2019)

OP-111**Ratiometric relationship between γH2AX imaging and Lutetium-177 is predictive of survival following radionuclide therapy in vivo**

E. O'Neill, G. M. Dias, B. Cornelissen;

University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: There is growing interest in progressing radionuclide therapies such as [¹⁷⁷Lu]Lu-DOTATATE from a palliative treatment with effective symptom control into a treatment with curative intent. Yet to justify any increase in radionuclide dose to patients and risk additional normal toxicity, a suitable metric is needed to determine the required ¹⁷⁷Lu dose for each tumour within a patient. We have previously shown that [¹¹¹In]In-anti-γH2AX-TAT is capable of visualising the DNA double strand break damage response to the radionuclide therapy [¹⁷⁷Lu]Lu-DOTATATE. Here, we demonstrate that by using the gamma emissions from [¹¹¹In]In-anti-γH2AX-TAT alongside those of the ¹⁷⁷Lu, a suitable SPECT image-based metric can be calculated that is predictive of in vivo therapeutic effect. **Materials and Methods:** Athymic mice bearing CA20948 somatostatin receptor positive tumour xenografts were treated with varying levels of [¹⁷⁷Lu]Lu-DOTATATE (5 to 30 MBq), staggered into two cohorts and injected with [¹¹¹In]In-anti-γH2AX-TAT at either day 0 or day 4 of treatment and imaged by SPECT to image γH2AX formation kinetics and ¹⁷⁷Lu retention over days 1,3,5,7,9 and 11 of treatment. Tumour growth was monitored by calliper up to 90 days and survival determined by tumour doubling times and ethical biological endpoints. The daily kinetics of γH2AX foci formation were investigated using CA20948 cells in vitro in response to varying levels of [¹⁷⁷Lu]Lu-DOTATATE by immunofluorescence up to day 11. **Results:** Voxel-based SPECT analysis of dual isotope images revealed the linear relationship between ¹¹¹In and ¹⁷⁷Lu within each xenograft tumour to undergo a pivotal change between days 5 and 7 post-injection of [¹⁷⁷Lu]Lu-DOTATATE. The ratio between day 5 and 7 of the linear gradient of ¹¹¹In: ¹⁷⁷Lu correlated significantly with survival (r = 0.98, P<0.0001), representing both loss of ¹⁷⁷Lu from cell death, and sustained γH2AX expression in tumour regions with retained lower ¹⁷⁷Lu levels. This pivot was investigated in vitro by immunofluorescence and revealed widespread apoptosis at day 6 with γH2AX foci counts negatively correlating with [¹⁷⁷Lu]Lu-DOTATATE clonogenic survival (r = -0.995, P = 0.0005). **Conclusion:** We describe the use of γH2AX imaging with ¹¹¹In: ¹⁷⁷Lu dual isotope imaging following ¹⁷⁷Lu radionuclide therapy as an attractive strategy to predict tumour growth inhibition. This

temporal ratiometric contrast approach can therefore be used to measure therapeutic success and as any potential inter-individual differences in [^{111}In]In-anti- $\gamma\text{H2AX-TAT}$ uptake is in effect normalised within each individual by temporal comparison it presents a promising dual isotope imaging strategy to support personalised radionuclide therapy. **References:** None

OP-112

Differences of ex vivo and in vivo DSB induction and repair after internal irradiation in PMBCs during radioiodine therapy

S. Schumann¹, H. Scherthan², P. E. Hartrampf¹, A. K. Buck¹, M. Port², M. Lassmann¹, U. Eberlein¹;

¹Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY; ²Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.

Aim/Introduction: A sub-study of the MEDIRAD project investigates the effects of low doses in patients with differentiated thyroid cancer (DTC) during radioiodine therapy. One aim is to analyse the time- and dose-dependent induction and repair of DNA double-strand breaks (DSBs) in peripheral blood mononuclear cells (PBMCs) in vivo and ex vivo after internal irradiation with [^{131}I]NaI. **Materials and Methods:** Radiation-induced DSBs were quantified in blood samples of 7 DTC patients taken before, and 1h, 2h, 3h, 4h and 24h after [^{131}I]NaI administration. One part of the blood sample taken before therapy start was exposed internally by adding [^{131}I]NaI to reach, after 1h incubation, an absorbed dose to the blood of 50mGy. The remaining non-irradiated blood served as baseline sample. To investigate the ex vivo repair, PBMCs isolated from all samples were either directly ethanol-fixed, or fixed after short time culture in RPMI for 4h and 24h. For the samples taken during the therapy, PBMCs were directly isolated and ethanol-fixed. All samples were immuno-stained with $\gamma\text{-H2AX}$ and 53BP1 antibodies and co-localized foci were counted manually. **Results:** After ex vivo irradiation, a mean of 0.57 ± 0.14 radiation-induced foci per cell (RIF) was observed after direct fixation. The mean number of RIF decreased to 0.27 ± 0.09 after 4h and 0.06 ± 0.04 after 24h. In vivo, the mean number of RIF was 0.40 ± 0.20 , 0.58 ± 0.21 , 0.67 ± 0.18 , 0.73 ± 0.18 , and 0.42 ± 0.17 at 1h, 2h, 3h, 4h and 24h after therapy start, respectively. The mean absorbed dose to the blood at the five time points was $(15 \pm 2)\text{mGy}$, $(29 \pm 5)\text{mGy}$, $(47 \pm 8)\text{mGy}$, $(65 \pm 12)\text{mGy}$ and $(193 \pm 37)\text{mGy}$. Comparing the directly fixed ex vivo values to the in vivo results, the number of RIF is comparable to the value 3h after therapy start at a similar absorbed dose to the blood. **Conclusion:** Due to the continuous irradiation in vivo, the number of DSBs increased up to 4h after therapy start and DSBs were not completely repaired 24h after administration. Ex vivo, DSB numbers were decreased 4h after washing out the activity and DSB repair was almost completed after 24h. This study shows

that the continuous irradiation with decreasing, however non-negligible, dose rates in patients leads to altered repair kinetics in vivo, as there is most likely still DSB induction competing with repair. This finding contrasts with the ex vivo exposure, where irradiation is stopped by removing the activity. Future steps involve patient-specific calculations of the dose-dependent repair kinetics and the inclusion of more patients. **References:** None

OP-113

A whole-body physiologically-based pharmacokinetic model of [^{212}Pb]Pb-DOTAMTATE in neuroendocrine-tumour bearing mice

N. Zaid, P. Kletting, A. Beer, G. Glatting;
Ulm University, Ulm, GERMANY.

Aim/Introduction: The use of alpha-emitter labelled somatostatin analogues for peptide receptor radionuclide therapy (PRRT) is a promising therapeutic option for neuroendocrine tumours (NETs). The short-range cytotoxic alpha particles reduce the nephrotoxicity and overcome the radioresistance of NETs to beta emitters in PRRT. Mathematical modelling helps performing cost- and animal-free investigations to study the pharmacokinetics of alpha-emitter labelled somatostatin analogues and speeds up the translation from bench to bedside. Therefore, we developed a physiologically-based pharmacokinetic (PBPK) model to describe the pharmacokinetics of [^{212}Pb]Pb-DOTAMTATE targeting somatostatin receptor type2 in AR42J-bearing mice to improve treatment planning in alpha-emitter based PRRT for NETs. **Materials and Methods:** A whole-body compartmental model was developed and selected among other developed models based on the Akaike Information Criterion (AIC) using the modelling software SAAM II (v2.3, The Epsilon Group, TEG, USA). The model describes all major physiological mechanisms (peptide distribution, extravasation, receptor binding, specific and non-specific uptake in the kidneys, internalization and excretion) and physicochemical decays (physical decay and chelator stability) with parameter values from the literature. Data of [^{212}Pb]Pb-DOTAMTATE biodistribution in mice bearing AR42J rat xenografts were used for evaluating the developed model¹. The fit was performed by intravenous injection of 0.0015 nmol of [^{212}Pb]Pb-DOTAMTATE with a molar activity of 0.13 GBq/nmol in a 30 g mouse. The time-activity curves for the tumour, pancreas, kidneys, spleen and lung were fitted to estimate the receptor densities as well as the plasma flow-rate to the tumour. The calculated receptor density responsible for non-specific uptake in the kidneys was 17 nmol/l. **Results:** The developed model could successfully describe the published experimental data. The fitted curves were good by visual inspection and $R^2 > 77\%$. The tumour-specific receptor density and plasma flow-rate were (27 ± 33) nmol/l and (0.05 ± 0.03) ml/min/g, respectively. The specific receptor

densities in pancreas, spleen, kidneys and lung were (5.8±2.0) nmol/l, (0.8±0.3) nmol/l, (3.7±1.6) nmol/l and (1.8±0.7) nmol/l, respectively. **Conclusion:** The model best supported by the data successfully simulated the ^{212}Pb]Pb-DOTAMTATE biodistribution study. The developed ^{212}Pb -PBPK model allows for simulating the biokinetics of radiolabelled and unlabelled pharmaceuticals and free radionuclides in the whole mouse body. The ability of the model to estimate important physiological parameters, such as receptor densities and specific and non-specific uptakes, and subsequently predict optimal dosing regimens will reduce the required time for translation from bench to bedside. Consequently, the model allows for generating hypotheses for experiments leading to improve alpha-emitter-based PRRT for NET. **References:** 1. Stallons et al., *MolCancerTher.* 2019;18(5):1012-1021.

OP-114

Modelling Show Alpha-emitter Astatine-211 is an Apposite Candidate for Intra-theal Radioimmunotherapy of Neuroblastoma Metastasized to the Central Nervous System

S. Palm¹, T. Bäck¹, E. Leidermark¹, S. Lindegren¹, E. Aneheim¹, H. Jensen², R. Hultborn¹, P. Albertsson¹, L. Jacobsson¹;

¹University of Gothenburg, Gothenburg, SWEDEN,

²Rigshospitalet, Copenhagen, DENMARK.

Aim/Introduction: At least two antibodies, 3F8 and 8H9, have been used in clinical trials with the beta-emitting radionuclide ^{131}I for intra-theal radioimmunotherapy of neuroblastoma metastasized to the central nervous system (1,2). Published models indicates that a better ratio of absorbed dose to tumor over that to critical healthy tissues can likely be achieved by instead using alpha-emitting radionuclides (3). In the current work, we model the possible effect of using alpha-emitter astatine-211 (half-life 7.2h) as radiolabel for 3F8 and 8H9. **Materials and Methods:** 3F8 antigen binding properties were taken from (4). The transport mechanisms were simulated using the software package STELLA (ISEE Systems, Inc.). The resulting time-dependent biodistribution was then used as input for dosimetry. Microdosimetry was performed by an in-house-constructed Monte Carlo program. **Results:** The model allow estimates of efficacy and toxicity for varying a range of input parameters. Based on this optimization of the therapy can be done. An example is provided for specific activity where 1 of 100 mAbs are radiolabeled with At-211 and cancer cells have 500.000 antigens specific for 3F8. For a maximum of 0.4 Gy to the bone marrow, 83 MBq ^{211}At -3F8 can be infused intra-theally to a 20 kg patient. Absorbed dose to single cancer cells within the cerebrospinal fluid (CSF) is estimated to 19 Gy. Unspecific absorbed dose to CSF surfaces is 5 Gy. Cancer cells directly accessed by blood will receive 5.2 Gy. **Conclusion:** Modelling show that safe amounts of ^{211}At -labelled 3F8 antibodies, delivered intra-theally, could eradicate neuroblastoma cells accessed by the cerebrospinal

fluid, and possibly also cells accessed by blood. **References:** 1. *J Clin Oncol* 25:5465-5470 2. *J Nucl Med* 2019; 60:1794-1801 3. *Eur J Nucl Med Mol Imaging* (2011) 38:334-342 4. *Oncoimmunology*. 2012 Jul 1;1(4):477-486.

Biodistribution and dosimetry studies for the optimization of pre-targeted radionuclide therapy using ^{211}At -labeled modified biotin

N. Ukon¹, K. Washiyama¹, A. Sugiyama², S. Zhao¹, T. Tatsumi², M. Aoki¹, K. Yamatsugu², K. Nishijima¹, S. Shimoyama¹, C. Tan¹, T. Joho¹, N. Oriuchi¹, M. Kanai², K. Takahashi¹, T. Kodama²;
¹Fukushima Medical University, Fukushima, JAPAN,
²The University of Tokyo, Tokyo, JAPAN.

Aim/Introduction: The pre-targeting strategy increases the absorbed dose to a tumor while reducing the side effects affecting normal tissues, resulting in a high therapeutic effect. Although the pre-targeting system has been selected and characterized, at least four variables remain to be adjusted: the dosage of the pre-targeting agent, pre-targeting interval (time between injections of the pre-targeting agent and radiolabeled effector), dosage of the effector, and detection time (time to sacrifice post-injection of the radiolabeled effector). The aim of this study was to optimize the pre-targeting interval time between injections of the pre-targeting agent and radiolabeled effector in our developed system. **Materials and Methods:** We used both mutated streptavidin with low immunogenicity, which can fuse to four single-chain variable fragments (scFv), called "Cupid", and a modified bis-iminobiotin corresponding to Cupid with a specific affinity, called "Psyche". Psyche-B, which is a Psyche, was labeled with ^{211}At . Anti-CEACAM5 scFv-conjugated streptavidin (CEA-Cupid, 100 pmol) was administered to carcinoembryonic antigen (CEA)-positive human gastric cancer cells xenograft BALB/c nu/nu mice. After 24, 48, and 72 h, the mice were injected with 250 kBq of ^{211}At -labeled Psyche-B (^{211}At -Psyche-B) and sacrificed at 1 min, 1 h, 6 h, and 24 h after the ^{211}At -Psyche-B injection. Samples were collected and measured for radioactivity using a gamma counter. The absorbed radiation dose for each interval condition was calculated using OLINDA/EXM ver. 2.0. **Results:** At the 24-h interval, ^{211}At -Psyche-B in blood decreased with time, and approximately 94% of the injected dose was excreted within 24 h. The tumor accumulation was 16.3 ± 4.1 %ID/g at 24 h after the ^{211}At -Psyche-B injection; this decreased to 11.28 ± 3.33 %ID/g and 1.47 ± 0.23 %ID/g at 24 h after ^{211}At -Psyche-B injection when the interval condition changed to 48 h and 74 h, respectively. The absorbed dose to the kidneys was greater as the pre-targeting interval condition was longer in the mouse model. The absorbed dose of the tumor was calculated using the sphere model, and the tumor-to-kidney ratio was calculated. The absorbed dose to the tumor was higher when the pre-targeting

interval condition was shorter. The tumor-to-kidney ratios showed the same trend. **Conclusion:** Tumor accumulation of ^{211}At -Psyche-B increased over time when the pre-targeting interval was 24 h. The results of our study suggested that a pre-targeting interval of 24 h may be optimal for our pre-targeted radionuclide therapy using Cupid and Psyche-B. **References:** Sugiyama et al., Proc. Jpn. Acad. Ser. B 95:602, 2019

OP-116

Multi-regional dosimetry of mouse kidneys for beta-emitters

C. Saldarriaga Vargas^{1,2}, P. Covens², M. D'Huyvetter², V. Cavellers², B. W. Miller^{3,4}, L. Struelens¹;

¹Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM,

²Vrije Universiteit Brussel, Jette, BELGIUM, ³University of Colorado School of Medicine, Aurora, CO, UNITED STATES OF AMERICA,

⁴University of Arizona, Tucson, AZ, UNITED STATES OF AMERICA.

Aim/Introduction: Conventional preclinical internal dose estimates typically assume a uniform distribution of radioactivity and dose deposition throughout organ tissues. This assumption can deviate from reality for β/α -emitting radioligands with a heterogeneous tissue activity distribution. In this study S-values for internal dosimetry of β^- emitters were calculated for a multi-region model of a mouse kidney. The significance of regional S-values was demonstrated for the mouse kidney biodistribution of a ^{131}I -labeled single-domain anti-HER2 antibody fragment with predominant uptake in the outer medulla outer stripe. **Materials and Methods:** A stylized computational model of a mouse kidney was developed, consisting on ellipsoids delimiting 5 tissue compartments: cortex, outer medulla outer/inner stripes (IS/OS), inner medulla and papilla. Electron energy absorbed fractions (\emptyset) for the different kidney regions were calculated for ^{131}I and ^{90}Y , from photon-electron transport simulations using MCNP6.2 code. A sensitivity study on the influence of model specifications (kidney volume, cortex occupancy) was performed. For the ^{131}I mouse study, time-dependent regional kidney-tissue activities were determined from the relative regional activity concentrations of kidney sections measured with digital β^- -particle autoradiography (using an iQID system), relative to the whole-kidney activity measured with conventional gamma counting. **Results:** For ^{131}I , a large fraction of the emitted β^- energy is absorbed within the sub-kidney source region itself ($\emptyset \geq 0.60$). Because of this and the smaller masses of sub-kidney tissues, the self-irradiation regional S-values are considerably higher (30% to >200% depending on kidney region) than whole-kidney S-values. Compared to ^{131}I , ^{90}Y regional self-absorbed fractions are lower ($\emptyset < 0.35$). Yet, the difference between self-irradiation regional and whole-kidney S-values is still very large ($\geq 100\%$) for most renal tissues. β^- cross-irradiation is significant (\emptyset often > 0.10) between most regions for ^{90}Y and between

adjacent regions for ^{131}I (e.g. cortex/OS, OS/IS). The sensitivity of self-absorbed fractions to the kidney model specifications was typically small for ^{131}I (<5% deviation between models) and moderate for ^{90}Y (<20%). For the ^{131}I mouse study, regional dose rates and time-integrated doses based on a heterogeneous activity distribution differ largely (-60% to >100% depending on region) from the uniform whole-kidney dose based on a homogeneous activity distribution. **Conclusion:** The calculated regional S-values, in combination with sub-kidney activity information, allow a more realistic estimation of the doses absorbed by different renal tissues from β^- -emitting radioligands with a heterogeneous kidney uptake. This provides new dose information relevant for preclinical investigations studying the risk of radiation-induced nephrotoxicity of these therapies. **References:** None

Transarterial radioembolization versus drug-eluting beads chemoembolization for treatment of inoperable early and intermediate hepatocellular carcinoma: interim results of the randomized controlled TRACE trial

B. Lambert¹, E. Dhondt², L. Hermie², X. Verhelst², L. Defreyne²;

¹Ghent University, Ghent, BELGIUM, ²Ghent

University Hospital, Ghent, BELGIUM.

Aim/Introduction: To compare the efficacy of Y90 radioembolization (TARE) with drug-eluting beads chemoembolization (DEB-TACE) for early and intermediate hepatocellular carcinoma (HCC), not amenable to curative treatment modalities. **Materials and Methods:** Patients with HCC in an early or intermediate Barcelona Clinic Liver Cancer (BCLC) stage A-B, extended to patients with ECOG 1 performance status and/or segmental portal vein thrombosis (PVT), and not eligible for surgery or thermo-ablation were included in a randomized controlled trial comparing TARE with DEB-TACE. Exclusion criteria were: prior tumor treatment in the same segment, > 50% tumor involvement, main and lobar PVT, a Child-Pugh score > 7 and ECOG \geq 2. DEB-TACE was performed as selective as possible with 100-300 μ m and 300-500 μ m DEB loaded with a total of 150 mg doxorubicin. DEB-TACE could be repeated up to 3 times per lesion. TARE, using Y90 glass microspheres, was administered lobar or more selective if possible. Bilobar disease was treated with a 30-45 days interval. The administered activity was calculated to deliver an 80-150 Gy dose in the targeted area. The primary endpoint was time to progression (TTP) at 2 years and was assessed by blinded, non-chronological central review according modified Response Evaluation Criteria In Solid Tumors (mRECIST). Secondary endpoints were time to local tumor progression (TLP) in the treated liver volume at 2 years, safety (adverse events and 30-day mortality) and overall survival. Adverse events were recorded according to the Common Terminology Criteria for Adverse Events (CTCAE). **Results:** 73 patients were included. Five patients were post-hoc excluded. 32 patients received TARE and 36 patients DEB-TACE. Median TTP in the TARE group was 514 days versus 285 days in the DEB-TACE group ($p < 0.001$). Median TLP for TARE was 514 days versus 300 days for DEB-TACE ($p = 0.001$). Median survival in the TARE group was 906 days versus 455 days in the DEB-TACE group ($p = 0.005$). Adverse events CTCAE grade ≥ 3 ($p = 0.3$) and 30-day mortality ($p = 0.2$) were similar in both treatment groups. **Conclusion:** In the selected BCLC stage A and B HCC patients, TARE was superior to DEB-TACE for tumor control and survival. Safety was similar for both groups. **References:** None

OP-121

Clinical and Dosimetric Parameters Associated with Contralateral Liver Hypertrophy after Lobar SIRT

F. Grisanti, P. Rodrigo, J. F. Bastidas, J. J. Rosales, A. Bronte, E. Prieto, C. Beorlegui, M. Iñarrairaegui, B. Sangro, M. Rodríguez-Fraile; Clinica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: To identify clinical and dosimetric parameters associated with contralateral hepatic hypertrophy after lobar selective internal radiation therapy (SIRT) with 90Y-resin microspheres. **Materials and Methods:** Patients underwent 90Y-PET/CT after lobar or extended lobar (right + segment IV) SIRT and were retrospectively studied with a 90Y-PET-based voxel dosimetry software (PLANET

Dose; DOSIsoft SA). Mean absorbed doses to tumoral and non-tumoral volumes (defined by excluding the tumor volume from the target liver; NTL) were obtained. Metrics were extracted from dose-volume histograms: D50, D70, D90, D95 and D98, as well as V30, V40, V50, V70, V100 and V120. Clinical variables were collected. Changes in volume of the treated and untreated lobes were calculated in imaging studies at <2 months (T1), 2-5 months (T2), and 6-12 months (T3) post-SIRT. The maximum percentage of hypertrophy of the untreated lobe (MHT) was obtained. Multivariable linear regression analyses were performed to identify predictors of MHT. Regression assumptions were verified (normality, homoscedasticity, and non-multicollinearity of residuals, as well as linearity of predictors). The best cut-off value to predict MHT \geq 20% was defined using ROC analysis. **Results:** Fifty patients were studied; most had primary liver tumours (74%), 50% had chronic liver disease, and 42% had been treated with chemotherapy prior to SIRT. Hypertrophy of the untreated lobe was found in T1 (21.6% \pm 28.9), T2 (38.6% \pm 56.5) and T3 (34.2% \pm 35.8). The ratio of spared volume to total liver volume increased from 39.2% at baseline to 46% at T1, 51.1% at T2 and 64.7% at T3. Mean MHT occurred at an average of 4.4 months (41.94% \pm 51.26). NTL-V30 (NTL volume receiving at least 30 Gy; $p = 0.001$) and baseline untreated volume ($p = 0.014$) were found to be independent predictors of MHT ($R^2 = 0.263$, adjusted $R^2 = 0.231$). Mean MHT increased 0.85% for each percent increase in NTL-V30 and decreased 3.6% for each 100 ml increase in baseline untreated volume. Regression assumptions were respected. Factors selected from the univariate analysis ($p < 0.2$) not significant in the multivariate analysis were: absence of cirrhosis, no previous transarterial chemoembolization, number of chemotherapy cycles, total administered activity and NTL-D98 (dose to 98% of the NTL volume). When 50% of NTL received at least 30 Gy, MHT \geq 20% was observed (sensitivity: 74.2%, specificity: 61.1%, AUC: 0.654). **Conclusion:** NTL-V30 and baseline volume of the untreated lobe are independent predictors of hypertrophy of the untreated liver lobe after lobar or extended lobar SIRT with 90Y-resin microspheres. **References:** None

OP-122

Predictive value of ^{99m}Tc -MAA SPECT-CT based dosimetry in liver radioembolization with resin microspheres

P. D'Abadie, N. Amini, P. Goffette, S. Walrand, M. Hesse, I. Borbath, M. Van den Eynde, R. Lhommel, F. Jamar; Cliniques universitaires Saint Luc, Brussels, BELGIUM.

Aim/Introduction: ^{99m}Tc - macroaggregated albumin SPECT/CT (^{99m}Tc -MAA) is performed before ^{90}Y liver radioembolization (RE) for evaluating lung shunt, ruling out extrahepatic deposition and sometimes for calculating the delivered activity for treatment using the partition model¹. This dosimetric model assumes a perfect correlation between ^{99m}Tc -MAA and ^{90}Y microspheres in the tumor and the normal

liver compartments. The aim of this study is to compare tumor doses (TD) and normal liver dose (NLD) observed on ^{99m}Tc -MAA SPECT-CT to the real doses observed with ^{90}Y PET-CT. **Materials and Methods:** Patients treated with resin ^{90}Y microspheres (SIR-spheres) between 2011 and 2020 were retrospectively analyzed. Only procedures with catheter tips in similar locations on both angiograms (^{99m}Tc -MAA and ^{90}Y resin microspheres) were selected, as determined by a senior interventional radiologist. TD_{MAA} was compared to $\text{TD}_{90\text{Y}}$ for each lesion and NLD_{MAA} compared to $\text{NLD}_{90\text{Y}}$ for each procedure, as determined using MIM software. The accuracy of the prediction of TD_{MAA} and NLD_{MAA} was estimated using the standard error of the estimate (SEE). **Results:** 66 procedures with 171 lesions were identified. ^{99m}Tc -MAA SPECT-CT predicts very poorly the real tumor dose with a SEE of 89.5 Gy. NLD_{MAA} was very close to $\text{NLD}_{90\text{Y}}$ with a SEE of 2.7 Gy in the 66 procedures. **Conclusion:** ^{99m}Tc -MAA SPECT/CT predicts TD with large errors, which may result in significant inaccuracies using the dosimetric partition model. However, NLD is very well predicted using ^{99m}Tc -MAA SPECT/CT. Delivered activities could be calculated using a new personalized dosimetric model based only on the ^{99m}Tc -MAA dose in the non target liver volume. **References:** 1- Bastiaannet, R., Kappadath, S.C., Kunnen, B. et al. OP-123

Antireflux catheter improves tumor targeting in liver radioembolization

P. D'Abadie, N. Amini, P. Goffette, I. Borbath, M. Van Den Eynde, R. Lhommel, A. Van Maanen, F. Jamar;
Cliniques universitaires Saint Luc- Institut
Roi Albert II, Brussels, BELGIUM.

Aim/Introduction: Liver radioembolization aims at reaching an efficient absorbed dose to tumors for tumor control. A better tumor targeting could improve clinical results of this treatment. The purpose of this study is to determine if antireflux catheter (Surefire System) is responsible for better tumor targeting in liver radioembolization. **Materials and Methods:** Patients treated by resin microspheres for primary and secondary liver malignancies were retrospectively analysed. Each patient realized a ^{99m}Tc -macroaggregated albumin (^{99m}Tc -MAA) SPECT/CT after the preliminary arteriography and a ^{90}Y Yttrium (^{90}Y) PET/CT after the therapeutic arteriography. MAA SPECT and ^{90}Y PET were matched with the baseline imaging to determine a tumor to normal liver ratio (T/NL MAA or ^{90}Y) and tumor dose (TD MAA or ^{90}Y). End-hole catheter was used for all preliminary arteriography (MAA injection). For ^{90}Y microspheres injection, two groups were defined depending of the type of catheter used : a Surefire group (antireflux catheter) and a control group (end-hole catheter). **Results:** 38 patients (115 lesions) and 23 patients (75 lesions) were analysed in the

Surefire and the control groups respectively. In the Surefire group, $\text{T/NL}_{90\text{Y}}$ and $\text{TD}_{90\text{Y}}$ were significantly higher than T/NL_{MAA} and TD_{MAA} (medians : 2,2 and 91 Gy versus 1.7 and 74 Gy, $p < 0.001$). Subgroups analyses demonstrated highly significant differences for neuroendocrine metastases and hepatocellular carcinoma and less spectacular differences for colorectal metastases. In the control group, no differences were found comparing $\text{T/NL}_{90\text{Y}}$ and $\text{TD}_{90\text{Y}}$ to T/NL_{MAA} and TD_{MAA} . **Conclusion:** Antireflux catheter significantly improves tumor microsphere deposition in liver radioembolization. **References:** None

Radioembolization of hepatocarcinoma with ^{90}Y glass microspheres: impact of the basal bilirubin level on treatment planning

C. Chiesa¹, M. Mira¹, M. Maccauro¹, S. Bhoori², G. Bormolini², C. Spreafico³, A. Cavallo⁴, S. Mazzaglia¹, G. Tagliabue⁵, A. Marchiano³, E. Seregni¹, V. Mazzaferro²;

¹Nuclear Medicine, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, ²HPB Surgery, Hepatology and Liver Transplantation, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, ³Interventional Radiology, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, ⁴Medical Physics, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, ⁵Tumour Registry, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY.

Aim/Introduction: According to all published papers reporting comparison between pre- and peri-treatment evaluations, absorbed dose predictions obtained with ^{99m}Tc albumin macro-aggregates SPECT/CT on non-tumoral liver (NT) are much more accurate than on tumours (T). Therefore, personalized treatment planning should focus mainly on the NT liver absorbed dose. Aim of this study was to determine the safety threshold to limit the risk of treatment related liver decompensation, in order to deliver the maximum tolerable absorbed dose. **Materials and Methods:** We analysed data of intermediate/advanced hepato-cellular carcinoma (HCC) patients with well compensated cirrhosis (Child-Pugh score A) treated with ^{90}Y glass microspheres. Injection was lobar in 133/139 patients (96%) and performed 4 days after the calibration date. Only treatment related liver decompensation requiring a medical action (LDC) was considered as toxicity event. We report LDC rates, ROC analysis between LDC and NO LDC absorbed dose distributions, NT complication probability (NTCP) curves, as well as univariate and multivariate analysis of risk factors associated with toxicity. We considered the whole cohort and stratifications on previous transarterial chemo embolization (TACE), presence/absence of portal vein tumoral thrombosis (PVTT), tumour pattern (nodular versus infiltrative), basal bilirubin level (high/low with cut-off 1.1 mg/dL). **Results:** A six month timeline was necessary to capture treatment-related toxicity events. Toxicity rate was 11% for the whole cohort. Significant difference in LDC rates

was obtained only according to the basal bilirubin level (20% versus 6%, $p=0.01$) with a relative risk of 3.7 for patients with values > 1.1 mg/dL. At the multivariate analysis, absorbed dose averaged over the whole non tumoral parenchyma (including the non injected lobe) was associated with liver decompensation (odds ratio=4.24). High bilirubin level was the second even more significant risk factor (odds ratio=6.35). NTCP analysis determined a 15% liver decompensation risk at 50 Gy / 90 Gy for bilirubin $> / < 1.1$ mg/dL. Limits of the study were absence of scatter correction in SPECT/CT, absence of ^{90}Y PET verification and segmentation on pure SPECT images. **Conclusion:** given the low accuracy of $^{99\text{m}}\text{Tc}$ -MAA on lesion absorbed dose prediction reported by all authors, an optimized TARE on HCC with ^{90}Y glass microspheres with lobar injection should aim to an absorbed dose averaged over the whole non tumoral liver of 50 Gy / 90 Gy for basal bilirubin higher / lower than 1.1 mg/dL respectively. This Investigator Initiated Study was supported by Biocompatibles UK Ltd, a Boston Scientific company. **References:** None

The response and survival rates of Y-90 radioembolization in patients with unresectable liver tumors; a single-centre experience

O. Ekmekcioglu¹, O. Tabakci², D. Has Simsek¹, A. Hasanefendioglu Bayrak², S. Bilgic³, G. Berk¹, C. Simsek¹, N. Kaplan⁴, M. Battal⁵;

¹Nuclear Medicine Dept, Sisli Etfal Education and Research Hospital, Istanbul, TURKEY, ²Interventional Radiology Dept, Sisli Etfal Education and Research Hospital, Istanbul, TURKEY, ³Nuclear Medicine Dept, Cerrahpasa Medical Faculty, Istanbul, TURKEY, ⁴Medical Oncology Dept, Sisli Etfal Education and Research Hospital, Istanbul, TURKEY, ⁵General and Hepatobiliary Surgery Dept, Sisli Etfal Education and Research Hospital, Istanbul, TURKEY.

Aim/Introduction: Locoregional therapies are successfully used in unresectable primary or metastatic liver tumors. Y-90 treatment has been shown to have advantages for patients with less side effects. Aim of this study is to share the experience from the patients we treated with Y-90 radioembolization in our department. **Materials and Methods:** The patients, referred to our department and planned to receive Y-90 treatment by the hepatobiliary council, were analyzed retrospectively. All patients were scanned either with PET, MRI or CT before and after treatment due to patient condition or type of the tumor. Patient selection for Y-90 treatment was evaluated due to recommendations from guidelines¹. All patients were performed hepatic angiography to investigate tumor vascular anatomy before treatment. Tc99m Macroaggregated albumin scintigraphy was performed for calculation of tumor uptake and lung shunt fraction during the first angiography session. Patients received Y-90 treatment during the second session in the week following after first angiography. All has been followed up for side effects. mRECIST criteria was used evaluating response 3

months after therapy. **Results:** Sixty-four (38 male, 26 female) of 93 patients were eligible for treatment. Hepatocellular cancer was the most common type of tumor (40,6%). Colorectal tumor metastases (29,6%), cholangiocarcinoma (4,6%), neuroendocrine tumor metastases (15,6%) and the other types of tumors were in our patient group. Mean age was $62,5 \pm 9,7$ (36-82). Mean dose for the treatment was 127 Gy (80-340). Abdominal pain discomfort (35%) and nausea (15%) were the most common clinical toxicities. Patients' survival data demonstrated that; %32,8 of the patients were alive during time of our data analysis. The maximum follow up duration was 44 months and median survival after treatment was 10 months. The response rates were 46,5% for partial and 6,2% for complete. Furthermore; 12,5% has stable disease and 14% of patients were progressive after treatment. From the partial response group; 10,9% of the patients' tumor were nearly totally decreased in size and activity. Additionally, 7,8% of the patients had substantially response in treatment region. Since some of the patients were followed-up in other centers 20% of the data were not found in our archives. **Conclusion:** For unresectable liver tumors, radioembolization with Y-90 is a safe and well-tolerated procedure. Our experience demonstrated that a significant percentage of patients had clinical benefit. Even it is more effective in hepatocellular carcinomas; hypervascular tumors like colon cancer and neuroendocrine tumor metastases are also shown to get advantage. **References:** 1. https://www.eanm.org/publications/guidelines/EANM_liver_treatment_guidelines_2012.pdf

OP-126

Trans-arterial Rhenium (Re) -188 lipiodol therapy in advanced hepatocellular carcinoma: HDD vs N-DED

S. Datta Gupta¹, S. A. Shamim¹, Shalimar¹, S. Gamanagatti¹, P. Gupta¹, M. B. Mallia², V. Chirayil², A. K. Dash², C. S. Bal¹;

¹All India Institute of Medical Sciences, New Delhi, INDIA,

²Bhabha Atomic Research Centre, Mumbai, INDIA.

Aim/Introduction: Advanced hepatocellular carcinoma (HCC) with portal vein thrombosis (PVT) contributes to 35-50% of all HCC. Conventional first line therapy in them remains tyrosine kinase inhibitors (TKIs), which prolongs overall survival from a mere 2-4 months to 6-8 months although with poor compliance. Rhenium (Re)-188 lipiodol based trans-arterial radionuclide therapy (TART) is a promising alternative in HCC with PVT. Various complexes have been developed to prepare Re-188 lipiodol, with 4-hexadecyl-1,2,9,9-tetramethyl-4,7-diaza-1,10-decanethiol (HDD) being used more widely. We attempt to explore novel agent bis-(diethyldithiocarbamate) nitrido (N-DED), attributed with higher labeling yield and lower cost, and compare its response and survival outcomes with Re-188 HDD lipiodol in HCC with PVT. **Materials and Methods:** Patients of radiological proven HCC with PVT were recruited for therapy. Those with ECOG

performance status more than 2, contrast allergy, Child-Pugh C or elevated PT/INR were excluded. Re-188 was eluted from W-188/Re-188 generator and in-house labeling with lipiodol was done using HDD and N-DEDC kits. Under fluoroscopy, trans-arterial injection of Re-188 lipiodol complex into tumor feeding vessels was performed. Response was assessed on MRI using mRECIST at 3 months and survival was assessed every 3 months till completion of study. **Results:** Fifteen therapies were performed in fourteen patients (13 male, 2 female). Eight therapies were done using Re-188 HDD lipiodol and seven with Re-188 N-DEDC lipiodol. The patients' characteristics and dose injected (HDD vs N-DEDC: 68.6 ± 11.2 mCi vs 72.7 ± 7.1 mCi, $p = 0.955$) in both groups were comparable. Overall objective response rate was 30.7 % with no difference in the two groups ($p = 0.424$). Disease control rate in HDD and N-DEDC groups were similar (85.7% vs 83.3%, $p = 0.727$). Mean completed follow-up duration in HDD group was 14 months and in N-DEDC group was 9.5 months. Overall survival (OS) and progression free survival (PFS) in both groups were 14.2 (95% CI: 7.8–20.5) months and 10.2 (95% CI: 7.2–13.3) months, respectively. Mean OS in HDD and N-DEDC groups was 14.3 and 11.3 months ($p = 0.999$) and mean PFS was 10.7 and 11.0 months ($p = 0.781$), both being comparable. **Conclusion:** Re-188 lipiodol TART in advanced HCC shows favorable response and survival outcome, compared to available data on TKIs in literature. In this pilot study, novel N-DEDC labeled Re-188 lipiodol therapy appears comparable in response and survival, to Re-188 HDD lipiodol TART, with the said advantage of higher labeling efficiency and affordability. **References:** None

OP-127

Boosting 90Y SIRT with SBRT: a planning study with 90Y PET and TCP/NTCP models

J. Mikell, K. Cuneo, Y. K. Dewaraja;

University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: Selective internal radiation therapy (SIRT) with microspheres is an established therapeutic intervention and has made strides focusing on earlier stage disease. In this work, we focus on multifocal disease within the liver and perform retrospective planning to combine lobar injection of Y90 glass microspheres followed by stereotactic body radiation therapy (SBRT). The idea being microspheres will successfully treat most of the lesions and then SBRT can be used to target underdosed lesions. The aim of this work is to compare differences in mean nontumoral liver dose (MLD) and liver normal tissue complication probability (NTCP) between the boost SBRT plan with a hypothetical SBRT plan to all the detectable lesions **Materials and Methods:** Prior study established a tumor control probability (TCP) curve for liver lesions treated with glass microspheres¹. Retrospectively, 5 HCC patients were selected after SIRT. Lesion absorbed doses from 90Y- PET/CT were evaluated with our TCP model to

predict response. An SBRT plan was created to target lesions with TCP < 50%, corresponding to mean Y90 dose of 290 Gy with recovery coefficients included. The entire lesion was not targeted, only regions receiving < 70 Gy, a threshold based on D90 TCP analysis to determine a minimum dose. SBRT plans were created to deliver 36 Gy in 3 fractions, assumed breath hold and used 5 mm isotropic margins. **Results:** Based on lobar Y90, 3/5, 1/1, 8/9, 4/4, and 1/2 lesions were predicted to have TCP < 50%. Planning tumor volumes in the boost decreased on average by 52% \pm 14% (112 cc \pm 81 cc) compared to treating with SBRT alone. The MLD from SBRT decreased in the combined treatment by 25% on average with decreases from 15% to 43%. The NTCP for RILD was on average 10% less for the boost SBRT; this was dominated by a single patient whose NTCP went from 59% to 5% when comparing SBRT alone to the SBRT boost after SIRT. **Conclusion:** For multifocal HCC, lobar 90Y SIRT followed by an SBRT boost may enhance the therapeutic ratio by increasing TCP due to the two pass treatment and decreasing NTCP compared to SBRT alone due to less liver parenchyma irradiated by external beam when targeting several lesions. Additional research is needed to combine 90Y and SBRT absorbed doses to develop reliable combined TCP and NTCP predictions. **References:** 1. J Nucl Med 2020 61:104-111

OP-128

Evaluation of PRRT after Selective Catheterization of the Hepatic Artery as Established Technique ('Aretaeion' Protocol) using ¹¹¹In-DTPA-Phe¹ Octreotide in Inoperable Liver Metastases Due to Neuroendocrine Tumors

G. Limouris¹, I. Kyriazanos², A. Zafeirakis³;

¹Nuclear Medicine, Medical School, National and Kapodistrian

University of Athens, Athens, GREECE, ²Surgery Clinic, Army

Naval and Veterans Hospital of Athens, Athens, GREECE,

³Army Share Fund Hospital of Athens, Athens, GREECE.

Aim/Introduction: To evaluate the efficacy of Auger and Internal Conversion Electron Emission of ¹¹¹In-DTPA-Phe¹-Octreotide and their tumoricidal effectiveness due to their high LET, in inoperable liver metastases, positive for sst2 receptor over-expression (verified by Octreoscan and confirmed by biopsy) due to neuroendocrine tumours (NETs). **Materials and Methods:** In 86 patients ¹¹¹In-DTPA-Phe¹-Octreotide was implemented after selective catheterization of the hepatic artery, in an average activity of 6.3 ± 1.3 GBq per patient/per session, consecutively, with a time interval between sessions of 6-8 weeks. Infusion repetition did not exceed the 12 sessions. Patients, being under repeated Sandostatin - LAR treatment (30 mg per 20 days) did not discontinued the dosage but they were intramuscularly injected 15 -20 days prior to the radioactive session. To reduce myelotoxicity, 75 mg of DTPA in trip-trop diluted in about 200 ml normal saline water was infused 30 min before the initialization of the radiopeptide therapy, lasting for about 4 hrs. For the

assessment of response, RECIST 1.1 standards were used. CT/MRI scans before, during and after the end of the whole procedure, as well as U/S images at monthly basis were performed. Absorbed doses delivered to metastases, kidneys and red marrow were calculated according to OLINDA/EXM 1.1 program. Toxicity (World Health Organization criteria) was measured using blood and urine tests of renal, hepatic and bone marrow function. **Results:** Three patients resulted in complete response (3.5%); partial response was assessed in 46 (53.5%), disease stabilization in 21 (24.4%) and progressive disease in 16 (18.6%). The median PFS and OS were estimated to be 32 and 47.5 months, respectively. The organ average radiation dose was estimated as follows: (a) Liver Tumor 15.2 mGy/MBq, (b) Liver 0.14 mGy/MBq, (c) Kidneys 0.41 mGy/MBq, (d) Spleen 1.4 mGy/MBq and (f) Bone marrow 0.0032 mGy/MBq. The average absorbed dose per session to a tumour for a spherical mass of 10 gr was estimated to be 10.8 mGy/MBq, depending on the histotype of the tumour. WHO toxicity grade 2 to 3 erythro-, leuko- and thrombocytopenia occurred in 9 (10.5%) cases observed about after the 3rd session. **Conclusion:** In unresectable metastatic liver lesions, positive for somatostatin receptors, repeated, trans-hepatic high doses of ^{111}In -DTPA-Phe¹-Octreotide resulted in an optimal therapeutic outcome with a disease control (CR+PR+SD) in an about 82% of the treated patients. Thus, ^{111}In -DTPA-Phe¹-Octreotide, intra-arterially applied, can be considered as a potent candidate in the therapeutic pharetra against NETs. **References:** None

OP-129

Sequential PRRT and SIRT. Evaluation of safety and best sequence treatment in liver dominant GEPNETs

F. Scalorbi, A. Lorenzoni, S. Mazzaglia, E. Garanzini, C. Chiesa, G. Aliberti, V. Fuoco, G. Argiroffi, S. Pusceddu, N. Prinzi, C. Spreafico, G. Centonze, J. Coppa, A. Marchiano, M. Milione, V. Mazzaferro, E. Seregni, M. Maccauro;
Istituto Nazionale Tumori Milano, Milan, ITALY.

Aim/Introduction: To investigate safety, tolerability and best sequence treatment in patients subjected to Peptide Radio-Receptor Therapy (PRRT) and Selective Internal Radiation Therapy (SIRT) for metastatic liver-dominant Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) **Materials and Methods:** Ninety-eight GEP-NET patients treated with PRRT and SIRT in our Institute, from March 2012 to January 2016, were retrospectively reviewed. Treatment toxicity was assessed according to the Common Terminology Criteria for Adverse Events (CTCAE). Dosimetric analysis of dose administered by SIRT was estimated by $^{99\text{m}}\text{Tc}$ -MAA-angioscintigraphy. Disease Control Rate (DCR), PFS and OS were calculated. Treatment response was evaluated by RECIST1.1 criteria. Kaplan -Meier analysis was performed to calculate PFS and OS curves **Results:** Eight patients who underwent both SIRT and PRRT were identified. All the

patients had histological diagnosis of G1-G2 GEP-NETs with unresectable liver-dominant metastasis. Among these patients, six were males, two were females (mean age 52 years-old, range 37-61). Five patients (Group 1) underwent SIRT before PRRT, three (Group 2) received PRRT followed by SIRT. In both groups the median interval between the last administration of first treatment (PRRT or SIRT) and the first administration of the second one was 18 months. Both therapeutic combinations showed limited toxicity, without delayed G3-G4 adverse events in accordance with CTCAE. The best SIRT response was observed at 3-months follow-up both in Group2 (DCR 66.7%) and in Group1 (DCR 60%). An excellent PRRT response (DCR 100%) was observed in Group2 at 3-months follow-up and was maintained at least for 12 months. Similarly, the DCR in Group1 was 100% at 3-month follow-up but decreased until 40% twelve months after PRRT. Dosimetric data obtained for SIRT planning were available for 7 of 13 procedures showing high cumulative dose to target lesions with low dose to healthy liver. Median PFS was briefer in Group1 than in Group 2 (26 vs 45 months) but Kaplan- Meier analysis fails to achieve statistical significance (Mantel- Cox 95% CI 17-60, P value: 0.655). OS curves show a strong evidence against the null hypothesis that the overall survival is the same in the two groups (Mantel- Cox 95% CI 14-59, P value: 0.024), with a median OS of 29 months in Group1 compared to 55 months in Group2. **Conclusion:** Therapeutic combination of PRRT and SIRT represented a reliable approach in terms of safety and tolerability in liver-dominant GEP-NETs. The preliminary results are favourable to opt for PRRT before SIRT, in the sequential treatment decision **References:** None

OP-130

High dose brachytherapy with not-sealed ^{188}Re (Rhenium) resin in patients with non melanoma skin cancers (NMSC): single center preliminary results

P. Castellucci¹, F. Savoia², A. Farina³, G. Lima³, A. Patrizi², F. Zagni⁴, C. Baraldi², S. Vichi⁴, C. Pettinato⁴, L. Strigari⁴, A. Morganti⁵, S. Fanti³;
¹Nuclear Medicine Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, ²Dermatology Unit, Sant'Orsola-Malpighi Hospital, Bologna, ITALY, ³Nuclear Medicine Department, Sant'Orsola-Malpighi Hospital, Bologna, ITALY, ⁴Medical Physics Department, Sant'Orsola-Malpighi Hospital, Bologna, ITALY, ⁵Radiation Oncology Department, Sant'Orsola-Malpighi Hospital, Bologna, ITALY.

Aim/Introduction: High dose brachytherapy using a non-sealed ^{188}Re Rhenium resin (^{188}Re Rhenium SCT Oncobeta, Munich, Germany) is a recently EU approved treatment option for Non-Melanoma Skin Cancer (NMSC). The aim of this prospective pilot study was to assess the efficacy and the safety of a tailored brachytherapy using a single application of non-sealed ^{188}Re Rhenium resin source in the treatment of NMSC. **Materials and Methods:** From October 2017 to January

2020, overall 48 consecutive patients (15F,33M, age56-97, mean81) showing 57 histologically proven NMSC (40BCC; 14SCC; 2Spino-CC; 1BCC&SCC) at presentation (37/57), or who relapsed after multiple previous therapies (20/57), were enrolled. Lesions were located on the face, ears, nose or scalp (45), extremities (8), trunk (4). Mean surface areas 6.4 cm² (range 1-36cm²); mean thickness invasion 1.1mm (range 0.2-2.5mm). Mean treatment time was 79 minutes (range 21-285 minutes). Mean radiation dose delivered to the whole volume of the lesion was 62 Gy (range 18-126 Gy depending on the location, the shape, the size and the thickness of each single lesion). Patients were followed-up after 14-30-60-90-180 days when a dermoscopy and a biopsy (if needed) were performed. Mean follow up was 18 months (range 3-30months) **Results:** Six months after ¹⁸⁸Rhenium treatment, 45 lesions have been studied with dermoscopy and/or biopsy: 44/45 lesions (97.7%) completely responded to ¹⁸⁸Rhenium SCT. One patient presenting a 9.5 cm² BCC in the nose showed a small (1 cm²) persistence of disease that was subsequently treated by small surgical excision. Twelve months after treatment, 30/30 lesions were free from relapse. No patient report pain during or soon after the procedure or showed any significant late side effect during follow up. In 31/57 lesions early side effects, resolving within 32 days, were consistent with skin erythema, faint or moderate edema (Grade 1-2-3 of the ROTG scale). In the remaining 26/57 lesions, little ulcerations and faint hemorrhages were observed (Grade 4). Only in 7/26 lesions these findings were more severe lasted up to 5-10 weeks, but resolved with optimal results except faint dischromia, slight atrophy of the skin or hair loss. **Conclusion:** High dose brachytherapy using a non-sealed ¹⁸⁸Re resin (¹⁸⁸Rhenium SCT) is a non-invasive, safe, easy to perform, effective and well tolerated approach to treat NMSC and it seems to be a useful alternative option when surgery is difficult to perform or not recommended. In our population 97% of the treated lesions responded completely after a single application. **References:** None

Rhenium-188 Epidermal treatment for Non-melanoma Skin Cancers

K. Mokoala, M. Vorster, L. Nonjola, N. P. Mokgoro, T. M. G. Boshomane, I. O. Lawal, M. M. Satheke;
University of Pretoria & Steve Biko Academic Hospital, Pretoria, SOUTH AFRICA.

Aim/Introduction: The incidence of non-melanoma skin cancers (NMSC), namely basal cell carcinoma (BCC) and squamous cell carcinoma (SCC) has been on the rise over the last three decades. With the growing demand on non-invasive treatment of NMSC with Rhenium-188 as an epidermal application is a growing modality in the management of skin cancers. We report on the clinical and cosmetic outcomes in patients treated for NMSC with Rhenium-188. **Materials and**

Methods: We treated 20 patients (33 lesions) of NMSC who presented with recurrence following surgery or radiation therapy, those who were not candidates for surgery or radiotherapy and those who refused surgery or radiotherapy. Rhenium-188 was delivered as a jelly-like matrix applied superficially on every target lesion. The duration per session ranged from 30 minutes to 4 hours depending on the activity administered and size of the lesion with the goal being to deliver 50Gy to the lesion per session. Participants were followed-up for 4-26 months to assess the side effects, cosmetic results, and local failures. **Results:** Out of the 33 histologically confirmed lesions, 30 were BCC and 3 were SCC lesions. There were 8 females and 12 males with a mean age of 70.17 (range: 34 - 84). The vast majority (90%) of the lesions were located in the head and neck region. The administered activity ranged from 64.2MBq to 479MBq. With the exception of one patient who was lost to follow-up, no recurrence or side effects were observed. The cosmetic results were excellent in 93.8% of treated lesions (n = 30), good in 3.1% (n = 1), fair in 3.1% (n = 1) after single application, applied in one single session. The one patient with fair results is scheduled for a second application because of the thickness of the tumour. **Conclusion:** Rhenium-188 as an epidermal application is a safe modality with excellent clinical and cosmetic results for the treatment of NMSC. **References:** None

18F-FDG PET/CT interpretation Criteria for the Assessment of Therapeutic Response in Patients with Advanced Stage of Lung Cancer: inter-reader reliability, accuracy and survival outcomes

M. Gazzilli¹, D. Albano², E. Cerudelli¹, F. Dondi³, A. Mazzeletti³, P. Bellini³, F. Bertagna², R. Giubbini²;

¹Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY, ²Università di Brescia e Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, ITALY, ³Università di Brescia, Brescia, ITALY.

Aim/Introduction: 18Fluorine-fluorodeoxyglucose positron emission tomography/computed tomography (¹⁸F-FDG-PET/CT) is useful in the evaluation of lung cancer (LC), both for staging and therapy assessment. For the evaluation of treatment response, shared criteria are not available. Recently Hopkins criteria, a 5-point score for qualitative interpretation of PET/CT, was introduced with promising results. We proposed a 3-point score, similar to Deauville score and compared its diagnostic accuracy with Hopkins

criteria for the evaluation of treatment response in LC. Our aim was to validate our qualitative interpretation system to assess therapy response and survival outcome in patients with advanced stage of lung cancer. **Materials and Methods:** We retrospectively included 93 patients with advanced stage (III-IV) LC who underwent ^{18}F -FDG-PET/CT assessment after completion of first-line treatment. PET/CT scans were interpreted by two nuclear medicine physicians with experience in this field and were evaluated according to a 3-point scale like Deauville score criteria (score 1=uptake lower than blood-pool activity; score 2=uptake higher than blood-pool but lower than liver activity; score 3= uptake higher than liver). Patients were followed up for a median of 18.5 months (range 2–139 months). Inter-reader variability was assessed using percent agreement and kappa statistics. Kaplan-Meier plots with a Mantel-Cox log-rank test were performed, considering death as the endpoint. **Results:** The sensitivity, specificity, positive predictive value, negative predictive value and accuracy of like Deauville score criteria were 91.9% [95% confidence interval (CI) 82.1–97.3%], 67.7% (95% CI 48.6–83.3%), 85% (95% CI 77.2–90.5%), 80.7% (95% CI 63.6–90.9%) and 83.8% (95% CI 74.8–90.6%), respectively. With the Hopkins criteria score we obtained sensitivity, specificity, positive predictive value, negative predictive value and accuracy of 85.4% [95% confidence interval (CI) 74.2–93.1%), 70.9% (95% CI 51.9–85.7%), 85.4% (95% CI 77–91.1%), 70.9% (95% CI 56.2–82.3%) and 80.6% (95% CI 71.1–88.1%), respectively. There was a high agreement between the two readers both using Hopkins criteria ($k=0.912$) and like Deauville score criteria ($k=0.956$). Applying 3-point scale criteria, patients with positive PET/CT after therapy had significantly shorter lower survival ($p=0.0021$). **Conclusion:** The use of 3-point scale criteria for post-therapy assessment in patients with advanced stage of LC represents an easy and reproducible method with substantial to almost perfect inter-observer agreement and high positive predictive value and accuracy; moreover, it is easily understood by referring physicians. **References:** None

SUV-derived Parameters Assessed on F-18-FDG PET/CT Predict EGFR Mutation in Lung Adenocarcinoma Patients: the Construction of CART Predictive Model

R. Wang^{1,2}, X. Liao¹, S. Chen³, M. Liu¹, X. Chen¹, L. Yin¹, D. Chen³;

¹Peking University First Hospital, Beijing, CHINA,

²Peking University International Hospital, Beijing,

CHINA, ³Peking University, Beijing, CHINA.

Aim/Introduction: To investigate the potential relationship between Epidermal growth factor receptor gene (EGFR) mutation status and standardized uptake value (SUV)-derived parameters from ^{18}F -fluorodeoxyglucose (F-18-FDG) positron emission tomography/computed tomography (PET/CT) examinations combining with other clinical characteristics

through classification and regression trees (CART) in patients with lung adenocarcinoma (ADC), in order to obtain the noninvasive predictive model for EGFR mutation. **Materials and Methods:** Data of 192 ADC patients pre-treatment, who underwent F-18-FDG PET/CT scans, EGFR gene mutations test for newly diagnosed ADC patients from December 2011 to April 2018, were retrospectively collected. Then a series of clinical parameters including EGFR mutation status, SUV-derived features of primary tumor [maximum standardized uptake value (SUV_{max}), average of standardized uptake value (SUV_{mean}), metabolic tumor volume (MTV), and total lesion glycolysis (TLG)], serum tumor markers and so on were gathered, which were analyzed through CART to build the model for EGFR mutation prediction. Predictive effectiveness of the model was validated by 1000-time Bootstrap. **Results:** Ratios of EGFR mutation were 33.3% (64/192). Age, smoking status, SUV_{mean} , pMTV(primary MTV), pTLG(primary TLG), CEA, SCC, NSE, TPA, and proGRP could be independently and significantly associated with EGFR mutation of ADC patients. The area under the curve (AUC) which for the predictive value of these factors were 0.785(95%CI: 0.743–0.827); Sensitivity and specificity were 85.5% and 71.4% respectively. **Conclusion:** SUV_{mean} , pMTV and pTLG were a set of independent predictors and could be integrated with other clinical factors (age, smoking status, CEA, SCC, NSE, TPA and proGRP) to enhance the discriminability on the EGFR mutation status in ADC patients. **References:** None

EPS-020

18F-FDG PET Parameters and Radiomics Features Analysis in Advanced NSCLC treated with Immunotherapy as Predictors of Therapy Response and Survival

G. Polverari¹, F. Ceci², V. Bertaglia³, M. Reale³, O. Rampado⁴, E. Gallio⁴, R. Passera², V. Liberini², P. Scapolì⁵, V. Arena¹, M. Racca⁵, A. Veltri⁶, S. Novello³, D. Deandrei⁵;

¹Affidea Irmec PET/CT Center, Turin, ITALY, ²Nuclear Medicine Unit, Department of Medical Sciences, University of Turin, Turin, ITALY, ³Department of Oncology, University of Turin, San Luigi Gonzaga Hospital, Orbassano, ITALY, ⁴Medical Physics Unit, S.C. Fisica Sanitaria, A.O.U. Città della Salute e della Scienza, Turin, ITALY, ⁵Nuclear Medicine, Istituto per la Ricerca e la Cura del Cancro (IRCC), Candiolo, ITALY, ⁶Radiology Unit, Department of Oncology, University of Turin, San Luigi Gonzaga Hospital, Orbassano, ITALY.

Aim/Introduction: Objectives: 1.1) to evaluate the association between baseline 18F-FDG PET/CT semi-quantitative parameters with progression free survival (PFS), overall survival (OS) and response to immunotherapy, in advanced NSCLC patients eligible for immunotherapy; 1.2) to evaluate the application of radiomics analysis to identify features predictive of response to immunotherapy; 1.3) to evaluate if tumor burden assessed by 18F-FDG PET/CT (N and M factors) is associated with PFS and OS. **Materials and Methods:** We retrospectively analysed clinical records of advanced

NSCLC patients (stage IIIb/c or stage IV) candidate to immunotherapy who performed 18F-FDG PET/CT before treatment to stage the disease. 57 patients were included in the analysis (F:M 17:40; median age=69 yo). 38/57 of patients had adenocarcinoma (AC), 10/57 squamous cell carcinoma (SCC) and 9/57 not otherwise specified (NOS). 47.4% patients were stage IVA, 42.1% IVB and 8.8% IIIB. Immunotherapy was performed as front-line therapy in 42/57 patients and as second line therapy after chemotherapy platinum-based in 15/57. Median follow up after starting immunotherapy was 10 months (range:1.5–68.6). Therapy response was assessed by RECIST 1.1 criteria (CT evaluation every 4 cycles of therapy) in 48/57 patients or when not feasible by clinical and laboratory data (fast disease progression in 9 patients). Radiomics analysis was performed applying ROIs of the primary tumor delineated manually by two operators and semi-automatically applying a threshold at 40% of SUVmax. **Results:** 1.1) MTV ($p=0.028$) and TLG ($p=0.035$) were significantly associated with progressive vs. non-progressive disease status. Patients with higher values of MTV and TLG had higher probability of disease progression, compared to patients presenting with lower values. SUVmax did not showed correlation with PD status, PFS and OS. MTV ($p=0.027$) and TLG ($p=0.022$) resulted also to be significantly different among PR, SD and PD groups while SUVmax confirmed to be not associated with response to therapy ($p=0.427$). 1.2) We observed association of several radiomics features with PD status. Namely, patients with high tumor volume, TLG and heterogeneity expressed by “skewness” and “kurtosis” had higher probability to fail immunotherapy. 1.3) M status at 18F-FDG PET/CT was significantly associated with PFS ($p=0.002$) and OS ($p=0.049$). No significant associations were observed for N status. **Conclusion:** 18F-FDG PET/CT performed before the start of immunotherapy might be an important prognostic tool able to predict the disease progression and response to immunotherapy in patients with advanced NSCLC since MTV, TLG and radiomics features (volume and heterogeneity) are associated with disease progression. **References:** None

EPS-021

Predictive value of ¹⁸F-FDG PET/CT based metabolic parameters in patients with non-small cell lung cancer treated with stereotactic body radiation therapy

L. García Belaústegui, M. Alcántara, R. Couto Caro, M. García García-Esquinas, J. Corona, J. Carreras Delgado;
Clinico San Carlos Hospital, Madrid, SPAIN.

Aim/Introduction: The aim was to determine temporal evolution and prognostic value of maximum standardized uptake value (SUV_{max}) and metabolic tumor volume (MTV) on the serial ¹⁸F-FDG PET / CT scans performed on patients with non-small cell lung cancer (NSCLC) treated with stereotactic body radiation therapy (SBRT) with curative intention.

Materials and Methods: This retrospective study evaluated 30 patients with T1-T3N0M0 NSCLC who had undergone SBRT between 2015 and 2017. Lesion size, SUV_{max} , $MTV_{2.5}$ and $MTV_{40\%}$ were measured from a total of 120 ¹⁸F-FDG PET / CT scans performed at baseline and 24-48 hours, 3 and 6 months after hypofractionated radiation. Variation over time of these parameters and their correlation with clinical evolution of the disease (progression vs. stability / remission) were studied. **Results:** The mean age was 75 years and 93.5% of the patients were men. The group of patients with disease progression presented equal or higher mean values of tumor parameters (size of 25.6 mm, SUV_{max} 12.5, $MTV_{2.5}$ 12.0 cm^3 and $MTV_{40\%}$ 5.8 cm^3) compared to those patients with stable disease / remission (size of 20.3 mm, SUV_{max} 12.5, $MTV_{2.5}$ 6.1 cm^3 and $MTV_{40\%}$ 3.12 cm^3). With respect to the baseline scan, we found a post-treatment mean decrease in tumor size of 6.5% at 24-48 hours, 28.6% at three months and 44% at six months; in SUV_{max} of 37.2%, 73.7% and 78.9%; in $MTV_{2.5}$ of 10.1%, 84.5% and 88.1% and in $MTV_{40\%}$ of 8.7%, 9.6% and 68.3%, respectively. **Conclusion:** While pretreatment SUV_{max} were similar for both groups, MTV was higher in those patients with a worse clinical outcome, therefore this parameter at baseline may provide additional prognostic information. In addition, after 6 months of treatment, MTV decreased an average of 88% while tumor size only 40%, for this post-treatment MTV could also be useful as a predictor of response. However, randomized studies are needed to confirm the results. **References:** None

EPS-022

Sensitivity and characterization of Lung Nodules (LNs) by using Fast-Recovery Fast Spin-Echo (FRFSE-XL) on PET/MR hybrid system

G. Salvatierra Apala^{1,2,3}, E. Marino^{1,4}, G. Peña¹;

¹Fundación Escuela de Medicina Nuclear (FUESMEN), Mendoza, ARGENTINA, ²Agencia Boliviana de Energía Nuclear (ABEN), La Paz, BOLIVIA, PLURINATIONAL STATE OF, ³Investigación Aplicada (INVAP), Bariloche, ARGENTINA, ⁴Comisión Nacional de Energía Atómica (CNEA), Bariloche, ARGENTINA.

Aim/Introduction: To compare sensitivity of detection of small lung nodules (LN) using STIR and FRFSE-XL magnetic resonance (MR) sequences and to characterize LN's malignancy by using two-point SUV_{max} measurement in a PET/MR hybrid system. **Materials and Methods:** LNs were identified by two radiologist-physicians in 16 oncological patients by using CT and PET/MR images. Intercomparison of sensitivity of MR-sequences using FRFSE-XL in respiratory gated ($S_{FRFSE-XL-GAT}$) and breath-hold ($S_{FRFSE-XL-BH}$), and STIR gated ($S_{STIR-GAT}$) were performed by LN's diameter interval (d1: $d < 4mm$, d2: $4 \leq d < 8mm$, d3: $d \geq 8mm$), using CT as reference ($S_{CT}=100\%$). Image performance was analyzed using signal-to-noise (SNR) and contrast-to-noise (CNR) ratios, and evaluating qualitatively noise and artifacts in

PET/MR images using 5-scored rating. LN's malignancy were classified by measuring SUVmax in two different times t1 and t2, at 60 and 105 minutes FDG post-injection. LNs were considered as: malignant ($SUV_{t_2} \geq 1.3 * SUV_{t_1}$), probably malignant ($SUV_{t_2} \geq SUV_{t_1}$), and $SUV_{t_2} < 1.3 * SUV_{t_1}$), probably benign ($SUV_{t_2} \leq SUV_{t_1}$ and $SUV_{t_2} \geq 0.9 * SUV_{t_1}$), and benign ($SUV_{t_2} < 0.9 * SUV_{t_1}$). **Results:** A total of 179 LNs were detected in CT images. At 95% of confidence level, $S_{FRFSE-XL-BH} = 34\%$ [confidence interval (CI): 24-46%], $S_{FRFSE-XL-GAT} = 18\%$ (CI:9-32%) and $S_{STIR-GAT} = 17\%$ (CI:8-30%) for d1. $S_{FRFSE-XL-BH} = 71\%$ (CI:60-80%), $S_{FRFSE-XL-GAT} = 68\%$ (CI:53-80%) and $S_{STIR-GAT} = 60\%$ (CI:46-72%) for d2. $S_{FRFSE-XL-BH} = 90\%$ (CI:67-98%), $S_{FRFSE-XL-GAT} = 90\%$ (CI: 66-98%) and $S_{STIR-GAT} = 69\%$ (CI:39-90%) for d3. Qualitative analysis showed higher scores for FRFSE-XL-BH (4.5/5, $p=0.37$) followed by FRFSE-XL-GAT (3.6/5, $p=0.18$) and STIR (3.2/5, $p=0.37$). Relative SNR and CNR was 2.7 and 7 times higher in FRFSE-XL-GAT than in FRFSE-XL-BH and STIR respectively. Based on SUVmax, 24LNs were found to be malignant in 7 patients, 39LNs probably malignant in 13 patients, 6LNs as probably benign and 38LNs as benign in 8 patients. **Conclusion:** FRFSE-XL (gated and breath-hold) showed great potential for the detection of small LNs, with better performance in terms of sensitivity, qualitative and quantitative analysis as compared to STIR. SUVmax measurements at two different times suggest clear differences between malignant and benign LNs. Further analysis is required to more accurately estimate specificity and sensitivity. **References:** None

EPS-023

Relationships of semiquantitative parameters assessed on F-18-FDG PET/CT for predicting EGFR mutation subtypes in Lung Adenocarcinoma

R. Wang^{1,2}, X. Liao¹, M. Liu¹, X. Chen¹, Y. Cui¹, L. Di¹, L. Yin¹, Z. Tong¹, H. Sun¹, C. Wu¹;

¹Peking University First Hospital, Beijing, CHINA, ²Peking University International Hospital, Beijing, CHINA.

Aim/Introduction: To explore the relationship of F-18-FDG standardized uptake value (SUV)-derived parameters and mutation subtypes (deletions in exon 19 and a mutation in exon 21) in lung adenocarcinomas parameters with mutant epidermal growth factor receptors (EGFR) gene. **Materials and Methods:** Data of 64 lung adenocarcinoma patients who underwent F-18-FDG PET/CT scans and EGFR gene mutation test were collected. The relationships of subtype mutation of EGFR gene with four parameters (maximum standardized uptake value, SUVmax), average of standardized uptake value (SUVmean), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of primary lesion based on F-18-FDG PET/CT and clinical characteristics were evaluated with univariate and multivariate Logistic regression, respectively. **Results:** The mutant ratio of exon 19 and exon 21 was 23:41.

When the parameters were continuous variables, univariate logistic regression showed exon 21 mutations were found more frequently in the EGFR positive patients with shorter maximum diameter of primary lesion (OR=0.942, 95%CI[0.890,0.998]) and low level of MTV of primary lesion (pMTV), (OR=0.957,95%CI [0.923,0.991]). As dichotomous variables, in univariate regression shorter maximum diameter of primary lesion (<26.5mm:OR=3.759,95%CI[1.284,11.005]), high level SUVmax(≥ 4.35 : OR=4.267, 95%CI[1.088,16.726]), low level pMTV(<11.2cm²: OR=7.000, 95%CI[1.798, 27.253]) would be significantly related to mutant exon 21 mutation. **Conclusion:** The primary-lesion SUV-derived parameters from F-18-FDG PET/CT of lung adenocarcinoma patients with EGFR-gene mutation associate with mutant subtypes (exon 19 and 21 mutation) to some extent, but this correlation might be limited. **References:** None

Soluble PD-L1 in NSCLC Patients Treated with Checkpoint Inhibitors

A. Castello, S. Rossi, L. Toschi, E. Lopci;

Humanitas Clinical and Research Hospital, Rozzano (MI), ITALY.

Aim/Introduction: Soluble PD-L1 (sPD-L1) is a potential biomarker recently identified into bloodstream. Its predictive role is still under debate with contrast results, particularly in the immune checkpoint inhibitors (ICI) context. Therefore, we investigated the role of sPD-L1 in NSCLC patients treated with ICI and its association with clinical outcomes and metabolic parameters by 18F-FDG PET/CT. **Materials and Methods:** Between July 2017 and May 2019, we enrolled 20 patients candidate to ICI therapy who had serum frozen samples and 18F-FDG PET/CT available, both at baseline and at the first restaging after approximately 7-8 weeks. This analysis is embedded into a larger prospective study (NCT03563482). **Results:** Nivolumab was administered to 12 out of 20 patients, whereas the others received pembrolizumab. Median sPD-L1 level at baseline was 27.22 pg/ml (range 11.23-61.27). We found a significant association between patients with elevated sPD-L1, above the median value, and high metabolic tumor burden, expressed by metabolic tumor volume (MTV, 115.3 vs 35.5, $p=0.034$) and total lesion glycolysis (TLG, 687 vs 210.1, $p=0.049$). At the first restaging after 7-8 weeks, median sPD-L1 levels significantly increased as compared to baseline median value (43.9pg/ml, $p=0.017$). No significant differences in response rates were detected, according to both morphological and metabolic response criteria. Likewise, no difference in survival outcomes were observed between low sPD-L1 and high sPD-L1 patients. **Conclusion:** Based on our findings, we speculated that increase of sPD-L1 concentrations during ICI treatment may reflect the expansion of tumor volume and the tumor lysis. Moreover, it is supposed that sPD-L1 has its own biological action, either by reducing membrane PD-1 sites available for nivolumab

or by inducing lymphocytes exhaustion after binding their membrane PD-1. Further larger studies are needed to confirm our preliminary results on the role of sPD-L1 during ICI therapy. **References:** The Italian Association for Research on Cancer (AIRC - Associazione Italiana per la Ricerca sul Cancro) is acknowledged for the support on research with the grant nr. 18923.

EPS-025

Metabolic Characteristics of Non-Small Cell Lung Cancer Lesions as Potential Predictor of Immunotherapy Response

A. Tabain, S. A. Rogan, S. Divošević;
Polyclinic Medikal, Zagreb, CROATIA.

Aim/Introduction: Various innovative therapy options, including immunotherapy, are available for treatment of advanced non-small cell lung cancer (NSCLC). The expression of programmed cell death-ligand 1 (PD-L1) on the surface of NSCLC cells, considered as predictor of immunotherapy response, is one of the factors that affect the therapy approach. Recently, the presence of tumour necrosis was also recognised as potential inflammation trigger associated with higher PD-L1 expression. We aimed to evaluate metabolic characteristics of primary NSCLC lesions, obtained with 18F-FDG PET/CT, according to the PDL-1 positivity. **Materials and Methods:** We retrospectively analysed 40 NSCLC pts in different stages of the disease, confirmed with biopsy or surgical resection, referred to 18F-FDG PET/CT for detection of malignancy or staging of already verified disease. Maximum standardised uptake value (SUV max), diameter and metabolic pattern of necrosis were evaluated. PDL-1 expression was assessed by immunohistochemistry assay. Samples were divided in three groups regarding positivity of tumour cell membrane staining: highly positive with $\geq 50\%$, mild positive between 1%–49% and negative $< 1\%$. **Results:** In total of 40 pts (17 females and 23 males, age range 41–88 years, 28 with smoking history, 25 in advanced stage of the disease) there were 25 pts with non-squamous and 15 with squamous NSCLC. Based on PD-L1 positivity: 11/40 (27.5%) pts were highly positive, with SUVmax values 6.4–35.7, 14.8, 13.9 (range, mean, median); 14/40 (35%) pts were mild positive, with SUVmax values 2.1–13.8, 7.6, 8.3 (range, mean, median) and 15/40 (37.5%) were PD-L1 negative with SUVmax values 1.7–15.9, 7.7, 6.9 (range, mean, median). Necrotic pattern of the lesion was observed in 24 pts, represented between PD-L1 positive, mild positive and negative pts with 72%, 50% and 60%, respectively. Mean diameter of necrotic lesions was 55 mm, related to 44 mm in case of lesions without typical photopenic necrotic sign. Squamous NSCLC pts dominated in the PD-L1 highly positive group (63.3% pts). **Conclusion:** Higher SUV max values observed in group of PD-L1 high positive samples could preliminarily indicate pts with favourable respond to immunotherapy. PD-L1 mild positive and PD-L1 negative lesions had overall lower

metabolic activity and we were not able to distinguish them regarding metabolic characteristics. In our group of pts, necrosis was present in PD-L1 positive as well as in negative pts, possible due to overall greater dimensions of the lesions, in association with later detection and advanced stages of the disease **References:** None

EPS-026

The value of hybrid 18F-FDG PET / MR in lung cancer and comparing with PET / CT

Y. Xu;

Hangzhou Universal Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: To explore the value of hybrid 18F-FDG PET / MR in radiotherapy target delineation of lung cancer and compare with PET/CT. **Materials and Methods:** 30 lung cancer patients planning to undergo radiotherapy, underwent whole body PET/CT and chest PET/MR on the same day. CT and PET images were acquired in free breathing mode, and then a breath-hold CT was performed. PET/MR gated acquisition under free breathing, MR and PET images acquired at the end of expiratory period. In PET/MR imaging, 8 cases of MR image artifacts were heavier, and the images met the standard after repeated scanning; The other 3 cases still had poor image quality after repeated scanning. The remaining 27 cases were analyzed by an experienced nuclear medicine physician and a radiotherapy physician. Compare the matching of PET and MR/CT between the two devices. The SUVmax and SUVmean of the lesion were measured. MTV (metabolic tumor volume) and TLG (total lesion glycolysis) were obtained with 30% of SUVmax as the threshold, GTV (gross tumor volume) was delineated on CT and MR images, and the PTV (Planning Target Volume) was obtained from the fusion image. Non-parametric test is used to compare the differences between the two devices' data. **Results:** Among the 27 cases, 18 cases had inaccurate matching between PET_{CT} and CT, with an average displacement of 1.3 (0.2, 1.5) cm and a maximum displacement of 2.5 cm, while PET_{MR} and MR were accurately matched. The radiation concentration of the lesions were more obvious in the PET/MR images. $SUV_{max-PET/MR}$ [26.43(23.42,33.38)] and $SUV_{mean-PET/MR}$ [14.11(11.71,19.21)] were higher than $SUV_{max-PET/CT}$ [19.16(12.22,20.87)] and $SUV_{mean-PET/CT}$ [9.72(6.27,11.27)], ($Z=-2.934,-2.837$, $P<0.05$); $MTV_{PET/MR}$ [52.30(31.11,109.00)] was lower than $MTV_{PET/CT}$ [58.16(33.51,124.00)], ($Z=-2.845,P<0.05$); $TLG_{PET/MR}$ [751.08(307.38,1835.29)] were higher than $TLG_{PET/CT}$ [684.78(250.06,1503.14)], ($Z=-2.936,P<0.05$). There were 18 cases of obstructive pulmonary atelectasis or obstructive pneumonia, in which PET_{MR} and MR could clearly distinguish the tumor from them in 16 and 15 cases, respectively; while PET_{CT} and CT could distinguish 10 and 8 cases, respectively ($\chi^2=4.98,5.90,P<0.05$). GTV_{MR} [60.55(29.25,108.00)] was lower than GTV_{CT} [68.58(30.08,122.00)], ($Z=-2.490,P<0.05$). There was no statistical difference between GTV_{MR} and $MTV_{PET/MR}$ ($Z=-1.956,P>0.05$), while GTV_{CT} was lower than $MTV_{PET/CT}$ ($Z=-$

2.401, $P < 0.05$). $PTV_{PET/MR}$ [55.65(29.52,107.00)] was lower than $PTV_{PET/CT}$ [62.23(30.08,122.00)], ($Z = -2.936, P < 0.05$). **Conclusion:** Compared with PET/CT, PET/MR has more accurate image matching in lung tumor imaging, it can more accurately locate the tumor body, and may become a more accurate imaging method for delineating target areas of radiotherapy. However, MR lung scanning technology is more demanding, the image is prone to artifacts, and often needs repeated scanning. **References:** None

EPS-027

Application Value of PET/MR Radiomics Features and Metabolic Parameters in Evaluating the Staging of Nasopharyngeal Carcinoma

J. Liang;

Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: The study aims to investigate the value of 18F-FDG PET/MR radiomics features and metabolic parameters in evaluating the T staging, N staging and clinical staging of nasopharyngeal carcinoma (NPC). **Materials and Methods:** The clinical data and PET/MR imaging data of 100 NPC patients with undifferentiated carcinoma from a medical center were collected. The patients were randomly divided into training group ($n = 70$) and test group ($n = 30$). The pathological and clinical diagnosis results were used as the gold standard for diagnosis. We measured the metabolic parameters (SUVmax, MTV, TLG) of the NPC primary focus, and used AK software to extract the most relevant radiomics features to NPC staging. To compare the differences of the parameters and features of different stages, and evaluate the diagnostic efficacy of statistically significant parameters and features through the receiver operating characteristic (ROC) curve in NPC staging, the cutoff value was calculated from the ROC curve. **Results:** We extracted 6 and 3 radiomics features most relevant to the staging of NPC from T2WI and PET images, respectively. The AUCs of the training and test group were 0.849 and 0.833 in the T2WI model. The AUCs of the training and test group were 0.840 and 0.815 in the PET model. The MTV, TLG, T2WI radiomics feature (MinIntensity) and PET radiomics feature (GLCMEntropy_angle0_offset4) had statistically significant differences between and within groups of T stages ($P < 0.05$). With the increase of T stage, the mean value of MinIntensity decreased gradually, while the others increased gradually. The MTV, TLG, MinIntensity, GLCMEntropy_angle0_offset4 had higher diagnostic efficiency in differentiating T-stage of NPC (AUC: 0.785-0.956). The TLG and PET radiomics feature (GLCMEntropy_angle0_offset4) had statistically significant differences between and within groups in clinical stages ($P < 0.01$). With the increase of clinical staging, the mean value of the two gradually increased, and they had higher diagnostic efficacy in differentiating clinical stage of NPC (AUC: 0.775-0.953).

The comparison between groups showed that the T2WI radiomics feature (GLCMEntropy_AllDirection_offset1_SD) was smaller in the patients with lymph node metastasis ($P < 0.05$). **Conclusion:** PET/MR radiomics features and metabolic parameters were of great value in evaluating T-stage and clinical stage of NPC, but they had limited value in N-stage. In the future, radiomics features are expected to be a more useful and economical tool for predicting local invasion and distant metastasis of NPC. **References:** None

EPS-028

Predictive value of 18F-FDG PET/CT in treatment response of Head and Neck squamous cell carcinoma using Deauville criteria

C. Ferrari, G. Santo, A. Nappi, A. Branca, C. Altini, A. Gaudio, A. Di Palo, A. Pisani, V. Lavelli, G. Rubini;
Nuclear Medicine Department, University of Bari "Aldo Moro", Bari, ITALY.

Aim/Introduction: Head and neck squamous cell carcinoma (HNSCC) is the six leading cancer by the incidence worldwide. The 5-years overall survival is 40-50% and recurrence rate reaches about 60%. For locally advanced disease, chemoradiotherapy is usually the standard of care. 18F-FDG PET/CT has proven to be a useful tool in post-treatment evaluation avoiding unnecessary neck dissections. Deauville criteria (DC), a 5-point scale used to assess metabolic response already validate in Hodgkin lymphoma, are currently proposed also for HNSCC. The aim of this study is to evaluate the predictive value of post-treatment 18F-FDG PET/CT in HNSCC by using DC. **Materials and Methods:** We retrospectively evaluated 36 patients (mean age 57; range 26-80), with histological proven of HNSCC, who underwent baseline (PET1) and end-of-treatment (PET2) 18F-FDG-PET/CT after first-line therapy. PET2 scans were visually interpreted according to DC assigned on both primitive tumor site (T) and lymph node (N) and scored as follows: 1. complete metabolic response; 2. probably complete metabolic response; 3. probably post-radiation inflammation; 4. probably persistent tumor; 5. persistent tumor. Patients were subsequently dichotomized into responders (score 1-2-3) and non-responders (score 4-5) groups. Disease free survival (DFS) was estimated by the Kaplan-Meier method and groups were compared using long-rank test. **Results:** Among 36 patients, primitive tumor site was pharynx ($n=12$), tongue ($n=6$), oral cavity ($n=6$), larynx ($n=5$), salivary glands ($n=3$), tonsil ($n=2$), paranasal sinus ($n=1$), occult ($n=1$). The time between the end of treatment and PET2 was 4 months on average (range 1-7 mo). Twelve/36(33%) patients experienced disease persistence/recurrence. DC evaluation were able to significantly predict metabolic response and remission of both T and N status. In particular, a statistically significant difference was found in DFS and DC(T), both with dichotomization ($p=0,015$) and without dichotomization ($p=0,019$); similarly, a statistically

significant difference was found in DFS and DC(N), both considering responder/non-responder ($p < 0.0001$) and for each score separately ($p < 0.0001$). **Conclusion:** Our preliminary results suggest that 18F-FDG PET/CT could be useful in predicting treatment response, in particular considering N status. Further larger studies are needed to validate the Deauville criteria in the HNSCC in order to avoid unnecessary lymph node dissections. **References:** None

EPS-029

Correlation between Apparent Diffusion Coefficients, Standardised uptake values and histological differentiation : preliminary results in anal cancer

A. Parsai¹, I. Zerizer², H. Jan³, E. Nowosinska³, S. Subhan⁴, A. Haroon³, Y. Bouchareb⁵, M. E. Miquel¹;

¹Queen Mary University London, London, UNITED KINGDOM, ²Royal Marsden Hospital, London, UNITED KINGDOM, ³BartsHealth NHS Trust, London, UNITED KINGDOM, ⁴The Queen Elizabeth Hospital, London, UNITED KINGDOM, ⁵Sultan Qaboos University, Oman, QATAR.

Aim/Introduction: To assess ADC and SUVmax values as predictors of histological differentiation in patients with anal squamous cell carcinoma (ASCC) at baseline and determine if there is a statistically significant difference for each tumour grade (well, moderately, poorly differentiated ASCC). **Materials and Methods:** A retrospective review of 41 patients (14 males, 27 females; mean age 65 ± 13 years) with ASCC after baseline FDG PET/CT and MRI (mean scan time interval 21 ± 11 days). SUVmax and ADC were measured using HERMES® and PACS respectively. The values were compared to histopathology and correlated with tumour grade (well, moderately or poorly differentiated) to assess for statistical difference using paired t-test. **Results:** The mean size and volume of the tumour was 3 cm and 16.5 cm³. The mean ADC value for well, moderately and poorly differentiated ASCC was 935, 952 and 809, respectively. The mean SUVmax for well, moderately and poorly differentiated ASCC was 8, 11.3 and 12.4, respectively. There was statistical difference between mean SUVmax values of poorly differentiated and well-differentiated ASCC ($p = 0.008$) as well as moderately differentiated and well-differentiated ASCC ($p = 0.03$). There was no significant statistical difference between mean ADC values and degree of tumour differentiation. **Conclusion:** There is a statistically significant correlation between SUVmax values and degree of differentiation in ASCC. There is however no statistical correlation with ADC values. This highlights the superiority of FDG PET/CT in predicting tumour grade and can be used as an adjunct to plan treatment. **References:** None

EPS-030

2-[¹⁸F]FDG PET/CT in Colorectal Cancer Liver Metastases

P. Soeiro, P. Lapa, R. Silva, G. Costa, J. Pedroso de Lima;
Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Resection of liver metastasis (LMCRC), in carefully selected colorectal cancer patients, can improve overall survival. However, selection criteria for surgery is a hotly debated subject. Some reports indicate that 2-[¹⁸F]FDG PET/CT can improve patient selection. In this study we aim to identify quantitative functional variables in 2-[¹⁸F]FDG PET/CT able to predict recurrence or mortality LMCRC. **Materials and Methods:** All LMCRC patients who underwent 2-[¹⁸F]FDG PET/CT followed by liver metastasis resection, since 1-1-2005 to 31-12-2019, were retrospectively selected. Patients under chemotherapy in the month of the 2-[¹⁸F]FDG PET/CT scan were excluded. PET/CT data was reviewed. All hepatic metastases uptake related variables, such as SUVmax, SUVmean, metabolic tumour volume (MTV) and total lesion glycolysis (TLG) were recorded. Three ratios were calculated: hepatic metastase SUVmax/normal liver SUVmax (MaxM_MaxL), hepatic metastases SUVmax/normal liver SUVmean (MaxM_MeL), hepatic metastase SUVmean/normal liver SUVmean (MeM_MeL). Demographic, clinical, time to relapse, time to hepatic relapse, time to death and histological variables were recorded. **Results:** 73 patients fulfilled the inclusion criteria, 63% (n=46) men and 37% (n=27) women (62 ± 11.7 ; 33-84 years). Most patients had sigmoid cancer (39,4%), followed by rectal cancer (18%). Almost half of the patient had pT3 (48%). The most frequent clinical stage was III (25%). The average number of hepatic metastases per patient was 2 ± 1.7 (1-12). 66% patients were also submitted to chemotherapy. Relapse rate was 79%. Median time to relapse was 512 ± 456 days (41-1851). Hepatic relapse rate was 62%. Median time to hepatic relapse was 512 ± 456 days (41-1851). Mortality rate was 68%. Median time to death was 1306 ± 1093 days (78-5252). Median metastase SUVmax and SUVmean was 10.4 ± 5.6 ng/ml (3.6-46.5) and 5.7 ± 2.9 ng/ml (2,5-23,6), respectively. Median normal liver SUVmax and SUVmean was 4.1 ± 0.9 ng/ml (2.4-7.2) and 2.0 ± 0.5 ng/ml (1.3-5.1), respectively. Median MTV was 50 ± 87 ml (1.4-447.6) and median TLG was 288 ± 523 ml (5.6-2992.5). No statistical significant correlation or difference was observed between variables. **Conclusion:** In our sample, contrary to the literature, 2-[¹⁸F]FDG PET/CT functional parameters were not able to predict recurrence or mortality, and therefore do not seem to be optimal for hepatic surgery selection in colorectal cancer. **References:** Shim JR, Lee SD, Han SS, Lee SJ, Lee DE, Kim SK, Kim SH, Park SJ, Oh JH, Prognostic significance of ¹⁸F-FDG PET/CT in patients with colorectal cancer liver metastases after hepatectomy. Eur J Surg Oncol. 2018 May;44(5):670-676. DOI:10.1016/j.ejso.2018.01.243

EPS-031**Correlation of CEA levels with metabolic tumor volume, assessed by FDG PET and RECIST compliant size measurement in patients with recurrent and/or metastatic colorectal cancer**

P. Bochev¹, Y. Bocheva², G. Mateva¹;

¹Acibadem Cityclinic UMBAL Mladost Oncology hospital, Sofia, BULGARIA, ²Medical University "Prof.d-r Paraskev Stoyanov", Varna, BULGARIA.

Aim/Introduction: Carcinoembryonic antigen (CEA) is a routine tumor marker in the management of patients with colorectal cancer (CRC) in staging, prognostication and surveillance. Its use in treatment response monitoring is less clear in terms of correlation with the actual tumor volume. Fluorodeoxyglucose Positron emission tomography (FDG PET CT) is frequently used in treatment response assessment to represent metabolic tumor volume (MTV). Data on direct correlation between tumor size assessed by contrast enhanced CT (CECT) and CEA levels is present, but those for MTV and CEA is scarce and unconvincing. Aim: To correlate the CEA levels with metabolic tumor volume and RECIST compliant size measurement in patients with recurrent/persistent/metastatic CRC. **Materials and Methods:** Inclusion criteria: CRC with recurrence/persistence/metastatic disease, which have measurable MTV on FDG PET/CT, RECIST compliant target lesions on CECT and has been monitored with CEA serum levels. CEA levels have been tested within 4 weeks of PET/CT and/or CECT. Only patients with ≥ 3 measure points were included. Exclusion criteria: CRC with measurable MTV, but normal CEA levels; Patients with high CEA levels, but low FDG uptake; Patients with only non-measurable disease on CECT; Chemo- or radiotherapy, applied between PET/CECT and CEA measurement. We retrospectively reviewed the database of Nuclear medicine department, Acibadem City clinic Oncology hospital, Sofia from Nov.2018 to Mar.2020. Eight patients met the inclusion criteria. All scans of those patients, that were coupled with CEA measurement were considered evaluable points and were further analyzed. A total of 90 evaluable points were identified (37 PET, 52 CECT, 1 PET with CECT). MTV and CEA level as well as CECT sum of largest diameters (target lesion only) and CEA were tested for correlation at individual level. CLIA method is used for CEA determination. **Results:** The correlation of CEA levels and MTV was strikingly high, $r=0,97$ (0,86 to 0,99). The correlation of CECT parameters ranged from low to high (0,27 to 0,99) with one case of negative correlation ($r=-0,27$) with CECT failing to correlate in cases of complex liver lesions with massive necrosis, after local treatment of liver metastases and in bone metastases. PET CT performed slightly worse in small volume lung metastases. **Conclusion:** MTV has an almost perfect positive correlation with CEA levels. RECIST measurements have highly variable correlation, ranging from low negative to high positive. In cases of major discrepancies between

CEA dynamics and CECT assessed response, arbitrary FDG PET CT should be recommended. **References:** None

EPS-032**The Relationship Between Ca-125 Level and ¹⁸F FDG PET/CT Findings in The Assessment of Progressive Disease in Epithelial Ovarian Carcinoma**

S. Tatlidil, B. Karasah, H. Sariyildiz, Z. Burak, Z. Ozcan; Ege University, Izmir, TURKEY.

Aim/Introduction: Elevated Ca-125 level in ovarian tumors might indicate disease progression and it is in use as an indication of ¹⁸F FDG PET/CT for restaging. In the current study, we aimed to investigate the relationship between imaging findings and serum Ca-125 level in patients with ovarian surface epithelial tumors who underwent ¹⁸F FDG PET/CT to evaluate the suspicion of recurrent disease. **Materials and Methods:** The database of 125 patients (pts) who underwent PET/CT for re-staging between 13.12.2011-29.05.2019 was reviewed. There were 88 pts fitting to the study inclusion criteria. The initial ¹⁸F FDG PET/CT scan which is performed for restaging was involved. Those pts without a Ca-125 test and PET/CT within a 2 week interval, or who had a histological diagnosis other than surface epithelium-originated tumors, who had a second primary malignancy, progression under treatment, or those with chronic granulomatous disease were excluded. Increasing lesion size and new lesions were considered as progression criteria and verified with clinical follow-up, imaging/clinical findings, or histopathological examination. **Results:** There were 34 (39%) cases with high grade and 33 (38%) low grade serous tumors. Other tumor subtypes were mucinous: 8 (9%), clear cell: 5 (6%), and 8 others (9%). Serum Ca-125 levels ranged from 2 to 2456U/ml. In 72 (82%) out of 88 cases, Ca-125 levels were elevated. While progressive disease was confirmed in 62 (86%) out of these 72 pts, disease progression was suspicious in 5 cases (7%). Five cases were clinically stable despite the increased Ca-125 level and PET/CT showed no evidence of disease progression in these pts. On the other hand, PET/CT showed progression of intra-abdominal lesions in 11 out of 16 patients (69%) whose serum Ca-125 levels were actually non-elevated. Tumor histology was high grade serous carcinoma in 10 (91%) of them. When Ca-125 levels during the last 6 months period were assessed it was stable in 10 (91%) pts. A gradual increasing trend of Ca-125 was noted in a single patient (9%) even though it was not exceeding the normal limit. **Conclusion:** Despite the limited number of cases, our findings indicate the detection of cases of with progressive findings on ¹⁸F FDG PET/CT scan without corresponding high Ca-125 levels. Therefore, a whole-body ¹⁸F FDG PET/CT scan might improve clinical evaluation particularly in cases with high grade serous carcinoma in which normal Ca-125 levels might be found at the time of recurrence. **References:** None

EPS-033**¹⁸F-FDG PET/CT and Ca-125 in the evaluation of ovarian cancer relapse or persistence: is there any correlation?**

F. Dondi¹, D. Albano¹, A. Calabrò², M. Gregorelli², A. Mazzeo², P. Bellini², M. Gazzilli³, E. Cerudelli³, F. Bertagna¹, R. Giubbini¹;

¹Università degli Studi di Brescia, Brescia, ITALY; ²Università degli studi di Brescia, Brescia, ITALY; ³Spedali Civili di Brescia, Brescia, ITALY.

Aim/Introduction: Ovarian cancer relapse can be diagnosed by serum tumor markers measurements and ¹⁸F-fluorodeoxyglucose positron emission tomography/computed tomography (¹⁸F-FDG PET/CT) findings. The aim of our study was to analyze the potential relationship between cancer antigen 125 (Ca-125) and PET/CT results in patients affected by ovarian cancer. **Materials and Methods:** 92 ¹⁸F-FDG PET/CT scans in 61 patients with diagnosis of ovarian cancer were analyzed and compared to Ca-125 values. PET/CT results were compared to other imaging modalities, histology or follow-up data in order to define its diagnostic accuracy. PET/CT studies were analyzed qualitatively and semiquantitatively by measuring the maximum and mean standardized uptake value body weight max (SUVbwmax, SUVbwmean), maximum SUV lean body mass (SUVlbm), maximum SUV body surface area (SUVbsa), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of hypermetabolic lesions. All measurements were compared with Ca-125 values. **Results:** 20 PET/CT studies were true negative, 63 true positive, 5 false positive and 4 false negative with sensitivity of 94%, specificity of 80%, negative predictive value of 83%, positive predictive value of 93% and accuracy of 90%. Ca-125 levels were significantly correlated with PET/CT results and all PET/CT semiquantitative parameters. Ca-125 cutoff values of 17 U/ml is the best compromise between sensitivity and specificity in discriminating between positive and negative PET/CT result. **Conclusion:** ¹⁸F-FDG PET/CT has good accuracy in evaluating patients with relapse or persistence of ovarian cancer. Ca-125 levels were significantly correlated with metabolic PET/CT parameters. **References:** None

EPS-034**Patterns and Time to Recurrence of Gynaecologic Malignancies on ¹⁸F-FDG PET/CT**

S. Gitau, K. Makhdomi, E. Nganga, K. Warfa;
Aga Khan University, Nairobi, KENYA.

Aim/Introduction: Patients with gynaecologic malignancies have varied patterns of disease recurrence as well as time to recurrence. There is paucity of literature on these patterns as assessed by ¹⁸F-Fluorodeoxyglucose positron emission tomography/computed tomography (¹⁸F-FDG PET/CT). This study aimed to characterize patterns and time to recurrence of gynaecologic malignancies as assessed on ¹⁸F-FDG PET/CT. **Materials and Methods:** Clinical data of patients treated for gynaecologic malignancies (cervical, endometrial and

ovarian cancers) and referred for a follow up FDG PET/CT to exclude recurrence was collected between January and December 2019. Patients with evidence of metabolically active recurrence were included in this study. Patients referred for staging FDG PET CT were excluded. The time to recurrence, in months, for the different gynaecologic malignancies was recorded. **Results:** A total of 84 (45 cervical cancer, 24 ovarian cancer and 16 endometrial cancer) patients met the inclusion criteria. 46/84 (55%) patients had metabolically active disease recurrence at completion of the initial treatment. This included 21/45(47%) cervical cancer, 14/24 (58%) ovarian cancer and 10/16 (63%) endometrial cancer) patients had Patterns of cervical cancer recurrence were as follows: 5 (24%) patients had central/local/vault recurrence, 3 (14%) had pelvic sidewall nodal recurrence and 13 (62%) had distant/multiple-site recurrence. Patterns of ovarian cancer recurrence were as follows: 12 (86%) patients had multiple-site recurrence and 2 (14%) had single-site nodal recurrence only. Patterns of endometrial cancer recurrence were as follows: 1 (10%) patient had central/local recurrence, 1 (10%) had pelvic nodal recurrence and 8 (80%) had distant/multiple-site recurrence. A total of 13/46 (28%) patients had recurrence above the diaphragm. The median time to relapse (TTR) in months was 32.5 for cervical cancer, 23 for ovarian cancer and 33.8 for endometrial cancer, an average of 30 months for the gynecologic malignancies. **Conclusion:** Gynaecologic malignancies predominantly recur at distant/multiple sites. The average time to recurrence for these malignancies is 2-3 years. **References:** Gerdin E, Cnattingius S, Johnson P, et al. SPECT imaging of SST2-expressing tumors with ^{99m}Tc-labelled somatostatin receptor antagonists is feasible depending on the chelator and the spacer

*R. Gaonkar*¹, *F. Wiesmann*¹, *E. Gourni*², *R. Mikołajczak*³, *L. McDougall*¹, *L. Del Pozzo*¹, *H. R. Maecke*², *R. Mansi*¹, *M. Fani*¹; ¹Division of Radiopharmaceutical Chemistry, University Hospital Basel, Basel, SWITZERLAND, ²Department of Nuclear Medicine, University Hospital Freiburg, Freiburg, GERMANY, ³National Centre for Nuclear Research, Radioisotope Centre POLATOM, Otwock, POLAND.

Aim/Introduction: Somatostatin receptor subtype 2 (SST2) is an established biomarker today for imaging of neuroendocrine

tumors using ^{68}Ga -labelled somatostatin receptor agonists (^{68}Ga)-DOTA-TATE or (^{68}Ga)-DOTA-TOC) and more recently antagonists (^{68}Ga)-NODAGA-JR11). Nevertheless, most of the nuclear medical examinations are conducted with $^{99\text{m}}\text{Tc}$, and [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-TOC is being used for SST2 imaging. Surprisingly, when [$^{99\text{m}}\text{Tc}$]Tc-HYNIC was conjugated to the antagonist SS01 (4-Cl-Phe-cyclo(D-Cys-Tyr-D-Trp-Lys-Thr-Cys)D-Tyr-NH₂) SST2 imaging was not feasible¹. This was not the case for [$^{99\text{m}}\text{Tc}$]Tc-N4-SS01 (N4: 6-carboxy-1,4,8,11-tetrazaundecane). HYNIC, a common bifunctional chelator for $^{99\text{m}}\text{Tc}$, seemed to be “incompatible” with SST2 antagonists. The aims of this work are to investigate whether: a) the “incompatibility” of HYNIC is a general phenomenon with SST2 antagonists and b) the introduction of spacers facilitates SST2 imaging with the HYNIC conjugates. **Materials and Methods:** The two somatostatin antagonists SS01 and JR11 having a distinct SST2 affinity were conjugated to N4, HYNIC and Ahx-HYNIC (Ahx: aminohexanoic acid). All six conjugates were labelled with $^{99\text{m}}\text{Tc}$ (EDDA was used as co-ligand for HYNIC) and evaluated head-to-head in vitro and in vivo using HEK-hSST2 cells. Their imaging properties were assessed by SPECT/CT in HEK-hSST2 xenografts. [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-TOC was used as a reference radiotracer. **Results:** Both [$^{99\text{m}}\text{Tc}$]Tc-N4 conjugates showed very high cellular uptake ($78.5\pm 0.3\%$ and $71.2\pm 1.45\%$ for [$^{99\text{m}}\text{Tc}$]Tc-N4-SS01 and [$^{99\text{m}}\text{Tc}$]Tc-N4-JR11 at 4h, respectively). On the contrary, the two [$^{99\text{m}}\text{Tc}$]Tc-HYNIC conjugates showed very low cellular uptake ([$^{99\text{m}}\text{Tc}$]Tc-HYNIC-SS01 <1% and [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-JR11 only $13.9\pm 1.0\%$, at 4h). The introduction of Ahx restored to a great extent the SST2-mediated cellular uptake, being $36.6\pm 0.2\%$ for [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-Ahx-SS01 and $56.9\pm 0.8\%$ for [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-Ahx-JR11; close to the level of [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-TOC ($49.4\pm 1.2\%$). As a result, SST2 imaging by SPECT/CT was successful with both [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-Ahx conjugates. With the exception of [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-Ahx-JR11 at 1h p.i. showing some abdominal uptake (attributed to stomach and pancreas), all four $^{99\text{m}}\text{Tc}$ -labelled conjugates were accumulated in the tumors and the kidneys and revealed excellent tumor-to-background contrast. Visually, both [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-Ahx conjugates show similar tumor uptake as the [$^{99\text{m}}\text{Tc}$]Tc-N4 counterparts, which in turn had distinguishingly higher kidney uptake. All four $^{99\text{m}}\text{Tc}$ -labelled conjugates illustrated similar or superior image contrast to [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-TOC. Quantitative biodistribution studies are on-going. **Conclusion:** HYNIC is a suitable chelator for the development of $^{99\text{m}}\text{Tc}$ -labelled SST2-antagonists when a spacer of appropriate length, like Ahx, is used. [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-Ahx-SS01 and [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-Ahx-JR11 compare fairly well with [$^{99\text{m}}\text{Tc}$]Tc-HYNIC-TOC as imaging agents. N4 is also a suitable chelator, which leads though to a higher accumulation in the kidneys. **References:** 1. Abiraj K et al, EJNMMI Research 2018;8:75

OP-148

Preclinical characterization of two $^{99\text{m}}\text{Tc}$ -labelled SSTR2 antagonists: Selection of a candidate for clinical translation

C. Decristoforo¹, R. Mansi², V. Weingärtner¹, P. Kolenc-Peitt³, P. Garnuszek⁴, M. Kroselj³, R. Mikolajczak⁴, C. Rangger¹, A. Hubalewska-Dydejczyk⁵, M. Fani²;

¹Department of Nuclear Medicine, Medical University Innsbruck, Innsbruck, AUSTRIA, ²Division of Radiopharmaceutical Chemistry, University Hospital Basel, Basel, SWITZERLAND, ³Department of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA, ⁴Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND, ⁵Department of Endocrinology, Jagiellonian University Medical College, Cracow, POLAND.

Aim/Introduction: Somatostatin receptors, predominantly of subtype 2 (SSTR2), overexpressed in neuroendocrine neoplasms (NEN) are an established target for radiopharmaceuticals. Recently, radiolabelled SSTR2 antagonists have demonstrated superior properties over agonists (e.g. DOTA-TATE, DOTA-TOC), with promising developments for PET imaging and therapy.[1] Considering the availability and diagnostic performance of SPECT/CT scans, usage of a suitable $^{99\text{m}}\text{Tc}$ -labelled SSTR2 antagonist would offer a wider applicability of this approach. The development of such candidates is so far very limited, clinical data are lacking. Within the ERA-PerMed project “TECANT” [2] two SSTR2 antagonists with the Tetraamine (N4) chelator for $^{99\text{m}}\text{Tc}$ -labelling (TECANT 1 based on the antagonist LM3 and TECANT 2 based on BASS) were compared preclinically regarding their pharmacological properties in vitro and in vivo for the selection of the best candidate for clinical translation. **Materials and Methods:** Receptor affinity (IC_{50}) displacement assays, internalization and dissociation studies were performed in HEK293 cells transfected with human SSTR2 (HEK-SSTR2). LogD values were determined using octanol/water partition, protein binding and stability were assessed in human serum. Biodistribution and SPECT/CT studies were carried out in nude mice bearing HEK-SSTR2-xenografts. Biodistribution studies provided the basis for dosimetry estimations from mouse to man. **Results:** [$^{99\text{m}}\text{Tc}$]Tc-TECANT 1 showed higher hydrophilicity ($\log D=-2.53$) and lower protein binding (20%) than [$^{99\text{m}}\text{Tc}$]Tc-TECANT 2 (-1.63 and 23%, respectively), stability was comparable. Competition assays revealed a high affinity of both [$^{99\text{m}}\text{Tc}$]Tc-TECANT 1 and [$^{99\text{m}}\text{Tc}$]Tc-TECANT 2 to SSTR2 with IC_{50} values of 4.1 ± 0.8 and 5.0 ± 1.1 nM, respectively. [$^{99\text{m}}\text{Tc}$]Tc-TECANT 1 showed higher SSTR2-mediated cellular uptake in vitro (>50%, @2h/37°C) and lower dissociation rate (<30%, @2h/37°C), as compared to [$^{99\text{m}}\text{Tc}$]Tc-TECANT 2 (<40% and >50%, respectively). [$^{99\text{m}}\text{Tc}$]Tc-TECANT 1 had lower blood values, kidney and muscles uptake than [$^{99\text{m}}\text{Tc}$]Tc-TECANT 2. Tumour uptake was comparable between the two

probes (26.0 ± 1.3 and 28.4 ± 4.8 %IA/g for [^{99m}Tc]Tc-TECANT 1 and [^{99m}Tc]Tc-TECANT 2, respectively), which was proven to be specific (<1% %IA/g in SSTR2-negative tumours). MicroSPECT/CT images confirmed the biodistribution results and indicated superiority of [^{99m}Tc]Tc-TECANT 1 as an imaging agent for SSTR2-expressing tumours. **Conclusion:** The preclinical studies provided the basis for selection of [^{99m}Tc]Tc-TECANT 1 for further pharmaceutical development in a kit formulation. Toxicity studies will be needed to complete the preclinical characterisation and to translate the first ^{99m}Tc -labelled SSTR2 antagonist into a clinical feasibility study in NEN patients. **References:** [1] Fani M, et al. PET-MRI imaging of neurotensin receptor-positive tumors with ^{68}Ga -labeled antagonists : “the chelate makes again the difference”

V. Goncalves¹, E. Renard¹, M. Moreau¹, P. S. Bellaye², M. Guillemin², F. Denat¹;

¹Université Bourgogne Franche-Comté, Dijon, FRANCE,

²Georges-François Leclerc Cancer Center, Dijon, FRANCE.

Aim/Introduction: Neurotensin receptor 1 (NTS₁) is involved in the development and progression of numerous cancers. A small-molecule NTS₁ antagonist, named [^{177}Lu]Lu-IPN01087 (previously [^{177}Lu]Lu-3BP-227) is currently evaluated in phase I/II clinical trials for the targeted radiotherapy of NTS₁-positive cancers. The identification of a PET companion diagnostic agent would greatly facilitate the selection of patients eligible for NTS₁-targeted therapy. In this study, we evaluated the influence of the nature of the chelator on the biodistribution of NTS₁ antagonists. **Materials and Methods:** Seven compounds were synthesized, based on the structure of the NTS₁ antagonist SR142948A, using different chelators for gallium-68 (NOTA, (R)-NODAGA, DOTA, DOTAGA and THP). The compound 3BP-227 and the NTS₁ peptide agonist NT20.3 were used as references. All these compounds were metalated with ^{68}Ga and their affinity for NTS₁ was determined on a competition assay on CHO cells overexpressing NTS₁. Their stability was assessed in mouse serum. The compounds were radiolabeled with ^{68}Ga , partition coefficients were measured and their biodistribution was studied in nude mice bearing a subcutaneous xenograft of HT-29 cells. PET-MRI images were recorded between 1.5 h and 2 h post-injection (3–8 MBq). Two hours post-injection, mice were sacrificed, organs were collected, weighed and γ -counted. **Results:** Seven novel antagonists were obtained through a convergent synthesis in 21 steps. K_i values were in the nanomolar range, demonstrating a high affinity for NTS₁. The NOTA/NODAGA/THP-based compounds were radiolabeled with ^{68}Ga in 5 min at 37°C, whereas 10 min at

95°C was required for the DOTA/DOTAGA-based compounds to achieve molar activities of ca. 15–20 MBq/nmol. Good radiochemical yields and purities (>95%) were obtained. PET-MRI images and ex vivo biodistribution studies showed significant differences between compounds. The THP derivative showed significant uptake in the lungs, spleen, and liver. The NOTA- and NODAGA-compounds showed a strong signal in gallbladder and intestines suggesting a partial hepatobiliary excretion pathway. All the other compounds were eliminated through kidneys. We identified a promising ^{68}Ga -PET tracer that showed rapid accumulation in the tumor (4.9%ID/g, 2 h p.i.) and fast clearance from healthy tissues. Blocking experiments confirmed the specificity of the uptake. **Conclusion:** Here, we evaluated, side-by-side, the influence of the nature and number of chelators on a series of NTS₁ small-molecule antagonists and identified a promising tracer, [^{68}Ga]Ga-bisNODAGA-16. We believe that this tracer could serve as a useful ^{68}Ga -PET diagnosis agent for multiple cancers and assist in the selection of patients eligible for NTS₁ radiotherapy. **References:** None

Longitudinal PET Imaging Allows for Non-Invasive Assessment of TSPO Expression in a Glioblastoma Mouse Model

A. Holzgreve¹, D. Pötter¹, M. Brendel¹, M. Orth², L. Weidner³, J. Maas², B. von Ungern-Sternberg¹, L. Gold¹, M. A. Kirchner¹, M. J. Riemenschneider³, P. Bartenstein¹, K. Lauber², N. L. Albert¹;

LMU Munich, Munich, GERMANY, ²Department of

Radiation Oncology, University Hospital, LMU Munich,

Munich, GERMANY, ³Department of Neuropathology,

Regensburg University Hospital, Regensburg, GERMANY.

Aim/Introduction: The 18kDa translocator protein (TSPO) is upregulated during activation of microglia and macrophages and has shown to be overexpressed in glioblastoma (GBM). However, few data exist on TSPO-targeted imaging of malignant brain tumors. Hence, we investigated the feasibility of longitudinal TSPO PET imaging in a GBM mouse model validated through autoradiography and immunohistochemistry. **Materials and Methods:** A total of 24 mice were orthotopically injected with either GL261 cells (GBM, n = 21 mice) or saline for control (sham, n = 3 mice). Longitudinal PET imaging with the TSPO ligand ^{18}F -GE-180 was performed in a subgroup of 12 mice at four time points (4, 7, 11 and 14 days post inoculation). Another subgroup (n = 12 mice) was scanned at one time point only (7, 11 or 14 days post inoculation). PET analysis consisted in quantification of tracer uptake at the site of inoculation and within a background region in the unaffected contralateral hemisphere. Mean and maximal SUVs as well as tumor-to-background ratios were calculated ($\text{SUV}_{\text{mean/max}}$; $\text{TBR}_{\text{mean/max}}$). Post-mortem analysis of TSPO expression was performed

by autoradiography and immunohistochemistry for qualitative comparison of regional distribution of TSPO with the tracer signal. T-test was used for group comparison between GBM and sham mice and analysis of variance for comparison between GBM mice at different time points. Level of significance was $p < 0.05$. **Results:** PET imaging, autoradiography and immunohistochemistry revealed elevated TSPO expression in all inoculated mice. Tumor extent was visually congruent between autoradiography, immunohistochemistry and histology. TSPO PET signal was significantly higher in GBM vs. sham mice (e.g. $TBR_{max} 3.0 \pm 0.4$ vs. 2.2 ± 0.3 , $TBR_{mean} 1.9 \pm 0.2$ vs. 1.29 ± 0.03 ; $p < 0.001$) 14 days post inoculation. In GBM mice, longitudinal PET imaging showed an increase of tumoral tracer uptake between day 4 and day 14 post inoculation (+57% for SUV_{mean} ($p < 0.001$), +23% for TBR_{max} ($p=0.013$) and +22% for TBR_{mean} ($p < 0.001$)). Interestingly, PET imaging indicated a slightly increased TSPO signal in the contralateral hemisphere in GBM mice ($SUV_{mean} 0.22 \pm 0.02$) compared to sham mice ($SUV_{mean} 0.20 \pm 0.02$, $p=0.02$) 14 days after inoculation. **Conclusion:** TSPO-targeted PET imaging is feasible in a GBM mouse model. Qualitative and quantitative PET evaluation allows for non-invasive assessment of tumoral TSPO expression over time. A reference region in the contralateral hemisphere should be used with caution, as background signal was increased in all GBM mice. **References:** None

OP-151

Low temperature radiolabelling of human serum albumin constructs with terbium-161 and ex vivo biodistribution to assess in vivo stability

I. Cassells^{1,2}, M. Ooms², J. Cornelis¹, A. R. Burgoyne², S. Ahenkorah^{1,2}, M. Van de Voorde², T. Cardinaels^{2,3}, C. M. Deroose⁴, G. Bormans¹, F. Cleeren¹;

¹Radiopharmaceutical Research, Department of Pharmaceutical and Pharmacological Science, University of Leuven, Leuven, BELGIUM, ²Nuclear Materials Science Institute, Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM, ³Department of Chemistry, University of Leuven, Leuven, BELGIUM, ⁴Nuclear Medicine, University Hospitals Leuven: Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, Leuven, BELGIUM.

Aim/Introduction: Targeted radionuclide therapy using Terbium-161 (¹⁶¹Tb) is a promising approach for β^- and Auger electron therapy. Heat-sensitive biomolecules (e.g. nanobodies) are increasingly being used as carriers in radiometal-based pharmaceuticals, however current radiolabelling techniques require heating (>85 °C) incompatible with heat-sensitive carrier molecules. In this study, we evaluated bifunctional chelators that allow ¹⁶¹Tb-labelling under mild conditions using human serum albumin (HSA) and assessed the in vivo stability of the constructs. **Materials and Methods:** ¹⁶¹Tb was produced and purified at

SCKCEN.¹ p-SCN-Bn-CHX-A"-DTPA (**L1**), p-SCN-Bn-DOTA (**L2**) and p-NCS-Bz-DOTA-GA (**L3**) were conjugated to HSA (0.1 M NaHCO₃, pH 8.5, 2h, 25°C) and purified (PD-10 column) resulting in HSA-**L1-3** with a chelator-to-HSA ratio of 1-3, as determined with ESI-TOF-HRMS. The constructs were labelled with 54 MBq ¹⁶¹TbCl₃ (10 μ M HSA-**L1-3**, 0.1 M NaOAc, pH 4.7, 1h, 40°C) and purified (PD-10 column, PBS, 5 mg/mL ascorbic acid). The in vitro stability was determined in human serum at 37°C (iTLC and SEC-HPLC). NMRI mice were injected with free ¹⁶¹TbCl₃ or ¹⁶¹Tb-HSA-**L1-3** (0.9-1.5 MBq, 0.2 mL, 10 nmoles) via a tail vein under anaesthesia, and sacrificed after 10 min, 1 h, 4 h, 24 h or 7 days (n=3/time point). Organs were harvested and the radioactivity quantified using a gamma counter. **Results:** All HSA constructs (HSA-**L1-3**) were labelled successfully with ¹⁶¹TbCl₃ at 40 °C (radiochemical yield >99 %). A limited amount of ¹⁶¹Tb (7%) bound to unmodified HSA (negative control). ¹⁶¹Tb-HSA-**L1-3** demonstrated high stability in human serum, even after 24 hours at 37°C (>96 %). Free ¹⁶¹TbCl₃ in NMRI mice showed significant uptake in bone ($SUV = 2.57 \pm 0.46$) at 1 h post injection, which was increased further after 7 days ($SUV = 3.53 \pm 1.01$). The HSA-**L1** construct showed increased bone uptake after 7 days ($SUV = 1.1 \pm 0.3$), suggesting **L1** is not a suitable ligand for terbium. In contrast, the DOTA constructs (**L2** and **L3**) showed only minor uptake in bone ($SUV = 0.13$, $p = 0.002$), suggesting a more stable chelation of terbium. **Conclusion:** We radiolabelled heat-sensitive biomolecules with ¹⁶¹Tb in quantitative yields for the first time. The DOTA variants (¹⁶¹Tb-HSA-**L2-3**) demonstrated high in vitro and in vivo stability and are promising chelators for terbium labelling. More interesting vector molecules will be radiolabelled using this method with different terbium isotopes for theranostic applications. **References:** 1. M. Ooms, et al., Eur. J. Nucl. Med. Mol. Imaging, 46, 2019, p. S40 1 p., OP-088

OP-152

Sensitive imaging of $\alpha v \beta 6$ -Integrin using Ga-68 labelled nonapeptide trimers

J. Notni, N. G. Quigley, F. Richter, K. Steiger, W. Weichert; Technical University of Munich, Munich, GERMANY.

Aim/Introduction: $\alpha v \beta 6$ -Integrin binds to latency-associated peptide (LAP) via a RGD sequence contained therein, and is a major activator of transforming growth factor beta (TGF- β). Many carcinomas (esp. pancreatic and squamous cell) express $\alpha v \beta 6$ -integrin, but it is also upregulated in other conditions associated with TGF- β dysregulation, such as fibrosis. We structurally optimized a previously described $\alpha v \beta 6$ -integrin selective nonapeptide [1] and designed trimeric Ga-68-labeled TRAP-conjugates thereof, aiming to reduce unspecific in-vivo uptake in non-target organs while maintaining target affinity and target-specific accumulation and retention. **Materials and Methods:** Peptides were synthesized by Fmoc technique. Integrin affinities were

determined by ELISA as described.[1] Ga-68 labelled trimeric TRAP (triazacyclononane-triphosphinate) conjugates thereof were synthesized via Click Chemistry (CuAAC) as described,[2] and characterized in H2009 ($\alpha\beta6+$) xenografted SCID mice by dynamic (90 min) and static (75 min p.i.) PET as well as ex-vivo biodistribution. Expression of $\alpha\beta6$ -integrin in tumor and non-target tissues was determined by $\beta6$ -immunohistochemistry. **Results:** The effect of altering different amino acids in the sequence of cyclo(FRGDLAfp(NMe)K) was investigated, regarding binding affinity, polarity, and biodistribution of the respective TRAP-based, Ga-68 labeled trimeric conjugates. All investigated compounds exhibited comparable $\alpha\beta6$ -integrin affinities in the sub-nanomolar range. Depending on the substitution patterns, varying reductions of non-specific uptake was observed (e.g., ranges in blood, liver, and pancreas from 2.4-0.25, 7.7-0.6, and 1.0-0.27 %ID/g, respectively). Since tumor uptakes were comparable (range 7.5-8.7 %ID/g), corresponding tumor/background ratios could be increased from 2.2, 1.2, and 10.1 %ID/g to 7.5, 10.5, and 28.5 %ID/g, respectively, resulting in high-contrast PET images. **Conclusion:** $\alpha\beta6$ -Integrin PET using Ga-68-labeled nonapeptide trimers holds great promise for improved clinical PET-diagnostics of carcinomas and fibrosis. **References:** [1] Färber SF, et al., ACS Omega 2018;3:2428. OP-153

Optimized Radiosynthesis of [3-¹¹C]Alanine and [3-¹¹C]Pyruvate for Imaging Central Carbon Metabolism In Vivo
J. Kelly, T. M. Jeitner, N. Waterhouse, N. Karakatsanis, S. Nehmeh, J. W. Babich;
Weill Cornell Medicine, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: Many cancer cells undergo metabolic reprogramming leading to high glucose consumption; known as the Warburg effect. Such metabolic reprogramming is typically imaged using FDG. Although FDG captures changes in glucose uptake, it provides no information about glucose utilization. This is particularly true in prostate cancer (PCa), in which FDG uptake is highly variable. To better understand metabolic reprogramming in cancer, and its relationship with pathogenesis and progression, probes that directly interrogate central carbon metabolism (CCM) are required. Pyruvate lies at the nexus of CCM, and the alanine-pyruvate-lactate axis is frequently altered in cancer. Our aims were to develop syntheses of [3-¹¹C]alanine and [3-¹¹C]pyruvate that would enable automation, and to demonstrate the feasibility of these probes for imaging elements of CCM metabolism in vivo by positron emission tomography (PET). **Materials and Methods:** [3-¹¹C]Alanine was synthesized from N-(diphenylmethylene)glycine tert-butyl ester and converted to [3-¹¹C]pyruvate using D-amino acid oxidase. All solvent exchanges and purifications were performed by solid phase extraction (SPE). Uptake of [3-¹¹C]alanine and [3-

¹¹C]pyruvate was determined in two PCa cell lines, and tissue distribution was visualized by microPET/CT in male athymic BALB/c nu/nu mice and healthy male Sprague-Dawley rats. **Results:** Racemic [3-¹¹C]Alanine and [3-¹¹C]pyruvate are isolated after 33±4 min and 53±7 min, respectively. Decay-corrected radiochemical yields were 68±13% and 22±7%. Radiochemical purity exceeded 98% for both tracers. [3-¹¹C]Alanine is taken up continuously by PC3 cells over 40 min, with a rate that exceeds that of FDG. In contrast, [3-¹¹C]Pyruvate is taken up very rapidly by both LNCaP and PC3 cells ($t_{max} < 5$ min). Activity clears more rapidly from PC3 cells. In vivo, [3-¹¹C]Alanine accumulates in the liver and thymus as well as in PCa xenografts. The distribution of [3-¹¹C]pyruvate in mouse and rat is characterized by high uptake in the heart, liver, brain, and eyes. **Conclusion:** Chemoenzymatic syntheses of [3-¹¹C]alanine and [3-¹¹C]pyruvate based on SPE have been developed. These syntheses are suitable for automation, allowing for large end-of-synthesis activities sufficient for clinical use. [3-¹¹C]Alanine clearly delineates tumors in vivo, [3-¹¹C]pyruvate highlights distinct metabolic fluxes in LNCaP and PC3 cells. Taken together, these early observations support a role for these tracers for imaging elements of CCM in tumors in vivo. **References:** None

Synthesis and in vitro comparison of squaric acid coupled lysine-urea-glutamate and glutamate-urea-glutamate based PSMA-inhibitors

T. Grus, H. Lahnif, M. Omralinov, F. Roesch;
Department of Chemistry, Johannes Gutenberg-University Mainz, Mainz, GERMANY.

Aim/Introduction: Prostate cancer (PC) is one of the most common cancer types worldwide. A promising target for PC is the prostate-specific membrane antigen (PSMA), which is highly overexpressed in PC and correlates with the severity of PC. The urea-based-target vector KuE (L-lysine-urea-L-glutamate) is the most used binding motif in PSMA inhibitors. Similar in vitro and in vivo study results were achieved with EuE (L-glutamate-urea-L-glutamate) based PSMA-radiotracer (1,2). In preliminary studies, we have identified squaric acid (SA) as promising linker moiety between KuE target vector and radiolabeling unit. In this study, we compared the PSMA-affinity of different SA.KuE and SA.EuE based tracer. **Materials and Methods:** DATA^{5m}.SA.KuE, DOTAGA.NH₂.SA.KuE, DATA^{5m}.SA.EuE and DOTAGA.NH₂.SA.EuE were synthesized and the binding affinity was determined in a competitive cell assay using PSMA-expressing LNCaP-cells. LNCaP-cells were incubated with 0.75 nM ⁶⁸Ga-PSMA-10 in the presence of different concentrations of the non-labeled PSMA-ligands. After incubation at RT and removal of free radioactivity, cell-bound activity was measured. PSMA-11 was used as reference. For comparison, DATA^{5m}.PSMA617 and DOTAGA.NH₂.PSMA-617 were also evaluated. **Results:** The SA.KuE and

SA.EuE building blocks were synthesized in two and three steps, respectively. Subsequently, the chelators were linked at pH 9. The binding affinity was determined for DATA^{5m}.SA.KuE (51.1 ± 5.5 nM), DOTAGA.NH₂.SA.KuE (20.2 ± 3.5 nM), DATA^{5m}.SA.EuE (386.2 ± 81.0 nM), DOTAGA.NH₂.SA.EuE (407.1 ± 19.2 nM), DATA^{5m}.PSMA-617 (92.1 ± 11.7 nM) and DOTAGA.NH₂.PSMA-617 (20.6 ± 3.4 nM). **Conclusion:** The results of the competitive binding assay showed that there is no difference in the affinity of SA.KuE based and PSMA-617 based DOTAGA-tracer. On the other side, DATA^{5m}.SA.KuE shows a better PSMA-binding affinity than DATA^{5m}.PSMA-617. Significant higher affinities of SA.KuE based and PSMA-617 based tracer were achieved in contrast to SA.EuE based tracer. Comparing the affinity of the Sa.EuE target vector without chelator unit (12.9 ± 7.4 nM) with the affinities of the tracers, a significant decrease in affinity is noticeable. The chelators seems to have a negative influence on the PSMA binding. **References:** 1. Hillier, S. OP-155

Evaluation and Specific Targets of a Novel Tc-99m-MAG₃-RRL Probe for Tumor Imaging in Hepatoma Xenografts Model: A Pilot Study

R. Wang^{1,2}, Y. Du¹, Z. Chen¹, P. Yan¹, X. Duan¹, Q. Jiang¹, J. Zhang¹;
¹Peking University First Hospital, Beijing, CHINA, ²Peking University International Hospital, Beijing, CHINA.

Aim/Introduction: Arg-Arg-Leu (RRL) selected from peptide display library is a functional tumor -homing tripeptide, but its binding target is unclear. So in this study, we intend to identify its binding targets and improve the imaging application. **Materials and Methods:** Fluorescence imaging and flow cytometry were used to screen appropriate cell sample. Immunoprecipitation-mass spectrometry (IP-MS) method was utilized to screen the RRL-targeted proteins. Fluorescence colonization and cell-uptake experiment were used to verify the binding proteins. Peptides were modified with bifunctional chelating agent MAG₃ and further were radiolabeled by a one-step method. Imaging value was evaluated by γ -camera imaging and biodistribution studies. **Results:** HepG2 was the suitable cell with highest mean fluorescence intensity (P<0.05). IP-MS analyze showed that the dominant RRL-targeted proteins were mainly from heat shock protein (HSPs) family, especially heat shock cognate 71kDa protein (HSC70). Fluorescent colocalization showed a strong colocalization signal with the Pearson correlation coefficient of 0.80±0.07 and the overlap coefficient of 0.85±0.06. The HSP70 family inhibitor VER-155008 can

significantly reduce cell ^{99m}Tc-MAG₃-RRL uptake by a factor of 3 (P<0.05). Correlation analysis showed that there was a strong correlation trend between inhibitor and RRL with 0.98 correlation coefficient. The labeling efficiency and radiochemical purity of Tc-99m-MAG₃-RRL were 96.72±1.01% and 97.10±0.27% respectively. Imaging results showed that Tc-99m-MAG₃-RRL could be significantly concentrated in tumor lesion with the tumor-to-muscle (T/M) ratio reaching up to 6.54 ± 0.30 at 2h, when compared to Tc-99m-MAG₃-GGG group (P<0.05) and blocking group (P<0.05). The peak %ID/g values were 8.95±0.28 at 30min and the highest (T/M) ratio of the %ID/g values was 5.61±0.38, which were significantly higher than control group at each time point (P<0.05). **Conclusion:** These results suggest that Tc-99m-MAG₃-RRL can hold great promise for imaging malignant tumor and detection the tumor expression of HSPs would be a meaningful application. **References:** None

OP-156

Auger Electron Emitter Radionuclide Therapy: In vitro Study of Thallium-201 Kinetics and Toxicity in Breast and Prostate Cancer Cells

K. Osytek, I. Costa, E. Verger, F. Al-Saleme, J. Cheng, S. Terry, V. Abbate, P. Blower;
 King's College London, London, UNITED KINGDOM.

Aim/Introduction: Auger electron emitters have potential in targeted treatment of small tumours due to their high-LET (linear energy transfer) but short range emissions. Thallium-201 (²⁰¹Tl), known for its previous use in myocardial perfusion scintigraphy, decays by electron capture releasing around 37 Auger electrons, with a total energy of 15.3keV, per decay (1). However, its radiotoxic and cancer therapeutic effects remain unexplored. In this study we assess ²⁰¹Tl kinetics, radiotoxicity and its potential for targeted radionuclide therapy. **Materials and Methods:** [²⁰¹Tl]TlCl was used for in vitro studies on two cell lines: breast cancer cells MDA-MB-231 and prostate cancer cells DU-145, treated with activities ranging from 50-2000kBq per 250 μ l medium. For the purposes of radiobiological evaluation, we chose to use membrane potassium channels, such as the K⁺/Na⁺-ATPase pump, as the mechanism of accumulation in cells, despite this not offering tumour selectivity. Uptake and efflux assays were performed to establish accumulation and wash-out of ²⁰¹Tl. We used clonogenic assays to assess survival after 90 minute incubation with ²⁰¹Tl and non-radioactive thallium and mercury as controls. The γ H2AX method was used to visualise and quantify nuclear DNA damage. Higher concentrations of KCl were used to block ²⁰¹Tl uptake in order to assess the impact of non-internalised ²⁰¹Tl. **Results:** Cellular uptake of ²⁰¹Tl ranged between 4-13% measured in 250000 cells. Intracellular to extracellular concentration ratio at equilibrium was estimated between 40-55. Accumulated ²⁰¹Tl 'washed out' from cells exponentially after the radioactive medium

was exchanged for fresh medium. Clonogenic assays showed significant reduction in the number of colonies formed for the highest ^{201}Tl activities used compared to non-treated cells, with an estimated average activity of 0.2–0.3Bq/cell for 90% reduction in clonogenicity. Non-radioactive thallium and mercury at comparable concentrations revealed no toxicity. ^{201}Tl ions present only in the external solution did not reduce clonogenic survival of cancer cells. ^{201}Tl caused on average significantly more DNA damage per nucleus compared to non-treated and $^{nat}\text{Tl}/^{201}\text{Hg}$ treated cells. **Conclusion:** Internalised ^{201}Tl showed considerable radiotoxicity, reducing cell proliferation and survival while increasing nuclear DNA damage. Furthermore, we confirmed that ^{201}Tl ions need to be internalised to exhibit the radiotoxic effect on cells. These findings justify more advanced in vitro studies and the design of ^{201}Tl therapeutic radiopharmaceuticals, including the development of suitable chelators, for an Auger electron emitter radionuclide therapy. **References:** 1. OP-157

Exploring the limits of intranuclear PET/SPECT imaging with IgG-TAT: how low can you go?

M. Veal, G. M. Dias, V. Kersemans, D. Sneddon, S. Faulkner, B. Cornelissen;
University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: Radioimmunoconjugate (RIC)-based PET/SPECT imaging has great potential for a variety of clinical applications. The conjugation of cell penetrating peptides (CPPs), such as TAT (GRKKRRQRRRPPQGYG), facilitate the imaging of intranuclear epitopes, greatly expanding the scope for RIC-based imaging possibilities. Here, we develop a nuclear EGFP targeting method to evaluate the detection limits of IgG-TAT-based imaging of intranuclear epitopes. We use this methodology to predict the lower target abundance limit in vitro and in vivo, critical to choosing future candidate imaging targets. **Materials and Methods:** We stably transfected H1299 cells with Histone 2B tagged Enhanced Green Fluorescent Protein (H2B-EGFP) and generated four cell lines expressing increasing levels of H2B-EGFP, quantified by ELISA. We evaluated the anti-GFP monoclonal antibody GFP-G1 for specificity and affinity using Western blot, immunofluorescence microscopy and flow cytometry. GFP-G1 was conjugated to the CPP TAT, and the chelating agent DTPA using SPAAC-based click chemistry prior to radiolabelling with $^{111}\text{InCl}_3$. In vitro radio-internalisation assays were carried out across all four transfected cell lines and WT H1299 cells to evaluate the uptake of $^{111}\text{In-DTPA-GFP-G1-TAT}$ with different expression levels of H2B-EGFP. Xenograft tumours with three of the H2B-EGFP cell lines plus WT H1299 cells were established on the flank of balb/c nu/nu mice. Animals were administered 5 μg (5 MBq) $^{111}\text{In-DTPA-GFP-$

G1-TAT followed by SPECT imaging at 24 and 72 hours post injection prior to being sacrificed for ex vivo biodistribution studies. **Results:** We generated four H2B-EGFP transfected cell lines, with expression levels ranging from 180,000 \pm 5,000 to 1,100,000 \pm 91,000 copies/cell. Immunofluorescence microscopy showed that antibody GFP-G1 colocalised with H2B-EGFP and flow cytometry demonstrated that binding of GFP-G1 bound H2B-EGFP with a dissociation constant of 5.1 nM (1.5 to 10.4 nM). We conjugated GFP-G1 with CPP TAT and chelating agent DTPA prior to radiolabelling with $^{111}\text{InCl}_3$. In vitro radio-internalisation assays showed that uptake of $^{111}\text{In-DTPA-GFP-G1-TAT}$ correlated linearly with increasing H2B-EGFP expression ($r = 0.76$, $P < 0.001$) with a predicted lower detection threshold of 180,000 copies/cell. In vivo xenograft models also demonstrated $^{111}\text{In-DTPA-GFP-G1-TAT}$ uptake correlated linearly with H2B-EGFP expression ($r = 0.63$, $P = 0.004$) with a raised detection threshold of 240,000 copies/cell. **Conclusion:** The ability to test the detection limit of IgG-TAT-based intranuclear imaging probes is essential when evaluating potential candidate imaging targets. This study demonstrates the current capabilities of RIC based intranuclear imaging whilst simultaneously creating a methodology for further optimisation of novel imaging probe designs. **References:** None

Increased Accumulation of ^{64}Cu -Labeled Liposomes after Photothermal Therapy in Syngeneic Murine Model of Colorectal Cancer

J. Jørgensen¹, K. Norregaard¹, M. Simón¹, A. E. Hansen², J. R. Henriksen², T. L. Andresen², A. Kjær¹;

¹Dept. of Clinical Physiology, Nuclear Medicine & PET and Cluster for Molecular Imaging, Dept. of Biomedical Sciences, Rigshospitalet and University of Copenhagen, Copenhagen, DENMARK, ²Department of Health Technology, Technical University of Denmark, Lyngby, DENMARK.

Aim/Introduction: Hyperthermia increases tumor blood flow and vascular permeability, and can thereby enhance liposomal drug delivery to tumors. Photothermal therapy (PTT) is a minimally invasive technique that utilizes light-absorbing nanoparticles and near infrared light to induce local hyperthermia. Using a murine model of colorectal cancer (CT26), we aimed to assess if PTT can be used to increase liposomal accumulation in tumor tissue. **Materials and Methods:** Labelling of liposomes with ^{64}Cu was performed as previously described [1]. Balb/c mice bearing subcutaneous CT26 tumors were grouped ($n = 5$), and PTT was performed by intravenously injecting gold nanoshells (190 μl and 4.9×10^{10} nanoshells/ml) and 24 h later irradiating the tumors with a laser ($P = 1.5 \text{ W/cm}^2$ for 5 min). The change in temperature on the tumor surface was monitored with a thermal imaging camera. Subsequently, the groups were administered ^{64}Cu -loaded stealth liposomes immediately (0

h group), 6 h (6 h group), and 24 h (24 h group) after PTT. Additionally, a group of mice was administered ^{64}Cu -loaded stealth liposomes without any PTT (control group). All animals were PET/CT scanned 10 min and 24 h after liposome administration and the radioactivity concentration in tumors was quantified. **Results:** All groups receiving photothermal therapy had very similar heating profiles reaching an average maximum temperature after 5 min of irradiation of 48.9 ± 1.2 °C (0 h group), 50.0 ± 0.9 °C (6 h group), and 49.9 ± 1.2 °C (24 h group). When the ^{64}Cu -loaded liposomes were administered immediately after PTT, the mean tumor uptake of was significantly enhanced both 10 min (2.2 ± 0.4 %ID/g) and 24 h (11.6 ± 1.5 %ID/g) post injection, compared to control animals (1.2 ± 0.1 %ID/g and 4.3 ± 0.5 %ID/g, respectively). In contrast, no difference in tumor uptake was observed when the liposomes were administered at a later timepoint after PTT. **Conclusion:** A significant increase in tumor accumulation could be obtained when ^{64}Cu -labelled liposomes were administered immediately after PTT, suggesting that PTT could potentially be applied to induce local hyperthermia and improve accumulation of liposomal encapsulated drugs. **References:** [1] Henriksen et al. European Diagnostic Reference Levels for Computed Tomography applications in nuclear medicine: results from the MEDIRAD project

G. Verfaillie¹, Y. D'Asseler², K. Bacher¹;

¹Ghent University, Ghent, BELGIUM, ²Ghent University Hospital, Ghent, BELGIUM.

Aim/Introduction: Depending on the clinical objective, CT image quality requirements and corresponding patient radiation doses in nuclear medicine may differ considerably. Unlike in diagnostic radiology, published national Diagnostic Reference Levels (DRLs) in Europe for CT acquisitions used in hybrid imaging are limited. This study aims to propose the first European DRLs for specific applications of CT in hybrid SPECT/CT and PET/CT. **Materials and Methods:** As part of the EU Horizon 2020 MEDIRAD project, a CT dosimetry survey was conducted from October 2018 until February

2020. Participating nuclear medicine departments were asked to provide patient-specific information (gender, age, length and weight) and CT dose indicators (CTDI_{vol}, DLP) from the most frequently performed diagnostic SPECT/CT and PET/CT examinations. Per scan type, data from 30 adult patients (weight of 70 ± 10 kg) were collected. In addition, information on the used instrumentation and the clinical purpose of the CT scan was collected. For each examination the minimum, 25th percentile, median, 75th percentile and maximum were then retrieved from the distribution of the median CTDI_{vol} and DLP values calculated for each dataset. European DRLs were defined as the 75th percentile value and were derived for examinations that included data of at least 10 facilities. **Results:** Data were received from 50 nuclear medicine departments in 20 European countries, of which 22 centres were part of a university hospital. As expected, CT doses were lower for attenuation correction than for localisation or diagnostic hybrid CT scans. Large variations (min/max) in median CTDI_{vol} and DLP values up to a factor of 16 were observed. Suggested European DRLs for CTDI_{vol} (and DLP) of ^{18}F -FDG half body PET/CT examinations are 2.5 mGy (230 mGy.cm) and 6.3 mGy (580 mGy.cm) for attenuation correction only and localisation CT scans, respectively. A value of 6.4 mGy (160 mGy.cm) is proposed for attenuation correction only ^{18}F -FDG brain PET/CT studies. For $^{99\text{m}}\text{Tc}$ -bone (trunk) and parathyroid SPECT/CT examinations, a DRL of 4.4 mGy (160 mGy.cm) for attenuation correction and localisation CT scans is suggested. Finally, the proposed European DRL for attenuation correction CT scans of $^{99\text{m}}\text{Tc}$ -cardiac SPECT/CT studies is 3.1 mGy (60 mGy.cm). **Conclusion:** European DRLs for typical CT applications in nuclear medicine were derived. The large variations in observed CT doses highlights the need for optimisation. **References:** None

OP-161

Automatic Exposure Control techniques in low dose CT - what benefit in PET/CT studies?

R. Ferreira, V. Sousa, M. R. Victor, S. Carmona, G. Cardoso, A. I. Santos; Hospital Garcia de Orta, Almada, PORTUGAL.

Aim/Introduction: Automatic exposure control (AEC) systems allow a reduction of patients' radiation dose during a CT acquisition, while maintaining image quality on diagnostic CT. But what can we expect from these techniques applied to low-dose CT for attenuation correction and anatomical reference, as performed on PET/CT? Our aim was to evaluate radiation dose and image quality associated with a low-dose CT (performed as part of a PET/CT study) using a combined tube current modulation technique (CARE Dose 4D) versus constant tube current values (CTCV). **Materials and Methods:** A retrospective sample of 978 PET/CT studies was collected and 7 studies were excluded because the maximum reference value of the tube current would be

exceeded if the AEC system was used. CARE Dose 4D was applied in 971 studies, performed to 601 (61,9%) males and 370 (38,1%) females; median age=67[P25:56.0;P75:74.0] years old and median weight=70[P25:60.8;P75:80.0]kg. The low-dose CT protocol acquisition parameters used were 110 kV and for mAs reference: 80 or 100 for obese patients. A whole-body CT protocol (comprising the head and torso) was applied in 712(73.3%) studies, with complementary body regions protocols in 259(26.7%). Dose Length Product (DLP) values were automatically generated by the scanner (DLP-AEC) and compared with those theoretically expected using CTCV (DLP-CTCV). Statistical analysis was performed with IBM SPSS Statistics. **Results:** The median DLP-AEC, equal to 353[P25:220.7;P75:442.3]mGy.cm, was statically significantly lower than the DLP-CTVC, equal to 563[P25:280.6;P75:634.3]mGy.cm [Related-Samples Wilcoxon Test;p<0.001], corresponding to a median dose reduction of 30[P25:16.8;P75:41.1]%. Adequate image quality was found in all 978 studies. The difference between DLP-AEC and DLP-CTCV was also statistically significant for different weight groups [Related-Samples Wilcoxon Test;p<0.001], with a median reduction of DLP using CARE Dose 4D equal to: 226[P25:111.7;P75:273.8]mGy.cm for patients weighing below 70 kg; 152[P25:60.8;P75:195.2]mGy.cm for patients weighing between 70 and 80 kg; and 47[P25:-1.9;P75:111.1] mGy.cm for patients weighing more than 80 kg. Regarding both acquisition protocols, there was also a statistically highly significant difference between DLP-AEC and DLP-CTCV [Related-Samples Wilcoxon Test;p<0.001], with a median reduction of DLP using CARE Dose 4D equal to 195[P25:130.4;P75:258.0]mGy.cm for whole-body acquisition; and 30[P25:7.8;P75:50.7]mGy.cm for complementary body-regions protocols. **Conclusion:** We found that combined tube current modulation techniques are effective in lowering the radiation dose in low-dose CT, as described in literature for diagnostic CT, performing better in slimmer patients and whole-body acquisitions. **References:** None

Simple daily algorithm to reduce biological detriment by PET/CT on the basis of the patient age

P. Sannino¹, M. Sicignano¹, L. Evangelista², E. Di Giorgio¹, S. Fiordoro¹, S. Imbimbo¹, V. Rizzo³, C. Del Vasto¹, C. Lanotte¹, D. Palma¹, G. Pecchia¹, C. Mainolfi⁴, M. Spadafora¹;

¹Nuclear Medicine Unit Ospedale del Mare, Naples, ITALY,

²Nuclear Medicine Unit, Department of Medicine (DIMED),

University of Padua, Padua, ITALY, ³Nuclear Medicine Unit Moscatti

Hospital, Avellino, ITALY, ⁴Department of Advanced Biomedical

Sciences, University of Naples Federico II, Naples, ITALY.

Aim/Introduction: In adults, the current international guidelines recommend in administering 18F-fluorodeoxyglucose (FDG) activity on the basis of patient's weight and technical performance of PET scanner. However, age at exposure time

and sex are key factors in increasing radiation risk detriment by a factor of 2 or more. Particularly, the rise in life expectancy also increases the cumulative risk of repeated exposures. ICRP Annals of 2020 suggests a sex- and age-nominal risk, avoiding average values, for a new radiation detriment calculation. Aim of the study was to develop a simple daily algorithm based on age to reduce the biological PET detriment in the execution of PET/CT. **Materials and Methods:** Twenty study sessions of whole-body PET/CT, including a total of 221 patients (56% male gender, mean age 64±15 years) were retrospectively analysed to estimate, for each age and sex category, scan-time and FDG dose, radiation exposure in effective dose (ED), and additional cancer risk (ACR) of PET. In the study population, these parameters were assessed in reference condition (REF) and after applying an algorithm (ALGO) that, on the base of time-dose equation, inversely modified the FDG dose and PET scan-time. To keep constant the overall scheduled times and FDG quantity, the ALGO changed in each study session, by ±20% time/dose relationship, in the opposite way between younger and older patients **Results:** In REF, mean scan-time of PET was 1155.5±160.3 sec, with a mean dose of 281.3±57.3 MBq. In the same group, the ED and ACR were 4.499±0.91 mSv and 0.0199±0.02%, respectively, whereas in ALGO they dropped to 4.488±1.1 mSv and to 0.0188±0.02% (both p<0.001). In REF, ACR was 0.0168±0.01% for males and 0.024±0.02%, for females, whereas in ALGO it dropped to 0.0162±0.01% (p<0.05) for males and to 0.0222±0.02% for females (p<0.001). ACR change was significant in each of the following age category: 17-45 years (p<0.001); 46-65 years (p<0.01); 65-89 years (p<0.001). **Conclusion:** The proposed protocol, acting by tailor changing the dose in relation to age, significantly affects ED and ACR of FDG-PET/CT. This protocol can be applied in a simple way in each daily study session, without any negative drawbacks in global time and tracer dose, in line with the most recent ICRP indications. **References:** None

OP-163

Low dose computed tomography protocol optimization and its influence in radiation dose to the patient

V. de Sousa, G. Cardoso, B. Bento, S. Carmona, A. I. Santos; Hospital Garcia de Orta, E.P.E., Almada, PORTUGAL.

Aim/Introduction: The increasing use of PET/CT systems and the recent installation of one in the department lead to a need of protocol optimization in order to achieve the best compromise between dose and image quality, also considering that the CT acquisition is only used for attenuation correction and anatomic referral, not for radiological diagnosis, and is routinely acquired using an automatic exposure control system, which modulates the tube current. Therefore, the aim of this study was to optimize the CT protocol for whole-body [18F]FDG in order to reduce the dose-length product (DLP) to the patient. **Materials**

and Methods: The department started using the protocol proposed by the manufacturer, with low dose CT scans acquired using 110 kV and 125 mAs of reference (group 1 - 16 male and 19 female). After a period of customization, reference mAs was first reduced to 100 (group 2 - 10 male and 6 female), and subsequently to 80 (group 3 - 153 male and 175 female). After each reduction, quality image was evaluated by clinicians. All scout scans were acquired with 110 kV and 25 mA and pitch was maintained constant through the study ($p=0.8$). DLP values were obtained from reports generated by the scanner. **Results:** The median value for DLP_{total} was initially 551.56 [P25:502.58; P75:647.64] mGy.cm. After the first step of optimization it decreased to 468.42 [P25:388.86; P75:551.13] mGy.cm. Finally, in group 3, a median DLP_{total} of 395.95 [P25:326.88; P75:469.18] mGy.cm was achieved. DLP_{total} is a sum of the DLP resulting from the scout acquisition and the DLP from the CT scan. In all groups, clinicians considered image quality acceptable for study reading. By applying Kruskal-Wallis test, no statistically significant differences were observed between patients' characteristics among the 3 groups, regarding both weight ($p = 0.399$) and height ($p = 0.676$). It was observed a strong positive correlation between mA_{max} and DLP_{total} ($p=0.750$) and a very strong positive correlation between mA_{med} and the DLP_{total} ($p=0.962$). **Conclusion:** Each step of the reduction in tube current led to a decrease in 15% of the DLP_{total} , allowing a total decrease of 28% from the first protocol to the actual protocol in use. Thus, there was clearly an optimization of the acquisition protocol, with dose reduction, keeping image quality acceptable for the diagnostic purposes of the studies. **References:** None

OP-164

Radiation Dose Optimization of a Dual Tracer PET/CT Protocol for Multiple Myeloma: a Whole Body Ultra-Low Dose CT

E. Prieto, J. M. Martí-Climent, J. D. Aquerreta, V. Morán, L. Irazola, J. F. Bastidas, I. Soriano, J. J. Rosales, P. Rodríguez-Otero, M. J. García-Velloso;

Clinica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: To design an optimized dual-tracer PET/CT protocol for multiple myeloma and to retrospectively review the radiation dose received by patients who underwent this procedure. **Materials and Methods:** In a research project carried out in our PET department, a dual-tracer PET/CT scan covering head to feet and a whole-body low dose CT (WBLDCT) were prescribed for patients with multiple myeloma. For the scope of optimization, PET/CT and WBLDCT were merged in a one-stop-shop. Thus, FDG PET/CT included a diagnostic CT (WBLDCT: 120 kV-80 mAs) while MET PET/CT included a CT dedicated only for attenuation correction, referred as whole body ultra-low dose CT (WBULDCT: 100 kV-40 mAs). Both PET/CT scans covered the whole

patient from head to feet, in supine position with the arms beside the body. Thirty-one patients with proven multiple myeloma who underwent this protocol were retrospectively reviewed. Demographic data and dose parameters (dose-length product, DLP) were recorded. Effective doses were calculated with CT-Expo for the CT component and with dose coefficients for the PET contribution (0.019 mSv/MBq for FDG and 0.0084 mSv/MBq for MET). **Results:** We analyzed 31 patients, 23 males and 8 females, aged 59 ± 10 years, with BMI 27.0 ± 3.8 kg/m². DLP expressed as median (interquartile range, IQR) was 790 (IQR: 282) mGy.cm for WBLDCT and 262 (IQR: 123) mGy.cm for WBULDCT ($p<0.0001$). Patients received a median effective dose of 6.4 (IQR: 2.0) mSv from the WBLDCT and 2.1 (IQR: 0.8) mSv from the WBULDCT ($p<0.0001$). Patients were administered 327 ± 75 MBq of FDG and 469 ± 50 MBq of MET. The resultant effective doses (mean \pm standard deviation) were 6.2 ± 1.4 mSv and 3.9 ± 0.4 mSv, respectively. Total effective dose for each PET/CT was 12.7 ± 3.0 mSv for FDG and 6.1 ± 0.8 mSv for MET. **Conclusion:** In this protocol for multiple myeloma evaluation, radiation dose optimization achieved due to both, the merge of nuclear medicine and radiological examinations, and to the inclusion of a WBULDCT (with a 66.7% dose reduction respect to the WBLDCT), entailed a great benefit for the patients. An effort in reviewing each PET/CT indication could lead to the customization and optimization of protocols and to the subsequent dose reduction. **References:** None

OP-165

Optimising CT scan range and dose levels for diagnosis of bone metastases for ¹⁸F-NaF PET-CT

P. Holdgaard¹, N. A. Bebbington²;

¹Lillebælt Hospital, Vejle, DENMARK, ²Siemens Healthcare A/S, Aarhus, DENMARK.

Aim/Introduction: Breast cancer patients are staged with radionuclide bone scintigraphy. Cross-sectional hybrid methods provide greater sensitivity and specificity than planar gamma-camera imaging, yet a disadvantage of ¹⁸F-NaF is the additional radiation burden from the wholebody CT. Very-low-dose CT allows attenuation correction (AC) of PET data and low-dose CT allows localisation/characterisation of tracer uptake. AC of PET data is generally considered essential for diagnostic PET image quality and quantification. However, NaF demonstrates an exceptionally high abnormal-to-normal bone uptake ratio, thus providing good image quality even in the absence of AC. The aim was to investigate whether CT scan range could be optimised on an individual patient basis from the appearance of PET images, in breast cancer patients prior to neoadjuvant chemotherapy. **Materials and Methods:** An expert observer classified bone abnormalities in 25 NaF patients as malignant, equivocal or benign, for both non-AC and AC PET data in the absence of CT, to evaluate the need for AC of PET images. To evaluate

the need for localisation/characterisation CT, the required localisation/characterisation CT scan length was noted for each patient from the appearance of the non-AC PET. It was then determined from the reference standard AC PET with wholebody characterisation CT, whether any lesions were missed that required localisation/characterisation CT for diagnosis. **Results:** Non-AC versus AC PET only: Metastases were suspected (including equivocal lesions) in 52% of patients with non-AC images, compared with 64% with AC images. A total of 50 suspicious and 50 benign lesions were identified with non-AC images, compared with 87 suspicious and 61 benign with AC. Requirement for localisation/characterisation CT: 36% of patients were identified as requiring CT for localisation, 36% for characterisation and CT (beyond AC purposes) was not required in 28%. Mean required localisation/characterisation CT scan range was 33±28cm (range 0-105cm), compared with the conventional mean 140cm wholebody characterisation CT. **Conclusion:** These findings demonstrate that CTAC of PET data is essential for the full PET scan range for evaluating bone metastases in ¹⁸F-NaF examinations, despite the exceptionally high abnormal-to-normal tracer uptake ratio. However, performing very-low-dose wholebody CT for AC plus individualised localisation/characterisation CT confined to the clinical area of interest on the PET images, may allow radiation dose reduction without compromising diagnosis of bone metastases, in breast cancer patients prior to neoadjuvant chemotherapy. Future work should quantify dose savings via the proposed method and evaluate its feasibility in the clinical environment. **References:** None

OP-166

¹³¹Iodine Concentration in mother's milk after treatment of a papillary thyroid cancer with 3700 MBq of Na¹³¹I under rhTSH

G. Le Rouzic, H. Besse, M. Bailly;

Centre Hospitalier Régional d'Orléans, Orléans, FRANCE.

Aim/Introduction: Breastfeeding and Na¹³¹I thyroid cancer treatment under thyroid hormone withdrawal as thyrotropin-stimulation are considered incompatible[1-3]. No study described the breast milk ¹³¹Iodine concentration under recombinant human thyrotropin (rhTSH) as thyrotropin-stimulation. Our nuclear medicine department had to treat a lactating woman with 3700 MBq of Na¹³¹I whose thyrotropin-stimulation was rhTSH. **Materials and Methods:** We collected mother's milk all along the hospitalization of our patient and measured ¹³¹Iodine concentration to evaluate rhTSH influence. In order to guaranty the child radioprotection (effective dose < 1 mSv or thyroid equivalent dose < 10 mSv), we calculated concentration and time from which breastfeeding could be continued [4-7]. Assuming that ¹³¹Iodine concentration in the milk was the same than in breasts, we also evaluated the dose delivered to mother's

breasts [1,8,9]. **Results:** Breastfeeding after the administration of 3700 MBq of Na¹³¹I could be discontinued at least 10 days after capsule ingestion according to the most optimistic hypothesis. Breasts dose for a lactating woman was evaluated at 1.08 Gy, inducing a 0.51% risk of breast cancer at some time following the treatment [4]. **Conclusion:** Even with the use of rhTSH stimulation in Na¹³¹I thyroid cancer treatment, time to wait for resuming breastfeeding seems to be redhibitory and breast dose must still be taken into account into the benefit-risk balance. **References:** 1. OP-167

Preventive measures and management of radiopharmaceutical extravasation with [¹⁷⁷Lu]Lu-DOTA-TATE

N. Eftychiou¹, R. Fernandez¹, S. Allen¹, V. Lewington^{1,2};

¹Guy's and St Thomas Foundation Trust, London, UNITED

KINGDOM, ²King's College London, London, UNITED KINGDOM.

Aim/Introduction: Literature data regarding radiopharmaceutical extravasation is sparse - particularly for therapeutic administrations. We describe the management of an extravasation incident which occurred during [¹⁷⁷Lu]Lu-DOTA-TATE administration. A 38 year old NET patient attended for his second treatment cycle. Following amino-acid infusion, 7360MBq [¹⁷⁷Lu]Lu-DOTA-TATE was administered slowly using a syringe driver via the antecubital fossa vein. Prior administration the cannula was checked. Administration proceeded uneventfully without patient complaint. Shortly after completion the patient reported discomfort around the elbow. Upon examination there was soft tissue swelling of the distal forearm. **Materials and Methods:** Extravasation was confirmed by rapid imaging on gamma-camera. Measures were applied immediately: a heat pad, elevation of the arm and massage of the area. Subsequent 4-hour and 24-

hour whole-body imaging was performed and confirmed systematic radiopharmaceutical uptake with no significant residual uptake at the injection site. Quantification was also performed using a sensitivity phantom and ROI analysis of planar images. Oral steroids and hydrocortisone cream were prescribed to prevent inflammation and skin irritation. **Results:** 1-hour post-extravasation analysis demonstrated approximately 5.3GBq [^{177}Lu]Lu-DOTA-TATE at the injection site, which reduced to 2.8GBq at 4-hours, following preventive measures. Redistribution of extravasated activity modelled using a dual compartment model and bi-exponential clearance. Extrapolation to 0-hours estimates 6.6GBq was initially extravasated. This corresponds to a maximum tissue dose of 17Gy at injection site and 11Gy to forearm/elbow following intervention and subsequent redistribution. Short-term side effects were minimal skin irritation. No long-term (follow-up >1 year) effects were noted. **Conclusion:** Rapid response and straightforward conservative procedures are proposed to minimise the effects of radiopharmaceutical extravasation and recover the intended therapeutic aim. **References:** None

OP-168

Comparative Dosimetry for ^{68}Ga -PSMA with Updated Reference Data and Impact for Patient Specific Dose Calculations

P. Gape, D. Rushforth, C. Abreu, I. Murray, J. Gear, G. Flux;
The Royal Marsden Hospital NHS Foundation
Trust, London, UNITED KINGDOM.

Aim/Introduction: Most dosimetry reports for ^{68}Ga -PSMA were calculated using RADAR phantoms and dose factors, and ICRP 60 organ weighting factors. The aim of this study was to investigate the impact of calculating organ absorbed doses and effective doses using the more anatomically realistic ICRP 110 phantoms and updated ICRP 103 weighting factors. Differences between patient anatomy and anatomical phantoms contribute to the uncertainty in patient specific absorbed dose calculations. The relative importance of this contribution is indicated by the difference in calculated absorbed doses to RADAR and ICRP phantoms. This is compared to the uncertainty in calculating the time integrated activity coefficient (TIAC) to investigate the dominant contribution to absorbed dose uncertainty. **Materials and Methods:** Dosimetry was performed for three patients participating in the Simplification of Low Level Internal Dosimetry (SOLLID) trial from an early three-phase dynamic scan, the clinical scan ($t = 1$ hour), and two additional scans ($t = 2, 4$ hours). Organs were delineated on CT and time-activity curves produced. A multi-phase exponential was fit to the data to calculate TIAC. TIACs for normal organs for a further 27 patients were collated from the literature. OLINDA and IDAC were used to perform absorbed dose calculations based on the RADAR and ICRP 110 phantoms for the combined dataset

($n = 30$). Effective doses were calculated using both ICRP 60 and 103 weighting factors. The uncertainty in the TIAC for the patients in the SOLLID trial were calculated in accordance with EANM guidelines. **Results:** ICRP 110 based dosimetry with ICRP 103 weighting factors resulted in a lower effective dose for 28/30 patients (0.0156 mSv/MBq) compared with RADAR and ICRP 60 weighting factors (0.0213 mSv/MBq). The average disagreement between the two methods for each patient was 45.9% (standard deviation = 32.0%). The kidneys received the highest absorbed dose, and this was found to be lower based on the updated reference data (0.175 mGy/MBq vs. 0.257 mGy/MBq). The average uncertainty in the organ TIAC for the imaged patients was 5.44% (0.017% - 20.42%). **Conclusion:** Absorbed and effective dose estimates for ^{68}Ga -PSMA PET studies are likely to be significantly overestimated if not based on the most recent phantoms and weighting factors. For patient specific dosimetry, the contributions to the uncertainty in the absorbed dose from the TIAC and the dose factor are likely to be of similar magnitude. Both should be considered to improve the accuracy of absorbed dose calculations. **References:** None

OP-169

Solid-Phase Extraction of ^{225}Ac for Internal Dosimetry and Incorporation Measurements

R. Cusnir^{1,2}, P. Froidevaux¹, L. Pfefferlé¹, M. Straub^{1,2};
¹Institute of Radiation Physics, Lausanne University Hospital and
University of Lausanne, Lausanne, SWITZERLAND, ²European
Organization for Nuclear Research (CERN), Geneva, SWITZERLAND.

Aim/Introduction: Emergence of ^{225}Ac (actinium-225, $t_{1/2}$ 10 days) as a promising alpha-emitting radionuclide for therapeutic applications demands adequate surveillance measures for occupational exposure of the personnel handling ^{225}Ac . Committed effective dose E_{50} of 1 mSv is attained by inhaling 154 Bq or by ingesting 42 kBq of ^{225}Ac . According to ICRP biokinetic model, a major fraction of ^{225}Ac is found in alimentary tract ($\geq 50\%$), while urinary excretion is in the order of 10^{-3} [1]. Urine is a convenient biological sample, however chemical separation of ^{225}Ac is indispensable to determine its concentration for a subsequent dose reconstruction in case of an accidental intake. We propose a method for radiochemical separation of ^{225}Ac in urine using a polymer resin imprinted with Y^{3+} ion [2]. ^{243}Am (americium-243, $t_{1/2}$ 7360 years) enables metrological traceability and quantification of ^{225}Ac with alpha spectrometry. **Materials and Methods:** To test the method, 500 mL urine sample was spiked with 50 mBq of ^{229}Th (providing ^{225}Ac in equilibrium) and 25 mBq of ^{243}Am tracers. Following acid digestion, actinides were pre-concentrated by co-precipitation with calcium phosphates. Solid phase extraction of $[\text{}^{225}\text{Ac}]\text{Ac}^{3+}$ and $[\text{}^{243}\text{Am}]\text{Am}^{3+}$ in diluted HCl at pH 3 was achieved on a 5 mL column containing 2 g of Y^{3+} -imprinted polymer resin. ^{225}Ac and ^{243}Am were released

from column with 1 M HCl, and electrodeposited on stainless steel discs for alpha spectrometry counting. **Results:** Alpha spectrometry counting of ^{225}Ac and ^{243}Am resulted in distinct peaks, enabling quantification of ^{225}Ac with reference to ^{243}Am internal tracer. Recovery yields of ^{225}Ac and ^{243}Am extracted from urine were equivalent, showing that ^{243}Am is a suitable metrological tracer for quantitative determination of ^{225}Ac . Overall recovery yield of ^{225}Ac and ^{243}Am from urine was 60 %. **Conclusion:** Solid-phase extraction on a Y^{3+} -imprinted polymer is suitable for chemical separation and quantitative determination of ^{225}Ac , while ^{243}Am as internal tracer confers metrological traceability. This method is amenable for determination of ^{225}Ac in other biological samples, such as biopsied tissues. Combined with a different detection technique, e.g. liquid scintillation counting or mass spectrometry, it can prove useful for analysis of other isotopes of actinium, such as ^{227}Ac . **References:** [1] ICRP, 2017. First-in-human dose escalation of AlphaMedix for targeted alpha-emitter therapy of neuroendocrine tumors

I. Tworowska¹, E. S. Delpassand¹, R. Esfandiari², J. Torgue³, J. D. Hurt³, R. Nunez²;

¹RadioMedix Inc., Houston, TX, UNITED STATES OF AMERICA, ²Excel Diagnostics and Nuclear Oncology Center, Houston, TX, UNITED STATES OF AMERICA, ³Orano Med LLC, Plano, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Peptide Receptor Radioligand Therapy (PRRT) is an effective treatment for patients with metastatic somatostatin-receptor (SSTR)-positive neuroendocrine tumors (NETs), however, interest in developing alpha-emitter-based therapies remains high. We present the initial results of the first-in-human (FIH) study of AlphaMedix™ (^{212}Pb -DOTAMTATE), a novel somatostatin-analog for Targeted Alpha-emitter-Therapy (TAT), in patients with SSTR-expressing-NETs (FDA IND 135150). The objective of this study is the determination of safety and pharmacokinetics, dosimetry and preliminary effectiveness of ascending doses of AlphaMedix™. **Materials and Methods:** 16 adult subjects, 7 men and 9 women, median-age 68 (range 27-75), with biopsy-proven unresectable or metastatic SSTR (+)-NETs from different primary sites (small bowel, pancreas, and lung) with at least one measurable lesion were enrolled in safety and dose escalation studies. Subjects with a history of prior PRRT were excluded. Patients enrolled in the first two cohorts received a Single, weight-based, Ascending-Doses (SAD) of AlphaMedix™. Once a partial response was observed, the third cohort received the Multiple-Ascending-Doses (MAD-cohort) consisting of 3-cycles of AlphaMedix™ administered every 8-weeks. All patients received amino acid for renal protection. Response to treatment was measured per RECIST 1.1 and the effect on the quality of life measured with the EORTC-QLQ-C30 -QOL. Patients enrolled in SAD1 and SAD2 received 30.7 and 40.0 $\mu\text{Ci}/\text{kg}$, respectively. MAD3 cohort received 3-cycles of treatment (52.0 $\mu\text{Ci}/\text{kg}$ per cycle). MAD4 cohort completed 4-cycles of therapy (67.6 $\mu\text{Ci}/\text{kg}$ per cycle) with a cumulative dose ranging from 19.2-22 mCi. This cohort was expanded and 3 new subjects received 3-cycles of treatment. **Results:** All 3 subjects in MAD 4-dosed with 4-cycles of treatment showed partial response with 73%, 71%, and 33% decrease in the size of the index-lesions, respectively. NETSPOT revealed almost a complete response in 2 subjects and a partial response in the third. There was no clinically significant investigational drug-related hematological and renal toxicity. The most common adverse events noted were alopecia 7/16 (43%), diarrhea 3/16 (19%), nausea 6/16 (38%), fatigue 7/16 (43%), hyperglycemia 8/16 (50%), lymphopenia 6/16 (38%), and decrease of WBC count 4/16 (21%). QOL parameters suggest significant improvement in pain, energy, and shortness of breath in the majority of subjects. **Conclusion:** This FIH-study

of AlphaMedix™ illustrates that PRRT with ^{212}Pb is feasible, well-tolerated, and provides an Objective Radiological response (ORR) in 100% of cases with substantial reduction in tumor burden in patients with unresectable, metastatic SSTR-expressing-NETs. The treatment was well tolerated with only mild adverse events. **References:** None

OP-175

Efficacy of ^{225}Ac -DOTATATE Targeted Alpha Therapy in Metastatic Gastroenteropancreatic Neuroendocrine Tumors Stable or Refractory to ^{177}Lu -DOTATATE PRRT

S. Ballal, M. Yadav, C. Bal;

All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: The objective of this study was to investigate and present the results on the efficacy, safety, and quality of life of ^{225}Ac -DOTATATE targeted alpha therapy (TAT) in patients with advanced, progressive, ^{177}Lu -DOTATATE refractory, and somatostatin receptor (SSTR) expressing metastatic GEP-NETs. **Materials and Methods:** In this prospective study, we recruited patients with metastatic GEP-NETs who demonstrated stable or progressive disease on ^{177}Lu -DOTATATE therapy. Patients underwent a screening ^{68}Ga -DOTANOC PET/CT scan to assure high SSTR expression and progressive disease to prior therapies. Systemic TAT was performed in all the patients with ^{225}Ac -DOTATATE (100 KBq/Kg body weight) at an interval of 8 weeks up to 7 cycles. The median follow-up duration was 13 months (range: 6 - 20 months). The primary end-point was to assess the objective response (measured by RECIST 1.1 and functional M. D. Anderson criteria). The secondary end-points included biochemical response assessment as per the Italian Trials in Medical Oncology (ITMO), adverse-event profile as per CTCAE v5.0, and clinical response assessment by the quality of life (assessed with EORTC QLQ-GI.NET21 patient-based questionnaire). **Results:** 65 patients (34 females, 31 males, mean age 57 ± 7 years, 35 - 72 years) with either stable disease after completing ^{177}Lu -DOTATATE therapy (44%) or progressive disease on ^{177}Lu -DOTATATE therapy (56%) were included in the study. The morphological response was assessed in 53 patients and revealed complete remission in 1, partial remission in 41, stable disease in 9 and disease progression in 2 patients. Death was recorded in 1 patient. There was a significant decrease in the plasma chromogranin level post- ^{225}Ac -DOTATATE therapy ($P < 0.0001$). None of the patients experienced grade 3 or 4 hematotoxicity, renal insufficiencies or hepatotoxicity. The most common adverse effects (AEs) were nausea, vomiting, gastritis, and appetite loss, but were limited to grade 1 or 2. Majority of the patients experienced these AEs at the time of amino acid infusion which was administered during ^{225}Ac -DOTATATE therapy and was resolved after few hours of amino acid infusion. All the other AEs such as fatigue or asthenia, diarrhoea, appetite loss, abdominal pain, abdominal distension, weight loss, peripheral edema, headache, dizziness, and flushing were

also identified which were limited to grade 1 or 2, except for 1 patient with grade 3 abdominal distension and fatigue.

Conclusion: Our results indicate ^{225}Ac -DOTATATE TAT safe with low and transient side-effects. It add to a new dimension in the treatment of end-stage GEP-NET who have exhausted all the standard treatment options. **References:** None

OP-176

Tolerability and Efficacy of Peptide Receptor Radionuclide Therapy in Elderly Neuroendocrine Tumour Patients: Results of a Case-Control Single Centre Study

D. Theiler¹, M. Cattaneo², L. O. Dierickx³, P. Igaz⁴, S. Grozinsky-Glasberg⁵, C. Bournaud⁶, T. O'Dorisio⁷, D. Wild^{1,8}, E. Christ^{9,8}, G. P. Nicolas^{1,8};

¹Division of Nuclear Medicine, University Hospital of Basel, Basel, SWITZERLAND, ²Department of Clinical Research, University of Basel, Basel, SWITZERLAND, ³Department of Nuclear Medicine, ENETS CoE, Institut Universitaire du Cancer Toulouse - Oncopole, Toulouse, FRANCE, ⁴Second Department of Internal Medicine, Semmelweis University, Budapest, HUNGARY, ⁵Neuroendocrine Tumor Unit, ENETS Center of Excellence, Department of Endocrinology, Hadassah-Hebrew University Medical Center, Jerusalem, ISRAEL, ⁶Department of Nuclear Medicine, Hospices Civils de Lyon, Lyon, FRANCE, ⁷University of Iowa, Iowa City, IA, UNITED STATES OF AMERICA, ⁸Endocrine and Neuroendocrine Tumour Centre, ENETS CoE, University Hospital of Basel, Basel, SWITZERLAND, ⁹Department of Endocrinology, University Hospital of Basel, Basel, SWITZERLAND.

Aim/Introduction: Peptide-Receptor Radionuclide Therapy (PRRT) is an effective and well-tolerated treatment for inoperable/metastatic, somatostatin receptor expressing neuroendocrine tumours (NET). Although, caution is recommended for patients ≥ 70 y due to potential toxicity, tolerability and efficacy of PRRT in elderly patients have not been systematically investigated, e.g. Netter-1 study: 63 ± 9 (years, mean \pm SD). The aim was to investigate safety and efficacy of PRRT in elderly patients (EP). **Materials and Methods:** All consecutive patients with inoperable/metastatic/progressive, G1/G2 NET, aged ≥ 79 y, treated with PRRT at the University Hospital Basel between 2006 and 2018, were enrolled in this case-control study. Each patient was manually matched with ≥ 1 younger patient (YP) aged between 60 and 70y (same gender, primary tumour location, grading, functional activity and estimated tumour load). The primary endpoint was safety and tolerability. Cell-blood count and eGFR were measured at baseline, 2-weekly after each PRRT cycle and 1, 2 and 3y after completion of PRRT. Subacute and long term toxicity were scored according to the common terminology criteria for adverse events (CTCAE) v5.0. All toxicity scores ≥ 3 , or whose delta to baseline was ≥ 2 (≥ 1 for eGFR), were considered significant. Differences in odds ratio for the occurrence of toxicity between cohorts was tested for non-inferiority. Overall survival (OS), with

or without correction for differences in the residual life expectancy, and clinical response to PRRT were assessed as secondary outcome measures. Kaplan-Meier curves and mortality hazard ratio were compared using a non-inferiority test and a Cox-regression stratified model. **Results:** Forty-eight elderly patients (EP) and 68 younger patients (YP) were enrolled, aged 81.7 ± 1.5 vs 67.6 ± 1.7 (years, mean \pm SD), respectively. EP and YP were balanced with regards to median time-since-diagnosis, tumour location, grading, treatment scheme (Lutetium-177-DOTATOC (14.8 [9.3-25.1] vs 14.8 [7.4-22.1] and Yttrium-90-DOTATOC (0 [0-6.5] vs 5.6 [0-7.4] (GBq, median[IQR] for EP vs YP, respectively) and baseline biochemical parameters, except eGFR: 61 ± 16 vs 78 ± 19 (ml/min/1.73m²) for EP vs YP. Grade ≥ 3 or $\Delta \geq 2$ subacute haematotoxicity occurred in 10 EP (21%) vs 19 in the YP (28%, $p = \text{NS}$). Long-term grade ≥ 3 renal toxicity was 20% vs 5%, for EP vs YP (Odds-ratio 5.25 [1.02, 27.14], $p = \text{NS}$). The median OS was 3.4. vs 6.0 (years, EP vs YP) (Hazard-ratio (HR): 1.50 [0.75, 2.98], $p = 0.094$; HR after adjusting for life-expectancy residual: 0.41 [0.17, 0.96], $p = 0.014$ (relative non-inferiority margin: 1.2). **Conclusion:** In selected EP, PRRT is a valid therapeutic option with similar toxicity and non-inferior survival compared to the YP. **References:** None

Aim/Introduction: SCAN assessed awareness, availability, quality and affordability of NET diagnostics and treatments. This analysis explored nuclear medicine (NM) tools' usage and affordability. **Materials and Methods:** During Sept-Nov-19, NET patients/carers and healthcare professionals (HCP) involved in NET management completed an online

survey (14 languages). **Results:** There were 2795 respondents from 68 countries across 6 continents (2359 patients/carers [Europe 1102; North America (NA) 727; Asia 280]; 436 HCPs [37 NM specialists; NMS). NM tools commonly led to NET diagnosis, particularly in Europe (All: Europe 58% [641/1102] vs. NA 43% [309/727] vs. Asia 42% [118/280], $p < 0.0001$ [Chi-squared]; FDG-PET: 13% [143/1102] vs. 9% [65/727] vs. 16% [46/280]; ⁶⁸Ga-DOTA-PET/CT: 19% [213/1102] vs. 11% [78/727] vs. 17% [48/280]; octreotide scan: 20% [221/1102] vs. 20% [145/727] vs. 8% [22/280]). NM treatment use appeared more infrequent (All: Europe 12% [136/1102] vs. NA 12% [85/727] vs. 7% Asia [19/280], $p = 0.0311$; mIBG: 0.3% [3/1102] vs. 0% [0/727] vs. 0% [0/280]; PRRT: 12% [128/1102] vs. 11% [82/727] vs. 7% [19/280]; SIRT: 0.5% [5/1102] vs. 0.4% [3/727] vs. 0% [0/280]). Ongoing monitoring with NM tools was prevalent globally (Total: Europe 43% [475/1102] vs. NA 42% [305/727] vs. Asia 38% [107/280]; ⁶⁸Ga-DOTA-PET/CT: 27% [299/1102] vs. 32% [230/727] vs. 23% [65/280]; FDG-PET: 16% [176/1102] vs. 10% [75/727] vs. 15% [42/280]). NMS reported greater availability of NM diagnostics (86% [159/185] vs. 60% [1317/2180], $p < 0.0001$) and treatment (PRRT: 92% [34/37] vs. 64% [277/436], $p = 0.0005$) than other HCPs. NMS believed NM diagnostics (34% [62/185] vs. 26% [560/2180], $p = 0.0203$) and treatments (PRRT: 46% [17/37] vs. 28% [123/436], $p = 0.0203$), were more affordable than other HCPs. For patients receiving PRRT, household income used for NET treatment was lower in Europe and NA than Asia (0-20%: 55% [70/128] vs. 52% [43/82] vs. 16% [3/19], respectively; ≥ 21 %; 13% [16/128] vs. 10% [3/82] vs. 68% [13/19]; no costs: 22% [28/128] vs. 21% [17/82] vs. 0% [0/19]; unknown: 11% [12/128] vs. 17% [12/82] vs. 16% [3/19]). Out-of-pocket costs over 12 months were lowest in Europe for ⁶⁸Ga-DOTA-PET/CT (median \$112 vs. NA \$500 vs. Asia \$1120) and PRRT (\$288 vs. \$406 vs. \$5600). Pricing was cheaper in Europe for ⁶⁸Ga-DOTA-PET/CT (\$105 vs. NA \$500 vs. Asia \$840) and PRRT (\$225 vs. \$202 vs. \$2800). **Conclusion:** NM tool usage is highest in Europe and NA, potentially due to affordability issues in developing countries. NMS state greater availability and affordability than other HCPs. Improving NM tools' accessibility and use can enhance NETs care worldwide. **References:** None

Compostela, SPAIN, ⁵Hospital Universitario HM Sanchinarro, Madrid, SPAIN, ⁶Clínica Universidad de Navarra, Pamplona, SPAIN, ⁷Hospital Universitario Gregorio Marañón, Madrid, SPAIN, ⁸Hospital Universitario Central de Asturias, Oviedo, SPAIN, ⁹Hospital Universitario Ramón y Cajal, Madrid, SPAIN, ¹⁰Hospital Universitario Virgen de la Arrixaca, Murcia, SPAIN, ¹¹Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, ¹²Hospital Universitario Doce de Octubre, Madrid, SPAIN, ¹³ICO-Bellvitge, Barcelona, SPAIN, ¹⁴Hospital Universitario Virgen de las Nieves, Granada, SPAIN, ¹⁵Hospital Universitario Getafe, Madrid, SPAIN, ¹⁶Hospital Universitario Son Espases, Palma de Mallorca, SPAIN, ¹⁷Hospital Universitario Burgos, Burgos, SPAIN, ¹⁸Hospital Universitario Dr Peset, Valencia, SPAIN, ¹⁹Hospital Universitario Salamanca, Salamanca, SPAIN, ²⁰Hospital Universitario Príncipe de Asturias, Madrid, SPAIN.

Aim/Introduction: The aim was to describe the characteristics of patients with advanced somatostatin receptor-positive neuroendocrine tumours (TNE) treated with ¹⁷⁷Lu-DOTATATE (PRRT) and to evaluate the efficacy and safety of the treatment. **Materials and Methods:** The data comes from the national and multicentre study SEPTRALU in which a multidisciplinary team of 18 centers participate. Survival was evaluated using the Kaplan-Meier method and Cox proportional risk regression. Toxicity was recorded according to CTCAEv3.0 criteria. **Results:** 200 patients were recruited. 51% were women. The median age was 57 years (range, 18-89) and the ECOG performance status was 1-2 in 92%. 57% were functional and Ki-67 was <20% in 93%. The most frequent primary site was gastrointestinal (44%), and pancreatic (37%). Metastases were mainly located in: liver (86%), lymph nodes (42%) and bone (26%). Prior to PRRT, patients had received a median of 3 lines (range, 1-7). Four cycles of PRRT were administered to 66% of patients (96% with 7.4 GBq). Partial response rate was 27%, complete response 3%, stable disease 57% and progression 13%. The median progression-free survival (PFS) and overall survival (OS) were 26.6 months (95% CI, 21.5-NA), and 38.2 months (27.6-NA), respectively. Grade 3-4 toxicities were recorded in 9%. In multivariate analysis, the factors associated with OS were ECOG (HR 1.16, p=0.001), Ki-67% index (HR 1.02, p=0.026) and the presence of extrahepatic/extranodal metastases (HR 2.63, p=0.018). The greater the number of pre-radionuclide treatment lines, and the increment of previous lines was associated with worse PFS (HR 1.33; (95% CI, 1.04-1.68), p=0.018), and increased mortality: OS (HR 1.25; (95% CI, 0.96-1.62), p=0.092). Patients who received >2 previous lines vs. those who received ≤2 had worse PFS, with median of 15.8 months (95% CI, 10.5-NC) vs 45.3 months (95% CI, 24.0-NC) (Log-rank, p=0.02), and worse OS, 26 months (95% CI, 19.5-NC), vs not reached (Log-rank, p=0.05). After adjusting for confounding factors, no evidence was found that these differences were attributed to specific previous therapies. **Conclusion:** Therapy with ¹⁷⁷Lu-DOTATATE (PRRT) is safe in clinical practice, with survival data comparable to those shown in clinical trials, and

better outcomes in those patients who are treated earlier. Prognostic factors have been identified, with potential impact on decision-making. **References:** None

OP-179

¹⁷⁷Lu-PRRT in advanced gastrointestinal neuroendocrine tumors: ten-year follow up of the IRST-Phase II prospective study

M. Sansovini¹, G. Paganelli¹, S. Nicolini¹, I. Grassi¹, V. Di Iorio¹, E. Amadori¹, E. Scarpi¹, A. Bongiovanni¹, C. Cittanti², L. Urso², S. Severi¹; ¹IRST, Meldola (FC), ITALY, ²Nuclear Medicine Unit, University of Ferrara, Ferrara, ITALY.

Aim/Introduction: In March 2014, we reported the activity and safety of ¹⁷⁷Lu-Dota-octreotate Lu-PRRT at 2 different dosages (18.5GBq and 27.5 GBq in 5 cycles) in patients with progressive metastatic gastrointestinal neuroendocrine tumors (GI-NETs). Disease control rate and toxicity were addressed. Herein we report the late toxicity, progression-free (PFS) and overall survival (OS) in the same cohort after a ten-year follow-up. **Materials and Methods:** We conducted an open-label, disease-oriented prospective phase II trial. From March 2008 to June 2011 43 patients received 3.7 GBq or 5.5 GBq of Lu-PRRT every 6 to 8 weeks, each cycle repeated 5 times. All patients showed ⁶⁸Gallium-DOTA-peptide PET/Octreoscan® positivity (score 3-4 Rotterdam scale) in known lesions. Tumor burden was estimated radiologically. Time-to-event data (PFS and OS) were described using Kaplan-Meier curves and compared with the log-rank test **Results:** Forty-three patients (28 males and 15 females) were evaluable and were monitored for a median period of 118 months (range 12.6-139.6). Median PFS in patients receiving 18.5 GBq was 59.8 months (95% confidence interval [95% CI] 14.3-79.6), identical to that of patients treated with 27.5 GBq (59.8 months, 95% CI 23.4-82.0). Median OS was 71.0 months (95% CI 46.1-107.3) in the group who received 18.5 GBq and 97.6 months (95% CI 64.3-not reached) in the group treated with 27.5 GBq (P=0.22). Patients with progression limited to lymph nodes showed significantly longer median PFS and OS than those with hepatic lesions (P=0.02 for PFS and P=0.04 for OS). Age over 65 years at the time of PRRT was also significant for OS. Of note, no late hematological or renal toxicity was observed in either group. **Conclusion:** The long-term follow-up of the IRST-Phase II study shows that Lu-PRRT is a safe and effective therapy for patients with advanced GI-NET, the most important prognostic factor being tumor burden, hepatic lesions and age. We believe that Lu-PRRT should be offered to patients with early-stage disease. **References:** Paganelli G, et al. ¹⁷⁷Lu-Dota-octreotate radionuclide therapy of advanced gastrointestinal neuroendocrine tumors: results from a phase II study. Initial experience with ¹⁷⁷Lutetium peptide receptor radionuclide therapy for pediatric patients with somatostatin-receptor-positive tumors

M. Pizzoferro¹, B. Cassano², C. Altini¹, A. Serra³, M. Cefalo³, A. Cacchione³, M. Villani¹, A. Castellano³, V. Cannatà², M. Garganese¹; ¹IRCCS Bambino Gesù Children's Hospital, Nuclear Medicine Unit/Imaging Department, Rome, ITALY, ²IRCCS Bambino Gesù Children's Hospital, Medical Physics Unit, Rome, ITALY, ³IRCCS Bambino Gesù Children's Hospital, Oncoemathology Unit, Rome, ITALY.

Aim/Introduction: Treatment of relapsed/refractory malignant pediatric tumor remains a clinical challenge by poor outcome despite intensive multimodal therapy. 177Lu-Peptide-Receptor Radionuclide Therapy (177Lu-PRRT) shows a promising role in somatostatin-receptor-positive tumors (SSTR-PT) with a potential clinical utility in pediatric patients. We report on our initial experience assessing somatostatin analogues therapy in heavily pretreated pediatric patients affected by progressive SSTR-PT. **Materials and Methods:** four pediatric patients with progressive tumor (2 boys and 2 girls, age range: 7-19 years) were submitted to 177Lu-PRRT for palliative purpose after molecular imaging showing an overexpression of somatostatin receptor in tumor sites and ethical committee approval. Two patients were affected by Relapsed/Refractory Metastatic High-Risk Neuroblastoma (HRNBL), one patient had bilateral metastatic pheochromocytoma and one had an advanced medulloblastoma. 4 cycles of PRRT (Lutathera®) were administered in 3 patients while one patient received the first cycle. Recommended administration procedure was applied and haematological exams were performed. An individualized dosimetry for red-marrow and kidneys was assessed collecting blood samples, and acquiring planar images. **Results:** HRNBL and pheochromocytoma patients received 4 cycles of palliative PRRT (4.4 GBq in the 1st cycle in the younger HRNBL patient; 7.4 GBq per administration in the other cycles). Medulloblastoma patient received a single cycles of 7.4 GBq. The absorbed doses to red-marrow and kidneys ranged from 0.6 to 1.1 Gy and from 40 to 54 Gy, respectively. No significant acute toxicity attributed to PRRT was registered. No regression of disease was obtained in HRNBL patients but early symptoms improvement (pain and/or dyspnea relief) was registered in both of them. In the patient with pheochromocytoma a stable disease was documented over one year even if there wasn't a significant tracer uptake in disease sites at post-therapy imaging. Medulloblastoma patient is on going and showed an intense uptake in

cerebellar lesion after the first initial cycle, without side-effects. **Conclusion:** our preliminary experience documented the feasibility of 177Lu-PRRT in pediatric clinical practice suggesting a potential role as new targeted therapy for palliative intent in children affected by SSTR-PT. 177Lu-PRRT showed a high tolerability and a significant clinical impact on patient quality life. 177Lu-PRRT requires a multidisciplinary approach and dosimetric implementation is mandatory to ensure 177Lu-PRRT administration safety avoiding exceeding the dose limits for organ-at-risk. Clinical trials, in larger patient cohorts, is warranted for evaluation of response to PRRT and for defining new combined therapeutic strategies including somatostatin analogues treatment in children affected by advanced progressive SSTR-PT. **References:** None

OP-181

PRRT/PRCRT in ¹⁸F-FDG-avid G3 NET-Patients

H. Svirydenka¹, L. Scarpa¹, B. Nilica¹, M. Rodrigues¹, S. Buxbaum¹, G. Di Santo¹, C. Uprimny¹, S. Bayerschmidt¹, B. Neururer¹, E. Gamper², I. Virgolini¹; ¹Universitätsklinik für Nuklearmedizin, Innsbruck, AUSTRIA, ²Division of Psychiatry II, Department of Psychiatry, Psychotherapy and Psychosomatics, Innsbruck, AUSTRIA.

Aim/Introduction: The efficacy and safety of PRRT in G1 and G2 NET-patients has been established in recent years. The peptide receptor radionuclide/chemoradionuclide therapy (PRRT/PRCRT) might be more efficient in patients with G3-NETs. In this study we determined the efficacy of a combined therapy strategy in ¹⁸F-FDG-avid NET-patients. **Materials and Methods:** Twenty patients (mean age 53± 15.3 years, range 29-79) with metastatic SSTR-avid NET on ⁶⁸Ga-DOTATOC PET/CT and at least one hypermetabolic lesion on ¹⁸FDG-PET/CT, before or in follow-up after PRRT were analyzed. The observation time was at least 1 year after completion of 4 cycles of PRRT. Dual-tracer imaging was performed at 6 months interval for the assessment of response. We divided the response finding in four categories according to PERCIST 1.1. Criteria: Complete Response (CR), Partial Response (PR), Stable Disease (SD) and Progressive Disease (PD). CR and PR were considered as overall response and clinical benefit was defined as CR+PR+SD. As long term predictors, we calculated the Progression-Free-Survival (PFS) and Overall-Survival (OS) since initialization of PRRT by Kaplan-Meier. Three months after PRRT adverse events, according to the Common Terminology Criteria for Adverse Events (CTCAE) V.5.0., and treatment's tolerability by Health-Related-Quality-of-Life (HRQoL) were monitored. **Results:** 75% of our cohort presents foregut localization of NETs and 25% midgut (26.3% G2 Grade, 73.7% G3 Grade). PRRT/PRCRT was performed after 36.4±47 months from diagnosis. 30% of patients received a single period (4 cycles) of PRRT, 70% had re-challenge PRRT/PRCRT. The mean accumulated activity was 38.1±13.0 GBq. All patients received a long-acting somatostatin analog

and 20% a concomitant radiosensitizing chemotherapy (temozolomide). 70% of patients had performed the comparable dual tracer study during the observation (35% were almost FDG positive before target-therapy and 35% become FDG avidity during follow-up). According to the last available follow-up (with FDG-PET, if possible, or with other imaging or laboratory diagnostic) at the end of the observation's time, 20% had CR, 10% PR, 30% SD, 40% PD. The overall response was observed in 30% and the clinical benefit in 60% of patients. The mean calculated OS and PFS were 102.5 months (range 78.9-126; CI 95%) and 47.2 months (range 32.4-61.9; CI 95%), respectively. No significant difference for OS was observed between patients with PRRT and PRCRT ($p=0.954$). None of our patients showed serious adverse events after PRRT/PRCRT during follow-up. Overall stable HRQoL was observed. **Conclusion:** PRRT/PRCRT promises to be a safe and efficient treatment strategy for ^{18}F -FDG-avid metastatic NET-patients. **References:** None

OP-182

Peptide Receptor Radionuclide Therapy In Broncopulmonary Neuroendocrine Tumours - Results Of A Single Centre Experience

G. Ferreira, S. Castro, C. Costa, L. Violante, J. Teixeira, H. Duarte, I. L. Sampaio;

Instituto Português de Oncologia do Porto
Francisco Gentil, Porto, PORTUGAL.

Aim/Introduction: Therapeutic options in unresectable and metastatic broncopulmonary neuroendocrine tumours (bpNET) remain limited. These tumours may overexpress somatostatin receptors (SSTR), allowing for Peptide Receptor Radionuclide Therapy (PRRT). The aim of this study was to explore the efficacy and safety of therapy with ^{177}Lu -DOTATATE in bpNET. **Materials and Methods:** We analyzed 20 patients with advanced or metastatic bpNET treated with PRRT between 2011 and 2018 in our institution, after progression on previous locoregional and/or systemic therapy. Adequate tumoral SSTR expression was confirmed according to a baseline ^{68}Ga -DOTANOC PET/CT scan, prior to the administration of 3 cycles of ^{177}Lu -DOTATATE (median cumulative activity 19.6 GBq). Patients were followed until last observation or death. We evaluated the objective response rate (ORR) according to morphologic criteria (modified RECIST), progression free survival (PFS) based on radiologic or ^{68}Ga -DOTANOC PET/CT findings, overall survival (OS), clinical benefit and treatment tolerability. We also investigated factors associated with PFS and OS according to LogRank tests and Cox regression analysis. **Results:** Patients were followed for 7.5 to 106.9 months (median 32.2). Median PFS was 19.2 months (95% CI 14.7-23.7) and median OS was not reached (estimated at 50.1 months). ORR was 50% (6 patients had partial and 4 had minor responses). None of the responders died during follow-up, while non-responders

had a median OS of 24.6 months (95% CI 6.1-43.1, $p<0.001$). Semi-quantitative uptake intensity (SUVmax) and visual interlesional uptake heterogeneity on baseline ^{68}Ga -DOTANOC PET/CT were independent predictors of PFS (HR 0.93 and 9.46, $p=0.019$ and $p=0.013$, respectively). Clinical benefit was attained in 6 of 11 previously symptomatic patients, whereas 7 of 9 patients remained asymptomatic during the entire follow-up period. No serious (grade 3/4) haematological, renal or hepatic toxicity was observed. **Conclusion:** PRRT demonstrated to be a compelling option in the management of bpNET, as it provided a good response rate, symptomatic control and favorable toxicity, whilst also being promising in prolonging patients' survival. Quantitative and qualitative parameters based on baseline ^{68}Ga -DOTANOC PET/CT may be useful in selecting patients for PRRT and prognostic stratification. **References:** None

OP-183

Comparison and Evaluation of n.c.a. ^{111}In -DTPA-Phe¹-Octreotide vs. n.c.a. ^{177}Lu -[DOTA0, Tyr3] TATE / n.c.a. ^{177}Lu -[DOTA0, Tyr3] TOC in (GEP-NENs) Treated Patients

G. Limouris¹, V. Krylov², M. B. Dolgushin³, M. Paphiti⁴, R. V. McCready⁵, A. Zafeirakis⁶;

¹Nuclear Medicine, Medical School, National and Kapodistrian University of Athens, Athens, GREECE, ²Nuclear Medicine Department, "A Tsyb Research Center", Obninsk, RUSSIAN FEDERATION, ³N.N. Blokhin Russian Oncological Research Center, Moscow, RUSSIAN FEDERATION, ⁴Nuclear Medicine Dept, National Health System, Athens, GREECE, ⁵Institute Cancer Research, Sutton Surrey and Royal Sussex County Hospital, Brighton, UNITED KINGDOM, ⁶Army Share Fund Hospital of Athens, Athens, GREECE.

Aim/Introduction: To evaluate and compare the dosimetry profile and efficacy of n.c.a. ^{111}In -DTPA-Phe¹-Octreotide vs. n.c.a. Lu-177 DOTA-TATE and n.c.a. Lu-177 DOTA-TOC in GEP-NEN patients, initially i.a. treated with ^{111}In -DTPA-Phe¹-Octreotide and after a median progression-free-survival (PFS) of more than 39 mo, further retreated with i.a. infusions with n.c.a. Lu-177 DOTA-TATE in combination with n.c.a. Lu-177 DOTA-TOC, the latter i.v. implemented, to confrontate the relapse observed. **Materials and Methods:** The average activity of n.c.a. ^{111}In -DTPA-Phe¹-Octreotide [Group A: 12 cases (63 liver trans-arterial catheterizations)] was 6.3 ± 1.3 GBq per patient/per session whereas the activity of n.c.a. Lu-177 DOTA-TATE, [Group B: 4 cases (24 liver trans-arterial catheterizations)] in tandem infused with n.c.a. Lu-177 DOTA-TOC to the same 4 cases (12 i.v. infusions, antecubital)] was 7.3 ± 2.3 GBq. For both groups repetitions were performed in intervals of 5-8 weeks to avoid a possible stunning effect. Blood samples were collected 30 min, 2, 4, 8 and 24 hrs p.i. as well as 24 hrs urine samples for dosimetry. The % max uptake in organs and tumours was estimated by creating ROIs. Tumour Dosimetric calculations were performed using the OLINDA/EXM 1.1 code. **Results:** Non-carrier-added ^{177}Lu -

[DOTA0,Tyr3]TATE blood and urinary radioactivity, expressed as a percentage of the injected dose was significantly lower compared as to non-carrier-added ^{177}Lu -[DOTA0,Tyr3]TOC, clearly depicted from the created time/activity curves; the tumour uptake (Bkg-corrected) was significantly higher as compared to non-carrier-added ^{177}Lu -[DOTA0,Tyr3] TOC. Absorbed dose kidneys' difference has been measured to be almost the same. The organ average dose in mGy / MBq of n. c. a. ^{111}In -DTPA-Phe¹-Octreotide was found as follows: (a) Liver tumour of 10 gr spherical mass was estimated to be 10.80 (b) Liver 0.14, (c) Kidneys 0.41 and (d) Bone marrow 0.0032. The organ average dose in mGy / MBq of n. c. a. ^{177}Lu -[DOTA0,Tyr3] TATE / TOC was found as follows: (a) Liver tumour of 10 gr spherical mass was estimated to be 33.0/ 13.0, (b) Liver 0.19 / 0.55, (c) Kidneys 0.46/ 0.66 and (d) Bone marrow 0.030 / 0.036. **Conclusion:** Comparing the i.a. infused n.c.a. ^{177}Lu -[DOTA0,Tyr3]-TATE vs. the i.v. implemented -TOC of β -low-LET emitters (a) a statistically significant 2.53-fold higher dose in tumour was found, in favor of ^{177}Lu -[DOTA0,Tyr3]-TATE advocating the efficacy profile of i.v. infused-TOC and the feasible continuation of the re-treatment procedure. Analyzing the Auger and Internal Conversion Electron Emission -high-LET of ^{111}In -DTPA-Phe¹-Octreotide an advantageous 8.9-fold lower dose in bone marrow was observed. **References:** None

Metabolic and Dopaminergic Correlates of intellectual enrichment in De novo PD patients

S. Raffa¹, M. Donegani¹, M. Bauckneht², M. Balma², D. Arnaldi³, N. Girtler³, M. Pardini³, A. Miceli¹, F. Biagini¹, F. Massa³, L. Filippi³, G. Sambuceti¹, M. Pagani⁴, F. Nobili³, S. Morbelli¹;

¹Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY, ²IRCCS Policlinico San Martino, Genoa, ITALY, ³Clinical Neurology, Department of Neuroscience (DINO GMI), Dept. of Excellence of the Italian Ministry for University and Research- MIUR), University of Genoa., Genoa, ITALY, ⁴Institute of Cognitive Sciences and Technologies, Consiglio Nazionale delle Ricerche (CNR), Rome, ITALY.

Aim/Introduction: To disclose brain metabolic and dopaminergic correlates of intellectual enrichment and cognitive reserve in de novo PD patients. **Materials and Methods:** 62 de novo PD patients (36 m; Age 70.1±8.5; MDS-UPDRSIII 20±9.9; Education 12.1±4.7; MMSE 28±1.9) underwent both brain ^{18}F -FDG-PET and Dopamine Transporter SPECT. CR-index questionnaire including a total

score (Total-CR) and 3 subscores concerning education (educational-CR), occupational complexity (occupational-CR) and leisure activities (leisure-CR) was administered. Specific binding ratios (SBRs) in the basal ganglia were computed with 'BasGan V2'. Age and sex-adjusted Z-scores of SBR in caudate (C) and putamen (P) nuclei and P/C ratio were obtained by comparing patients with 122 CTR recruited in the 'ENC-DAT' study. Z-scores were used as the dependent variables in repeated measures of general linear model. Correlation between whole brain metabolism and CR-scores was evaluated by means of SPM8 (age, gender and UPDRS as nuisance). Moreover patients were divided according to the median value of CR scores. Clinical variables, brain metabolism and SBR-values were compared between patients with high and low CR-related scores (two-sample t-test). To evaluate the interplay between brain metabolism and dopaminergic function in these group of patients, voxel-based correlation between SBR values and FDG PET data was also assessed. **Results:** MDS-UPDRS score and brain metabolism were not significantly different in patients with high and low CR-scores. SBRs were significantly higher in patients with higher CR (especially higher leisure-CR) despite expressing the same level of motor impairment. A direct correlation was highlighted between CR-scores on one side and SBRs (namely P/C ratio and SBR of putamen of both hemispheres, $p < 0.03$) while an inverse correlation was highlighted between total and occupational-CR and brain metabolism in cerebellum ($p < 0.001$). SBR-values of both putamen were directly correlated with metabolism in right occipital and parietal cortex and again inversely correlated with cerebellum ($p < 0.001$). **Conclusion:** Given the less marked dopaminergic deficit highlighted in patients with higher CR, it is likely that more active patients with high leisure-CR are earlier aware of their symptoms and are thus in an earlier stage of disease. This difference is captured by the sensitivity of DAT-SPECT and not yet by MDS-UPDRS. The inverse correlation of both CR-scores and SBR-values with the cerebellum support this hypothesis. Cerebellum is relatively hypermetabolic with respect to the cortex in PD. Accordingly this relative hypermetabolism may reflect a compensative mechanism less needed in PD de novo with high reserve given their lower dopaminergic deficit. **References:** None

OP-185

Striatal Dopamine Transporter SPECT Quantification: Head-To-Head Comparison Between Two Tridimensional Automatic Tools

S. Raffa¹, E. Cella¹, M. Donegani¹, D. Arnaldi^{2,3}, F. Massa³, S. Capitano², M. Bauckneht², A. Miceli¹, S. Morbelli^{1,2}, F. Nobili^{2,3};

¹Dept of Health Science (DISSAL), University of Genoa, Genoa, ITALY, ²IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, ³Dept of Neuroscience (DINO GMI), University of Genoa, Genoa, ITALY.

Aim/Introduction: Several methods have been proposed for semiquantification of DAT SPECT with results varying depending upon region of interest (ROI) identification method. We aimed to perform a head-to-head comparison between two automatic tools for semi-quantification of striatal dopamine transporter (DAT) specific-to-non displaceable (SBR) ratio brain SPECT values and to comparatively correlated data with a clinical measure as an 'external' reference in a naturalistic cohort of patients. **Materials and Methods:** We analyzed DAT SPECT scans from one-hundred and fifty-one consecutive outpatients submitted to brain DAT SPECT for a suspected parkinsonism. The scans were corrected for attenuation using the Chang's method, were reconstructed with an OSEM algorithm (10 subset, 10 iterations). Images were post-processed using a commercial (Datquant®, G.E. Healthcare) and BasGanV2 (free software by the AIMN-Neurology study group) software. Then, the individual results were compared with the control population embedded in each software and were compared with reading by experts considered as the gold standard. Finally, caudate and putamen SBRs were correlated with the MDS-UPDRS-III score in a subset of thirty-five patients with altered DAT SPET according to experts and degenerative parkinsonism at follow up. **Results:** Good correlations were achieved between the two tools (right caudate $r = 0.76$; left caudate $r = 0.73$; right putamen $r = 0.84$; left putamen $r = 0.82$; right P/C ratio 0.76; left P/C ratio 0.65; all $p < 0.0001$). Concordance with the gold standard was 82.5% for BasGan V2 and 84% for Datquant ($p = n.s.$). Correlations of BasGan V2 with UPDRS-III score was $r = -0.44$ with caudate SBRs of both sides ($p < 0.01$), $r = 0.32$ with left putamen SBR ($p < 0.05$) and not significant with right putamen SBRs. Correlations of Datquant® with UPDRS-III score was $r = -0.39$ ($p < 0.01$) with right caudate SBRs and $r = -0.35$ with left caudate SBRs ($p < 0.05$), but not significant with putamen SBRs of both sides. **Conclusion:** Both Datquant® and BasGanV2 give highly correlated SBR values and performed equally well compared with the gold standard (although correspondence with expert reading was slightly higher with Datquant®). Correlation with severity of motor impairment was higher with BasGan V2 and was higher at the caudate level with both methods, and this finding expresses the better ability of caudate SBR to track disease severity for the nigro-caudate pathway than putamen SBR. Both tools have their own strength and pitfalls that must be known in detail by users in order to obtain the best help in visual reading and reporting of DAT SPECT. **References:** None

OP-186

Machine Learning Assisted DAT PET in the Discrimination of Parkinsonism Disorders

Q. Xu;

North Huashan Hospital, Shanghai, CHINA.

Aim/Introduction: To explore the discriminative performance of DAT PET in Parkinsonism disorders, including Parkinson's disease (PD), multiple system atrophy (MSA-P) and progressive supranuclear palsy (PSP), with the assistance of computer based automatic segmentation, feature extraction and machine learning. **Materials and Methods:** 107 confirmed idiopathic patients (50 PD, 37 MSA-P, and 20 PSP) were recruited in our study. Subjects have been screened by two senior specialists of movement disorders, and were divided into early/advanced stage (ES/AS) group based on disease duration (24 months) at PET imaging. 11C-CFT PET and T1-weighted MRI imaging were performed on each subject within one week. Firstly, Striatum and midbrain were segmented from MRI image and registered rigidly to corresponding PET image, and resulting transformation matrix was used to transfer label information to the PET image. Then, 14 sub-regions were isolated from the PET image using a k-means clustering algorithm, including bilateral anterior, middle and posterior caudate and putamen, and bilateral pallidum. Maximum, minimum, median, quantiles, and mean value of tracer uptake in above sub-regions were extracted as features and presented as striatal-to-occipital ratio (SOR). Afterwards, Support-Vector-Machine (SVM) was used to train the disease classifier to make diagnosis for each subject. Furthermore, we applied different training strategies with leave-one-out cross-validation method to assess the diagnostic ability of this method for ES patients. Lastly, the importance of striatum and midbrain during the diagnosis process was investigated using random forest algorithm. **Results:** Sensitivity, specificity, PPV and NPV was 86%, 84%, 83% and 87% for diagnosis of PD patients, 78%, 89%, 78% and 89% for MSA-P patients, and 70%, 95%, 78% and 93% for PSP patients. Classification accuracy of PD, MSA-P and PSP from others achieved 85%, 78%, 89% respectively. Diagnostic accuracy achieved 77.78% when using both ES and AS groups as training set, which was better than other strategies. The caudate and putamen showed significantly higher weight of diagnostic importance than pallidum, especially the anterior caudate (18.52%), middle putamen (16.87%) and middle caudate (16.27%). The accuracy of diagnosis was not obviously different with and without midbrain. **Conclusion:** DAT PET has been confirmed to have potential to be applied in the diagnosis of parkinsonism diseases with the assistance of computer based automatic segmentation, feature extraction and machine learning method, even in the early stage of diseases. Caudate and putamen were found to play important role in the diagnostic process, while pallidum and midbrain do almost no help. **References:** None

OP-187**Cerebral glucose metabolism abnormalities and dopaminergic dysfunction in patients with Parkinson's disease with bilateral onset**

P. Wu¹, L. Li¹, J. Song¹, X. Li¹, J. Lu¹, J. Ge¹, J. Wu², J. Wang², C. Zuo¹;

¹PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA, ²Department of Neurology, Huashan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: Parkinson's disease (PD) is usually characterized by unilateral onset and by loss of dopamine transporter (DAT) and a unique PD-related pattern (PDRP). However, we indeed found that some patients presented bilateral onset and were diagnosed as PD by follow-up in clinical practice. Thus, we conducted this study to explore the abnormal cerebral glucose metabolism and dopamine distribution in PD patients with bilateral onset and compare with those with unilateral onset. **Materials and Methods:** Twenty PD patients with bilateral onset (PD-Bi) and 45 with unilateral onset (PD-Uni), matched for age, sex, duration and UPDRS-III scores, were recruited. 20 age-matched normal controls (NC) were also recruited. All subjects underwent ¹⁸F-FDG and ¹¹C-CFT PET at the same time. Scans from PD-Uni patients with predominantly right-sided symptoms were flipped and those from PD-Bi patients and NC were flipped randomly. PDRP expression was computed in each subject based on the PDRP we previously identified. Regional FDG metabolism was compared among groups using SPM. ¹¹C-CFT uptake of bilateral caudate, anterior and posterior putamen was calculated respectively by the striatal-to-occipital ratio (SOR) using ScAnVp toolbox and the asymmetric index was calculated as the absolute value of (bilateral SOR difference/bilateral SOR average). **Results:** The asymmetry indices of UPDRS-III scores were significantly lower in PD-Bi group than those in PD-Uni group ($P < 0.001$). The PDRP scores significantly increased in both PD groups relative to NC ($P < 0.001$), but there was no difference between the two PD groups. Compared with PD-Uni, PD-Bi patients presented hypometabolism in left middle frontal gyrus and inferior parietal lobule and relative hypermetabolism in the right temporal, left parietal lobe and bilateral limbic lobe ($P < 0.001$). DAT level significantly decreased in both PD groups compared with NC ($P < 0.001$), and was lower in the posterior putamen in PD-Bi group than that in PD-Uni group ($P = 0.035$). The asymmetric indices of both anterior and posterior putamen in PD-Bi group were significantly lower than those in PD-Uni group ($P < 0.05$). **Conclusion:** The difference of both cerebral glucose metabolism abnormalities and dopamine dysfunction between PD-Bi and PD-Uni patients suggests PD-Bi might be another clinical phenotype of the disease. **References:** None

OP-188**Cerebral glucose metabolism, cognitive performance and emotional state in tremor dominant and akinetic-rigid subtypes of Parkinson's disease**

J. Khomenko¹, I. Miliukhina², G. Kataeva¹, E. Gracheva², E.

Gromova¹;

¹N.P. Bechtereva Institute of Human Brain of the Russian Academy of Sciences, Saint-Petersburg, RUSSIAN FEDERATION, ²Institute of Experimental Medicine, Saint-Petersburg, RUSSIAN FEDERATION.

Aim/Introduction: Parkinson's disease (PD) has a significant phenotypic heterogeneity. Clinical differences between akinetic-rigid (AR) and tremor dominant (TD) PD subtypes PD, in addition to the specific motor disorders, include cognitive and emotional dysfunction. Study of the pathogenesis of PD heterogeneity is important for the prognosis and therapy. **Materials and Methods:** 71 PD patient were examined (47 - AR, 24 - TD). PET study with ¹⁸F-fluorodeoxyglucose (FDG) was performed on GE-Discovery710 scanner. PET images were normalized with SPM8, regional cerebral glucose metabolism rate (rCMRglu) in Brodmann areas (BA) were calculated using WFU-Pickatlas. rCMRglu in sensorimotor cortex was used as a referent. Mini-mental State Examination (MMSE), Frontal Assessment Battery (FAB), Montreal Cognitive Assessment (MoCA), and Hospital Anxiety and Depression Scale (HADS) were used for neuropsychological evaluation. **Results:** rCMRglu in the AR group was lower in frontal cortex (BA 6,8,9,46) in right hemisphere and left BA46 ($p < 0.05$) compared to the TD group. Cognitive tests scores correlated with different cortical areas in the studied groups. In TD group, MMSE and MoCA scores correlated positively with rCMRglu in BA7 and 9 bilaterally, BAs 6,8,10,11,47,24 in right hemisphere, and left BAs 22,32,46. In AR group, MMSE and MoCA scores correlated with rCMRglu in BAs 7,23,26,29,30,31 in both hemispheres ($r = 0.4-0.6$; $p < 0.05$). In the TD group, the HADS-depression scores correlated negatively with rCMRglu in left frontal (BA 8,46), anterior cingulate (BA32) and parietal cortex (BA40), and right BA39 ($r = -0.5-0.7$; $p < 0.05$). The HADS-anxiety scores in AR group correlated with rCMRglu in BA7 (bilateral), $r = -0.4-0.5$; $p < 0.05$. At the same time, there were no significant differences in anxiety and depression scores in 2 groups. MOCA negatively correlated with depression score in both groups ($r = -0.4$, $p < 0.05$). In TD group, both depression and anxiety scores correlated negatively with FAB score ($r = -0.4$, $p < 0.05$). **Conclusion:** In different PD subtypes cognitive performance and emotional state was associated with rCMRglu in different cortical areas: frontal, temporal, parietal, and anterior cingulate in TD, and parietal and posterior cingulate in AR group. Presumably, it is a result of differences in the cognitive and emotional disorders pathogenesis in different PD types. **References:** None

OP-189**¹⁸F-PI-2620 Tau-PET in Corticobasal Syndrome**

M. Brendel¹, C. Palleis¹, C. Prix¹, A. Finze¹, K. Bötzel¹, A. Danek¹, M. Höllerhage², L. Beyer¹, J. Sauerbeck¹, B. Rauchmann¹, A. Stephens³, A. Drzezga⁴, T. van Eimeren⁴, H. Barthele⁵, M. Patt⁵, O. Sabri⁵, V. Villemagne⁶, P. Bartenstein¹, R. Perneczky¹, C. Haass⁷, J. Levin¹, G. Höglinger⁸;

¹University Hospital of Munich, Munich, GERMANY, ²Technical University of Munich, Munich, GERMANY, ³Life Molecular Imaging, Berlin, GERMANY, ⁴University Hospital of Cologne, Cologne, GERMANY, ⁵University of Leipzig, Leipzig, GERMANY, ⁶University of Melbourne, Melbourne, AUSTRALIA, ⁷DZNE Munich, Munich, GERMANY, ⁸Hannover Medical School, Hannover, GERMANY.

Aim/Introduction: The pathology of Corticobasal syndrome (CBS) is characterized by 4-repeat (4R)-tau aggregation in Corticobasal Degeneration (CBD) and Progressive Supranuclear Palsy (PSP) in ~50%, or by (3/4R)-tau aggregation in Alzheimer's disease (AD) in ~25% of patients. The tau-PET ligand ¹⁸F-PI2620 showed high affinity to 3/4R-tau in AD and also revealed affinity to 4R-tau pathology in vitro. The aim of this study was to investigate ¹⁸F-PI2620 in patients with CBS that are part of the interdisciplinary AD study "Activity of Cerebral Networks, Amyloid and Microglia in Aging and Alzheimer's Disease (ActiGliA)". **Materials and Methods:** ActiGliA comprises a comprehensive clinical assessment, multimodal prospective imaging in vivo and fluid biomarker analyses. Thirty-six patients (70±8y) with probable or possible CBS according to MDS-PSP or Armstrong-criteria underwent ¹⁸F-PI2620 PET together with ten age-matched healthy controls. Distribution volume ratios (DVR, 0-60 min) of subcortical and prefrontal cortical brain-regions were generated using cerebellar reference tissue. DVR-data were quantitatively and visually compared between CBS and healthy controls. Regional ¹⁸F-PI2620 binding was compared with clinical severity (PSP Rating Scale), and disease duration. Amyloid-PET served for assessment of β-amyloid status. **Results:** 26% (9/36) of CBS patients (PSP Rating Scale: 25±13) were amyloid-positive. Overall, a visually discernible ¹⁸F-PI2620 was observed in 27 subjects (75%) and in 89% of amyloid-positive CBS patients. Significantly elevated ¹⁸F-PI2620 DVR was observed in the whole group of CBS patients versus healthy controls in the putamen, the globus pallidus, the subthalamic nucleus, the dentate nucleus and the prefrontal cortex (all p<0.01). The prefrontal cortical signal was higher in amyloid-positive when compared to amyloid-negative CBS patients. Visually assessed cortical binding in CBS was heterogeneous (positive in 50%; 18/36). Asymmetry of ¹⁸F-PI2620 binding matched the contralateral clinical dominance in 94% of CBS cases. ¹⁸F-PI2620 binding was associated with disease severity in the globus pallidus (R=0.412, p=0.032) and with disease duration in the prefrontal cortex (R=0.426, p=0.021), after controlling for age, sex and β-amyloid-status.

Conclusion: ¹⁸F-PI2620 tau-PET is a potential biomarker for evaluation of CBS, facilitating detection of heterogeneous neuropathology and variable cortical and subcortical deposition sites. Longitudinal and autopsy correlation studies need to evaluate the suitability of ¹⁸F-PI2620 tau-PET as biomarker of disease progression and target engagement. **References:** None

OP-190**Brain metabolic correlates of gait initiation in Progressive Supranuclear Palsy**

G. Marotta¹, C. Palmisano², M. Todisco³, J. Volkmann², C. Pacchetti³, C. Frigo⁴, R. Leo¹, C. Sdraiati¹, D. Capolongo¹, E. Orunesu¹, G. Pezzoli⁵, I. U. Isaias²;

¹Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ITALY, ²Department of Neurology, University Hospital and Julius Maximilian University of Würzburg, Würzburg, GERMANY, ³Parkinson's Disease and Movement Disorders Unit, IRCCS Mondino Foundation, Pavia, ITALY, ⁴MBMC Lab, Department of Electronics, Information and Bioengineering, Politecnico di Milano, Milan, ITALY, ⁵Centro Parkinson ASST G. Pini-CTO, Milan, ITALY.

Aim/Introduction: Progressive supranuclear palsy (PSP) is a neurodegenerative disease characterized by early impairment of balance and frequent falls. Gait initiation (GI) is a centrally-mediated motion achieved in a principled, controlled manner, including predictive mechanisms (anticipatory postural adjustments, APA) that destabilize the antigravity postural set of body segments for the execution of functionally- optimized stepping. The neural correlates of postural imbalance and falls in PSP are largely unknown. We compared the biomechanical resultants of APA at gait initiation (imbalance, unloading, and stepping phases) with clinical findings and brain metabolic abnormalities measured using [18F]FDG-PET. **Materials and Methods:** We recruited 26 patients with probable PSP and 14 age-matched healthy controls (HC). Biomechanical data were correlated with clinical findings in all subjects, and with brain metabolic abnormalities measured using FDG-PET in 11 patients, compared with a group of 12 age- and gender-matched HC. PET data were analyzed using the Statistical Parametric Mapping (SPM 12). We considered the clusters with k≥200 voxels and threshold of p<0.05 FWE- corrected as significant. SPM findings were confirmed by a post hoc volume of interest (VOI) analysis. For each VOI, we extracted the [18F]FDG uptake values that were divided by the whole cortex uptake to reduce between-patient variability. The resulting [18F]FDG uptake ratios were then used to explore correlations with GI parameters. **Results:** Patients with PSP showed impaired modulation of the center of pressure displacement for a proper setting of the center of mass momentum and subsequent efficient stepping. Biomechanical measurements correlated with "Limb

motor” and “Gait and midline” subscores of the PSP Rating Scale. We identified five hypometabolic brain regions in the PSP group: the right dorsolateral prefrontal cortex, the left supplementary motor area, the middle cingulate cortex, the left caudate nucleus and the medial thalamus. Hypometabolism of the caudate nucleus and the middle cingulate cortex correlated positively with a key kinematic feature of APA pre- programming of the GI task, and medial thalamic hypometabolism correlated with the resultants of APA efficacy for a proper forward stepping. **Conclusion:** Our results show that postural instability at gait initiation in patients with PSP correlates with deficient APA production and is associated with dysfunction of the basal ganglia, cingulum, and thalamus. In conclusion, specific brain regions selectively regulate different phases of GI: while the caudate nucleus and cingulate cortex could directly influence APA programming, the thalamus predominantly influenced the biomechanical resultants of the APA during the stepping phase. **References:** None

Progressive supranuclear palsy and its variants: pattern similarities and differences in 18F-FDG-PET

G. Martí-Andrés¹, J. J. Rosales¹, E. Prieto¹, L. van Bommel², F. Grisanti¹, S. K. Meles², R. V. Kogan², V. Gurvits², R. Valentí¹, M. Riverol¹, M. R. Luquin¹, K. Leenders², J. Arbizu¹;

¹Clínica Universidad de Navarra, Pamplona, SPAIN, ²University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: An accurate early diagnosis of Progressive Supranuclear Palsy (PSP) is still a clinical challenge. In a previous study, we performed a multicentre study including patients with different variants of PSP and defined a PSP-related pattern based on covariance analysis techniques. The pattern showed an optimal diagnostic accuracy to differentiate PSP patients from Parkinson’s Disease (PD) and healthy subjects (HC). Currently, we aim to identify similarities and differences in the metabolic pattern among the PSP variants. **Materials and Methods:** A retrospective study was conducted on a multicentre cohort of 73 early-stage PSP patients who were referred for an FDG-PET scan (longitudinal clinical diagnosis based on the Movement Disorders Society-PSP criteria 2017): Richardson’s Syndrome (PSP-RS), n=47; parkinsonian variant (PSP-P), n=18; and progressive gait freezing, n=8. Additionally, we included 55 HC and 58 PD patients as reference groups. We used a univariate analysis (Statistical Parametric Mapping) to assess the regional similarities and differences in metabolism (ANCOVA test adjusted by age, sex and PET procedures, p<0.05 corrected by family-wise error or p<0.001 uncorrected). Additionally, we applied the AAL3 atlas and obtained the mean glucose metabolism per ROI and clinical group, which were correlated using Pearson’s rho correlation coefficient. **Results:** The

demographical and clinical data of each group studied are shown in table 1. Compared to HC and PD, all the PSP variants exhibited hypometabolism in the thalamus and caudate, and hypermetabolism in the sensorimotor cortex and cerebellum. PSP-P and PSP-RS showed a larger spread of the subcortical metabolic abnormalities than PSP-PGF, displaying a hypometabolism in the midbrain. PSP-RS also showed more severe and widespread cortical abnormalities, displaying hypometabolism in the frontoinsula cortex and, compared to PD, hypermetabolism in the occipital cortex. Moreover, the mean glucose metabolism in each ROI was highly correlated between PSP variants, but there was a low correlation between any of the PSP variants and PD patients (table 2). Interestingly, PSP-RS and PSP-P patients showed a parallel clinical progression, but PSP-P patients showed a significantly delayed onset regarding the PSP core features (O1-2 and P1-2, table 3a-b). PSP-PGF showed a parallel progression to PSP-RS regarding the postural instability domain, and parallel to PSP-P regarding the oculomotor dysfunction. **Conclusion:** While both cortical and subcortical abnormalities are present in PSP-RS, subcortical abnormalities are predominant in PSP-P and PSP-PGF variants. Nevertheless, the presence of an early core common subcortical metabolic pattern and progressive phenotypical convergence among PSP variants differ from PD. **References:** None

Aim/Introduction: The in vivo diagnosis of progressive supranuclear palsy (PSP) is currently established on clinical grounds and supported by MR imaging findings. As recently reported, the second-generation tau PET tracer [18F]PI-2620 is able to provide valuable diagnostic information in PSP patients. The aim of this follow-up evaluation was to investigate how the diagnostic potential

of [18F]PI-2620 relates to that of the current imaging gold standard in PSP, i.e. midbrain (MB) atrophy MRI. **Materials and Methods:** The [18F]PI2620 PET and structural MRI data of 36 patients with clinical diagnosis of PSP (age=71±8yrs, 16 female, n=22 with PSP-Richardson's syndrome (RS) and n=14 with PSP-non RS, disease duration=3.3±2.6yrs, PSP Rating Scale scores=31±13, Schwab and England Activities of Daily Living Scale scores=60±19) and those of 10 age- and gender-matched healthy controls (HCs) were analysed. PET imaging was carried out dynamically 0–60min p.i. of ~300MBq, and distribution volume ratios for the typical tau-in-PSP target regions (globus pallidus, putamen, subthalamic nucleus, substantia nigra and dentate nucleus) were determined in PMOD by MRTM2 and by taking the lower cerebellum as reference region. In the MR images, the MB diameter, MB area, MB/pons area ratio, and MR Parkinsonian Index which also considers the relative (in relation to the middle cerebellar peduncles) atrophy of the superior cerebellar peduncles were measured on a Hermes workstation. **Results:** For the MRI parameters, the MB/pons area ratios and the MR Parkinsonian Index discriminated best between the PSP patients and the HCs (Cohen's d effect sizes=1.96 and 1.54). For the PET parameters, this was the case for the globus pallidus internus and the globus pallidus externus DVRs (1.92 and 1.90). Taking the respective HC data to define normality (mv±2sd) resulted in sensitivities/specificities in the separation between PSPs and HCs of 69%/100% for MR Parkinsonian Index, and of 64%/100% for globus pallidus internus DVRs. Of interest, the combination of MR Parkinsonian Index and globus pallidus internus DVRs (≥1 abnormal parameter defined abnormality) resulted in 78% sensitivity and 100% specificity in discriminating PSPs from HCs. All of the above PET and MRI measures apart from the MR Parkinsonian Index correlated with age (p=0.017 to <0.007), while correlations with the PSP Rating Scale scores were only found for the MRI measures (p=0.001 to <0.001). **Conclusion:** [18F]PI-2620 tau PET has the potential to improve the MR imaging-based PSP diagnosis by providing super-additive information independent of the severity of the clinical phenotype. **References:** None

OP-193

Graph theoretical analysis of the structural connectivity in progressive supranuclear palsy in relation to tau burden: A [18F]PI-2620 PET/MRI study

G. Aghakhanyan^{1,2}, M. Rullmann², J. Rump³, M. L. Schroeter⁴, M. Patt², J. Classen³, O. Sabri², H. Barthel²;

¹Regional Center of Nuclear Medicine, University Hospital of Pisa and Department of Translational Research on New Technologies in Medicine and Surgery, University of Pisa, Pisa, ITALY, ²Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, ³Department of Neurology, University of Leipzig, Leipzig, GERMANY, ⁴Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY.

Aim/Introduction: Progressive supranuclear palsy (PSP) is a primary 4R tauopathy. Evidence supports the concept of disrupted/reorganized structural connectivity in PSP as a consequence of accumulating tau pathology. We aimed to assess the structural connectivity network properties in PSP and their relation to tau burden. **Materials and Methods:** Ten PSP patients (age 72±7 years, 6 female) underwent 60 minutes of dynamic PET imaging following 300 MBq bolus injection of [18F]PI-2620 on an integrated 3T PET/MRI system. The binding potential (BP) was estimated using non-invasive pharmacokinetic modeling (MRTM2 in PMOD) for 88 cortical/subcortical brain regions. DTI was acquired simultaneously and compared to measurements of ten healthy controls (age 65±8 years, 4 female). A graph theory approach was applied to investigate PSP-related structural connectivity network characteristics derived from probabilistic tractography. A possible association between tau load and various graph/vertex attributes was studied. Between-group differences in a given vertex measure was assessed with a vertex-wise general linear model and false discovery rate (FDR)-corrected p<0.05 was considered as significant. Student's t-test and Spearman's rank correlation coefficient were used, respectively, for between-group differences of the global network attributes and their association with BP. **Results:** At the global network level, the number of triangles, density, and the spatial distance were lower, while assortativity degree and vulnerability were higher in PSP patients compared to controls (p<0.05). At the vertex level, transitivity, edge asymmetry, average nearest neighbor strength, "hubness" scores, vulnerability, and eccentricity showed variable group differences (pFDR<0.05). Positive relationships were found between BP in the right cerebellar crus and clustering coefficient (r=0.74, p<0.05); BP in the left rolandic operculum and the global efficiency (r=0.65, p<0.05). Inverse relationships were observed between BP in the right precentral, bilateral frontal regions, caudate and subthalamic nuclei and the network vulnerability (r>0.60, p<0.05). The "hubness" scores demonstrated a negative association with BP in the left cerebellar crus (r=-0.76, p<0.05), and a trend towards significance in the medulla, right cerebellar crus and bilateral cerebellum (r=0.60, p<0.08). **Conclusion:** Graph theory analysis of the brain connectomics depicted various divergences of the structural network properties in PSP patients compared to controls. It seems that PSP-related tau pathology is associated with lower network integration. Cerebellum, cerebellar crus and medulla might impede the smoothness of the information passage in association with increased tau load. These results support the network degradation/reorganization concept in response to tau pathology, and motivate future investigations in a larger PSP patient cohort. **References:** None

OP-194**Aberrant functional connectivity in progressive supranuclear palsy is associated with tau load in the dentate nucleus: A [18F]PI-2620 PET/MRI study**

G. Aghakhanyan^{1,2}, M. Rullmann², J. Rumpf³, M. L. Schroeter⁴, M. Patt², J. Classen³, O. Sabri², H. Barthel²;

¹Regional Center of Nuclear Medicine, University Hospital of Pisa and Department of Translational Research on New Technologies in Medicine and Surgery, University of Pisa, Pisa, ITALY, ²Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, ³Department of Neurology, University of Leipzig, Leipzig, GERMANY, ⁴Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY.

Aim/Introduction: Progressive supranuclear palsy (PSP) is a primary 4R tauopathy. The evidence supports an ongoing reorganization of cortical/subcortical functional connectivity in PSP that might be influenced by tau pathology. Thus, we assayed the functional network connectivity (FNC) with cluster-based inference and the impact of subcortical tau load on cortical/subcortical connectivity in PSP patients. **Materials and Methods:** Ten PSP patients with predominant PSP Richardson/parkinsonian/cortico-basal phenotype (age 72±7 years, 6 female) underwent 60 minutes dynamic PET imaging following 300 MBq bolus injection of [18F]PI-2620 on an integrated 3T PET/MRI system. The binding potential (BP) was estimated using non-invasive pharmacokinetic modeling (MRTM2 in PMOD) within thirteen selected PSP-target regions of interest (ROI), consisted of the putamen, globus pallidus, subthalamic nucleus, substantia nigra, periaqueductal gray matter, red nucleus and cerebellar dentate nucleus (DN). Resting-state fMRI was acquired in 520 echo planar imaging (EPI) volumes in PSP patients and ten healthy controls (age 65±8 years, 4 female) for ROI-to-ROI functional connectivity (RRC) analysis. We used the default atlas-based definition of 132 cortical and subcortical ROIs (a combination of the Harvard-Oxford atlas and the AAL atlas) implemented in the CONN toolbox (v18.a). FNC with cluster-level inferences based on multivariate statistics was applied to create RRC matrices that represent the level of effective connectivity between each pair of ROIs after discounting effects that may be mediated or accounted for by other ROIs. Under the General Linear Model (GLM) framework the between-subject effect and regression model were designed and a two-sided cluster-level false discovery rate (FDR) for multiple testing correction of pFDR < 0.05 was applied. **Results:** In total, 17292 functional connections among 132 ROIs were analyzed. Between-subject effect depicted three clusters, showing increased connectivity between frontal-orbital cortex and cerebellar vermis and decreased connectivity between putamen and mid-temporal gyrus in PSP patients compared to controls (pFDR < 0.05). Regression analysis showed a negative relationship between BP in the

bilateral DN and cerebellar-putaminal/cerebellar-pallidal connectivity (pFDR < 0.05). **Conclusion:** We demonstrated clusters of aberrant cortical-cerebellar and cortical-striatal FNC in PSP patients. Tau-pathology in the cerebellar DN seems to influence the frontal-cerebellar functional connectivity profile. **References:** None

OP-195**HDAC6 distribution in amyotrophic laterals sclerosis**

D. Van Weehaeghe¹, M. Koole¹, J. De Vocht¹, T. M. Gilbert², F. A. Schroeder², J. E. Kranz², J. M. Hooker³, P. Van Damme¹, K. Van Laere¹;

¹UZ/KU Leuven, Leuven, BELGIUM, ²Eikonizo, Cambridge, MA, UNITED STATES OF AMERICA, ³Athinoula A. Martinos Center for Biomedical Imaging, Charlestown, MA, UNITED STATES OF AMERICA.

Aim/Introduction: Histone deacetylase 6 (HDAC6) is a class IIb deacetylase implicated in the deacetylation of the non-histone target tubulin, important for efficient axonal transport (1). In mice and human induced pluripotent stem cell models of amyotrophic lateral sclerosis (ALS) a beneficial effect of HDAC6 inhibition has been demonstrated. Nevertheless, in postmortem tissue no significant difference in HDAC6 mRNA expression level between ALS and controls has been observed. Therefore, in this pilot study we aimed to investigate in-vivo HDAC6 expression changes in ALS patients compared to controls, using ¹⁸F-EKZ-001, a new, promising HDAC6 PET ligand. We hypothesized that HDAC6 expression is increased in patients with ALS as the expression of HDAC6 is co-regulated by TDP-43, a pathological hallmark of ALS. **Materials and Methods:** Ten symptomatic ALS patients (61.9±11.6 years, 5F) were recruited in a tertiary neuromuscular clinic. Ten age- and sex-matched controls (57.0±3.4 years, 5F) were selected from an existing image database (2). All subjects were imaged with ¹⁸F-EKZ-001 using the GE Signa PET-MR scanner. For ALS patients a coffee break protocol, with scanning intervals from 0 to 60 minutes and from 90 to 120 minutes post injection, was used to facilitate patient recruitment and increase comfort (average injected dose 124.8±8.8 MBq). Distribution volume estimates were calculated using a Logan plot with a fixed blood volume of 5% and t* of 40 minutes post injection. VOI- and voxel-based group comparisons were performed (General Linear Model) (p_{height} < 0.001 and p_{cluster FWE-corr} < 0.05). Sex was used as covariate as the first-in-human study showed a significant sex difference in HDAC6 distribution volume (2). **Results:** The voxel-based analysis revealed a global decrease of distribution volume in ALS compared to controls in all cortical and subcortical regions, cerebellum and the brainstem. These findings were confirmed by the VOI-based analysis which showed a significantly decreased ¹⁸F-EKZ-001 uptake in frontal, parietal, temporal, occipital, hippocampus,

pre- and postcentral cortex in ALS compared to controls ($p < 0.01$). At a lower threshold ($p < 0.05$), ^{18}F -EKZ-001 binding was also decreased in striata, thalami and brainstem. No significant interaction effects were observed between group and sex. **Conclusion:** Our results demonstrate HDAC6 is globally decreased in symptomatic ALS patients, in line with the findings of Chen et al. where HDAC6 expression in an ALS mice model was low at disease onset and decreased even more in later stages (3). **References:** 1. ^{18}F -NaF Activity Related with Fibrous Dysplasia of Bone Lesions is Positively Associated with Established Bone Turnover Markers (BTMs)

G. Papadakis^{1,2,3}, G. C. Manikis², A. H. Karantanas¹, K. Marias², M. T. Collins³, A. M. Boyce³;

¹Department of Medical Imaging, Medical School, University of Crete, Heraklion, GREECE, ²Computational Biomedicine Laboratory (CBML), Foundation for Research and Technology Hellas (FORTH), Heraklion, GREECE,

³National Institute of Dental & Craniofacial Research (NIDCR), Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Fibrous dysplasia (FD) of bone is a benign skeletal disorder characterized by replacement of normal bone and normal bone marrow with abnormal fibro-osseous tissue leading to significant morbidity. In a cohort of 15 FD patients we reported positive association between FD-related ^{18}F -NaF activity in the entire skeleton, with established markers of bone activity, including serum levels of alkaline phosphatase (Alk Phos) and osteocalcin (OC), and urine levels of N-terminal telopeptide (NTX) [1]. Aim of the current study was to confirm these findings in a much larger cohort of 44 FD patients. **Materials and Methods:** Forty four FD patients (26 females, 18 males) underwent whole-body ^{18}F -NaF-PET/CT scans at the NIH Clinical Center. Mean age \pm std at the time of the scan was: 30.1 \pm 14.9 years. PET scans were obtained (mean \pm SD) 61.8 \pm 5.1 minutes after intravenous administration of an average \pm std of 2.69 \pm 0.73mCi of ^{18}F -NaF. Low dose, non-

contrast, CT scans were acquired for co-registration and attenuation correction purposes. FD-related ^{18}F -NaF activity was assessed by using MIM vista (version 6.5.9). Firstly, a VOI encompassing the entire skeleton was drawn, and afterwards a SUVmax threshold-based approach -customized per patient- was employed in order to include all FD-related bone uptake. Separate VOIs encircling all areas above the SUVmax threshold, were automatically generated, while areas with physiologic or non-FD related ^{18}F -NaF activity (e.g. activity in the urinary tract, inflammatory uptake) were manually removed. Subsequently, the following skeletal disease indices were automatically obtained: Total Volume (TV) of all ^{18}F -NaF positive skeletal FD lesions and FD-related ^{18}F -NaF activity (TA) in the entire skeleton determined as the product of TV multiplied by SUVmean of all FD lesions (TA = TV \times SUVmean). **Results:** Pearson's correlation test revealed that TV and TA obtained from ^{18}F -NaF-avid FD-lesions in the entire skeleton were positively associated with serum levels of alkaline phosphatase, osteocalcin and urine levels of NTX:(TV: $r=0.744$, $p < 0.001$ Alk Phos; $r=0.429$, $p=0.013$ OC ; $r=0.746$, $p < 0.001$ NTX)(TA: $r=0.460$, $p=0.009$ Alk Phos; $r=0.382$, $p=0.022$ OC ; $r=0.475$, $p=0.007$ NTX)(P-values were adjusted for false discovery rate) **Conclusion:** We confirm in a larger cohort of FD patients that FD-associated ^{18}F -NaF activity strongly correlates with established bone turnover markers, further enhancing the finding that ^{18}F -NaF-PET/CT accurately reflects underlying bone processes encountered in FD, and implying the employment of the modality for the in vivo assessment of FD activity. **References:** 1. Papadakis GZ, et al. " ^{18}F -NaF PET/CT IMAGING IN FIBROUS DYSPLASIA OF BONE." J Bone Miner Res. 2019 Sep;34(9):1619-1631.

Lesional uptake decreases on [^{18}F]NaF PET-CT in patients with Fibrous Dysplasia/McCune Albright syndrome treated with Denosumab

W. van der Bruggen^{1,2}, M. E. Meier^{3,4}, F. Smit^{1,5}, P. D. S. Dijkstra^{3,4}, L. E. M. Winter³, L. F. de Geus-Oei^{1,6}, N. M. Appelman-Dijkstra³, D. Vriens¹;

¹Section of Nuclear Medicine, dept. of Radiology, Leiden University Medical Center (LUMC), Leiden, NETHERLANDS, ²Dept. of Nuclear Medicine, Slingeland Hospital, Doetinchem, NETHERLANDS, ³Center for Bone Quality, dept. of Internal Medicine, division of Endocrinology, Leiden University Medical Center (LUMC), Leiden, NETHERLANDS, ⁴Dept. of Orthopaedic surgery, Leiden University Medical Center (LUMC), Leiden, NETHERLANDS, ⁵Dept. of Nuclear Medicine, Alrijne Hospital, Leiderdorp, NETHERLANDS, ⁶Biomedical Photonic Imaging Group, University of Twente, Enschede, NETHERLANDS.

Aim/Introduction: [$^{99\text{m}}\text{Tc}$]-TcHDP uptake does not change after bisphosphonate-treated Fibrous Dysplasia (FD). Despite the recently described relation between FD

disease burden measured with [^{18}F]NaF PET-CT and serum biomarkers of bone turnover, the effect of treatment on lesional [^{18}F]NaF-uptake in patients with FD is unknown. **Materials and Methods:** We retrospectively studied fifteen FD patients who underwent [^{18}F]NaF PET-CT at least twice (37 scans) and received antiresorptive treatment. Baseline and follow-up [^{18}F]NaF-uptake parameters of healthy bone and FD-lesions and serum biomarkers of bone turnover around treatment with denosumab (n=8) or on bisphosphonates (n=7) were assessed. **Results:** Individualized patient healthy bone cut-offs on [^{18}F]NaF PET-CT were again found to be preferential over a fixed cut-off for adequate normalization. This individual cut-off did not change in the whole group (p=0.233), nor after denosumab (p=0.237) or bisphosphonates (p=0.575) treatment. However, volumetric parameters of FD-burden on [^{18}F]NaF PET-CT showed significant decrease after start of denosumab. Median fluoride total volume (FTV), previously shown to be the preferred [^{18}F]NaF PET-CT parameter to quantify FD burden [3], decreased from 199 cm³ on baseline scan to 97 cm³ during follow-up (p=0.030). However, FTV did not change in patients receiving bisphosphonates (p=0.249). FTV correlated positively with serum biomarkers Alkaline Phosphatase (ALP) ($\rho_{\text{Spearman}}=0.406$; p=0.006; n=37) and with P1NP ($\rho_{\text{Spearman}}=0.730$; p<0.001; n=36). Relative changes in FTV and either serum biomarker of bone turnover correlated positively (ΔFTV versus ΔALP and ΔP1NP , $\rho_{\text{Spearman}}=0.518$ and 0.489; p=0.024 and 0.032, respectively). When trichotomizing changes in imaging-parameters and serum biomarkers in 'increasing' (>+10%), 'unchanged' or 'decreasing' (<-10%), moderate agreement of categorized FTV change with categorized ALP change were observed (Cohen's $\kappa = 0.432$; p=0.007; n=35) and fair agreement with categorized P1NP change (Cohen's $\kappa = 0.391$; p=0.017; n=34). In several patients, either ALP or P1NP (n=5) or both (n=3) were within laboratory reference ranges at both time points, still FTV adequately quantified disease and response to antiresorptive treatment, as measured by pain scores, and possibility to reduce pain medication. **Conclusion:** FD-disease burden measured by FTV on [^{18}F]NaF PET-CT correlates with changes in serum biomarkers of bone turnover after antiresorptive treatment. No changes were seen in healthy bone [^{18}F]NaF-metabolism during follow-up. Therefore [^{18}F]NaF PET-CT could be used as an objective parameter of local treatment response in FD in addition to serum biomarkers of bone turnover, pinpointing location and extension of FD-burden. [^{18}F]NaF PET-CT might be of paramount importance in patients with normal(ized) serum biomarkers but clinical complaints. **References:** None

OP-199

Ultrafast 10x whole-body Na¹⁸F digital photon counting PET/CT for assessing osteoblastic metastases: A Phase 1a intra-individual comparison trial

C. Wright, K. Binzel, Y. Hsieh, E. Folefac, D. A. Diaz Pardo, D. G. Stover, M. V. Knopp;
The Ohio State University, Columbus, OH,
UNITED STATES OF AMERICA.

Aim/Introduction: Sodium fluoride (Na¹⁸F) PET/CT is used clinically for the detection and characterization of osteoblastic lesions in both oncologic and non-oncologic patients. In patients with symptomatic bony disease, standard whole-body Na¹⁸F PET image acquisition times (60 - 120 s/bed) remain longer than desired and new approaches to meaningfully reduce whole-body PET image acquisition time are needed. New clinical PET/CT systems equipped with digital photon counting PET (dPET) detector technology enable new approaches to reduce PET image acquisition times even at reduced PET radiotracer doses. The aim is to assess a 10x faster, whole-body, Na¹⁸F PET imaging approach using dPET/CT technology for the detection and assessment of osteoblastic lesions. **Materials and Methods:** This Phase 1a intra-individual comparison trial of whole-body Na¹⁸F dPET/CT (Vereos, Philips) was performed using target Na¹⁸F doses of 185 MBq in 55 oncologic patients. Investigational dPET acquisitions were performed at a 10x faster rate of 9 s/bed (~80 min post injection) and then at the standard 90 s/bed (~85 min post injection). All dPET image data sets were reconstructed using standard definition voxel volumes (4x4x4 mm³) and Time-of-Flight. Using an Intellispace Portal workstation, all matched and individual data sets were reviewed by a blinded reader panel to assess lesion detectability as well as overall image quality and background quality. **Results:** All 55 patients had evaluable dPET datasets (n = 110) for qualitative and quantitative assessment of osteoblastic lesions and ¹⁸F biodistribution. With ultrafast 9 s/bed dPET acquisitions, ¹⁸F-avidity within normal bone and osteoblastic lesions was visually comparable to the standard 90 s/bed acquisitions and no discordant osteoblastic lesions were identified. Average SUVmean values were comparable for 9 s/bed and 90 s/bed acquisitions in terms of ¹⁸F activity in normal vertebral bone (6 ± 1 and 6 ± 1, respectively) and background skeletal muscle (0.6 ± 0.1 and 0.7 ± 0.1, respectively). The average SUVmax of 85 osteoblastic metastases were also comparable for 9 s/bed and 90 s/bed acquisitions (31 ± 31 and 36 ± 32, respectively and not significantly different). **Conclusion:** Given the unmet clinical need for shorter PET image acquisition times in oncology patients with symptomatic body disease, this Phase 1a trial demonstrates that 10x faster whole-body Na¹⁸F PET imaging (~3 min total PET imaging time) is achievable with digital photon counting PET detector technology without loss of overall image quality, lesion detectability or quantitative accuracy. **References:** None

OP-200**Hybrid bone SPECT/CT with diagnostic-quality CT for recurrent pain following spinal fusion surgery: accuracy and impact on clinical management**

B. Lambert¹, B. Van Den Bossche², J. Bleyen², J. Mertens², T.

Matton², T. Vandekerckhove², T. Van den Wyngaert³;

¹Maria Middelaers Hospital and Ghent University,

Gent, BELGIUM, ²Maria Middelaers Hospital,

Gent, BELGIUM, ³UZA, Antwerp, BELGIUM.

Aim/Introduction: We designed a retrospective study to 1. investigate the sensitivity and specificity of bone SPECT/CT for identifying a pain generator in the post-operative spine 2. document the impact of bone SPECT/CT on the clinical management. **Materials and Methods:** We selected patients referred to our department for bone scintigraphy because of recurrent pain following cervical or lumbar spondylosis. We limited our search to patients referred by a single experienced neurosurgeon within a 6-24 months post-surgery. The SPECT/CT images with non contrast enhanced diagnostic quality CT were acquired on Symbia T6 and Intevo T6 SPECT/CT-cameras (Siemens). SPECT/CT-scans were re-read by 2 experienced nuclear medicine specialists, blinded to the clinical data. A radiologist read the diagnostic CT-scan and a joint diagnosis was proposed. A standardized scoring method was used, aiming to assess the surgical spine levels as well as potential pain generators outside the operated spine levels (adjacent disc-or facetarthrosis, referred pain from the pelvis, hips or shoulders). All patient files were reassessed and all the applied therapeutic strategies were listed. The neurosurgeon retrospectively established a final clinical diagnosis, taking into account all available follow up data. **Results:** We included 71 patients: 23 males vs 48 females, median age of 50 years (min 26-max 83 y). A total of 77 SPECT/CT-scans (18 cervical vs 59 lumbar spine) were included since 6 patients were scanned twice. The mean interval since surgery was 15 months. In 4 patients no explanation for the pain was found, when retrospectively reviewing the clinical file. In the other patients the final clinical diagnoses were pseudoarthrosis or delayed union (32%), screw loosening (15%), screw irritation (16%), adjacent segment disease (26%), extraspinal referred pain (8%). Hybrid bone SPECT/CT did not yield any positive finding in 9 scans, of which 4 also remained clinically without diagnosis. At the fusion levels SPECT/CT showed a sensitivity of 98% and a specificity of 73%. For pain generators identified outside the fusion level, sensitivity and specificity of SPECT/CT were 97% and 94%. The positive SPECT/CT findings impacted the clinical management in 55 out of 77 cases. SPECT/CT-scan guided the treatment strategy completely and partly in 42% and 38%, respectively. **Conclusion:** A systematic reanalysis of bone SPECT/CT studies with diagnostic-quality CT acquisitions in homogeneous group of patients after spinal

fusion surgery showed a good sensitivity and specificity for identifying the main pain generator. SPECT/CT affected clinical management in 80% of patients. **References:** None

OP-201**Tc-99m-diphosphonate bone scan quantification: Fibrous dysplasia versus metastasis of prostate cancer**

M. Jreige, F. Becce, B. Rozier Aubry, N. Schaefer, J. O. Prior, M.

Nicod-Lalonde;

Lausanne University Hospital, Lausanne, SWITZERLAND.

Aim/Introduction: Bone scintigraphy with Tc-99m-labeled diphosphonate can identify fibrous dysplasia (FD), which typically exhibits markedly increased tracer uptake. Metastatic bone lesions of prostate cancer also show similar scintigraphic aspect on delayed planar images. The aim of this study was to investigate the emerging role of Tc-99m DPD uptake quantification to compare the value of SUV in FD and metastases. **Materials and Methods:** We retrospectively assessed 8 patients (49±15y) with a confirmed diagnosis of FD and 9 patients (79±13y) with known bone metastases from prostate cancer. SPECT/CT images were acquired with the Siemens Symbia Intevo providing SUV quantification on post-processed images. SUVmax, SUVmean and SUVmin were measured in all suspicious bone lesions, as well as in normal bone in both groups. **Results:** A total number of 77 FD and 73 metastatic bone lesions were analyzed, showing a median SUVmax, SUVmean and SUVmin (g/mL) with a 95% CI of 10.1 (3-44.8), 6.2 (1.9-25.3) and 4.3 (1.2-17.9), and 28.5 (9.8-114), 17.2 (6.3-85.3) and 11.4 (3.9-45.6), respectively. SUVmax, SUVmean and SUVmin were significantly lower in FD compared to metastases (p<0.001). Normal bone uptake showed significantly lower uptake value of SUVmax, SUVmean and SUVmin in the FD group as compared the metastatic groups (p≤0.005). **Conclusion:** This study shows a significant difference in diphosphonate uptake on bone scan between FD and prostate metastases based on quantitative data analysis, with lower SUVmax, SUVmean and SUVmin in FD. Therefore, further analysis of bone scan quantitative data can be helpful in characterizing bone lesions. **References:** None

OP-202**SPECT/CT with ^{99m}Tc-Tektrotyd in imaging tumors secreting fibroblast growth factor 23 (tumor-induced osteomalacia)**

K. Slashchuk, M. Degtyarev, P. Rumyantsev, S. Serzhenko, O.

Baranova, A. Trukhin;

Endocrinology Research Center, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Tumor-induced osteomalacia (TIO) is a rare paraneoplastic syndrome usually caused by tumors that overexpress fibroblast growth factor 23 (FGF23) with phosphaturic effect. The clinical signs of TIO are non-

specific and include fatigue, bone pain, muscle weakness, pathological bone fractures and compression fractures of the vertebrae, which makes timely diagnosis of the disease difficult and treatment is often delayed. Well-timed diagnosis is essential and if combined with complete tumor resection leads to complete relief of symptoms. Due to the risk of recurrence or metastases, patients with TIO require long-term management and follow-up. The article presents an analysis of 10 patients with TIO of various localizations who underwent somatostatin receptor scintigraphy (SRS) and SPECT/CT. Radiopharmaceutical was used as a tracer for SRS: it was prepared on the basis of a lyophilisate developed by Polatom (Poland) — Tektrotyd, EDDA/HYNIC-TOC labeled with ^{99m}Tc . **Materials and Methods:** Prospective study included 10 cases of patients aged 20–62 years (mean age $39,9 \pm 9,4$), mean duration of osteomalacia was 7,4 years. Female to male ratio was 1:1. In all cases of biochemically confirmed TIO, the average levels were, blood P: $0,49 \pm 0,09$ mmol/l (N: 0,74–1,52); urine P in 24 hours: $43,3 \pm 18,1$ mmol/l (N: 12,9–43,9); alkaline phosphatase $366,7 \pm 220,9$ U/l (N: 40–150). Scintigraphy was performed with SPECT/CT (GE model 670 Discovery NM/CT) in 2–4 hours after intravenous administration of 500–700 MBq of ^{99m}Tc -Tektrotyd. **Results:** Tumor localization was determined in 9 (90%) of 10 patients. In 3 cases the tumor found in soft tissue of: popliteal region, 2 - femur, 1 - tibia, 1 - inguinal region, 1 - plantar side of the foot, 1 - in the left ethmoid labyrinth of the skull bones. In 3 cases imaging was performed after previous surgical treatment (tumor recurrence). All 9 patients underwent surgery with the diagnosis being confirmed by histological examination. In 1 case tumor was not visualized and patient is following up. **Conclusion:** SPECT/CT with ^{99m}Tc -Tektrotyd demonstrated good capacity in molecular imaging of osteolytic tumors secreting fibroblast growth factor 23 that cause the phosphopenic form of tumor-induced osteomalacia with severe bone disorders. It can be used as an alternative to PET/CT with ^{68}Ga -labeled octreotide peptides if it's not available. Further investigations of diagnostics accuracy in compare with PET/CT have to be evaluated. **References:** None

OP-203

Bone scintigraphy in oncological patients: The added value of SPECT-CT

D. Vega, M. J. Tabuenca Mateo, V. Godigna Guilloteau, A. Galiana Moron, S. Ruiz Solis, M. Martin Ferrer, E. Martinez Albero, P. Pilkington Woll, P. Sarandeses Fernandez, A. Gomez Grande, J. M. Estenoz Alfaro;
Hospital 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: The objective of this study is to determine the impact of carrying out an additional study SPECT-CT in cancer patients who have undergone a total body scan with bone scintigraphy showing indeterminate

findings. **Materials and Methods:** For our study, we have retrospectively selected in our hospital all SPECT-CT (Single-photon emission computed tomography-computerized tomography) studies performed in cancer patients with undetermined bone scans during the year 2019. A total of 73 SPECT-CT studies were performed in patients with various oncological pathologies (15.07% prostate, 31.51% breast, 9.59% lung, 2.74% kidney, 19.18% gastrointestinal, 2.74% melanoma, 15.07% head and neck, and 4.1% other tumors). The mean age was 66 years (35–91 years), 43.83% were men and 56.17% women. Bone scintigraphy, SPECT-CT, CT and MRI (performed when necessary) were analyzed in each patient. The findings were divided into two categories: malignant lesions and benign / indeterminate lesions in each of the imaging tests. The lesions were considered malignant on the SPECT-CT when areas appeared with increased uptake distributed asymmetrically, longitudinal rib lesions and, in regards to the spine, lesions with increased uptake in the pedicles, the posterior segment or the entire vertebral body. Afterwards, a comparison was made between these findings and the final diagnosis established by the oncologist, based on the results (laboratory and imaging studies) and the treatment received focusing on the newly diagnosed lesions. **Results:** The analysis of the lesions detected with bone scintigraphy obtained a sensitivity of 96%, and a specificity of 35%. SPECT-CT obtained a sensitivity of 96% and a specificity of 95%. CT achieved a sensitivity of 92% and a specificity of 92%, and MRI had a sensitivity and specificity of 100% in the 10 indeterminate cases, in which it was necessary to clarify the nature of the lesions. **Conclusion:** The increased sensitivity and specificity of SPECT-CT compared to conventional bone scintigraphy in cancer patients allows to determine more precisely the nature of the lesions and reduces the number of additional diagnostic test, thus allowing for earlier and more specific treatment. **References:** None

OP-204

^{18}F - FDG PET/CT in Synovial Sarcoma: Staging, Response and Surveillance

S. Datta Gupta, G. Arora, S. Shamim, T. P. Singh, P. Kaushik, R. Kumar;
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Synovial sarcoma (SS), a rare soft tissue sarcoma (STS), contributes to 6–10% of all STS. Due its insidious nature of onset, diagnosis and induction of treatment is often delayed. Long term local as well as metastatic recurrence is often seen, with up to 50% of local recurrence occurring in 2 years and 50–70% of metastases in 5 years after completion of treatment. We aimed to assess the role of ^{18}F -FDG PET-CT in staging at baseline, treatment monitoring and long-term follow-up of SS. **Materials and Methods:** All patients of SS, who were referred for ^{18}F -FDG

PET/CT to our department from July 2017 to February 2020, were retrospectively analyzed in this study. Indications for PET/CT included baseline staging, post excision residual disease, response assessment and surveillance. PET/CT was acquired 45–60 minutes after i.v. injection of 8–10mCi ^{18}F -FDG. Two expert nuclear physicians independently analyzed the images of PET/CT. Response was assessed as per PERCIST criteria. Cases were followed up clinically thereafter. **Results:** Fifty studies in 33 patients (17 male; 16 female) were analyzed. Mean age of the patients was 27.7 ± 10.5 years. Ten of the 50 scans (20%) were referred for baseline staging, 9 (18%) for post excisional status, 24 (48%) for response assessment and remaining 7 (14%) were for surveillance. Among the baseline evaluations most common site of primary was found to be lower limbs (50%), and additional involvement of lung (50%), lymph nodes (40%) and skeletal (10%) sites were also observed. Of the nine post-resection scans, four showed residual disease, 2 had lung nodules, 5 had lymph nodal involvement and two scans were normal. Of the 24 response scans, eight (33%) showed complete metabolic response, 7 (29%) had partial metabolic response, 8 (33%) had stable disease and 1 (5%) had progression on FDG scan. Amongst the seven patients on surveillance post completion of treatment, four were positive on PET/CT. Two of these four cases revealed local recurrence (1 in lower limb, 1 in neck), one showed local recurrence (in lower limb) along with lung metastases and another scan revealed only pulmonary metastases. **Conclusion:** ^{18}F -FDG PET-CT may have a significant role in steering the management of synovial sarcoma by baseline staging, response assessment as well as detecting recurrent and residual disease. Since its long-term recurrence is relatively common, ^{18}F -FDG PET-CT can be considered as an important tool in the surveillance of synovial sarcoma for timely detection and management of recurrence. **References:** None

OP-205

Role of ^{18}F FDG PET/CT in Staging and Determining the Grade of Soft Tissue Sarcoma. Relationship between Metabolic Parameters and Histopathological Features in Primary Lesion

A. Blanes, M. N. Cabrera Martín, L. García Beláustegui, C. G. Wakfie Corieñ, R. Valhondo Rama, M. García García-Esquinas, A. Crespo Rodríguez, L. Ortega Medina, J. L. Carreras Delgado; Hospital Clínico San Carlos, Madrid, SPAIN.

Aim/Introduction: The aim of this study was to analyze different metabolic biomarkers of pretreatment ^{18}F -FDG PET/CT in soft tissue sarcoma (STS) located in trunk and limbs and to correlate them with tumor grade and necrosis. **Materials and Methods:** Consecutive patients (five years) with ^{18}F -FDG PET/CT for initial staging of STS with histopathological study (surgical specimen) of the primary

tumor (gold standard). SUVmax, SUVpeak, MTV, TLG and texture parameters (first and second order, LIFEx software) were calculated. Statistical analysis with non-parametric tests and ROC curves. **Results:** 50 patients (32 males), 59.9 years (18–90). 34 local disease, 4 N1 and 8 N1M1. SUVmax/SUVpeak/TG2.5 ($p < 0.05$) differences between degrees were observed. SUVmax was the best predictor of tumor grade. In grade 1 ($N = 7$) SUVmax average 3.2, grade 2 ($N = 11$) of 11.2 and grade 3 ($N = 32$) of 19.8; $p < 0.05$. Optimal SUVmax to predict high grade was 10.9 (AUC-ROC: 0.865), sensitivity 78%, specificity 88.9%. Malignant fibrous histiocytoma (SUVmax 30.1), angiosarcoma (25.1), malignant peripheral nerve sheath tumor (24.1), leiomyosarcoma (16.7), and liposarcoma (10.9) showed higher uptake intensity. SUVmax/SUVpeak were significantly higher in those patients with lymph node extension and distant disease ($p < 0.05$). Subtypes with the highest dissemination were: malignant fibrous histiocytoma (4/8), malignant peripheral nerve sheath tumor (4/7), leiomyosarcoma (2/8) and desmoplastic round cells (2/2). First order texture parameters (entropy, energy and obliqueness) and most of second order parameters showed significant differences between necrotic tumors (scores 1–2) and non-necrotic tumors (score 0) and between histological grades. However, these data have not been contrasted with progression-free survival and overall survival, because most of patients have been recently diagnosed. **Conclusion:** ^{18}F -FDG PET/CT can be a useful tool in the staging of STS, especially in grades 2–3 and in subtypes with a greater probability of distant spread. Texture parameters could provide additional prognostic information. **References:** None

OP-206

SCOREp of clinical and FDG-PET/CT features at staging as risk index of poor response and relapse in Ewing Sarcoma

A. Martini¹, M. Allocca¹, R. Di Dato¹, M. Di Paolantonio¹, I. Pagliani², E. Spinelli², D. Volterrani², R. Sciagrà¹, C. Olianti¹; ¹University of Florence, Florence, ITALY, ²University of Pisa, Pisa, ITALY.

Aim/Introduction: The risk of poor histo-pathological response (HP-R) after induction-chemotherapy (i-CHT) and primary tumor (PT) surgery and relapse in Ewing Sarcoma (ES), is not evaluable at staging. Prognosis depends overall from the necrosis percentage found after i-CHT and PT surgical resection. We tested the prognostic power of clinical and ^{18}F FDG-PET/CT features for predicting risk of poor response and relapse in a 5-years follow up. **Materials and Methods:** 39 Patients with ES, 24 males (61%) and 15 females (39%) were enrolled in ISG-EW1(26) and ISG-EW2(13) protocols. We evaluated age at staging, PT SUVmax, TLG41% (Tumor Lesion Glycolysis 41%) and diameters ratio at the staging vertex-feet ^{18}F FDG-PET/CT. Than SCOREp was calculated as the value attributed to

each parameter proportionally (p) to the $\text{Exp}(B)$ of Cox regression, by multiplying it by 10 and approximating to the unit: 10 for $\text{age} < 12.5$, 12 for $\text{SUV}_{\text{max}} > 4.8$; 3 for $\text{TLG}_{41\%} > 136.13$, and 10 for diameters ratio < 1.46 . Otherwise the SCOREp was considered null. Total SCOREp was the sum of the single values. For statistical analysis we used U-test of Mann-Whitney, ROC-analysis, univariate/multivariate Cox regression and Kaplan-Maier curve-analysis. **Results:** Patient age was 13.9 ± 6.2 y (range: 2–29); 28 localized (72%) and 11 metastatic (28%) ES. ROC-analysis related to HP-R showed a significant AUC for SUV_{max} (0.76, $p = 0.02$; cut-off 5.5, 79% spec., 60% sens.) and $\text{TLG}_{41\%}$ (0.72, $p = 0.04$; cut-off 127.69, 71% spec., 67% sens.). ROC-analysis for relapse showed AUC for SUV_{max} (0.81, $p = 0.03$; cut-off 4.8, 71% sens., 86% spec.), $\text{TLG}_{41\%}$ (0.80, $p = 0.03$; cut-off 136.13, 79% sens., 86% spec.), age (0.80, $p = 0.03$; cut-off 12.5 y, 64% sens., 86% spec.) and diameters ratio (0.83, $p = 0.02$; cut off 1.46, 86 % sens., 71 % spec.). Mean \pm SD SCOREp was 9.7 ± 1.57 for Good Responders (48%) and 23.29 ± 0.43 for Poor Responders (52%) ($p < 0.001$). Mean \pm SD SCOREp was 13.24 ± 2.42 for not-relapsed ES and 23.72 ± 0.6 for relapsed-ES ($p < 0.008$). ROC-analysis for SCOREp revealed statistical significance AUC for HP-R (0.81, $p = 0.001$) and the risk of relapse (0.75, $p = 0.007$) with a cut-off SCOREp value of 24 (80% sens., 79.2% spec., 79% accuracy for HP-R and 77.8% sens., 67% spec. and 69% accuracy for risk of relapse). **Conclusion:** SCOREp seems able to summarize the capability of baseline variables to predict the evolution of HP-R in good or poor responders, and the risk of relapse. It could be therefore useful to stratify ES prognosis at staging PET/CT. **References:** None

Salivary gland dosimetry in therapy of metastatic castrate-resistant prostate cancer with ^{177}Lu -PSMA-617

C. Happel, L. Völler, W. T. Kranert, J. Baumgarten, D. Gröner, F. Grünwald, A. Sabet;

University Medical Center Frankfurt, Department of Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: Therapy with ^{177}Lu -PSMA-617 is established for the treatment of metastatic castrate-resistant prostate cancer. Prostate-specific membrane antigen (PSMA) is a surface protein expressed on prostate cancer cells and is the target structure for the therapeutic radioligand ^{177}Lu -PSMA-617. It is also expressed physiologically on kidney and salivary gland (SG) tissue. Therefore, these tissues should be monitored for accumulated dose. The German Society of

Nuclear Medicine recommends a non-dose limiting toxicity limit of 40Gy for SGs. Aim of this study was to calculate the dose to the salivary glands and to evaluate it in comparison to the above recommendation. **Materials and Methods:** Sixty ^{177}Lu -PSMA-617 therapy cycles of 21 patients were evaluated retrospectively. Median age of the patients was 74.7 years (59.6–88.8) at administration and median administered activity was 7.1 GBq (1.1–11.2). The masses of the SGs were determined by PET/CT-isocontouring (40%) with an assumed volumic mass of $1\text{g}/\text{cm}^3$. Dosimetry of 120 parotid and 104 submandibular glands was performed. To ensure reliable measurement quality of the two smaller major SGs the calculation of both the submandibular and sublingual glands was summed-up. The monitoring process implemented whole-body scintigraphy imaging 24, 48 and 72h after administration from which doses were calculated with a mono-exponential fit in MS-EXCEL-2010 describing the activity over time. **Results:** Mean masses of the parotid and submandibular glands were 21.4 ± 11.8 and 7.46 ± 2.96 g, respectively. Mean activity of parotid and submandibular glands was 7.05 ± 5.92 and 3.67 ± 3.52 MBq correlating to 0.10 and 0.05% of the administered activity. Mean dose of the parotid and submandibular glands was 1.59 ± 1.75 and 2.43 ± 2.79 Gy. Mean dose per administered activity of the parotid glands was 0.25 ± 0.27 Gy/GBq and of the submandibular glands 0.36 ± 0.50 Gy/GBq. The mean effective half-life was 29.1 ± 9.81 and 32.7 ± 22.2 h for the parotid and submandibular glands. **Conclusion:** The accumulated dose could be reliably monitored applying the presented method. Assuming an administered activity of 6 GBq per cycle and postulating the calculated mean dose, 20 treatment cycles are necessary to exceed the dose limit of 40 Gy. However, assuming the maximum calculated dose (2.8 Gy/GBq) the dose to the SGs may converge to that limit in rare individual cases within 3 treatment cycles. In special cases when SGs may be affected in the past, their function should be monitored dosimetrically and included in the therapeutic considerations. **References:** None

EPS-036

Dosimetric evaluation of the lacrimal glands in patients undergoing therapy with ^{177}Lu -PSMA

C. Happel, L. Völler, W. T. Kranert, D. Gröner, B. Bockisch, C. Nguyen Ngoc, F. Grünwald, A. Sabet;

University Medical Center Frankfurt, Department of Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: Targeted treatment with ^{177}Lu -labelled prostate-specific membrane antigen ligands (^{177}Lu -PSMA-617) represents a promising therapeutic option for patients with metastatic castration-resistant prostate cancer. It is amply documented and investigated that ^{177}Lu -PSMA physiologically accumulates in the kidneys and the salivary glands. Although the lacrimal glands (LG) are

affected as well, it is unusual to monitor them dosimetrically in daily routine. This study aims to calculate and discuss the organ dose to the LG of patients undergoing ^{177}Lu -PSMA therapy. **Materials and Methods:** For dosimetric evaluation 50 ^{177}Lu -PSMA therapies with a total of 100 LGs were included. The mean administered activity was $6,809 \text{ MBq} \pm 29\%$. The mean age of the patients was $75 \text{ years} \pm 9\%$. Dosimetric analysis was performed by a region-based analysis using the ventral views of scintigraphic scatter corrected whole-body images one, two and three days post administration with an Anyscan scintillation camera (Mediso) (scan speed: 20 cm/min; matrix 256×1024 pixel, symmetric window at 208 keV; width 20%; 3-window scatter correction). Absolute quantification was achieved by previous performed sensitivity calibration for ^{177}Lu for the scintillation camera. **Results:** The mass of each LG was calculated by a region-based analysis using the metabolic volume (40% isocontour) from accompanying ^{68}Ga -PSMA-PET/CT. The density of LGs was assumed as 1 g/cm^3 . The mean mass of the 100 LGs was $1.9 \text{ g} \pm 49\%$. The calculated mean accumulated activity in the LGs was $1.6 \text{ MBq} \pm 74\%$ corresponding to $0.023\% \pm 65\%$ of the administered activity. The organ dose was calculated by integration of the exponentially fitted time activity curve. ^{177}Lu -PSMA dosimetry indicated a mean organ dose of $4.57 \text{ Gy} \pm 111\%$ per administration, corresponding to a mean activity-related dose of $700 \text{ mGy/GBq} \pm 105\%$. Mean effective half-life in the LG was $27.8 \text{ h} \pm 33\%$. **Conclusion:** Assuming a dose of 700 mGy/GBq and an administered activity of 7.4 GBq , a total of eight ^{177}Lu -PSMA therapy cycles is possible without exceeding the threshold of 40 Gy to the LGs that is known to cause organ damage. However, assuming the worst-case scenario of the maximum determined dose (3.490 mGy/GBq), two ^{177}Lu -PSMA therapy cycles may lead to an exceedance of the threshold. A ROI-evaluation of the ventral views of scintigraphic whole-body images 1, 2 and 3d post administration appears to be adequate for dosimetry of the LG. The LG are not dose-limiting organs at risk. However, an individual calculation of the organ dose may help to explain affections of dry eyes and initiate therapy especially when patients are treated with several cycles. **References:** None

Performance comparison of different dosimetry methods with respect to complexity and accuracy

J. Brosch¹, C. Uribe², A. Gosewisch¹, L. Kaiser¹, P. Bartenstein¹, A. Todica¹, H. Ilhan¹, A. Rahmim³, A. Celler³, S. Ziegler¹, G. Böning¹; ¹University Hospital, LMU Munich, Munich, GERMANY, ²PET Functional Imaging, BC Cancer, Vancouver, BC, CANADA, ³Department of Radiology, University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: Personalized dosimetry is of great importance for the improvement of therapy outcome.

Different facts hinder the implementation of dosimetry in clinical workflows. The existing dosimetric approaches require varying numbers of processing steps, computation effort, manpower and time. The aim of this study is to directly compare the required resources and the accuracy of the absorbed dose estimates of three different dosimetry approaches using organ-specific S-values derived from simulations with reference phantoms, more advanced voxel-S-values (VSVs) simulated for a specific tissue type, and patient-specific full Monte Carlo (MC) simulation. **Materials and Methods:** Seven Lutetium-177-PSMA-I&T patients ($8.12 \pm 0.78 \text{ GBq}$) with QSPECT/CT 24h, 48h, 72h p.i. were evaluated. Rigid registration was applied based on CTs. Whole-body and kidneys were delineated on the 24h CT. Tumor lesions were segmented via k-means algorithm on 24h SPECT (PMOD v4.005). VOI-based effective half-life was determined from mono-exponential fitting. Subsequently a time-integrated activity map (TIAM) was generated for each patient. Doses to kidneys and bone lesions estimated with OLINDA and with soft-tissue Lu-177-VSVs from GATE v8.2 MC simulations convolved with TIAM (with MATLAB R2019b) were compared with values from GATE MC simulations using patient CT and TIAM. Processing times and required staff were compared. **Results:** OLINDA S-values were adjusted for patient organ/tumor mass. The mean percentage difference compared to MC for kidneys was -2% (OLINDA), $+1\%$ (VSVs); for 102 tumors $+9\%$ (OLINDA), $+19\%$ (VSVs). MC simulation of VSVs and full patient MC required a physicist. All methods required the same segmentation efforts. OLINDA requires fitting and no image creation and is fast (incl. pre-processing $<30 \text{ min}$). VSVs need to be simulated only once. VSV dosimetry performance was as fast as OLINDA. Full MC simulation per patient was run on 20 parallel CPUs and took 5h (simulation+preprocessing). **Conclusion:** For kidney dosimetry, all approaches revealed comparable dose results. OLINDA and VSV showed a strong overestimation and are therefore less appropriate for bone lesion dosimetry. OLINDA and VSVs assume soft tissue density instead of the actual bone density. However, OLINDA and VSVs were comparable with respect to organ dosimetry and time effort. MC, in contrast, requires powerful computers, is slow compared to both other methods, and requires specially trained personnel. Yet, MC can account for tissue heterogeneities and provides most accurate dose estimates for all volumes of interest (organs+tumors). Further investigations regarding bone lesion dosimetry methods, e.g. with density adjustments, are required. **References:** None

EPS-038

Determination of tumour control probability curves for treatments with ^{225}Ac -PSMA of metastatic castration resistant prostate cancer by means of microdosimetry calculations

P. Miguez Gabiña, A. Esteban Figueruelo, M. Nevares Herrero, R. Valverde Jorge, R. Nuñez Muñoz, Y. Carreres Ortega, I. Fernandez Tercero, E. Rodeño Ortiz de Zarate; Osakidetza, Barakaldo, SPAIN.

Aim/Introduction: The aim of this study was to determine tumour control probability curves (TCP) for treatments with ^{225}Ac -PSMA of metastatic castration resistant prostate cancer (mCRPC) by means of microdosimetry calculations of the alpha-particle emissions. **Materials and Methods:** We performed Monte Carlo simulations with a previously tested program to determine by means of microdosimetry calculations the average number of hits to the cell nucleus required to reach a given TCP and the single-event mean specific energy for the α particles emitted by ^{225}Ac . The absorbed dose to reach a given TCP was calculated as the product of these two variables. The main alpha particle emissions in the ^{225}Ac to ^{209}Bi decay were considered. Realistic values of cell radiosensitivity, lesion size and cell size were considered, as well as non-uniform PSMA expression. For cell radiosensitivity, values of the specific energy deposited within an individual cell that reduces the average cell survival to $1/e$, z_0 , of 0.3 Gy and 0.7 Gy were considered; for lesion sizes values of 1 cm^3 , 10 cm^3 and 100 cm^3 ; and for cell sizes nucleus radii values of $5\mu\text{m}$, $7.5\mu\text{m}$ and $10\mu\text{m}$ (ratio of cell radius to nucleus radius of 1.5:1). The following distributions of the ^{225}Ac atoms were considered: ^{225}Ac atoms homogeneously distributed without any constraint (Case I); a distribution of ^{225}Ac atoms excluding the nuclei (Case II) and ^{225}Ac atoms distributed only in the cytoplasm (Case III). **Results:** Absorbed doses to reach a TCP of 0.9 ranged from 7.0 Gy ($z_0=0.3\text{ Gy}$, lesion size 1 cm^3 and nucleus radius $10\mu\text{m}$) to 23.3 Gy ($z_0=0.7\text{ Gy}$, lesion size 100 cm^3 and nucleus radius $5\mu\text{m}$). Assuming a relative biological effectiveness (RBE) of 5 for α particles, the absorbed doses to reach a TCP=0.9 ranged between 35.0 Gy and 116.5 Gy. The smaller the cell size, the larger the lesion size and the lower the cell radiosensitivity, the higher the absorbed dose to reach a given TCP, the highest variations occurring with cell radiosensitivity. The different ^{225}Ac distributions resulted in changes of absorbed dose to reach a TCP of 0.9 < 5%. **Conclusion:** We determined TCP curves for treatments with ^{225}Ac -PSMA of mCRPC by means of microdosimetry calculations. The obtained results can be a first step in the process of individualisation of the activities to administer in these treatments **References:** None

EPS-039

Towards in-silico dosimetry studies for (novel) radiopharmaceuticals based on physiology based pharmacokinetic models

R. Bouwman, G. de With; NRG, Arnhem, NETHERLANDS.

Aim/Introduction: Physiology based pharmacokinetic (PBPK) models have the potential to be used as part of the individual dosimetry assessment of therapeutic radiopharmaceuticals. For somatostatin (SST2) targeting ligands for the treatment of neuroendocrine tumours a PBPK model has been developed. Currently SST2 targeting ligands are labelled with β emitting radionuclides while research focusses on a translation to α emitting radionuclides. In this study we show the potential value of PBPK model to conduct insilico dosimetry studies for the development of novel radiopharmaceuticals and to define future steps to develop and optimize them. **Materials and Methods:** A previously developed PBPK model has been implemented and results were reproduced to generate a virtual patient dataset. Subsequently simulations were conducted using the half maximum inhibitory concentration of three different radiopharmaceuticals: ^{177}Lu -DOTATATE, ^{90}Y -DOTATATE and ^{213}Bi -DOTATATE. From the time activity curves, ratios of accumulated activity in the organ at risk (kidney) and the target (tumour) compartment are determined for a fixed administrated activity. Subsequently for ^{90}Y -DOTATATE the equilibrium dissociation constant (k_D), an important parameter related to the binding, was varied to quantify its importance. **Results:** The simulations show that based on pre-therapeutic scans and individual physiologic characteristics individual time activity curves for the three different radiopharmaceuticals can be obtained. The ratios of the accumulated activity had the lowest value for ^{177}Lu -DOTATATE for 3 out 4 data points and for ^{213}Bi -DOTATATE for 1 out 4 (lowest dose to the organ at risk, compared to the tumour dose), indicating that there is room to optimize the optimal radionuclide with a specific ligand. Varying k_D ($0.05 - 10\text{ nmol l}^{-1}$) for a single subject and radiopharmaceutical, the tumour dose may decrease 50 to 90% compared to the highest value but also affected the dose ratio for organs at risk and the tumour. Suggesting that k_D is indeed important. **Conclusion:** PBPK-models seems to have potential to be used for in-silico dosimetry studies of novel radiopharmaceuticals for known targeting ligands. However further research is needed to validate and optimize the approach before implementing the model for in-silico dosimetry studies. This includes selection of appropriate boundary conditions and more experimental data to obtain more knowledge regarding the uncertainty in model parameters. For radiopharmaceuticals based on endocytosis, knowledge of binding is one of the most important parameters. **References:** Kletting, P. et al. Gamma Camera Calibration to Perform SPECT/CT-based Dosimetry in ^{177}Lu -DOTATATE Treatments

T. Monserrat Furtés¹, N. Montenegro Iglesias¹, D. Álvarez

Llorente¹, M. Peinado Montes¹, D. San José Olmedo¹, P. Mínguez Gabiña²;

¹Hospital Universitario Central de Asturias, Oviedo, SPAIN,

²Hospital Universitario Cruces/Gurutzeta, Bilbao, SPAIN.

Aim/Introduction: The objective of this work is to establish the acquisition and processing parameters that optimize the quantification of the SPECT images of ¹⁷⁷Lu, as well as obtaining the appropriate calibration and correction factors to calculate dose in patients. **Materials and Methods:** All acquisitions were performed on a Discovery NM/CT 670 gamma camera from General Electric (GE). Data were reconstructed in a GE Xeleris workstation using the ordered-subset expectation maximization (OSEM) method. To compare the quantification accuracy of the different options under study, four different phantoms were used: three spheres of 5.6, 11.2 and 28.8 cm³ and one cylindrical phantom of 300 cm³, all of them inside warm backgrounds of different activity concentrations. The activity measured in each of them was compared with the actual activity. Calibration geometry. Two geometries were compared: point source and cylindrical volume of 5677 cm³. Acquisitions parameters. Two SPECT options were compared: 120 projections of 30 seconds/projection and 60 projections of 60 seconds/projection. Dead time. Several acquisitions were made of a 28 cm³ spherical insert with different activity concentrations in a water background. The relationship between activity and SPECT counts for a wide range of activities of ¹⁷⁷Lu was analyzed. Scatter correction. To analyze scattered radiation correction, the results obtained with the dual (DEW) and triple (TEW) energy window scatter correction methods were compared, as well as those obtained with no scatter correction at all. Detector-collimator effect. The effect of introducing the information of the point spread function (PSF) in the reconstruction was studied. Partial volume effect (PVE). The NEMA image quality phantom with 6 spheres of different volumes and concentrations inside a water background was used to calculate the recovery coefficients. The effect of changing the number of iterations and subsets on the OSEM reconstruction was analyzed. **Results:** The conditions and parameters that resulted in greater accuracy in the quantification were: cylindrical calibration phantom, acquisition with 120 projections, 30 seconds/projection, scattered radiation correction with DEW, correction with PSF applied and OSEM reconstruction with (8 iterations, 10 subsets). Correction for dead time is not necessary, since dead time effects begin to be relevant at activity concentrations much higher than those observed in clinical practice. **Conclusion:** The parameters obtained have been established in the clinical routine of patient dosimetry in treatments with ¹⁷⁷Lu-DOTATATE. **References:** None

EPS-041

Patient Specific Peri- and Post-Treatment Analysis of ¹⁷⁷Lu-DOTATATE Injected NET Patients

O. Yaylali¹, S. Beykan², D. Yüksel³, G. Ergiyen Buldu⁴, B. Nacar⁴, A. Gültekin³, T. Şengöz³, M. Lassmann², I. Karaaslan⁴;

¹Pamukkale University Medical Faculty Department of Nuclear Medicine, Denizli, TURKEY, ²Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY,

³Pamukkale University Medical Faculty Department of Nuclear Medicine, Denizli, TURKEY, ⁴Graduate School of Health Sciences, Yeditepe University, İstanbul, TURKEY.

Aim/Introduction: Main goal is to perform the patient specific kidney and tumor analysis for the NET patients in each peri- and post-treatment of ¹⁷⁷Lu-DOTATATE. In addition, the influence of used imaging method was investigated by comparing the single time-point SPECT/CT dosimetry (STS) results with combination of 2D/3D imaging dosimetry (MP1S). **Materials and Methods:** 24h SPECT/CT and 6 WB planar images (up to 150h) were acquired for 11 NET patients after an administration of 6.5-7.4 GBq ¹⁷⁷Lu-DOTATATE. Amino acid kidney protection was performed to all patients. Kidneys and tumor' time-integrated activity coefficients (TIACs) were calculated for each treatment cycle by using NUKFIT. Kidney absorbed doses(ADs) per treatment cycle were calculated by using OLINDA/EXM and compared with the STS. **Results:** MP1S based KidneyADs were in the range of 5.7-13 Gy. Nevertheless 24h STS based KidneyADs resulted in either underestimations up to 33% or overestimations up to 25% in compare to MP1S. Instead of empiric treatment, with the aim of administration of maximum-possible-activity with avoiding 23Gy kidneyAD, up to 22 GBq of ¹⁷⁷Lu-DOTATATE can be safely administered to the patients. And as a result, by a factor of 2-4 higher tumorADs can be received. Direct relationship between the kidney and tumor TIACs per treatments is observed. Varied DOTATATE uptake of the liver for the patients 3/11 (20-40%) decreased, 6/11 stayed constant and 2/11 increased. **Conclusion:** The inconsistent DOTATATE uptake pattern in the kidneys for each treatment cycle is highly associated with the tumor regression or receptor-binding probabilities. Dosimetry results, biokinetics analysis, varied DOTATATE uptake-pattern and TIACs for kidneys and tumors per treatment cycle showed the necessity of patient-specific treatment protocol especially after the first ¹⁷⁷Lu-DOTATATE treatment. In addition, if the treatments were performed based on maximum-possible-activity administration, the tumors will receive higher doses with avoiding kidney toxicity, which may result in better treatment responses. ake-pattern, kidneyTIACs and tumorsTIACs were observed in 7/11 patients. Similar KidneyTIACs resulted in similar TumorTIACs and no change in tumor volumes (4/11 patients) per treatment cycle whereas decreased KidneyTIACs resulted in either stable tumor stage (2/11 patients) or progress (2/11 patients). Increased KidneyTIAC resulted in tumor regression (3/11patients).Additionally it's

observed that the tumors' volumes located outside. **References:** None

EPS-042

Establishing a clinical dosimetry protocol for ^{177}Lu -DOTATATE peptide receptor radionuclide therapy

S. Bissell¹, E. Ross¹, H. McMeekin², E. Seal¹, K. Ogunwale¹;

¹University Hospitals Birmingham, Birmingham, UNITED KINGDOM, ²Hermes Medical Solutions, London, UNITED KINGDOM.

Aim/Introduction: In the UK NET patients can undergo 4 cycles of ^{177}Lu -Dotatate therapy. Dosimetry is required to evaluate the effectiveness of this therapy and to establish dose-response relationships. The long term aim of this project is to establish a practical dosimetry method providing quantitative assessment of uptake which can be related to clinical response. The current focus is selection of a dosimetry software package. **Materials and Methods:** During cycle 1 of ^{177}Lu -Dotatate therapy patients undergo imaging at four time points: SPECT-CT acquired 4 hours post-administration and SPECT only acquisitions acquired on day 1, 5 and 7. SPECT-CT systems have been calibrated to provide quantitative image reconstructions that can be fed into dosimetry software. Patient variables were used for reconstructing images for a sample of 10 patients. Two software packages were used for quantitative comparison. The first package performs Organ Dosimetry (OD) using OLINDA based on the MIRL formalism; the second employs Voxel Based Dosimetry (VBD). VOIs of the spleen and kidneys were delineated by 4 operators using CT images obtained on day 0. The OD software was used to register the VOIs to each time point image, creating time activity curves and organ doses. For VBD the 4 SPECT images were co-registered and therapy variables used to create dosemaps. The previously delineated VOIs were registered to the dosemaps to calculate mean organ doses. **Results:** Average organ doses were calculated with the standard deviation resulting from operator variability expressed as a percentage. Using OD the mean organ dose for the kidneys was $3.76\text{Gy} \pm 4.45\%$ and for the spleen $4.01\text{Gy} \pm 3.52\%$. Using VBD mean organ doses were $3.81\text{Gy} \pm 7.10\%$ for the left kidney, $4.69\text{Gy} \pm 4.48\%$ for the right kidney. Combined kidney dose was $4.25\text{Gy} \pm 8.76\%$ and spleen dose was $3.74\text{Gy} \pm 10.32\%$. Direct comparison of both software packages reveals a 12% increase in dose using VBD ($p < 0.005$) and a 7% decrease in dose for the spleen ($p < 0.1$). **Conclusion:** Our results suggest that there is a significant difference in kidney dose between OD and VBD ($p < 0.005$), with statistically insignificant variation for the spleen ($p < 0.1$). This is likely due to the inclusion of cross-talk in VBD. Operator variability was lower than anticipated. Work has begun to assess the dose delivered to tumours and how this relates to clinical response. **References:** None

EPS-043

Comparison of the 24h-uptake value obtained from planar images with a gamma camera and from measurements with a thyroid uptake probe in patients with benign thyroid disease

P. Miguez Gabiña, A. Esteban Figueruelo, M. Nevares Herrero, R. Valverde Jorge, R. Nuñez Muñoz, Y. Carreres Ortega, J. Genolla Subirats, E. Rodeño Ortiz de Zarate; Osakidetza, Barakaldo, SPAIN.

Aim/Introduction: We aimed to compare the 24h-uptake value in patients with hyperthyroidism when it is determined from measurements with a thyroid uptake probe and from planar images with a gamma camera.

Materials and Methods: Forty patients with different types of hyperthyroidism were included (15 Graves, 10 autonomous adenoma and 15 multinodular goitre). A capsule of ^{131}I (1.5MBq-3.0MBq) was administered to patients in order to perform treatment planning. Approximately 24h after the administration, uptake was first measured by trained staff with a thyroid uptake probe. The probe was centred at the patients' neck and counts were obtained during 60s. The acquisition window was centred at 364keV. A background measurement was performed with the probe in contact with the patients' thigh. A capsule of the same activity given to patients was measured at the time of the administration in order to obtain the relative thyroid uptake. A static planar image of the neck region was acquired in a gamma camera with a HEGP collimator during 600s. An energy window centred at 364keV with a 20% width was used, and a matrix size of 256x256. A 3x3 smoothing filter was applied. A ROI was delineated for the thyroid region with a 20% threshold of the pixel with maximum counts. Counts of this ROI were background corrected from the counts of a ROI taken below the thyroid. The camera was calibrated with a capsule of the same activity given to the patients, and the relative thyroid uptake was obtained. No attenuation correction was performed in either of the methods. The uptake values obtained for each of the two methods were tested for normality using the Shapiro-Wilks test. The differences between both groups were tested to see if they were significant. A Pearson correlation test was performed to study the correlation of that difference with the uptake value and with the type of hyperthyroidism. **Results:** Both groups followed normal distributions and after performing an independent samples t-test, it was found that uptake values obtained with the probe were significantly lower than those obtained with the gamma camera ($p < 0.05$). No correlation was found, either with the uptake value or with the type of hyperthyroidism. **Conclusion:** The unexpected significant differences between both methods call for research to find the reason for which one of the two methods is overestimating or underestimating the relative uptake value, as it may be relevant in regular treatment

planning of some centres. **References:** None

EPS-044

Improved patient dosimetry for radioactive iodide by adjusting the ICRP iodide compartment model to individual thyroid uptake

M. Andersson, S. Mattsson;

Medical Radiation Physics, Malmö, SWEDEN.

Aim/Introduction: Iodine is an essential component of the thyroid hormones thyroxine (T4) and triiodothyronine (T3), which regulate metabolic processes and are critical to growth and development. The thyroid uptake of iodide depends both of the hormone levels of T4, T3 and on the dietary intake of iodide. In the ICRP biokinetic compartment model for iodine the daily intake set to 160 µg. However, patient treated with iodide can both deviate from the hormone levels of T3, and T4 and the daily iodide intake. These patients often undergo thyroid activity measurements and therefore the actual uptake is known. The aim of this project is to automatically adjust the ICRP iodide compartment model to the measured individual patient thyroid uptake. This will provide not only a better and more representative absorbed dose to the thyroid, but also a realistic absorbed dose to all other tissues and organs. **Materials and Methods:** The biokinetic model of iodide includes 30 different compartments and 48 transfer coefficients to model the bio-distribution of iodide in the human body. Of these are two compartments used to describe the iodide uptake and retention in the thyroid, one for inorganic iodide and one for organic iodide, with four transfer coefficients. It is these four transfer compartments which are optimized to fit the biokinetic model to the patient specific uptake. However, as the model is a recirculation iodine model the optimization is performed using the whole model. Absorbed dose calculations are performed for all 30 different compartments. **Results:** The mathematical code was tested on measured activity data for I-131 for a Graves' hyperthyroidism patient. The transfer coefficient from blood to thyroid was changed from 7.2 day⁻¹ to 16.2 day⁻¹. The increased thyroid uptake from blood will decrease the excretion to faeces and urine and 1.6 more thyroid I-131 decays will occur within the body. This increased thyroid uptake will also result in a 2.5 times higher thyroid absorbed dose (from 0.364 mGy/MBq to 0.939 mGy/MBq). For all other radiosensitive organs, the absorbed dose will in average increase with a factor of 2, due to adjusting the biokinetic model to the measured patient data. **Conclusion:** The uptake of iodide in thyroid can deviate between patients and healthy persons. The goal of this project is to adjust for this differences to perform more representative absorbed dose calculations for both the thyroid and all other radiosensitive organs. **References:** Rich Leggett. An age-specific biokinetic model for iodine. *J. Radiol.*

Cancer Research, London, UNITED KINGDOM.

Aim/Introduction: Background: Multi-centre trials are often required within molecular radiotherapy (MRT) to acquire sufficient data to power the trial. For many trials involving a novel pharmaceutical, detailed administration protocols and common patient questionnaires ensure compatibility across centres. However, trials involving radiopharmaceuticals can be particularly complex, especially where dosimetry is required, due to the number of stages required in the production of quality data. Recent experience has highlighted challenges that may arise within multi-centre MRT trials that involve dosimetry. The aim of this review was to address aspects of the trial structure and consider recommendations for future trial design in order to prevent future complications. **Materials and Methods:** **Results:** Recommendations for trial design: Compromises may be necessary where teams of varying expertise participate in the trial particularly with budgetary or times constraints. **Conclusion:** The challenges arising within a multi-centre clinical trial that involves patient-specific dosimetry necessitate a high level of comprehension at all participating sites and clear communication throughout. Issues faced by a trial coordinator and a lack of comprehension by all parties can affect the quality of their individual contributions. These considerations should be taken into account at the initial design phase. **References:** None

Aim/Introduction: A multidisciplinary expert panel convened to formulate state-of-the-art recommendations for optimisation of selective internal radiation therapy (SIRT) with yttrium-90 (⁹⁰Y) resin microspheres, by standardisation of multimodality treatment approaches, personalisation of activity prescription methods, and performance of post-treatment dosimetry. **Materials and Methods:** A steering committee of 23 international experts representing all participating specialties formulated recommendations for SIRT with ⁹⁰Y resin microspheres activity prescription and post-treatment dosimetry based on literature searches and the responses to a 61-question survey that was completed by 43 leading experts (including the steering committee members). The survey asked for opinions on best practice in areas of pre-SIRT work-up and interventional strategy, dosimetry method for activity prescription, dose thresholds for normal-liver and tumours, and post-treatment dosimetry. The survey was validated by the steering committee and completed anonymously. In a face-to-face meeting, the results of the survey were presented and discussed. Recommendations were derived and level of agreement defined (strong agreement $\geq 80\%$, moderate agreement 50%–79%, no agreement $\leq 49\%$). A follow-up meeting allowed the committee to consolidate these recommendations and levels of agreement. **Results:** Survey participants had a median of 14 years of experience with ⁹⁰Y resin microspheres. Fifty-two recommendations were made, which included: a multidisciplinary team should define treatment strategy and therapeutic intent (strong agreement); 3D imaging with CT in an angiography suite such as cone-beam CT and ^{99m}Tc-MAA-SPECT/CT are recommended for extra-/intra-hepatic deposition assessment, treatment field definition and calculation of the ⁹⁰Y resin microspheres activity needed (moderate/strong agreement). A personalised approach, using dosimetry (partition model [MIRD-based] and/or 3D voxel-based dosimetry), is recommended for activity prescription, when either whole liver or selective, non-ablative or ablative SIRT

is planned (strong agreement). A mean absorbed dose to non-tumoural healthy liver of 40 Gy or less is considered safe (strong agreement). To target tumour ablation a minimum mean-absorbed dose to tumour of 100–120 Gy is recommended in hepatocellular carcinoma, liver-metastatic colorectal cancer and cholangiocarcinoma (moderate/strong agreement). Post-SIRT imaging evaluation should be visual and quantitative, and therefore, post-SIRT ⁹⁰Y-PET/CT or SPECT/CT is highly recommended, and ⁹⁰Y-PET/CT is preferred for accuracy of quantitative imaging (strong agreement). Post-SIRT dosimetry is also recommended (strong agreement). **Conclusion:** Optimised SIRT with ⁹⁰Y resin microspheres requires personalised activity prescription and dosimetry (voxel-based or MIRD-based partition method) and multidisciplinary management for safety and efficacy. Practitioners are encouraged to work towards adoption of these recommendations. **References:** None

Combined Quality and Dose Volume Histograms demonstrates the predictive value of ^{99m}Tc-MAA SPECT/CT simulation for personalizing radioembolization treatment in liver metastatic colorectal cancer

H. Levillain^{1,2}, M. Burghelea¹, I. Duran Derjickere², T. Guiot¹, A. Gulyban¹, B. Vanderlinden¹, M. Vouche³, P. Flamen², N. Reynaert¹; ¹Medical Physics Department, Jules Bordet Institute, Brussels, BELGIUM, ²Nuclear Medicine Department, Jules Bordet Institute, Brussels, BELGIUM, ³Radiology Department, Jules Bordet Institute, Brussels, BELGIUM.

Aim/Introduction: The aim of this work was to analyse differences between simulation ^{99m}Tc-MAA-SPECT/CT and treatment ⁹⁰Y-microsphere-PET/CT dosimetry using different metrics. Dose distribution was compared voxel-to-voxel using quality-volume-histograms (QVH), which was further used for identifying potential clinical parameters that induce discrepancies between simulation and treatment dosimetry. **Materials and Methods:** Thirty liver-only metastatic colorectal cancer patients were included in this monocentric retrospective investigation. Individual lesions were delineated on baseline FDG-PET/CT using a fixed SUV threshold (130 delineated lesions). Clinical workstation was used for initial co-registration and 3D voxel-based dosimetry computation for simulation and treatment dosimetry ($D^{\text{Simulated}}$ and $D^{\text{Treatment}}$ respectively). Lesions delineated on FDG-PET/CT were projected on the anatomically registered $D^{\text{Treatment}}$ and whole tumoral-liver (TL) and non-tumoral-liver (NTL) were delineated. Dose-volume-histograms were computed from $D^{\text{Simulated}}$ and $D^{\text{Treatment}}$ for each individual lesion, TL and NTL. The DVH-based indices D90, D70, D50, Dmean and D20 were analysed for all predefined volumes. The QVH were computed using an in-house Python code. QVHs represent decumulative histograms of the voxel-

based quality ratio, defined as: $\log_{10}(D^{\text{Treatment}}/D^{\text{Simulated}})$. When the simulated dose distribution perfectly matches the treatment dose distribution, the ratio is equal to 0 for every voxel within the given volume. QVHs were computed for TL, NTL and all lesions. Quality-factors representing the spread of the QVH curve around 0 (ideal QF=0) were determined for lesions, TL and NTL. QVHs were classified into good, acceptable and poor correspondence based on QF-values. **Results:** DVH indices showed no statistically significant differences between simulation and treatment across all volumes. Furthermore, in agreement with previous studies, the DVH analysis showed no difference in terms of D_{mean} . For lesions and TL, dose- and quality-volumes-histograms were mostly concordant: 69% of lesions had a QF within the good/acceptable categories (40% good) and 65% of TL had a QF within the good/acceptable categories (23% good). For NTL mixed results were obtained with 48% QF within the poor concordance category. The delay between simulation and treatment (>9days vs. ≤9days) was a significant predictor of discrepancies between simulation and treatment dosimetry, the median QF was 0.53 vs. 0.39 ($p=0.04$) for individual lesions, 0.62 vs. 0.42 ($p=0.02$) for TL and 1.20 vs. 0.60 ($p=0.002$) for NTL. **Conclusion:** The combination of DVH and QVH confirmed the predictive value of ^{99m}Tc -MAA SPECT/CT simulation for personalizing radioembolization activity prescription and could be used as a quality assurance process in mono/multi-centre trials as well as in clinical routine. **References:** None

EPS-048

Radioembolization of hepatocarcinoma with ^{90}Y glass microspheres: voxel dosimetry or mean dose approach to predict clinical outcomes?

C. Romano¹, S. Mazzaglia¹, M. C. De Nile², S. Bhoori³, A. Gabutti⁴, G. Maffi⁴, C. Spreafico⁴, A. Marchianò⁴, V. Mazzaferro³, M. Maccauro¹, E. Seregni¹, C. Chiesa¹;

¹Nuclear Medicine Division, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, ²Postgraduate Specialization School in Medical Physics, University of Milan, Milan, ITALY, ³HPB Surgery, Hepatology and Liver Transplantation, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, ⁴Radiology 2, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY.

Aim/Introduction: To retrospectively investigate if voxel dosimetry could improve correlation with clinical outcomes with respect to mean absorbed dose in hepatocellular carcinoma patients which underwent trans-arterial radioembolization (TARE). Our previous published study showed that no voxel dosimetry variable (Ψ) could significantly improve clinical outcome prediction with respect to the mean absorbed dose. However that study suffered from several methodological limitations: a limited number of cases (43), a non-consolidated method for radiological response evaluation, absence of hybrid SPECT/

CT, scatter correction, and post-therapy ^{90}Y -PET verification. In this study, a larger patient cohort was considered, and all the previous limitations were overcome. **Materials and Methods:** We retrospectively evaluated ^{99m}Tc -MAA SPECT/CT ^{90}Y -PET/CT data of 101 patients treated with ^{90}Y glass microsphere 8 days after the calibration day. The following voxel-based Ψ were computed both for liver healthy parenchyma and tumours: mean absorbed dose (D), Equivalent Uniform Dose (EUD), average of the Biologically Effective Dose (BEDave), Equivalent Uniform Biologically Effective Dose (EUBED), the minimal dose of the 98%, 70%, 50% and 2% of the VOI (D_{98} , D_{70} , D_{50} and D_2), and homogeneity index (HI). We studied the correlation between each Ψ and liver decompensation (LD) or lesion local mRECIST response. Tumour control probability (TCP) curves were assessed. The area under the receiver-operating characteristic (ROC) curve (AUC) of the two classes with/without LD and of responding/non-responding lesions was calculated. **Results:** 4 over 101 patients presented LD. This scarce number of LD cases hinder the Ψ -toxicity analysis. A local disease control rate of 97% for measurable lesions was reported. An unexpectedly poor Ψ -response correlation was obtained in both pre- and post-treatment data. No Ψ reached an AUC value significantly higher than the mean absorbed dose. ($\text{AUC}=0.56\pm 0.06$). The poor class separation in terms of any Ψ between responding and non-responding lesions prevented to derive a reliable treatment efficacy threshold. ^{90}Y -PET data presented slightly higher AUC values than ^{99m}Tc -MAA SPECT data. Despite high D up to 800 Gy, TCP curves did not reach 100%, rather showing an unexpected plateau at 75%. Lesion radiosensitivity α from TCP fit was confirmed (0.003/Gy). **Conclusion:** This study confirms that no voxel dosimetry based parameter, neither using pre- nor post-therapy imaging, significantly improved clinical outcome prediction with respect to the mean absorbed dose. These findings, the poor dose-response correlation obtained and the TCP curve plateau can be explained by the clustering effect of 8-days decayed microspheres and maybe other biological factors. **References:** None

EPS-049

Absorbed dose assessment in ^{90}Y radioembolization patients with GATE: a comparison between total-body PET and conventional PET imaging

G. Costa, B. Spencer, M. Rusnak, D. T. Caudle, C. Foster, C. T. Vu, E. Roncali;

University of California, Davis, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Radioembolization based on the delivery of ^{90}Y microspheres to liver tumors through selective hepatic artery branches is an established radionuclide therapy, although current methods of verifying dose delivery suffer from poor accuracy. Despite the difficulties of measuring and quantifying the very low branching ratio

of ^{90}Y positron emission (32 ppm) [1], ^{90}Y PET can be used for therapy evaluation to estimate the absorbed dose [2] in the liver/tumor using Monte Carlo simulations. **Materials and Methods:** The patient received three injections of ^{90}Y microspheres (Theraspheres, BTG) with a total activity of 3.363 GBq and was scanned on both the total-body PET scanner uEXPLORER (United Imaging Healthcare) and the mCT Biograph (Siemens) five hours after injection. The dose distribution was estimated using Monte Carlo simulations (GATE 8.2), in which PET images were used as the activity distribution (source) and the CTs provided the tissue properties and anatomy. Volumes of interest (VOI) were created as image masks where the mCT mask was co-registered on uEXPLORER and vice-versa. These VOIs were overlaid with both the source images to force primary events to be generated only inside the VOI, and with the output dose-map to estimate the absorbed dose. **Results:** The number of counts obtained in the VOIs was significantly higher (up to 35.1%) on uEXPLORER as a result of its higher sensitivity. Absorbed doses estimations were 223.2 Gy and 230.7 Gy (3.2 % difference) for uEXPLORER and mCT simulations, respectively, with uEXPLORER mask, while the values with mCT's mask were 247.5 Gy and 260.6 Gy (5.0 %). **Conclusion:** GATE simulations showed promising results to estimate the absorbed dose from PET images. It must be noted that the absorbed dose is dependent on the VOI, for example, uEXPLORER simulations showed values of 223.2 Gy and 245.5 Gy with uEXPLORER and mCT masks, respectively. Furthermore, it is equally important to properly identify the volumes where primary events will occur while keeping noise and artefacts to a minimum. Further studies will be conducted to assess the impact of noise and artefacts on absorbed dose estimation. **References:** 1 - Strydhorst, Jared et al. Comparison of Pre-Treatment Imaging for Radioembolization Using Tc-99m, Ho-166 and Y-90

J. Wielaard^{1,2}, B. Kunnen¹, G. C. Krijger¹, R. van Rooij¹, H. W. A. M. de Jong¹;

¹University Medical Center Utrecht, Utrecht, NETHERLANDS,

²St. Antonius hospital, Nieuwegein, NETHERLANDS.

Aim/Introduction: Tc-99m-macroaggregated albumin particles are commonly used as a surrogate to therapeutic Y-90 microspheres to identify lung shunting and extrahepatic depositions in radioembolization. A potential better estimation can be derived by using a safe low dosage of the therapeutic microsphere, as is clinically studied for Ho-166 radioembolization, but also suggested for Y-90

microspheres[1,2]. This phantom study is performed to compare quantitative accuracy of the lung shunt fraction (LSF) estimation and detection of extrahepatic deposition, based on planar scintigraphy and SPECT/CT (Siemens Intevo) for Tc-99m, Ho-166 and Y-90. **Materials and Methods:** An anthropomorphic phantom (model ECT/TOR/P, IEL, Chilcompton, UK) with liver, lung (filled with styrofoam beads) and extrahepatic deposition compartments (2 and 8 mL) was filled several times to acquire an LSF of 0, 5, 15 and 20% in combination with activity concentrations in the extrahepatic depositions of 10 times the liver concentration. The total activity of the liver and lung compartments was kept at either 150 MBq, 250 MBq and 100 MBq, in 0.5 M HCl, for Tc-99m, Ho-166 and Y-90 respectively. Planar scintigraphy and SPECT/CT images were acquired and reconstructed with our current clinical protocols. In addition, for Y-90 and Ho-166 SPECT/CT, Monte Carlo (MC)-based reconstruction was performed. The LSF as well as the contrast-to-noise ratio (CNR) of the extrahepatic depositions were retrieved by automatic registration of CT-defined masks. **Results:** In all cases SPECT/CT imaging was more accurate than planar imaging for LSF estimations and resulted in higher CNRs for the extrahepatic depositions. However, Y90 and Ho-166 SPECT/CT still overestimated the LSF. MC-based reconstructions led to more accurate LSF estimations and increased CNRs. **Conclusion:** This study shows that all three radioisotopes led to comparable LSF estimations. The advantage of using Ho-166 and Y-90 for the pre-treatment procedure is the use of a low dosage identical therapeutic microspheres. For both radioisotopes MC-based reconstructions improved image quality and lowered LSF overestimation. **References:** [1] Braat, A. et al. *Eur Radiol.* 2019; 28(3): 920-928. EPS-051

Comparison of Different Time-Activity Curve-Fitting Methods for Voxel-based In-111 Zevalin SPECT Targeted Radionuclide Therapy Dosimetry

Y. Lyu, G. Chen, G. Mok;

Biomedical Imaging Laboratory (BIG), Department of Electrical and Computer Engineering, Faculty of Science and Technology, University of Macau, Taipa, MACAO.

Aim/Introduction: Curve fitting is commonly applied on sequential activity data to calculate the time-integrated activity (TA) for targeted radionuclide therapy dosimetry. This study aims to compare different exponential curve fitting methods (mono-, bi- and tri-) on voxel-based dosimetry based on In-111 Zevalin SPECT scans with 3 or 5 imaging time points. **Materials and Methods:** We used an analytical projector of a medium energy general purpose collimator to generate 128 realistic noisy SPECT projections, modeling attenuation, scatter, and geometric collimator-detector-

response (GCDR), based on a population of 9 4D XCAT phantoms varying in anatomies and In-111 Zevalin activity distributions. The noisy projections were reconstructed using the OS-EM algorithm (8 iterations and 16 subsets) with attenuation, effective source scatter estimation and GCDR compensation. The time-activity curves for each voxel were fitted individually with mono-, bi- and tri-exponential functions (vox_adj) using the nonlinear least squares method based on sequential quantitative SPECT images, i.e., 3 time points of 1, 24 and 144 hrs, or 5 time points of 1, 12, 24, 72 and 144 hrs post injection, assuming physical decay after the last time point. The area under curves were then obtained to get the TA for kidneys, spleen and liver. Fitting parameters were also determined for the individual organ and fixed for voxels of the same organ (vox_fixed). Sum of squares for error (SSE) was calculated for all fitting methods while TA differences were compared using ANOVA test with Bonferonni correction by SPSS. **Results:** $SSE_{\text{vox_adj}}$ is much smaller than $SSE_{\text{vox_fixed}}$, i.e., the average %difference is up to ~-300% for 3 time points and -145% for 5 time points. The median SSE of bi-exponential function is smallest generally. The TA obtained from mono-exponential fitting is generally larger than other fitting methods. Using bi-exponential method as reference, the % of TA absolute difference is <4% for all organs of interest when using mono- or tri-exponential method. There is no statistically significant difference between TA obtained from 3- and 5-time-point regardless of the fitting methods, and there is also no statistically significant difference among TA obtained from different fitting methods regardless of number of imaging time points. **Conclusion:** There is no substantial difference in terms of TA for different curve-fitting methods and imaging time points for In-111 Zevalin SPECT-based dosimetry yet bi-exponential voxel-based fitting provides the lowest SSE. Considering clinical resource and computational time, bi-exponential fitting using 3-time point data is recommended for this application. **References:** None

Changes in D₂R and SERT Availability in the Rat Brain After Depressive-like Behavior Recovery in the Repeated Social Defeat Model

R. Moraga-Amaro¹, D. A. Vazquez-Matias¹, L. Reali Nazario¹, J. Stehberg², R. A. J. O. Dierckx¹, J. Doorduyn¹, E. F. J. de Vries¹; ¹Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, ²Laboratorio de Neurobiología, Instituto de Ciencias Biomédicas, Facultad de Medicina y Facultad de Ciencias de la vida, Universidad Andres Bello, Santiago, CHILE.

Aim/Introduction: Dopaminergic and serotonergic neurotransmission are believed to play an important role development and progression of major depressive disorder (MDD). Studying neurotransmission changes in a longitudinal manner in animal models of depression, promise to be useful for further understanding of disease mechanisms, potentially leading to improved therapy. In this regard, Positron emission tomography (PET) scanning is a valuable resource for studying longitudinal changes in the brain in a non-invasive way. To determine the dopaminergic and serotonergic neurotransmission changes in animals submitted to the repeated social defeat (RSD) model of depression, by measuring changes in dopamine receptor

2 (D₂R) and serotonin transporter (SERT) availability in the brain after depressive-like behavior recovery, using PET. **Materials and Methods:** Experimental male Wistar rats (RSD group) were exposed to social defeat by larger male Long-Evans rats during 5 consecutive days. Changes in depressive-like behavior were assessed with the sucrose preference test (SPT) before RSD (baseline), 1 day and 14 days after RSD. Bodyweight changes were used as an additional parameter to validate the RSD model. Changes in brain availability of D₂R and SERT was measured by PET in the same animal after RSD using [¹¹C]-Raclopride (day1 and 14) and [¹¹C]-DASB (day2 and 15) 60-min dynamic scans respectively. The non-displaceable binding potential (BP_{ND}) was calculated regionally with a SRTM (cerebellum as reference) for both tracers. General estimated equations (GEE) models were used to analyze all parameters in a longitudinal way, using as control group animals not exposed to RSD. **Results:** RSD induced a reduction in body weight gain on day1 after RSD (p<0.0001), which was recovered at day14. Additionally, animals submitted to RSD showed a decrease in sucrose preference on day1 (p<0.0001) which did not last until day14, indicating that animals recovered from depressive-like behavior. PET imaging showed an increase in [¹¹C] Raclopride BP_{ND} in the caudate putamen (p<0.05), and in [¹¹C]DASB BP_{ND} in the whole brain (p<0.01), insular cortex (p<0.01), thalamus (p<0.05), brainstem (p<0.05), midbrain (p<0.05), but only after recovery of symptoms (day14 and day15 respectively). **Conclusion:** Our results showed changes in dopaminergic and serotonergic neurotransmission when animals recovered from the depressive-like behavior (day14), but not after its development (day1). These results support the idea that time-points in disease progression are important for the treatment of the disease. Further studies are needed to determine if these changes are due to changes in SERT or D₂R availability, or changes of neurotransmitter concentrations in the brain. **References:** None

OP-220

In vivo comparison of the sensitivity of PET radioligands to detect moderate changes in P-gp function at the blood-brain barrier

L. Breuil, F. Caillé, S. Marie, S. Goutal, S. Auvity, M. Goislard, C. Coulon, T. Lekieffre, W. Saba, N. Tournier; Laboratoire d'Imagerie Biomédicale Multimodale (BIOMAPS), Université Paris-Saclay, CEA, CNRS UMR9011, Inserm UMR1281, Service Hospitalier Frédéric Joliot, Orsay, FRANCE.

Aim/Introduction: The P-glycoprotein (P-gp) is a major efflux transporter expressed at the blood-brain barrier (BBB) which plays a key role in brain protection and homeostasis. In patients, complete repression or inhibition of P-gp function is not likely to occur. However, partial inhibition/deficit is suspected in pathophysiological situations and

drug-drug interactions. PET imaging using radiolabeled substrates of the P-gp is the most advanced technique to study this transporter at the human BBB. However, the sensitivity of current radiolabeled P-gp substrates to detect moderate changes in P-gp function remains to be compared. We conducted an *in vivo* study to compare the sensitivity of the clinically validated P-gp substrates ^{11}C -metoclopramide, ^{11}C -verapamil and ^{11}C -N-desmethyl-loperamide (^{11}C -NdLop) to partial inhibition of P-gp function by tariquidar (TQD). **Materials and Methods:** First, the effect of increasing doses of TQD (injected *i.v.* 15 minutes before PET imaging) on the brain kinetics of ^{11}C -metoclopramide were studied using microPET imaging in rats. Brain exposure was estimated by the area under the time-activity curve of brain kinetics from 10 to 30 min ($\text{AUC}_{10-30\text{min}}$). The doses that inhibited 50% and 100% of the P-gp mediated transport of ^{11}C -metoclopramide ($\text{ID}_{50\%/ \text{Meto}}$ and $\text{ID}_{100\%/ \text{Meto}}$, respectively) were graphically estimated with brain $\text{AUC}_{10-30\text{min}}$ as a function of injected dose of TQD (0, 1, 1.4, 2, 3, 4 and 8 mg/kg). Then, PET experiments were performed using ^{11}C -metoclopramide, ^{11}C -verapamil and ^{11}C -NdLop at baseline (0% inhibition) and after injection of TQD at either $\text{ID}_{50\%/ \text{Meto}}$ or $\text{ID}_{100\%/ \text{Meto}}$ ($n=2-7$ per condition). Mean $\text{AUC}_{10-30\text{min}}$ obtained in each condition for each radiotracer were compared using an ANOVA and Tukey's post-hoc analysis. **Results:** $\text{ID}_{50\%/ \text{Meto}}$ was estimated at 1 ± 0.15 mg/kg TQD dose. The 1 mg/kg dose of TQD increased the brain exposure to ^{11}C -metoclopramide and ^{11}C -verapamil by 2.0 and 2.5-fold respectively but did not increase the brain uptake of ^{11}C -NdLop. The $\text{ID}_{100\%/ \text{Meto}}$ of TQD was estimated at 8 mg/kg. This dose significantly increased the brain exposure to ^{11}C -metoclopramide (+3.0 and 1.5-fold), ^{11}C -verapamil (+8.8 and 2.4-fold) and ^{11}C -NdLop (+6.8 and 4.4-fold) compared with baseline and $\text{ID}_{50\%/ \text{Meto}}$, respectively. **Conclusion:** P-gp substrates probes show significantly different sensitivity to inhibition. Especially, ^{11}C -NdLop may lack sensitivity to detect partial (50%) decrease in P-gp function at the BBB, which may be detected using either ^{11}C -metoclopramide or ^{11}C -verapamil, that both show similar sensitivity to TQD inhibition. Sensitivity should be considered when selecting radiolabeled substrate for PET imaging to explore situations where moderate decline in P-gp function at the BBB is expected. **References:** None

OP-221

Evaluation of a Novel P-glycoprotein Inducer Using [^{18}F]MC225 and PET

L. Garcia Varela¹, D. Vázquez García¹, M. Perez Rodriguez², R. Moraga-Amaro¹, N. A. Colabufo³, P. Aguiar⁴, T. Sobrino², R. A. J. O. Dierckx¹, A. van Waarde¹, P. H. Elsinga¹, G. Luurtsema¹;

Compostela, SPAIN, ³University of Bari Aldo Moro, Department of Pharmacy, Bari, ITALY, ⁴Clinical University Hospital, IDIS Health Research Institute, Department of Nuclear Medicine and Molecular Imaging, Santiago de Compostela, SPAIN.

Aim/Introduction: P-glycoprotein (P-gp) is an efflux pump located at the blood-brain barrier (BBB). Its main function is the protection of the central nervous system via the efflux of neurotoxic compounds from the brain (1). A decline in P-gp function has been related to the pathogenesis of neurodegenerative diseases, like Alzheimer's and Parkinson's disease (2). Drugs called P-gp inducers have the potential to restore the P-gp function and are considered as possible candidates for the treatment of neurodegenerative diseases. MC111, (4'-((4-cyclohexylpiperazin-1-yl)methyl)-[1,1'-biphenyl-4-ol]), was selected as a promising P-gp inducer due to its ability to increase P-gp expression and function in colo-320 cells (3). Our study aims to evaluate the P-gp inducing effect of MC111 *in vivo* using the P-gp tracer [^{18}F]MC225 (4) and Positron Emission Tomography (PET). **Materials and Methods:** Eighteen healthy male Wistar rats were treated with either vehicle solution, 4.5mg/kg of MC111 (low-dose group) or 6mg/kg of MC111 (high-dose group) ($n=6$ per group). Animals underwent a 60-minutes dynamic-PET scan with arterial-blood sampling, 24 hours after the treatment with the inducer. Data were analysed using a 1-Tissue-Compartment-Model fit, fixing the volume of blood to 5% and using metabolite-corrected plasma as input function. K_1 and V_T were used to measure the P-gp function (4). **Results:** The administration of MC111 decreased K_1 and V_T of [^{18}F]MC225 in the whole-brain and all the selected brain regions. In the high-dose group, whole-brain K_1 decreased by 34% ($K_1\text{-high-dose}=0.2 \pm 0.02$ vs $K_1\text{-control}=0.3 \pm 0.02$; $p \leq 0.001$) and in the low-dose group by 7% ($K_1\text{-low-dose}=0.28 \pm 0.02$ vs $K_1\text{-control}=0.3 \pm 0.02$; $p=0.411$) compared to controls. Whole-brain V_T decreased by 25% in the high-dose group ($V_T\text{-high-dose}=5.8 \pm 0.37$ vs $V_T\text{-control}=7.8 \pm 0.37$; $p \leq 0.001$) and by 6% in the low-dose group ($V_T\text{-low-dose}=7.35 \pm 0.37$ vs $V_T\text{-control}=7.8 \pm 0.37$; $p=0.371$) compared to controls. k_2 values did not vary after treatment. Moreover, the treatment did not affect the metabolism of [^{18}F]MC225. **Conclusion:** The decrease in K_1 and V_T values after treatment with the inducer indicates an increase in the P-gp functionality at the BBB of treated rats. Therefore, the results verify that MC111 has an induction effect *in vivo*. These data also confirm the ability of [^{18}F]MC225 to measure increases in the P-gp function at the BBB in rats. **References:** 1. Mahringer A, Fricker G. OP-222**Binding of the experimental dual-action antiparkinsonian drug AG-0029 to dopamine D₂ and histamine H₃ receptors: a PET study in healthy rats**

A. Van Waarde¹, N. Ghazanfari¹, J. W. A. Sijbesma¹, D. Vallez Garca¹, M. Kominia², M. Koelewijn², K. Attia¹, T. J. Visser², A. Heeres², A. T. M. Willemsen¹, R. A. J. O. Dierckx¹, P. H. Elsinga¹;
¹University Medical Center Groningen, Groningen, NETHERLANDS, ²Syncom, Groningen, NETHERLANDS.

Aim/Introduction: Drugs interacting with multiple targets are under study for the treatment of disorders of the central nervous system. AG-0029¹ combines very potent agonist affinity (0.08 nM) to the dopamine D₂ receptor with moderate antagonist affinity (111 nM) to the histamine H₃ receptor. These receptor interactions of AG-0029 were proven by measurement of extracellular dopamine levels in rat striatum and histamine levels in rat prefrontal cortex by microdialysis. AG-0029 showed anti-Parkinson action (contralateral rotation), and a cognition-enhancing effect in the novel object recognition test of 6-OHDA-lesioned rats. This drug may improve both the motor and cognitive symptoms of Parkinson disease. The present study aims to quantify the target engagement of AG-0029. **Materials and Methods:** Healthy male Wistar rats were scanned in a small animal PET camera (μ PET Focus 220), using the dopamine D₂/D₃ receptor ligand [¹¹C]raclopride or the histamine H₃ receptor ligand [¹¹C]GSK189254, before and after treatment with an intravenous, acute, single dose of AG-0029 (0.1 or 1 mg/kg for [¹¹C]raclopride, 1 mg/kg for [¹¹C]GSK189254). Dynamic [¹¹C]raclopride scans (60 min duration) were made without arterial blood sampling, and were analysed using the simplified reference tissue model with cerebellum as reference tissue. Dynamic [¹¹C]GSK189254 scans (90 min duration) were made with arterial blood sampling. **Results:** Binding potential values of [¹¹C]raclopride in the striatum were dose-dependently reduced after administration of AG-0029 (10 min before tracer injection), from 1.45±0.10 (n=9) to 1.04±0.17 (after a 0.1 mg/kg dose, n=4) and to 0.33±0.18 (after a 1 mg/kg dose, n=5), corresponding to D₂/D₃ receptor occupancy values of 27±12 and 78±4%. These data (0, 0.1, 1 mg/kg dose) are well-fitted by a one-site model for receptor binding ($r^2 > 0.99$), half-maximal receptor occupancy being reached at a dose of 0.27 mg/kg and maximal occupancy being 99.3%. Data acquisition and analysis for the [¹¹C]GSK189254 scans is still in progress. Frontal/occipital cortex ratios of radioactivity were reduced from 3.04±0.74 (n=4) at baseline to 2.58±0.13 (n=3) after administration of 1 mg/kg AG-0029, which may correspond to a H₃ receptor occupancy of 23%. However, due to high variability of [¹¹C]GSK189254 binding at baseline, the decline of binding potential at this dose was not statistically significant. **Conclusion:** Dopamine D₂/D₃ receptor occupancy by the agonist AG-0029 could be reliably measured with [¹¹C]raclopride and

small animal PET. Histamine H₃ receptor occupancy by AG-0029 may be detectable in PET scans with [¹¹C]GSK189254, but may require a higher dose than 1 mg/kg. **References:** ¹ 7-(4-(3-(4-(morpholinomethyl)phenoxy)propyl)piperazin-1-yl)benzo[d]oxazol-2(3H)-one.

OP-223**Impact of A_{2A}R agonist and antagonist on binding of the dopamine D₂ receptor ligand [¹¹C]raclopride in the rodent striatum**

K. Prasad, E. F. J. de Vries, J. W. A. Sijbesma, K. A. Attia, C. Kwizera, L. Garcia-Varela, D. A. Vazquez-Matias, R. Moraga-Amaro, D. Vallez-Garcia, A. T. Willemsen, R. A. J. O. Dierckx, A. van Waarde;
 University Medical Center Groningen (UMCG), Groningen, NETHERLANDS.

Aim/Introduction: Adenosine A_{2A} and dopamine D₂ receptors in the basal ganglia form heterotetrameric structures that are involved in the regulation of motor activity and neuropsychiatric functions. Although allosteric interactions between the receptors were established in-vitro and in-vivo in immunoprecipitation studies, further studies are required to demonstrate their functions. The present study examines the A_{2A} receptor-mediated modulation of D₂ receptor binding in vivo using PET with the D₂ antagonist tracer [¹¹C]raclopride. **Materials and Methods:** Healthy male Wistar rats (n=8) were scanned (60-min dynamic) with [¹¹C]raclopride at baseline and following the administration of A_{2A} agonist CGS21680 (1mg/kg), using a μ PET Focus-220 camera. Binding potential (BP) values were calculated, using a simplified reference tissue model (SRTM) and cerebellum as the reference tissue. Other rats underwent dynamic [¹¹C]raclopride scans with arterial-blood sampling after pretreatment with vehicle (n=4), a single dose of CGS21680 (1mg/kg, n=5) or A_{2A} antagonist KW6002 (1mg/kg, n=4). BP values were calculated using a reversible two tissue compartment model (2TCM) and a metabolite-corrected plasma input function. Time-activity curves were extracted by projecting voxels of interest onto a dynamic scan. **Results:** Striatal and cerebellar areas-under-the-curve (AUC) were significantly higher after CGS21680 administration ($p < 0.05$, Cohen's $d = 2.4$) compared to baseline. SRTM analysis did not find significant changes in BP ($p = 0.102$, Cohen's $d = 0.6$), but relative tracer delivery (R_t) with respect to the reference was significantly increased after treatment ($p = 0.049$, Cohen's $d = 0.84$) compared to the baseline. Since tracer kinetics in the reference region were altered by the treatment, we performed arterial-blood sampling to obtain BP in a second group of animals. Tracer concentration in whole-blood or plasma was not significantly changed by the pretreatments (Cohen's $d = 0.07-0.27$). The striatal AUC was significantly higher in CGS21680 compared to control and KW6002 rats ($p = 0.02$, Cohen's $d = 2.4$). BP decreased significantly from 2.43±0.52 in vehicle to 1.15±0.2 after administration

of CGS21680 and non-significantly to 1.69 ± 0.41 after administration of KW6002. The efflux constant (k_2) was significantly reduced in CGS21680-treated animals ($p=0.01$, Cohen's $d=2.79$) compared to control and KW6002 groups. **Conclusion:** A_{2A} receptor stimulation causes changes in the binding characteristics of dopamine D_2 receptors. Since [^{11}C]raclopride uptake in the reference region is affected by agonist treatment, BP values obtained from SRTM are not reliable, but changes in BP can be reliably measured using a 2TCM with arterial input. Altered D_2 receptor affinity as a consequence of allosteric interactions in A_{2A} - D_2 receptor heterotetramers can be detected with PET. **References:** None

Aim/Introduction: Base on the clinical studied, [^{18}F]THK-5351, originally developed as a PET imaging tracer for detection the accumulated tau proteins in Alzheimer's disease (AD), have been revealed to show an off-target binding to monoamine oxidase B (MAO-B) with high affinity. This limitation led us aim to optimise the structure for higher selective binding to aggregated tau proteins and for the optimal pharmacokinetic profile. In this study, we designed and synthesised new heteroaromatic compounds for tau imaging and then investigated in vitro and in vivo profiles of them. **Materials and Methods:** The newly designed derivatives were synthesised and evaluated the binding affinity for tau and MAO-B by in vitro competitive binding assay using [3H]MK-6240 and [3H]THK-5351. The new tracers were prepared from the corresponding precursors and an activated fluorine-18 (^{18}F)/K222 by microscale one-pot radiosynthesis method developed in-house. Then the binding properties of the ^{18}F -derivatives were characterised by in vitro autoradiography of frozen human AD brain sections and by competitive binding assay using AD brain homogenate rich in neurofibrillary tangles (NFTs) and recombinant MAO-A and MAO-B. Pharmacokinetics and metabolism were assessed in normal mice after

intravenous injection of the ^{18}F -derivatives as well. **Results:** Through the analysis of the structure-activity (binding) relationship among the new derivatives, we found a novel core structure suitable for detection of tau-rich proteins in human AD. The derivatives with the core structure showed higher binding affinity for NFTs as sub-nanomolar range and less binding affinity for MAO-B in comparison to the 2-arylquinoline derivatives such as THK-5351. The microscale one-pot radiosynthesis of the derivatives were successfully synthesised in moderate to good radiochemical yields and the preclinical biological properties were also acceptable. Among the derivatives, [^{18}F]SNFT-1 (THK-5562) was found as the potent candidate for a tau selective PET tracer (IC_{50} : 0.8 nM for tau; >1000 nM for beta-amyloid, MAO-A and MAO-B). In vitro autoradiogram of the AD brain sections with [^{18}F]SNFT-1 displayed no off-target binding to MAO-A and MAO-B and an intense laminar binding to neocortex. The distribution of radioactivity was well consistent with the immunohistochemical distribution of tau. Additionally, [^{18}F]SNFT-1 showed high initial brain uptake and rapid clearance suitable for brain PET imaging. Preferably, the radiolabelled metabolites of [^{18}F]SNFT-1 did not penetrate the blood-brain barrier in mice. **Conclusion:** These results suggested that the novel ^{18}F -labelled tracer [^{18}F]SNFT-1 is a promising candidate for visualising the accumulated tau proteins in the AD brain with less of off-target binding. **References:** None

OP-225

[^{18}F]FEPPA PET/CT Imaging to Assess STAT Inhibitor Effect in LPS-induced Neuroinflammation Mouse Models

C. San^{1,2}, P. Millot^{1,3}, M. Brault², F. Hontonnou², L. Sarda-Mantel^{2,4}, N. Vignal^{1,2,4}, F. Mouton-Liger^{1,3}, B. Hosten^{1,2};

Aim/Introduction: Signal transducer and activator of transcription 3 (STAT3) is a transcription factor involved in the regulation of several cellular activities. STAT3 abnormal activation promotes tumour growth and proliferation and plays a key role in mediating inflammatory signals. Thus, STAT3 inhibitors have become of major interest for treatment of cancers but also chronic inflammatory diseases such as neurodegenerative diseases. Our previous work has shown that our lipopolysaccharides (LPS)-induced neuroinflammation models present a translocator protein (TSPO) overexpression and STAT3 excessive activation. Besides, these models have also been studied by PET imaging with a TSPO ligand, [^{18}F]FEPPA. The aim of the study was to investigate the anti-inflammatory response

of a STAT3 inhibitor (Stattic) with [^{18}F]FEPPA PET imaging in these models. **Materials and Methods:** Eight-week-old C57Bl/6 male mice ($n=5/\text{group}$) were used for this study. Two groups of neuroinflammation model induced by i.p injection of LPS (acute: 5mg/kg for 1 day and chronic: 1mg/kg for 3 days) and a saline control group were explored. Each mouse also received an i.p injection of either 20mg/kg Stattic or a vehicle composed of 2% DMSO and 30% PEG300. 24 hours after the treatment, mice received 10MBq of [^{18}F]FEPPA and underwent a 1-hour dynamic PET followed by a CT scan. Image analysis and pharmacokinetic modelling using 2TCM-1K model were performed with Pmod v3.9: cerebral time activity curves (TAC) were obtained after ROI automatic drawing based on an atlas. To confirm LPS effect on STAT3 phosphorylation and STAT3 effect on microglial activation, immunoblot of phospho-STAT3/STAT3 and Iba1 immunofluorescence coupled with morphometric analysis of microglia were respectively performed on mouse hippocampus ($n=7-9/\text{group}$). **Results:** [^{18}F]FEPPA cerebral uptake and phospho-STAT3/STAT3 ratio are significantly higher in chronic LPS group compared to control. However, no significant change in [^{18}F]FEPPA cerebral uptake in the Stattic groups is observed compared to the vehicle groups. Interestingly, an increase of K1 (but not significant) is observed in the Stattic groups which might be explained by an increase of [^{18}F]FEPPA plasmatic unbound fraction in these groups. STAT3 inhibition reduces significantly phospho-STAT3/STAT3 ratio and microglial activation as a decrease of microglial body size and an increase of branching processes size are observed in Stattic groups. **Conclusion:** Although biochemical analysis revealed a decrease of microglial activation by Stattic, this study suggests that TSPO PET imaging is not sensitive enough to investigate Stattic anti-inflammatory effect. Besides, further studies should be pursued to evaluate Stattic effect on [^{18}F]FEPPA plasmatic unbound fraction. **References:** None

OP-226

Brain distribution and retention of ^{89}Zr and ^{111}In labeled bispecific antibody in an amyloid beta mouse model

T. Gustavsson¹, T. Tran², S. Syvänen¹, D. Sehlin¹;

¹Department of Public Health and Caring Sciences, Uppsala University, Uppsala, SWEDEN, ²Department of Radiopharmacy, Karolinska University Hospital, Stockholm, SWEDEN.

Aim/Introduction: Brain uptake of antibodies is restricted by the blood-brain barrier (BBB) at the vasculature of the brain. We have created a bispecific antibody, RmAb158-scFv8D3, which binds to the mouse transferrin receptor (8D3 moiety) and is transported over the BBB via transcytosis. We have previously used it as a PET ligand to target amyloid-beta (A β) in the brain [1]. The aim of this study was to evaluate brain uptake and retention, blood pharmacokinetics, and biodistribution of RmAb158-scFv8D3 labeled with ^{89}Zr

and ^{111}In in a mouse model of A β pathology (tg-ArcSwe). **Materials and Methods:** RmAb158-scFv8D3 conjugated with DFO* or CHX-A"-DTPA was labeled with ^{89}Zr or ^{111}In , respectively. Binding of RmAb158-scFv8D3 following labeling was evaluated with ELISA. Radiolabeled products were incubated in plasma and stability was assessed with instant thin-layer chromatography. Labeled RmAb158-scFv8D3 was i.v. injected in 18 months old tg-ArcSwe and wild type mice (WT) and blood pharmacokinetics were evaluated from 4 h to 72 h after injection. Mice receiving [^{111}In]-RmAb158-scFv8D3 were SPECT scanned after 3 days. Ex vivo brain uptake of [^{89}Zr]RmAb158-scFv8D3 and [^{111}In] RmAb158-scFv8D3 was quantified at 2 h and 72 h after injection in tg-ArcSwe and WT mice. Biodistribution and ex vivo brain autoradiography were performed after 72 h. **Results:** Specific activity for ^{89}Zr and ^{111}In labeled RmAb158-scFv8D3 was 74 MBq/ng and 280 MBq/ng, respectively. Post-labeling ELISA demonstrated that labeled RmAb158-scFv8D3 retained binding to transferrin receptor and A β protofibrils, and was stable in plasma for 24 h. Half-life in blood for [^{89}Zr]RmAb158-scFv8D3 and [^{111}In]RmAb158-scFv8D3 were 19 h and 9 h, respectively. SPECT scanning demonstrated no difference between tg-ArcSwe and WT mice 3 days after injection of [^{111}In]RmAb158-scFv8D3, which displayed ex vivo brain concentrations (%ID/g(brain)) of 1.31 ± 0.13 at 2 h post injection and 0.7 after 72 h. Brain uptake of [^{89}Zr]RmAb158-scFv8D3 was 1.12 ± 0.67 at 2 h after injection, and 0.42 ± 0.04 and 0.24 ± 0.07 in tg-ArcSwe and WT mice, respectively, after 72 h. Ex vivo brain autoradiography showed a high and specific [^{89}Zr] RmAb158-scFv8D3 signal in brain regions with abundant A β pathology. Both ^{89}Zr and ^{111}In were highly retained in liver, spleen, and bone. **Conclusion:** This study demonstrates that bispecific brain penetrating antibodies labeled with radiometals are retained in the brain 2 h after injection. Still, the in vivo stability of radiometal labeled antibodies during transcytosis and prolonged retention in brain parenchyma needs further investigation. **References:** [1] Theranostics. 2017 Jan 1;7(2):308-318

OP-227

TSPO expression in vivo is moderated by sex in response to amyloidosis but not to tau pathology in mouse models of neurodegenerative diseases

G. Biechele¹, N. Franzmeier¹, M. Ewers¹, T. Blume², F. Eckenweber¹, C. Sacher¹, J. Luque², L. Beyer¹, F. Ruch-Rubinstein¹, S. Lindner¹, F. Gildehaus¹, B. von Ungern-Sternberg¹, P. Bartenstein¹, A. Rominger³, G. Höglinger⁴, J. Herms¹, M. Brendel¹;

¹University Hospital of Munich, Munich, GERMANY, ²DZNE Munich, Munich, GERMANY, ³Inselspital Bern, Bern, SWITZERLAND, ⁴Hannover Medical School, Hannover, GERMANY.

Aim/Introduction: In vivo assessment of neuroinflammation by 18 kDa translocator protein positron-emission-

tomography (TSPO-PET) ligands receives growing interest in preclinical and clinical research of neurodegenerative disorders. Higher TSPO expression in females has been reported for cognitively normal humans, but such effects have not yet been evaluated in rodent models of neurodegeneration and their controls. Thus, we aimed to investigate the impact of sex on TSPO expression in amyloid and tau mouse models and wild-type controls. **Materials and Methods:** Longitudinal ^{18}F -GE-180 TSPO-PET (^{18}F -GE180) data of C57Bl/6 (wild-type), App^{NL-G-F} (β -amyloid model), and P301S (tau model) mice were evaluated between two and twelve months of age. App^{NL-G-F} received additional longitudinal β -amyloid-PET imaging (A β -PET; ^{18}F -florbetaben). Immunohistochemistry served for validation of PET data by microglial (Iba1, CD68) and tau (AT8) markers. PET and immunohistochemistry were quantified in cortical regions and compared by linear mixed models (PET) and analysis of variance (immunohistochemistry) between sexes. **Results:** TSPO-PET values in wild-type mice indicated an increase with time (female: +23%, male +4%) and a significant time x sex interaction was found ($T=-4.171$, $p<0.001$). The A β model App^{NL-G-F} revealed a distinct cortical increase of TSPO-PET values from 2.5 to 10 months in female mice (+31%), whereas male App^{NL-G-F} mice only showed minor increases (+6%). The linear mixed model indicated a significant sex x time interaction ($T=-2.953$, $p=0.0048$), validated by Iba1 and CD68 immunohistochemistry. A β -PET quantification in the same App^{NL-G-F} mice indicated no significant time x sex interaction ($T=0.425$, $p=0.673$). The P301S tau model showed strong cortical increases of TSPO-PET from 2 to 8.5 months of age (female: +32%, male: +36%) but no significant sex x time interaction ($T=-0.671$, $p=0.504$) and no sex differences in Iba1, CD68 or AT8 were observed. **Conclusion:** Female mice indicate a sex dependent elevation of TSPO expression in response to amyloidosis but not to tau pathology. Sex requires attention when TSPO-PET is used as biomarker of glial activation in mouse models of neurodegeneration and requires detailed studies in human disease. **References:** None

Aim/Introduction: Accumulation of α -synuclein is a neuropathological hallmark of Parkinson's disease, multiple system atrophy, and dementia with Lewy bodies. There is an unmet need for the development of an imaging biomarker for α -syn. Initial studies suggested that the tau tracer [^{11}C]PBB3 displays some degree of binding to α -syn [1,2]. Based on these findings, a library of compounds structurally related to PBB3 was developed. The aim of the present study was to identify the compound(s) displaying the strongest fluorescence signal to Lewy aggregates and to characterize the binding properties of the best candidate (C05-01) using in vitro binding techniques. **Materials and Methods:** A series of 44 compounds derived from the PBB3 scaffold were examined with fluorescence imaging using a qualitative assessment of the strength of the signal to α -synuclein, amyloid- β and tau aggregates. Five compounds were selected and the fluorescence signal was assessed semiquantitatively using tissue microarrays (TMAs) derived from brain samples with different proteinopathies. In vitro binding studies using α -synuclein fibrils and human brain homogenates were performed to measure the affinity for α -synuclein. Autoradiography studies using fresh frozen tissue and TMAs were performed to assess the binding in brain tissue. **Results:** C05-01 was the compound selected from the initial screening and semiquantitative assay. In vitro binding assays using human brain homogenates and recombinant fibrils indicated that C05-01 had higher affinity for α -synuclein ($K_D/K_i \approx 25$ nM for fibrils, $K_i \approx 3.5$ nM for brain homogenates) as compared with PBB3 ($K_D \approx 60$ nM). In autoradiography studies using fresh frozen human tissue and TMAs, [^3H]C05-01 displayed specific binding in cases with α -synuclein pathology. C05-01 showed specific binding also in AD tissue with amyloid- β and tau pathology, as well as relatively high non-specific and off-target binding. None of the possible off binding target studied, such as MAO-A, MAO-B, amyloid- β , Tau, Sigma 1 receptors seemed to be responsible for this off-target binding. **Conclusion:** C05-01 is the first PBB3 analogue developed as potential compound targeting α -synuclein. Despite improved affinity for α -synuclein, additional efforts are needed to optimize the pharmacological and physicochemical properties of this series of compounds as ligands for α -synuclein. This study also showed that the construction of TMAs from different proteinopathies provides a tool for evaluation of fluorescent or radiolabeled compounds binding to misfolded proteins. **References:** 1. OP-229**Amyloid beta (A β) imaging in transgenic mice - comparison of [11 C]PiB and an antibody-based ligand**

S. Meier¹, J. Rokka², J. Eriksson², S. Roshabin¹, U. Neumann³, D. Sehlin¹, S. Syvänen¹;

¹Department of Public Health and Caring Sciences, Uppsala, SWEDEN, ²Department of Medicinal Chemistry, Uppsala, SWEDEN, ³Neuroscience Research, Novartis Institutes for BioMedical Research, Uppsala, SWITZERLAND.

Aim/Introduction: Amyloid-beta (A β) positron emission tomography (PET) has become an important inclusion criterion for enrolment of patients with Alzheimer's disease (AD) in clinical trials. However, all available radioligands for A β , such as [11 C]PiB, reflect levels of insoluble A β plaques. Thus, they may not be able to quantify effects of candidate drugs aimed at reducing other forms of A β , e.g. by decreasing the intra-brain production of A β and early formed soluble A β aggregates. In a previous study, we showed that PET with a radiolabeled antibody could quantify a reduction in soluble A β aggregates after treatment with a BACE-1 inhibitor in an early stage of A β pathology in a mouse model(1). The aim of the present study was to compare the antibody-based PET approach to [11 C]PiB in transgenic mice with advanced A β pathology, including mice that underwent treatment with a BACE-1 inhibitor. **Materials and Methods:** Transgenic animals (tg-ArcSwe, model of A β pathology) at the age of 16 months when the study started, were treated during 2 months with BACE-1 inhibitor NB-360(2) (n=14) and compared to an untreated control group (n=14). After treatment, the animals received a [11 C]PiB PET scan followed by a scan with the A β protofibril selective radioligand [124 I]RmAb158-scFv8D3(5). A baseline group (n=14), aged 16 months, also underwent [11 C]PiB and [124 I]RmAb158-scFv8D3 PET scanning. Brain tissue was isolated after PET and analyzed ex vivo. **Results:** Hippocampal SUV for [124 I]RmAb158-scFv8D3 in treated animals was 0.059 ± 0.021 and significantly lower compared to controls 0.078 ± 0.022 (P=0.023) (Figure 1A). Hippocampal [124 I]RmAb158-scFv8D3 SUV of treated animals and baseline group (0.052 ± 0.023) was not statistically different. In contrast, hippocampal SUV quantified with [11 C]PiB was not significantly different between the treated animals 0.26 ± 0.18 and the controls 0.28 ± 0.16 . In the baseline group the hippocampal SUV was 0.13 ± 0.07 . **Conclusion:** Protofibril selective radioligand [124 I]RmAb158-scFv8D3 was able to monitor treatment effects with PET imaging in tg-ArcSwe mice with advanced A β pathology. [11 C]PiB PET was not able to detect these changes in side by side comparison, indicating a need for improved PET imaging to study effects of AD treatments in clinical trials. **References:** 1. Channel 6

OP-230**Simulation and first measurements of a prototype ultra-long FOV PET/CT scanner**

M. Conti, M. Aykac, H. Bal, B. Bendriem, D. Bharkhada, J. Cabello, L. Eriksson, V. Panin, H. Rothfuss, S. Siegel; Siemens Medical Solutions, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: There is great interest in long axial field-of-view (FOV) PET/CT scanners: their capability to simultaneously image multiple organs and their high sensitivity enables novel research and clinical applications. Design criteria of such devices must include state-of-the-art technology that not only exploit the very high sensitivity, but also offers excellent time of flight (TOF) performance and spatial resolution. Furthermore, the design should consider trade-off between performance and cost. Using Monte Carlo (MC) simulation, this work focuses on axial coverage, acceptance angle for lines-of-response (LORs), time coincidence window, and their effects on spatial resolution and sensitivity. Based on the technology introduced with Biograph Vision, a 106-cm long axial FOV prototype was designed and assembled, and initial characterization and phantom experiments are presented. **Materials and Methods:** The work included Monte Carlo GATE and numerical simulation of the scanner, with incorporation of synthetic images derived from patient data sets acquired on Vision scanners. Sensitivity was studied as a function of the axial coverage of a PET scanner, of the LOR acceptance angle, and of the time coincidence window. Preliminary time and spatial resolution, and sensitivity measurements, as well as a standard image quality phantom, were performed on a 106-cm long prototype. **Results:** The MC simulation confirmed the excellent sensitivity a 106-cm long PET/CT scanner, together with other design choices: a time coincidence window below 5 ns allowed to collect more than 90% of the true coincidences in typical patient scans, thus reducing excessive random coincidences; opening the acceptance angle from 20° to 52° (full acceptance angle for the 106-cm long prototype) increases the sensitivity by about a factor 2; the simulated spatial resolution is very similar to that of the Biograph Vision. The experimental data confirmed excellent spatial

and time resolution, comparable to previously published values for the Biograph Vision scanners. The increase in sensitivity enables dose and/or scan time reduction, while maintaining the phantom image quality of the Biograph Vision: a visual and quantitative comparison with Vision data is presented. **Conclusion:** Simulation and preliminary data from a 106-cm long prototype PET/CT scanner are presented. Excellent time and spatial resolution, as well as sensitivity, are demonstrated by preliminary measurements. Phantom images demonstrate the feasibility of lower dose or shorter scan time. **References:** None

OP-231

Fully digital-PET is unaffected by any deterioration in TOF resolution and TOF image quality in the wide range of routine PET count rates

J. Salvadori¹, F. Odille¹, G. Karcher², P. Marie³, L. Imbert¹;
¹IADI UMR1254, Vandoeuvre-lès-Nancy, FRANCE, ²Nancyclotep molecular imaging platform, Vandoeuvre-lès-Nancy, FRANCE, ³UMR1116, Vandoeuvre-lès-Nancy, FRANCE.

Aim/Introduction: Digital PET involving silicon photomultipliers (SiPM) provides an enhanced time-of-flight (TOF) resolution, as compared with photomultiplier (PMT)-based PET, but also, a better prevention of the count-related rises in dead time and pile-up effects mainly due to smaller trigger domains (i.e. the detection surfaces associated to each trigger circuit). This study aimed to determine whether this latter property could help prevent against deteriorations in TOF resolution and TOF image quality in the wide range of the PET count rates documented in clinical routine. **Materials and Methods:** Variations, according to count rates, in timing resolution and in TOF-related enhancement of the quality of phantom images, were compared between the first fully digitalPET (Vereos) and a PMT-based PET (Ingenuity). Single count rates values were additionally extracted from the list mode data of routine analog- and digital-PET exams at each 500-ms interval, in order to determine the ranges of routine PET count rates. **Results:** Routine PET count rates were lower for the Vereos than for the Ingenuity for which the upper limits were estimated at approximately 21.7 and 33.2 Mcps after the injection of respectively 3 and 5 MBq.kg⁻¹ of current 18F-labeled tracers. At 5.8 Mcps, corresponding to the lower limit of the routine count rates documented with the Ingenuity, timing resolutions provided by the scatter phantom were 326 and 621 ps for Vereos and Ingenuity, respectively. At higher count rates, timing resolution was remarkably stable for Vereos but exhibited a progressive deterioration for Ingenuity, respectively reaching 732 and 847 at the upper limits of 21.7 and 33.2 Mcps. The averaged TOF-related gain in signal/noise ratio was stable at approx. 2 for Vereos but decreased from 1.37 at 5.8 Mcps to 1.15 and 1.01 at respectively 21.7 and 33.2 Mcps for Ingenuity.

Conclusion: Contrary to the Ingenuity PMT-based PET, the Vereos fully digital PET is unaffected by any deterioration in TOF resolution and consequently, in the quality of TOF images, in the wide range of routine PET count rates. This advantage is even more striking with higher count-rates for which the preferential use of digital-PET should be further recommended (i.e. dynamic PET recording, higher injected activities). **References:** None

OP-232

Clinical impact of fully automated multiparametric PET imaging using direct Patlak reconstruction: Evaluation of 100 dynamic whole-body 18F-FDG PET/CT scans

A. H. Dias, M. F. Pedersen, H. Danielsen, O. L. Munk, L. C. Gormsen; Aarhus Universitetshospital, Aarhus, DENMARK.

Aim/Introduction: Imaging guidelines for 18F-FDG PET/CT endorse static images at a single time-point, usually 60 minutes after tracer administration. The method is well-proven, but hampered by the inherent omission of tracer kinetics from injection to acquisition. Recent methodology allows for whole-body dynamic PET/CT scanning using conventional PET-cameras. The dynamic whole-body data can be used for direct reconstruction of parametric images of the metabolic rate of glucose using Patlak linearization¹, thus utilizing the entire information contained in the blood input function and tissue time-activity curves. Our goal was to evaluate whether parametric images have superior lesion target-to-background and if this translates clinically. **Materials and Methods:** Retrospective analysis of 100 patients spanning a range of mostly malignant diseases, scanned using a multiparametric PET acquisition protocol on a Siemens Biograph Vision 600 PET/CT scanner. A 70-min dynamic whole-body PET scan was performed immediately after injection of 18F-FDG. The scan included a 6-min dynamic scan of the chest region followed by multiple whole-body passes from 6-70 min. Parametric Patlak images were reconstructed using data from 40-70 min and an image-derived aorta input function. In addition, a standard-of-care static PET image was reconstructed using data from 60-70min. Patlak images of metabolic rate (K) and distribution volume (V) were compared to standard 60-min static SUV images. Standard SUV values of target regions were compared with parameters obtained from dynamic scanning using Patlak reconstructions. **Results:** Whole-body parametric Patlak images were of good visual quality and comparable to standard static SUV images. Observed lesion target to background contrast was superior in the parametric K images (p<0.001), allowing for easier detection of lesions, particularly in organs with high blood pool signal. There was no observable difference between disease groups in background normalized K/SUV ratios. In four patients with focal FDG uptake in the upper arm, Patlak imaging correctly omitted the signal from the K-image avoiding false positives

and subsequent biopsies. However, although lesions were easier to detect by Patlak K-images, no additional lesions were detected. **Conclusion:** Whole-body parametric Patlak-PET/CT imaging provides supplementary information, which may improve the evaluation of PET images. Pointedly, parametric imaging reduced the number of false positive lesions and had superior target-to-background ratios enabling easier image interpretation. Future prospective studies will clarify if parametric PET/CT may also detect more lesions in diseases characterized by relatively low target-to-background ratios on conventional static PET/CT. **References:** 1.Patlak,C,et al. OP-233

Use of population input functions for FDG whole-body Patlak imaging

J. van Sluis¹, M. Yaqub², A. H. Brouwers¹, W. Noordzij¹, R. Boellaard²;

¹University Medical Center Groningen, Groningen, NETHERLANDS, ²Amsterdam University Medical Center, Amsterdam, NETHERLANDS.

Aim/Introduction: SUV derived from PET scans are widely used in clinical practice for diagnosing and evaluating treatment response in oncology. However, SUV can be influenced by changes in plasma kinetics due to treatment possibly causing inaccurate assessments. Recently, whole-body Patlak images can be obtained from a combined acquisition of first 10 min of dynamic imaging over the heart to obtain the arterial input function (IF) followed by multiple whole-body sweeps up to 60 min pi. Population averaged input function (PIF) could exclude the first dynamic scan and minimize whole-body sweeps to an interval of 30-60 min pi. Here, the effects of (incorrect) PIFs on the accuracy of the proposed Patlak method were assessed. In addition, the extent of mitigating these biases through rescaling of the PIF to image derived values at 30-60 min pi was evaluated.

Materials and Methods: Using a representative IF and rate constants from literature, various tumor time activity curves (TACs) were simulated. Variations included multiplication of the IF with a positive and negative gradual bias over 60 min of 5, 10, 15, 20, and 25% and use of rate constants (K_1 , k_3 , and both K_1 and k_2) multiplied by 2, 1.5, and 0.75. The blood volume fraction was fixed at 8.9%. Subsequent Patlak analysis using the original IF (representing the PIF) was used to obtain the influx constant (K_i) for the differently simulated TACs. In addition, the PIF was scaled towards the correct value using the 30-60 min pi time-interval, simulating scaling of the PIF to image derived values. Next, K_i were obtained using these rescaled PIFs. Influence of variabilities in IF and rate constants, and rescaling the PIF on bias in K_i was evaluated. **Results:** Percentage bias in K_i

seen using simulated incorrect IFs varied from -15 to 15% depending on the simulated amplitude and direction of the IF modifications. Subsequent scaling of the PIF reduced these K_i biases between -2 and 4% and between -0.9 and 1%, respectively. Bias in K_i due to use of non-rescaled incorrect PIFs tended to be larger for TACs with higher simulated K_i . In most cases, rescaling the PIF mitigated these K_i biases to below 5%. **Conclusion:** Simulations suggest that scaling of an (incorrect) PIF to IF values seen in whole-body dynamic imaging from 30-60 min pi will provide accurate K_i estimates (<5% bias). Consequently, whole-body Patlak imaging from 30-60 min pi offers possibilities for clinical application. **References:** None

OP-234

Two short ¹⁸F-FDG PET/CT dynamic acquisitions to evaluate with accuracy the influx constant with Patlak method in patients with lung cancer

V. Scolozzi¹, A. Capotosti², L. Indovina², S. Taralli¹, M. Lorusso¹, C. Caldarella¹, M. L. Calcagni^{1,3};

¹Fondazione Policlinico Universitario A. Gemelli IRCCS, UOC Medicina Nucleare, Dipartimento di Diagnostica per Immagini, Radioterapia Oncologica ed Ematologia, Rome, ITALY, ²Fondazione Policlinico Universitario A. Gemelli IRCCS, UOS Dosimetria Clinica e Radioprotezione, Dipartimento di Diagnostica per Immagini, Radioterapia Oncologica ed Ematologia, Rome, ITALY, ³Università Cattolica del Sacro Cuore, Istituto di Medicina Nucleare, Rome, ITALY.

Aim/Introduction: Patlak graphical analysis is a quantitative method that allows an accurate estimation of ¹⁸F-FDG influx constant (K_i), known to be more reliable than more common semiquantitative parameters. It is less used in clinical practice since it requires a long-lasting (60min) dynamic acquisition. Aim: to propose a new approach for estimating K_i with Patlak method using two short dynamic acquisitions ($K_{i,SDA}$) instead of the standard one (K_i). **Materials and Methods:** Twenty-four non-small-cell lung cancer patients, prospectively enrolled, underwent 60min dynamic PET acquisition over the thorax after ¹⁸F-FDG injection (134-507MBq). A venous blood sampling was performed at 45min to obtain ¹⁸F-FDG plasmatic activity. To estimate K_i , the entire dynamic acquisition was used: image derived input function (IDIF) was obtained drawing VOI on descending aorta (0-60min) using the plasmatic activity as quality control; tissue response drawing VOI on tumour (10-60min). To estimate $K_{i,SDA}$, only the early (0-10min) and the late phase (40-60min) of dynamic acquisition were used. IDIF_{SDA} was obtained utilizing data of early phase (0-10min) of dynamic acquisition and reconstructing the last part with mean values of mono-exponential fitting of all patients (since it can be expressed by a mono-exponential function), and using the plasmatic activity at 45min as constrain. Spearman's rank, Intraclass Correlation Coefficient, Passing-

Bablok regression and Bland-Altman method were used for correlation and concordance between K_1 and $K_{1,SDA}$. **Results:** In all patients (n=24) the correlation coefficient (R^2) between Integral IDIF and Integral IDIF_{SDA} was equal to 0.9977. The mean values of K_1 and $K_{1,SDA}$ were 0.0388 ± 0.0268 and 0.0374 ± 0.0261 , respectively. Spearman's correlation coefficient (ρ) between K_1 and $K_{1,SDA}$ was equal to 0.991 ($p < 0.001$). The comparison between the two methods showed a slope of 0.97 (95%CI: 0.91–1.00) and intercept of 0.00005 (95%CI: 0.00132–0.00118) and mean of differences of 0.001497 (95%CI: 0.0007–0.0021). **Conclusion:** Our approach is reliable and easily achievable. The excellent correlation between Integral IDIF and Integral IDIF_{SDA} demonstrates that only a short early dynamic acquisition and a venous sample are enough to accurately reconstruct IDIF. The great correlation between K_1 and $K_{1,SDA}$ supports the possibility to apply Patlak method using two short dynamic acquisitions, instead of the standard longer one. The use of two short acquisitions in order to perform Patlak method implies two important practical advantages in clinical routine: 1) more comfort for patients and less risk of movement artefacts; 2) the possibility to obtain the influx constant, especially useful in the response assessment, in a larger number of patients. **References:** None

OP-235

Comparing the accuracy of global and blockwise deadtime correction for the BrainPET scanner

A. Issa¹, J. Scheins¹, L. Tellmann¹, C. Régio Brambilla^{1,2}, H. Xu¹, N. Shah^{1,2,3}, C. Lerche¹;

¹Institute of Neuroscience and Medicine 4, INM-4, Forschungszentrum Jülich, Jülich, GERMANY, ²Institute of Neuroscience and Medicine 11, INM-11, JARA, Forschungszentrum Jülich, Jülich, GERMANY, ³JARA - BRAIN - Translational Medicine, Aachen, GERMANY.

Aim/Introduction: All components in the PET detector system contribute to dead time (DT) losses. DT affects the quantitation of PET, especially for high activity in the field of view. Thus, DT distorts the measured time-activity curves (TAC). The uncorrected count rate in each detector block varies significantly which leads to different DT for each block. Therefore, processing the DT losses on the block-wise DT correction frame potentially provides more accurate results. The main goal of this work is to improve the DT correction by implementing an independent DT correction for each block of the Siemens 3T MR/BrainPET scanner. **Materials and Methods:** On our Siemens 3T MR/BrainPET scanner, the standardly applied DT correction has been implemented as a global, count rate-dependent, average correction factor. For this, the constant fraction discriminator (CFD) counts for each block are summed to estimate the global single counts, and the overall DT induced single count losses. For typical PET measurements, global single count rates

(sum of all 192 blocks) and the corresponding corrections are compared to individual single count rates and the corresponding corrections. **Phantom measurements.** Decay experiments using a cylindrical phantom filled with high activity (685 MBq and 257 MBq) of [¹⁸F, 20 hours' duration] centered inside of FOV. **Patient measurements.** ([¹⁸F] FET, 50 minutes' duration) measurement for brain tumors, the injected activity of 234 MBq. Moreover, ([¹¹C] ABP688, 65 minutes' duration) measurement, the injected activity of 437 MBq. **Results:** DT losses are very different for each detector block according to the various count rates, which is caused by the block position concerning the activity distribution. For the phantom measurements, the blockwise single counts follow the non-paralyzable model (NPM). For the NPM, the average of blockwise dead time was about 200 ns (Scheins, 2018). For the patients' measurements, the single counts of the 192 blocks depend strongly on the angular and axial block positions, due to the cylindrical geometry of the BrainPET insert. Therefore, global dead time correction is potentially insufficient for high activity and diverse blockwise count rates. Therefore, the independent DT correction for each detector block is necessary to achieve higher accuracy in quantitative imaging. **Conclusion:** The block counts follow the non-paralyzable model in the Siemens Brain PET insert. There are important differences between average single counts and blockwise single counts for the different blocks depending on their geometrical positions. **References:** Scheins, J. J., et al. "PET Quantification." Hybrid MR-PET Imaging. 2018. 162-182.

Aim/Introduction: EasyPET technology is a novel concept for high-resolution PET imaging based on the smart rotation of detector modules. Its uniquely cost-effective scanning method achieves excellent imaging performance with only 10-20% of the components used in other PET systems, being able to finely scan millions of LORs in minutes and cover full body mouse axial imaging with a much smaller number of detectors. EasyPET achieves a great level of

detail and spatial resolution, very uniform in all the FOV due to the intrinsic capacity to mitigate parallax errors, since its detectors are always collinear, unlike ring-based scanners. Detector arrays can have different geometries and each scan can be performed with different parameters in order to achieve different sensitivity, level of desired detail/speed or image specific regions of interest within the FOV, which is also a unique capability of this technology. This study aims to present and characterize the performance of iPET, a new preclinical scanner based on easyPET technology, following NEMA NU 4-2008 standards. **Materials and Methods:** The iPET system uses 2 arrays of 50x6 LYSO crystals of 1.5x1.5x20 mm³ pixel size coupled to corresponding arrays of silicon photomultipliers with 1 mm² active area, covering an axial FOV of 8 cm length and maximum radial FOV of 6 cm diameter. A dedicated 3D reconstruction method was developed based on OSEM and MLEM algorithms, considering the original geometry of the scanner and high number of possible LORs. **Results:** Based on NEMA NU 4-2008 standards, scans of NEMA IQ and NEC phantoms filled with ¹⁸F-FDG and a point-like ²²Na source were simulated and carried out in available systems, in order to determine spatial resolution, sensitivity, uniformity and other results achieved by easyPET based scanners. Imaging studies of murine models of disease carried out at iCBER will also be presented. Image improvements based on the selection of regions of interest and a dedicated reconstruction algorithm will be shown. **Conclusion:** EasyPET is the most efficient technology for cost reduction of preclinical PET scanners, without compromising their capacity for high-resolution molecular imaging of small animal models of disease including fast dynamic studies with short-lived radionuclides such as ¹⁸F or ⁶⁸Ga. **References:** Patent WO/2016/147130. Channel-based Energy Resolution of TOFPET2C-read PET Detectors

V. Nadig¹, D. Schug^{1,2}, H. Radermacher¹, B. Weissler^{1,2}, V. Schulz^{1,2,3};
¹Physics of Molecular Imaging Systems, RWTH Aachen University, Aachen, GERMANY, ²Hyperion Hybrid Imaging Systems GmbH, Aachen, GERMANY, ³Institute of Physics III B, RWTH Aachen University, Aachen, GERMANY.

Aim/Introduction: In time-of-flight positron emission tomography (ToF-PET), clinical systems aim to resolve the timing information of a coincidence event with a resolution of around 200 ps, resulting in a high gain in the signal-to-noise ratio of PET images [1]. Additionally, an energy resolution of about 10 - 12 % is required to reliably filter out scatter. Whether this resolution can be achieved, strongly depends on the employed detector blocks, i.e.,

the scintillators, photo-sensors, and readout electronics used. Amongst others, important advances have been accomplished in electronics during the past decades [2]. A ToF-PET system constitutes ten-thousands of detector channels requiring several hundred application-specific circuits (ASICs) for readout. Thus, it is essential to consider the performance spread of individual readout channels and its impact on the system resolution. **Materials and Methods:** We used two detector blocks, each consisting of a 8 x 8 12-mm-high lutetium-yttrium-orthosilicate (LYSO) scintillator matrix one-to-one coupled to a S14161-3050-HS-08 photo-sensor (pitch 3.2 mm) using a two-component dielectric gel. Signals from the 64 channels of each detector block were read out consecutively by twelve samples of the latest version of the TOFPET2 ASIC (version 2c), in which research and industry developed an increasing interest in recent years. This way, the impact of the ASIC on the performance of individual channels is tested. Employing Sodium-22 point sources with a total activity of approximately 2 MBq, the linearity of the energy spectra and the energy resolution of each of the in total 768 ASIC channels was determined. **Results:** For each ASIC sample, channel linearity ratios and energy resolutions showed Gaussian distributions. Effects of single channels, i.e., border effects, non-linearities and short circuits, can be identified and excluded from further evaluation or noted for an adjustment of their configuration, e.g., applied thresholds. Computing the performance globally, all ASIC samples achieved energy resolutions of approx. 10.3 %. **Conclusion:** We found a low spread in channel energy resolution, which supports the usage of a large number of TOFPET2 ASICs as readout electronics in a clinical ToF-PET system, without the need for excessive calibration/matching effort or the risk of ASIC-dependent performance variation. Still, the possibility to identify individual channels behaving differently allows for the adjustment of their configuration parameters. The low energy resolution can be used to filter out scatter. **References:** [1] Surti et al. (2015): Advances in time-of-flight PET, doi:10.1016/j.ejmp.2015.12.007. [2] Berg et al. Optimizing energy window width for digital SPECT-CT in myocardial perfusion imaging

R. Hirvilammi¹, M. Seppänen^{1,2}, M. Hakulinen³, J. Knuuti², T. Noponen^{1,4};

¹Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND, ²Turku PET Centre, Turku University Hospital, Turku, FINLAND, ³Department of Clinical Physiology and Nuclear Medicine, Kuopio University Hospital, Kuopio, FINLAND, ⁴Department of Medical Physics, Turku University Hospital, Turku, FINLAND.

Aim/Introduction: Good energy resolution of digital SPECT-CT systems allow imaging with a narrow energy window. Narrow energy window can reduce the number of scattered photons improving image quality. In this study the benefits of narrowing the energy window was studied with cardiac phantoms. **Materials and Methods:** Two custom designed 3D printed cardiac phantoms (Kuopio Cardiac Phantom) modeling the left ventricles were used. Other phantom included 5 and other 9 mm long cube shaped defects located in the middle of cylindrical wall. Both phantoms were filled with ^{99m}Tc -pertechnetate with activity concentration of 67.5 kBq/ml. Phantoms were fixed inside a plastic background box containing 24.5 l of ^{99m}Tc -pertechnetate with the concentration of 10.6 kBq/ml. Data were acquired using Discovery NM/CT 670 CZT system (GE Healthcare, Tirat Hacarmel, Israel) with wide-energy high resolution collimators using following parameters: 60 projections over 180° with 40-s time-per-projection, L-mode, 64X64 matrix and energy window of 140 keV \pm 7.5%. Attenuation correction was done using low-dose CT. The data acquisition was carried out in list-mode which allowed the changing of energy window afterwards. New sinograms were created with energy windows from ± 6 to $\pm 2\%$. Sinograms were reconstructed using iterative OSEM based algorithm with and without collimator correction. From reconstructed images count profiles containing the cube shaped defects were extracted using MATLAB (version R2020A, Natick, Massachusetts, USA). Double Gaussian function was fitted to count profiles to calculate the contrasts of defects. Also, noise was calculated as standard deviation from the apical data points of the phantoms. **Results:** When the energy window was narrowed from ± 7.5 to $\pm 4\%$ the contrast of defects increased from 28% to 32%. When the energy window was further narrowed to $\pm 3\%$ the contrast decreased by 2 percentage points compared to the contrast in images with $\pm 7.5\%$ energy window. Collimator correction decreased noise especially in images with energy window of $\pm 7.5 - \pm 4\%$ and increased the contrast by 2.1 percentage point when $\pm 7.5\%$ energy window images were compared with and without the correction. In images with $\pm 4\%$ or narrower energy windows the contrast decreased with collimator correction when compared to the images without the correction. **Conclusion:** Narrowing energy window can improve the contrast of defects in myocardial perfusion imaging. Energy window of $\pm 4\%$ seems to produce the best contrast. By using collimator correction it is possible to decrease noise in myocardial images to further improve their quality. **References:** None

OP-239

Bone metabolism may be monitored through the absolute quantification provided by a whole-body 360° CZT SPECT/CT camera during the healing period of vertebral fractures

A. Bahloul, L. Imbert, A. Blum, G. Karcher, A. Verger, P. Marie;
Nancy University Hospital, Vandoeuvre-les-Nancy, FRANCE.

Aim/Introduction: Bone scintigraphy (BS) is routinely performed for assessing vertebral fractures (VF) and subsequent follow-up, although this investigation is mainly based on subjective visual analysis. Nowadays, absolute quantification with SUV values may be obtained on bone SPECT recordings provided by new SPECT/CT systems. This study aimed to determine whether the absolute quantification of bone scintigraphy provided by the Veriton® CZT-SPECT/CT system (Spectrum Dynamics Medical) is reliable, as assessed through phantom experiments, and whether it provides consistent results for monitoring VF healing. **Materials and Methods:** SPECT/CT images were recorded with the Veriton® system and reconstructed with corrections of attenuation, scatter and partial volume. In a first step, absolute quantification was assessed on an IEC phantom filled-in with a ^{99m}Tc -solution, with spheres of various diameters. In a second step, this quantification was applied on 29 paired ^{99m}Tc hydroxymethylene diphosphonate-scintigraphy recordings, each pair obtained in the same patient (age: 71 ± 13 years, 38% male) who had first been imaged at 2.0 ± 2.0 months from the date of an acute VF (ie. baseline) and subsequently at 5.4 ± 2.2 months for a control whilst under medical treatment. **Results:** On the IEC phantom, the % errors in SUV measurement were: 2.3%, 0.2%, 3.8%, 1.2%, 5.7% for spheres with respective diameters of 37, 28, 22, 17 and 13 mm. In patients, the SUVmax from VF exhibited a marked decrease between baseline (12.9 ± 6.8) and control scans (7.5 ± 2.7 , $p < 0.001$), whereas the corresponding values for the non-fractured vertebrae were much lower (for the T1 vertebra: 4.2 ± 1.8 at baseline and 3.3 ± 1.5 at control). The relationship between all VF SUVmax values recorded at baseline or control and the time elapsed since fracture, corresponded to a decreasing logarithmic function ($p < 0.001$, $R^2 = 0.21$). The duration of the healing period, to the point of normalized VF SUVmax values, was estimated to be 9-months on average, but with marked inter-individual variations. **Conclusion:** The time taken for a return to normal bone metabolism is lengthy and highly variable in acute VF treated medically, however this may be monitored with the absolute quantification of bone scintigraphy provided by the whole-body Veriton® CZT-SPECT/CT system. **References:** 1. OP-240**Compared visual analyses of whole-body planar bone scintigraphies obtained from conventional Anger camera and from retro-projections after CT-based corrections of a high-speed SPECT recording using a 360° CZT-camera**

A. Bahloul, A. Verger, M. Perrin, M. Claudin, G. Karcher, P. Marie, L. Imbert;

Nancy University Hospital, Vandoeuvre Les Nancy, FRANCE.

Aim/Introduction: Reconstructed planar projections (the so-called "MVP" or multi-view planar) may be obtained from a single high-speed whole-body 3D SPECT recording (6 to 7 bed positions of 3 minutes each) using the Veriton® 360° CZT-SPECT camera (Spectrum Dynamics Medical) after CT-based corrections of attenuation and of partial volume effect. This study aimed to assess the concordance of results from visual analysis of such MVP bone scans in comparison with analysis of conventional planar images from an Anger camera (Symbia, Siemens Healthineers). **Materials and Methods:** Whole-body anterior and posterior bone scans were obtained in the same 25 patients (67±14 years, 11 women, 22 with known or suspected bone metastasis) consecutively with an Anger camera and with the CZT-camera. Presence or absence of definite uptake abnormalities was scored by two blinded experienced nuclear physicians on all scans, presented in a random order, and by using a 24-segment division of the skeleton. **Results:** The global concordance of image analyses between the two systems was excellent for both observers (with respective global accuracies of 92 and 96% and kappa scores of 0.78±0.03 and 0.87±0.03). Discordant results affected only 77 of the total 1200 segments analyzed by the two observers. Interestingly, 34 of these discordant results corresponded to abnormalities documented only on MVP scans, with 23 being documented on the few segments corresponding to the axial skeleton. **Conclusion:** Visual analysis of MVP whole-body bone scintigraphy obtained with this CZT-camera is highly concordant with the visual analysis of corresponding planar images from an Anger-camera. However, these MVP images are associated with higher detection rate of abnormalities on the axial skeleton, a location where the detection sensitivity of conventional planar images is known to be rather low. **References:** None

OP-241**Going quicker for dopamine transporter DaTSCAN imaging using SPECTStep & Shoot Continuous**

M. Bailly¹, G. Le Rouzic¹, G. Metrard¹, M. Ribeiro²;

¹CHR Orléans, Orleans, FRANCE, ²CHRU Tours, Tours, FRANCE.

Aim/Introduction: Dopamine transporter imaging with ¹²³I-DaTSCAN is an established diagnostic tool in parkinsonism and dementia. Conventional DaTSCAN SPECT acquisitions are quite long-lasting in those difficult

patients. In this study, we evaluated a 25% reduction of the acquisition time using a Low Energy High Resolution and Sensitivity (LEHRS) collimator and step-and-shoot continuous scanning mode, and its effect on visual or quantitative analysis. **Materials and Methods:** An anthropomorphic striatal phantom filled with ¹²³I solution at different striatum-to-background radioactivity ratios was acquired with low energy high sensitivity (LEHR) collimator and LEHRS collimator with and without step-and-shoot continuous mode. 25%-time reduction was also assessed on the LEHRS step-and-shoot continuous SPECT phantom data. SPECT data from 30 normal individuals (12 men, 18 women; age range 39-91 years, mean 71 years) and 30 Parkinson disease (16 men, 14 women; age range 43- 84 years, mean 69 years) were retrospectively included. All clinical data were acquired using LEHRS collimator and step-and-shoot continuous scanning mode. Data were retrospectively reconstructed with full time and 25%-time reduction and were visually analyzed by multiples raters. In addition, Striatal Binding Ratios (SBRs) were calculated. **Results:** Visual analysis remained stable and SBRs differences were insignificant whether using full time or with 25%-time reduction ($p < 0.001$) both on phantom and clinical study. There was an excellent inter-rater agreement and no effect of time-reduction on diagnosis, nor on user-rated image quality. **Conclusion:** Using LEHRS step-and-shoot continuous SPECT mode, 25%-time reduction can be applied to DaTSCAN acquisition protocols, without impairing visual or quantitative analysis. Dose reduction could also be applied without shortening time of acquisition. **References:** None

¹⁸F-FDG PET/CT baseline radiomics features are predictive of outcome in diffuse large B-cell lymphoma patients

J. Eertink¹, T. van de Brug², S. E. Wiegers¹, G. J. C. Zwezerijnen³, E. Pfaehler⁴, P. J. Lugtenburg⁵, B. van der Holt⁶, H. C. W. de Vet², O. S. Hoekstra³, R. Boellaard³, J. M. Zijlstra¹;

¹Amsterdam UMC, Vrije Universiteit Amsterdam, department of Hematology, Cancer Center Amsterdam, Amsterdam, NETHERLANDS, ²Amsterdam UMC, Vrije Universiteit Amsterdam, department of Epidemiology and Biostatistics, Amsterdam Public Health research institute, Amsterdam, NETHERLANDS, ³Amsterdam UMC, Vrije Universiteit Amsterdam, department of Radiology and Nuclear Medicine, Cancer Center Amsterdam, Amsterdam, NETHERLANDS, ⁴Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, ⁵Erasmus MC Cancer Institute, department of Hematology, Rotterdam, NETHERLANDS, ⁶Erasmus MC Cancer Institute, HOVON Data Center, department of Hematology, Amsterdam, NETHERLANDS.

Aim/Introduction: Up to one third of diffuse large B-cell lymphoma (DLBCL) patients experience relapse or fail to achieve complete remission during first-line treatment. Identification of poor prognosis patients might be further improved by radiomics. Radiomics analysis of imaging data provides quantitative features of tumor characteristics such as intensity, shape, volume, texture and intra- and inter-lesion heterogeneity. The aim of this study is to develop a prediction model for 2-year time to progression (TTP) using baseline quantitative radiomics features. **Materials and Methods:** 296 newly diagnosed DLBCL patients with baseline ¹⁸F-FDG PET/CT scans from the HOVON84 trial (EudraCT: 2006-005174-42) were included. Lesions were delineated using a fully automated preselection of ¹⁸F-FDG avid structures defined by a SUV \geq 4.0 and volume $>$ 3mL. Missed lesions were added and non-tumour regions were removed (accurate tool, <https://petralymphoma.org>). Next, 490 radiomics features were extracted from the total metabolic tumor volume (MTV) using RaCat (Pfaehler et al, 2019). To reduce feature space dimensions, we made a preselection of clinically most relevant radiomics features (SUV_{max}, SUV_{mean}, SUV_{peak}, TLG, MTV, dissemination features and sphericity) and used logistic regression with backward feature selection to predict 2-year TTP, defined as time from baseline PET/CT to progression. Patients who died without progression were censored at date of death. Furthermore, we tested the predictive value of known clinical predictors

(age, WHO performance status (WHO), Ann Arbor stage, extranodal involvement, lactate dehydrogenase (LDH) level and bulky disease) and of a model that combined radiomics and clinical parameters. Model performance was assessed using repeated cross-validation (5 folds, 2000 repeats) yielding the mean receiver-operator-characteristics curve integral (AUC). **Results:** The highest performance for the radiomics model was observed for MTV combined with SUV_{peak} and the maximal distance between the largest lesion and any other lesion (Dmax_{bulky}), which yielded in a cross-validated AUC (CV-AUC) of 0.75 \pm 0.07, which was significantly higher than the MTV model (CV-AUC: 0.66 \pm 0.08, p = 0.01). LDH, WHO and extranodal involvement showed the highest performance for the clinical prediction model with a CV-AUC of 0.71 \pm 0.08. When combining radiomics features with clinical predictors, the highest performance was observed for MTV combined with SUV_{peak}, Dmax_{bulky}, WHO and age, with a CV-AUC of 0.77 \pm 0.07. **Conclusion:** Prediction models using quantitative radiomics features extracted from baseline ¹⁸F-FDG PET/CT scans are able to identify patients at risk of relapse at baseline and have added value compared to currently used clinical and PET predictors. **References:** None

OP-248

Correlation of baseline TMTV/TLG with early metabolic response in Hodgkin Lymphoma and integration with the iPET gene-based predictive model

R. Durmo, B. Donati, S. Luminari, M. Casali, A. Ruffini, M. Zanelli, A. Ciarrocchi, F. Merli, A. Versari; AUSL-IRCCS of Reggio Emilia, Reggio Emilia, ITALY.

Aim/Introduction: Interim-PET (iPET) is prognostic for classical Hodgkin Lymphoma (cHL). However, iPET response is defined two months after treatment start and cannot be anticipated at the time of diagnosis. Total metabolic volume (TMTV) and total lesion glycolysis (TLG) are promising prognostic metabolic parameters in cHL. We recently developed and validated a 5-gene signature (iPET predictive model) from pre-treatment biopsies that anticipates at diagnosis the iPET response in cHL patients. The aim of this study was to investigate the predictive significance of baseline TMTV and TLG and their value in addition to the iPET gene-based predictive model in cHL patients. **Materials and Methods:** We selected a retrospective cohort of 150 stage I-IV cHL patients who underwent baseline ¹⁸F-FDG PET/CT between 2007-2019 with available iPET after 2 ABVD courses. TMTV and TLG were computed from baseline PET. iPET was reported according to the five-point Deauville scale (DS1-5). iPET were considered positive for DS4-5 (iPET+). TMTV and TLG were dichotomized according to the median value within our cohort. iPET predictive model from our previous study was included (Score positivity \geq -0.93). Univariate and multivariate analyses were performed by generalized linear

model to test the relationship between these variables and iPET response. ROC curve was built to determine variables' performance in predicting iPET+. **Results:** Median TMTV was 106 cm³(range 6–1196) and median TLG was 601(range 52–6453). iPET predictive model was available for 116 patients. Median age was 38years (15–79); 64(55%), 18(16%), and 34 patients (29%) had stage I-II, III and IV respectively. Twenty-three patients (19,8%) had iPET+. In univariate analysis, TMTV (OR 2.60, CI 1.00–6.72, p=0.05), TLG (OR 4,29, CI 1.55–11.88, p=0.005) and iPET model (OR 10.34, CI 3.60–29.67, p<0.001) were associated with iPET+. In multivariate analysis, TLG (OR 8.71, CI 1.24–61.40, p 0.03) and iPET model (OR 10.41, CI 3.44–31.50, p<0.001) were confirmed independent predictor of iPET+. No significant correlation of histotype, age, stage and risk group with iPET was observed. Integrating iPET model with TMTV and TLG we were able to increase AUC of the model obtained by ROC analysis from 0.76 (CI 0.66–0.86) to 0.83 (CI 0.75–0.92); main difference was observed for specificity that changed from 78% to 81%. **Conclusion:** TLG is an independent predictor factor of iPET+ and improves risk stratification of patients with cHL. Integration of TMTV and TLG to iPET gene-based predictive model improved specificity of the model. **References:** Luminari et al. ClinCancerRes.2020;26(2):373–383. doi:10.1158/1078-0432.CCR-19-2356

Aberrant patterns of PET-CT response for diffuse large B-cell lymphoma patients with MYC rearrangement

J. Eertink¹, F. Celik², J. Huijbregts³, A. I. J. Arens⁴, S. E. Wiegers¹, C. N. Burggraaff¹, O. S. Hoekstra⁵, S. Stroobants⁶, R. Boellaard⁵, H. C. W. de Vet⁷, M. E. D. Chamuleau¹, J. M. Zijlstra¹;

¹Amsterdam UMC, Vrije Universiteit Amsterdam, department of Hematology, Cancer Center Amsterdam, Amsterdam, NETHERLANDS, ²Department of Radiology and Nuclear Medicine, Deventer Ziekenhuis, Deventer, NETHERLANDS, ³Department of Radiology and Nuclear Medicine, Gelre Ziekenhuis, Apeldoorn, NETHERLANDS, ⁴Department of Radiology and Nuclear Medicine, Radboud University Medical Center, Nijmegen, NETHERLANDS, ⁵Amsterdam UMC, Vrije Universiteit Amsterdam, department of Radiology and Nuclear Medicine, Cancer Center Amsterdam, Amsterdam, NETHERLANDS, ⁶Department of Nuclear Medicine, Antwerp University Hospital (UZA), Antwerp, BELGIUM, ⁷Amsterdam UMC, Vrije Universiteit Amsterdam, department of Epidemiology and Biostatistics, Amsterdam Public Health research institute, Amsterdam, NETHERLANDS.

Aim/Introduction: Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous subtype of malignant lymphoma. DLBCL generally tends to relapse in previously involved sites. MYC oncogene rearrangement occurs in approximately 10–15% of DLBCL patients and has been associated with a poor prognosis. The aim of this study was to analyse the patterns

of response for MYC-rearrangement positive DLBCL (MYC+ LBCL) patients. **Materials and Methods:** 82 Patients from the prospective phase II HOVON130 study (Eudra-CT: 2014-002654-39, Chamuleau et al, Haematologica 2019) were included for this analysis. ¹⁸F-fluorodeoxyglucose positron emission tomography computed tomography (¹⁸F-FDG PET/CT) scans were performed at baseline, after 3 cycles of treatment (I-PET) and at end of treatment (EoT) and were centrally reviewed. I-PET and EoT scans were evaluated according to the Deauville 5-point scale (DS). DS 1–3 was regarded as PET-negative and DS 4–5 as PET-positive. To assess volumetric changes, Metabolic tumour volume (MTV) was calculated using a fully automated preselection of ¹⁸F-FDG avid structures defined by an SUV ≥ 4.0 at baseline using the ACCURATE tool. For I-PET and EoT, we used the method with the most complete tumour segmentation without flooding, which could be either SUV4.0, SUV2.5, 41%max, 50%peak, MV2 or MV3. Progression was defined as an increase in MTV and/or the presence of new lesions. **Results:** 79 I-PET scans and EoT scans were centrally reviewed. At I-PET, 24 patients were PET-positive (30.3%), whereas 55 patients were PET-negative (69.7%). 1 patient showed progression compared to baseline. At EoT, 26 patients were PET-positive (32.9%), of which 23 showed progression compared to I-PET. 12 I-PET positive patients remained PET-positive at EoT. From these 12 patients, 7 patients also presented with new extranodal and nodal lesions. 14 out of 55 I-PET negative patients were PET-positive at EoT. In total, 21 out of 26 PET-positive patients at EoT presented with new nodal and/or extranodal lesions compared to I-PET. From these 21 patients, 9 patients showed new lesions at EoT in regions that were not initially involved at baseline. 23 out of 26 PET-positive patients at EoT showed increased MTV compared to I-PET. **Conclusion:** MYC+ LBCL patients demonstrate aberrant PET response patterns with progressive disease during treatment after I-PET negative assessment with nodal and extranodal lesions at sites that were not initially involved. **References:** None

OP-250

Baseline ¹⁸F-FDG PET/CT Metabolic Parameters Combined with Interim PET/CT Improve Risk Stratification in Patients with Hodgkin Lymphoma

M. Rashki¹, E. Triviño-Ibáñez¹, L. Lamarca Eraso², E. Gámez Jiménez², F. Hernández Mohedo², C. Ramos Font¹;

¹Servicio de Medicina Nuclear. Hospital Virgen de las Nieves, Granada, SPAIN, ²Servicio de Hematología y Hemoterapia. Hospital Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: To study the predictive value of baseline volumetric parameters in combination with interim PET/CT (iPET) to improve risk stratification in Hodgkin lymphoma patients. **Materials and Methods:** Between 2013 and 2018, 92 patients with newly diagnosed HL were retrospectively

evaluated. Baseline PET/CT images were qualitatively and semiquantitative analyzed by measuring the volumetric parameters: total metabolic tumor volume (TMTV), total lesion glycolysis (TLG), and SUV_{max} , SUV_{mean} , SUV_{peak} , SUV_{min} of the lesion with the highest SUV_{max} value. All iPET scans were defined as PET/CT performed after 2-4 cycles of chemotherapy. Response on iPET and end-of-treatment PET was assessed using the Deauville 5-point scale, with a score of 4-5 reflecting positivity. The therapeutic response was established based on the Lugano's criteria. We analyzed the relation between qualitative and semiquantitative PET/CT features and OS and PFS. **Results:** 92 patients (mean age: 36.74±16.51, 55% male). 49% were stage II, followed by stage III (23%) and IV (16%). 90% received treatment according to the ABVD scheme. Nineteen patients (21%) relapsed or progressed and 7 (8%) died. Median OS was 42.2 months and PFS of 36.5 months. Factors associated with survival were: younger age at diagnosis (35.2±15.7 vs 58±25.5; $p<0.001$), advanced stage ($p=0.025$), positive iPET (OR 9.71, $p<0.001$) and positive end-of-treatment PET (OR: 28.83, $p<0.001$). Factor associated with recurrence were: SUV_{peak} of baseline PET/CT study ($p=0.038$), SUV_{mean} ($p=0.044$), IPI ($P=0.006$), iPET positive ($p<0.001$). TMTV and TLGt were associated with shorter PFS ($p<0.05$). ROC curves analysis showed an optimal cut-off point of 150cm³ for TMTV and 790cm³ for TLGt. Predictive factors of survival in univariate analysis (Cox's regression) were: TMTV>150cm³ (HR4.65, $p=0.003$), TLGt>790cm³ (HR: 4.90, $p=0.002$) and positive iPET (HR: 8.25, $p<0.001$). In multivariate analysis, only positive iPET was a prognostic factor. A combination of the baseline TMTV and iPET variables stratifies patients into 4 risk categories from worst to best prognosis: baseline MTVt>150+iPET(+), baseline MTVt<150+iPET(+), baseline MTVt>150+iPET(-), baseline MTVt<150+iPET(-). A statistically significant difference was observed between the four groups ($p<0.001$) in the Cox proportional hazard regression analysis. **Conclusion:** Tumor burden determined by volumetric parameters in basal PET/TC and positive iPET were associated with relapse of HL and PFS. The combination of both parameters can help identify the worst prognosis group of patients. **References:** None

Aim/Introduction: Mantle-cell lymphoma (MCL) represents 2-10% of all B-NHL. In 15-30% of cases, MCL may affect the gastrointestinal tract (GI), but the real frequency could be underestimated. It is unknown if the 18F-FDG-PET/CT is able to detect the GI involvement and eventually guide or omit the endoscopic exams. The objective of the study was to evaluate Sensitivity, Specificity, PPV, NPV and Accuracy of 18F-FDG-PET/CT in GI involvement detection in patients with MCL, in comparison to endoscopy with biopsy. **Materials and Methods:** We retrospectively evaluated 79 patients (median age: 66.8 years, range 27-83) with newly diagnosed MCL from 7 centres. All patients performed a pre-/post-treatment 18F-FDG-PET/CT scan and esophagogastroduodenoscopy (EGD)/colonoscopy at staging, according to the best clinical local practice. EGD/colonoscopy were repeated only if it was positive at staging. **Results:** Patients were staged III-IV in 89.9%, with B-symptoms observed in only 8%. Mostly, MIPSI score was intermediate (35.5%) or high (39.2%). EGD with gastric biopsy was performed in 52 pts (65.8%); colonoscopy with colorectal biopsy in 31 (39.2%). At staging, gastric biopsy was positive in 13 pts (29.5%), while colorectal biopsy was positive in 11 pts (28.2%). At re-staging, only 1 patient presented a persistent colorectal positivity confirmed with biopsy. We found a GI positivity in 30 18F-FDG-PET/CT: upper GI involvement in 18 patients vs colorectal in 12 patients. In upper GI tract, false-negative 18F-FDG-PET/CT were observed in 8 patients; while 5 pts were false-positive. Sensitivity, specificity, PPV, NPV and accuracy were 61.90% (38.44-81.89%), 83.87% (66.27-94.55%), 72.22% (52.14% to 86.12%), 76.47% (64.84% to 85.14%) and 75.00% (61.05% to 85.97%) respectively. Comparing 18F-FDG-PET/CT and colorectal biopsy, false-negative results were in 5 and a false-positive only in 1 patient. Sensitivity, specificity, PPV, NPV and accuracy were 68.75% (41.34-88.98%), 93.33% (68.05-99.83%), 91.67% (61.67% to 98.69), 73.68% (57.21% to 85.43%), 80.65% (62.53% to 92.55%) respectively. **Conclusion:** Our data demonstrated a better performance of 18F-FDG PET/CT in detecting colorectal involvement compared to the upper GI one. Endoscopy with biopsy still need to be considered the gold standard in MCL patients. However, these promising results suggest that molecular imaging could replace colonoscopy if they will be confirmed on larger and prospective cohort. **References:** None

OP-252**Total Metabolic Tumor Volume Measured on Baseline 18F-FDG PET/CT Gaves Added Predictive Value to the Four Prognostic Scores in Patients with Peripheral T-cell lymphoma (PTCL)**C. Jiang¹, C. Ding², Z. Zhou¹, J. Xu³;¹Department of Nuclear Medicine, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing Unive, Nanjing, CHINA, ²Department of Nuclear Medicine, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, CHINA, ³Department of Hematology, Nanjing Drum Tower Hospital, the Affiliated Hospital of Nanjing University Medical School, Nanjing, CHINA.

Aim/Introduction: The aim was to explore the prognostic value of total metabolic tumor volume (TMTV) on baseline 18F-FDG PET/CT in patients diagnosed with peripheral T-cell lymphoma (PTCL). **Materials and Methods:** Fifty-seven PTCL patients who underwent baseline 18F-FDG PET/CT between December 2012 and January 2019 and did not receive any treatment were enrolled in this retrospective study. The FDG-avid lesions in each patient were segmented using semiautomated software to calculate the maximum standardized uptake value (SUV_{max}), total metabolic tumor volume (TMTV), and total lesion glycolysis (TLG) values using the boundaries of voxels presenting with SUV ≥ 2.5 . Progression-free survival (PFS) and overall survival (OS) were used as end points to evaluate patient prognosis. The log-rank test and Cox regression analyses were used to evaluate PFS and OS. **Results:** ROC curve analysis demonstrated that the ideal TMTV cut-off value was 418.9 cm³. During the follow-up period of 5-70 months (23.1 \pm 16.9 months), high TMTV was significantly associated with worse PFS and OS. Multivariate analysis revealed that TMTV and the modified prognostic index for T-cell lymphoma (m-PIT) were independent predictors of PFS and OS. The combination of TMTV and International prognostic index (IPI), Prognostic index for T-cell lymphoma (PIT) International peripheral T-cell lymphoma Project score (IPTCLP) as well as m-PIT can be allowed for a significantly better risk sub-stratification in PFS and OS of PTCL patients. **Conclusion:** Both TMTV and m-PIT are independent predictors of the PTCL patient survival outcome. Moreover, the combination of TMTV and IPI, PIT, IPTCLP as well as m-PIT improved patient risk stratification and might contribute to the ability to personalize therapeutic regimens. **References:** None

OP-253**PET/CT-based Prognostic Biomarkers in Diffuse Large B-cell Lymphoma**S. Czibor¹, F. Redondo², R. Carr³, J. Cercí⁴, D. Paez⁵, S. Fantí⁶, T. Györke¹;¹Semmelweis University, Budapest, HUNGARY, ²Fundación Arturo Lopez Perez, Santiago, CHILE, ³Guy's & St. Thomas' Hospital,King's College London, London, UNITED KINGDOM, ⁴Quanta Diagnóstico e Terapia, Curitiba, Sao Paulo, BRAZIL, ⁵International Atomic Energy Agency, Vienna, AUSTRIA, ⁶Policlinico S. Orsola Malpighi, University of Bologna, Bologna, ITALY.

Aim/Introduction: In diffuse large B-cell lymphoma (DLBCL) several F-18-fluoro-deoxy-glucose (FDG) positron emission tomography/computed tomography (PET/CT) based biomarkers have emerged in the last decade to define prognosis. Our aim was to investigate some of these in patients recruited into a previously reported international multicentre study. **Materials and Methods:** We report analysis of 107 patients with de novo DLBCL (mean age: 53.7y; range: 16-83y), most were recruited in Hungary (57) and Chile (36), others from Thailand (8), Philippines (4), and Italy (2). 58% patients presented with advanced stage disease. Lymphoma lesions on baseline PET/CT images were delineated with $>SUV_4$ method. Metabolic Tumour Volume (MTV) and Total Lesion Glycolysis (TLG) values were calculated, as well as introducing body weight-adjusted (bwa) MTV and TLG values, normalised for patient body weight. Interim PET/CT (I-PET) scans were analyzed visually according to the Deauville criteria, (DS 1-5), and semiquantitatively with the calculation of ΔSUV_{max} , modified qPET [mqPET, calculated as $SUV_{peak}(lesion)/SUV_{mean}(liver)$] and rPET [$SUV_{max}(lesion)/SUV_{max}(liver)$] values. The outcome assessed was 24-month progression-free survival (PFS). Receiver operating characteristics analyses were performed to define optimal cut-off points for baseline (MTV, TLG, bwaMTV, bwaTLG) and I-PET (ΔSUV_{max} , mqPET, rPET) values. **Results:** Two-year PFS in the whole cohort was 75%. Dividing the patients into two groups according to calculated optimal PET/CT cut-offs or pre-defined values (1-3 vs. 4-5 in case of DS) resulted in significantly different PFS between low- and high-risk groups for baseline MTV, bwaMTV, TLG, bwaTLG, as well as I-PET parameters DS, ΔSUV_{max} , mqPET, and rPET. Univariate Cox-regression analyses showed significant survival difference between low- and high-risk groups except for low/high bwaTLG, with calculated hazard ratios (HRs) lowest for bwaMTV (HR=2.3) and highest for rPET (HR=9.09) among the remaining PET parameters. Combined analysis was performed based on four groups defined by low/high MTV and DS 1-3 vs. 4-5. Kaplan-Meier curves showed good survival rate for DS 1-3 patients and poor PFS for DS 4-5 patients, irrespective of MTV. A similar analysis with ΔSUV_{max} and MTV resulted in relatively good PFS for all ΔSUV_{max} negative patients and also ΔSUV_{max} positive patients with low MTV. ΔSUV_{max} positive patients with high MTV formed a group with distinctly poor PFS. **Conclusion:** PET/CT baseline volumetric parameters and response assessment can be analyzed to generate several different prognostic biomarkers in DLBCL. The analyses reported here demonstrate that early treatment response has a greater

impact on survival than baseline volumetric assessment.

OP-254

Imaging CXCR4 receptors expression for staging multiple myeloma by using 68Ga-Pentixafor PET-CT: Comparison with 18F-FDG PET-CT

B. Singh^{1,2}, A. S. Shekhawat², A. Watts², H. Singh², R. K. Basher², P. Malhotra²;

¹Society of Nuclear Medicine, India, Chandigarh, INDIA, ²PGIMER, Chandigarh, INDIA.

Aim/Introduction: 68Ga-Pentixafor PET imaging targets CXCR4 expression which is over-expressed in multiple myeloma (1,2). In this study, we evaluated the diagnostic utility of 68Ga-Pentixafor PET/CT for imaging CXCR-4 expression in multiple myeloma and compared results with 18F-FDG PET/CT. **Materials and Methods:** Thirty-four (21M; 13F; median age= 57.5 years) treatment naive multiple myeloma patients were recruited. All the patients underwent 18F-FDG-PET/CT and 68Ga-Pentixafor PET/CT imaging within one week. Freshly prepared 68Ga-Pentixafor (148-185 MBq) was injected intravenously and whole-body PET/CT (low dose CT) was acquired at 1-h post-injection. The pattern of uptake (diffuse, focal or mixed) and the mean SUV_{max} value of all lesions (when lesions were ≤ 5) or of the 5 most tracer avid lesions (when lesions was > 5) were evaluated. Tumor to background ratio (TBR_{max}) was calculated for both the tracers. Durie Salmon plus staging (DSPS) was used for disease staging on PET and the results were compared with International staging system (ISS). **Results:** 68Ga-Pentixafor PET-CT showed higher disease extent than seen on 18F-FDG PET in 23/34 patients (68.0%), lesser disease extent in 2/34 (6%) and similar disease extent in 9/34 (26%) patients. Significantly (p<0.001) higher TBR_{max} values (5.7; IQR 9.1) were observed on 68Ga-Pentixafor PET as compared (2.9; IQR =4.0) to 18F-FDG PET values. Both the techniques detected extramedullary lesions in 6 patients. On the other hand, 68Ga-Pentixafor detected medullary lesions in 5, whereas, 18F-FDG PET in 3 patients. Further, only 68Ga-Pentixafor TBR_{max} correlated significantly (rho =0.421; 0.013) with bone marrow plasma cell percentage. When compared to ISS, 68Ga-Pentixafor PET upstaged more number (9/29) of patients as compared to (4/29) on 18F-FDG PET imaging. On the other hand, 18F-FDG-PET down-staged 9/29, whereas, 68Ga-Pentixafor PET down-staged only 3/29 patients. **Conclusion:** 68Ga-Pentixafor PET imaging detected more number of involved sites than 18F-FDG PET. The dual tracers imaging may provide additional information on spatial and temporal heterogeneity of MM and may have significance for response evaluation to CXCR4 targeting pharmacologic or endoradiotherapeutic therapies in CXCR4⁺ and FDG⁻ disease variant of multiple myeloma. **References:** Herrmann K, Schottelius M, Lapa

¹⁸F-FDG PET/CT role in detecting Richter's transformation of Chronic Lymphocytic Leukemia and predicting overall survival

D. Albano¹, E. Cerudelli², M. Gazzilli², F. Dondi¹, A. Mazzeletti¹, P. Bellini¹, L. Camoni², F. Bertagna¹, R. Giubbini¹;

¹University of Brescia and Spedali Civili of Brescia, Brescia, ITALY, ²Spedali Civili of Brescia, Brescia, ITALY.

Aim/Introduction: Chronic lymphocytic leukemia (CLL) is an indolent, low-grade B cell lymphoproliferative disorder, which may transformed into aggressive lymphoma, called Richter's syndrome (RS). Our aim was to study the accuracy of ¹⁸F-FDG-PET/CT and its semiquantitative parameters for the detection of RS and the impact on overall survival (OS). **Materials and Methods:** Between January 2009 and December 2019, 80 patients with histologically proven CLL were retrospectively enrolled; all patients underwent ¹⁸F-FDG-PET/CT for the suspicious of RS in presence of enlarged lymph nodes. The PET images were analyzed visually and semi-quantitatively by measuring the maximum standardized uptake value body weight (SUVbw), the maximum standardized uptake value lean body mass (SUVlbm), the maximum standardized uptake value body surface area (SUVbsa), lesion to liver SUVmax ratio (L-L SUV R), lesion to blood-pool SUVmax ratio (L-BP SUV R), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of the hypermetabolic lesion then submitted to biopsy. For the entire population, receiver operating characteristic curve analysis was used to identify the optimal cutoff point of semiquantitative parameters in the light of risk of RS. OS curves were plotted according to the Kaplan-Meier method. **Results:** Seventy-eight patients had positive ¹⁸F-FDG-PET/CT, while the remaining 2 were not ¹⁸F-FDG-avid. RS was diagnosed in 18 cases (22.5%): final diagnosis was DLBCL in 13 patients and HL in 5. All PET/CT metabolic parameters were significantly higher in RS groups compared to no RS group, except of metabolic volumes (MTV and TLG). Using ROC curves analysis, the best threshold identified were 9 for SUVbw, 5.3 for SUVlbm, 1.7 for SUVbsa, 2 for L-L SUV R and 4.8 for L-BP SUV R. After a median follow-up of 32 months, 24 patients died; OS was significantly shorter in patients with RS than patients without RS (27.8 vs 16.5 months, p 0.001). SUVbw ≥9, SUVlbm≥5.3, SUVbsa≥1.7,

L-L SUV $R \geq 2$, L-BP SUV $R \geq 4.8$ $PS \geq 2$, Binet stage and B symptoms were independently associated with shorter OS.

Conclusion: In conclusion, in our study we demonstrated that semiquantitative PET/CT parameters SUV-related may be useful in discriminating patients with high risk to RS and also for predicting outcome survival. Instead, MTV and TLG showed no significant impact on predicting RS and OS.

Patients with Erdheim-Chester Disease who Harbor the BRAF V600E Mutation, Exhibit Significantly Higher Metabolic Activity in the Adrenal glands Assessed by ^{18}F -FDG PET/CT, when Compared to Mutation-Negative Counterparts

G. Papadakis^{1,2}, F. Hannah-Shmouni³, G. C. Manikis², A. H. Karantanas¹, K. Marias², K. J. O'Brien⁴, W. A. Gahl⁴, J. I. Estrada-Veras⁵;

¹Department of Medical Imaging, Medical School, University of Crete, Heraklion, GREECE, ²Computational Biomedicine Laboratory (CBML), Foundation for Research and Technology Hellas (FORTH), Heraklion, GREECE, ³Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD, UNITED STATES OF AMERICA, ⁴Office of the Clinical Director, National Human Genome Research Institute, National Institutes of Health, Bethesda, Bethesda, MD, UNITED STATES OF AMERICA, ⁵Medical Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Erdheim-Chester disease (ECD) is a rare non-Langerhans cell histiocytosis characterized by uncontrolled inflammation resulting in fibro-inflammatory damage in multiple organs, including the hypothalamic-pituitary-adrenal axis (1). The aim of the current study was to investigate potential associations between disease-causing BRAF V600E variants and adrenal metabolic activity assessed by ^{18}F -FDG PET/CT imaging (2). **Materials and Methods:** 20 ECD patients (mean age \pm SD at first ECD manifestations: 56.3 ± 10.25 y.o.) were evaluated with whole-body ^{18}F -FDG-PET/CT scans. 13 patients harbored the BRAF V600E mutation, while 7 were BRAF-negative. PET-acquisition commenced 60 minutes after intravenous administration of approximately 10mCi of ^{18}F -FDG, while a non-contrast, low dose CT scan was performed for attenuation correction and co-registration purposes. Metabolism in the adrenal glands was assessed by quantifying ^{18}F -FDG uptake, using the MIM Vista workstation (version 6.5.9). A VOI encompassing both adrenal glands was drawn, and an automated SUVmax threshold-based approach was applied in order to include all ^{18}F -FDG-avid regions of the adrenal glands, while excluding low-level background activity (SUVmax threshold was set at 1.5). The software enables automatic generation of separate

VOIs encircling all areas above the SUVmax threshold set by the user. Afterwards, the following parameters were automatically obtained: SUVmax, SUVmean (average SUV), total ^{18}F -FDG-avid adrenal volume (Metabolic Tumor Volume; MTV) and total glycolytic activity (TGA) of the adrenal glands, determined as the product of SUVmean multiplied by MTV (TGA=SUVmean x MTV). Finally, statistical analysis was performed using R software (version 3.3.3).

Results: Mann-Whitney-Wilcoxon test revealed statistical differences ($p < 0.05$) between BRAF-positive and BRAF-negative ECD patients, with mutation carriers exhibiting significantly higher ^{18}F -FDG activity by the adrenal glands in terms of all the obtained PET-parameters: SUVmax $p = 0.018$, SUVmean $p = 0.026$, MTV $p < 0.01$, and TGA $p < 0.001$. (P-values were adjusted using false discovery rate (FDR) correction to account for multiple hypothesis testing.) **Conclusion:** ECD patients who harbor the disease-causing BRAF V600E variant present with hypermetabolic adrenal glands when compared to mutation negative ECD patients, implying increased susceptibility of BRAF-positive ECD-patients to adrenal involvement and potentially adrenal insufficiency. **References:** 1. OP-257

Role of [^{18}F]FDG PET/CT in patients with Monoclonal Gammopathy of Unknown Significance (MGUS)

T. Rudolphi-Solero, R. Sánchez Sánchez, E. Triviño-Ibáñez, M. Rashki, J. Fernández Fernández, Á. C. Rebollo Aguirre; SAS, Granada, SPAIN.

Aim/Introduction: The monoclonal gammopathy of undetermined significance (MGUS) is a clinically asymptomatic premalignant clonal plasma cell or lymphoplasmacytic proliferative disorder. It is the most common type of plasma cell dyscrasia. The risk of progression to multiple myeloma and associated malignancies is variable depending on risk stratification. The aim of this study is to evaluate the role of [^{18}F]FDG PET/CT in the correct classification and monitoring of MGUS patients. **Materials and Methods:** Retrospective analysis of patients who underwent [^{18}F]FDG PET/CT, after MGUS diagnosis from 2012 to 2018. They were classified in three subgroups according to the risk of progression to myeloma (low, intermediate, high). A positive [^{18}F]FDG PET/CT study for myeloma is considered if it presents areas of focal hypermetabolism outside of areas of physiological distribution or diffuse increase in bone marrow of activity, superior to the background seen in patients without infiltration of the marrow. All statistical analysis was carried

out using SPSS version 23. The descriptive analysis of categorical variables were described as frequencies and the numeric variables as mean and standard deviation. We studied the possible association between all the collected variables and a positive [18F]FDG PET/CT result through bivariate analysis. After the non-normality confirmation of the population regarding the monoclonal component rate by Kolmogorov-Smirnov test, the Mann-Whitney U test was performed. Significant differences were observed respecting the PET/CT result. Receiver Operating Characteristics (ROC) curve analysis was done to assess a cutoff representing the best accuracy in terms of best compromise between sensitivity and specificity in evaluating active myeloma. **Results:** A total of 255 patients with MGUS (mean age $72,1 \pm 12,5$ years old, 50,2% women) were included. 25 had a positive [18F]FDG PET/CT, 15 in diagnosis and 10 in follow-up (average time to progression: $21,3 \pm 10,4$ months). We found a significant statistical association between the monoclonal component rate and a positive [18F]FDG PET/CT. The cut-off point with a better sensitivity and specificity relation ($S=70\%$ and $E=70\%$) through ROC curve analysis was 1 g/dL (AUC 0,795). **Conclusion:** [18F]FDG PET/CT allows the correct classification of patients with MGUS, highlighting those patients with a small monoclonal component or even non-secretors who have active bone disease and therefore are already myeloma. The monoclonal component rate seems to be the variable most related to the probability of presenting a positive [18F]FDG PET/CT study for myeloma. **References:** None

OP-258

Prognostic value of FDG-PET/CT derived visual and semi-quantitative parameters in Multiple Myeloma (MM) patients

A. Farina¹, E. Zamagni², S. Strolin³, L. Strigari³, L. Dozza², M. Cavo², S. Fanti¹, C. Nanni¹;

¹Nuclear Medicine Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, ²Hematology Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, ³Medical Physics Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY.

Aim/Introduction: At staging and before maintenance PET/CT provides prognostic parameters such as the number of hot focal lesions and the diffuse involvement of the bone marrow (BM). However, they are a surrogate for the volume of active disease, that can be more accurately measured with dedicated semi-automatic softwares. Aim of this study is to explore the prognostic value of metabolic tumor volume (MTV) and total lesion glycolysis (TLG) in the context of other PET parameters MM patients. **Materials and Methods:** We conducted a retrospective study on a group of patients affected by MM referred from the Hematology-Unit of AOU S.Orsola-Malpighi for a basal and a post therapy

scan. MTV, TLG, DS of the hottest focal lesion, SUVmax of the hottest focal lesion, DS of the BM uptake were measured before and at completion of therapy. Overall Survival (OS) and Progression free survival (PFS) were analyzed from the begin of therapy. Possible prognostic values were extracted from Volumes-of-Interests (VOIs) contoured on co-registered basal and interim scans using MIM Vista Software with semiautomatic approach. The Kaplan-Meier method was used to estimate PFS and OS. Survival curves were compared using the log-rank test. ROC-curves were used to select cut-offs. Cox-multivariate proportional hazard models were used to identify independent prognostic factors affecting to PFS and OS. Furthermore, the predicted probabilities of PFS and OS were presented with help of nomograms reporting all the statistically significant covariates included in the fitted models. **Results:** 42 patients (20F, 22M, mean age 55 yo, mean follow up 51 months) were retrospectively enrolled from 2011 to 2014. Several prognostic parameters were found. Survival curves allowed to stratify patients into 2 risks groups with appropriate cut-offs, even though most of them demonstrated a p-value only close to significance level probably because of the relatively low number of patients. In particular at staging: presence of FDG avid extramedullary disease ($p < 0.001$) and $MTV > 130$ ($p = 0.07$) were predictive for a worse OS. At completion of therapy, $DS \geq 4$ of the diffuse BM uptake (0.06) was predictive both for worse PFS and OS while $MTV > 2$ and $TLG > 5.2$ were both predictive for worse OS ($p = 0.04$ both). On a multivariate analysis, MTV after therapy, TLG after therapy and SUV max of the hottest focal lesion seems to be independent factors affecting OS (Overall model P-value = 0.07). **Conclusion:** The novel tools seem to provide promising parameters for the risk stratification of MM pts, both at staging and after therapy. These parameters can be included into nomograms for risk assessment, an easy and useful method to employ in the clinical practice. However, these parameters need to be tested on a wider population of patients to better confirm a statistical significance. **References:** None

OP-260**Parathyroid scintigraphy pre-surgery: comparison between methods in primary hyperparathyroidism**

L. Torres, A. Oliveira, J. Pereira;

Centro Hospitalar Universitário São João, Porto, PORTUGAL.

Aim/Introduction: Most of primary hyperparathyroidism (pHPT) cases are due to a single hyperfunctioning adenoma (about 85%) (1), occasionally more, surgical excision being the only cure. In the age of minimally invasive parathyroidectomy, preoperative parathyroid scintigraphy can be useful in reducing the duration and extent of surgical exploration. Different protocols and techniques include dual-phase, double tracer and SPECT-CT. We aimed to study each of these methods' diagnostic value in detecting abnormal parathyroid glands, as well as the possible influence of concomitant thyroid disease.

Materials and Methods: We retrospectively reviewed patients with biochemical pHPT who underwent parathyroid scintigraphy in our department from June/2018 to December/2019. Out of 164 patients who met these criteria, 47 had undergone surgery with histological analysis (gold standard), and were included in the study. All patients were submitted to a 3-method protocol consisting of planar imaging using ^{99m}Tc-Sestamibi at 15 mins and 2 h post-injection, SPECT-CT acquisition, 2 h post-injection, followed by ^{99m}Tc-pertechnetate injection and final planar imaging. The acquired ^{99m}Tc-pertechnetate thyroid planar image was then subtracted from the early ^{99m}Tc-Sestamibi planar image. Results of the different techniques were analyzed and compared. **Results:** 30 patients (64%) had previously documented thyroid disease. Review of the histopathological reports revealed 39 single parathyroid adenomas (83%), three multiple adenomas (6%), one parathyroid carcinoma (2%) and four cases (9%) with no lesions. Overall sensitivity, specificity, PPV, NPV and accuracy values of the three methods were: 91,4%, 16,7%, 0,76, 0,40 and 72,4% for SPECT-CT; 77,8%, 27,3%, 0,78, 0,27 and 66,0% for dual-phase; 70,3%, 30,0%, 0,79, 0,21, and 61,7% for the subtraction method. In patients with thyroid disease, the sensitivity and diagnostic accuracy values were lower when compared to patients with no thyroid disease in SPECT-CT (90,0% vs 92,3% and 73,3% vs 75,0%, respectively), and more significantly in dual-phase (69,6% vs 92,3% and 63,3% vs 70,6%) and subtraction (62,5% vs 84,6% and 60,0% vs 73,3%). **Conclusion:** Our results suggest that, despite its lower specificity, parathyroid imaging with SPECT-CT is a more sensitive and accurate method in detecting abnormal parathyroid glands than the dual-phase or subtraction. In accordance with previous literature, concomitant thyroid disease seems to lower the diagnostic performance of this exam. **References:** 1. OP-261**The contribution of protocol selection to diagnostic accuracy in MIBI parathyroid scintigraphy: reevaluation with SPECT/CT and histopathologic findings**

B. Özdemir, Ü. Korkmaz, S. Soyluoğlu, E. Gökdemir, G. Durmuş

Altun;

Department of Nuclear Medicine, Trakya

University, Edirne, TURKEY.

Aim/Introduction: The evolving procedures provide additional information about localization of parathyroid lesions after SPECT/CT added in routine protocols. Dual phase parathyroid scintigraphy has been used to determine parathyroid lesions and to assist minimally invasive procedures. Thyroid lesions is the main cause of misdiagnosis and additionally the most important lesions that reduces sensitivity and diagnostic accuracy. In our study, we aimed searching the optimal imaging time to revised protocols, also determining the SPECT/CT's contribution to dual phase parathyroid scintigraphy. **Materials and Methods:** We studied 188 patients (mean age 57±12,8 years; 40 male, 144 female) who underwent preoperative parathyroid scintigraphy and ultrasonography between January 2017 and September 2019. Imaging included dynamic blood flow, blood pool, 15-60th images as early Tc 99m MIBI images and 2nd-4th hour Tc99m MIBI images as delayed ones. Also was added 60th minute Tc 99m MIBI SPECT/CT images and Tc99m pertechnetate thyroid images. Lesions characterized with visual analog scale (0-3) according to the MIBI accumulation pattern. Each data was evaluated with clinical information, histopathologic and laboratory findings. **Results:** In 95 of 188 patients, scintigraphic findings showed parathyroid lesions at any side. At the 60th minute, 71 (sensitivity 75%) patients became positive, while 87 (sensitivity 92%) focus was detected on the SPECT / CT that taken right after 60th minute. Eight of 95 lesions were detected as ectopic foci. In 87 patients; lesions were localized on perithyroidal area. One patient was diagnosed with parathyroid carcinoma and 3 patients were diagnosed with parathyroid hyperplasia based on histopathological findings. Benign/malignant thyroid disease was detected in 9 patients, and this patient group was accepted as the ones that caused false positivity. Thyroid pathology was detected in 6 patients, but dual phase parathyroid scintigraphy did not show a positivity. Diagnostic accuracy of the SPECT/CT was calculated as 82.5% based on histopathological data. **Conclusion:** In detecting parathyroid lesions, SPECT / CT sensitivity was 92% and diagnostic accuracy was 83%. The false positivity rates of the lesions were high in early images and these false positivity rates decreased with delayed images or SPECT/CT. Also we found out 4th hour images didn't make significant contribution to second hours.

SPECT/CT is the most accurate method to localisation of biochemically proven parathyroid lesions. **References:** None

OP-262

F-18 Choline PET-CT is valuable in the assessment of normocalcemic primary hyperparathyroidism

C. Pirich¹, D. Schaffler-Schaden², G. Schweighofer-Zwinkl¹, G. Rendl¹, L. Hehenwarter¹, M. Beheshti³;

¹Dpt. of Nuclear Medicine and Endocrinology, University Hospital Salzburg, Salzburg, AUSTRIA, ²Institute of General Practice, Family Medicine and Preventive Medicine Paracelsus Medical University, Salzburg, AUSTRIA, ³Clinic for Nuclear Medicine, RWTH, University Aachen, Aachen, GERMANY.

Aim/Introduction: Normocalcemic primary hyperparathyroidism (pHPT) is increasingly seen as clinically relevant condition. In this prospective study, we evaluated the value of ¹⁸F-choline (FCH) PET-CT for detection of parathyroid adenoma in patients with normocalcemic pHPT. **Materials and Methods:** FCH PET-CT was performed on a Philips Ingenuity TF (Philips Healthcare, PC Best, The Netherlands) in 90 patients (mean age 56.7±7.0 years) with biochemical evidence of pHPT (median 142 pg/ml, range: 68–246), and normal serum calcium level (median: 2.53 mmol/l, range: 2.09–2.63). A median activity of 197 MBq F-18 choline was injected intravenously and imaging performed 1 hour later. Images were reconstructed using a three-dimensional ordered-subsets iterative TOF (BLOB-OS-TF) algorithm after correction for scatter and attenuation. At least one abnormal FCH focus corresponding to a parathyroid gland or ectopic parathyroid tissue was considered as positive finding by visual analysis. Histopathological analysis was performed from any surgically removed parathyroid tissue. Based on WHO classification of bone mineral density measurement by DXA 35, 43, and 12 patients had osteoporosis, osteopenia or normal bone mineral density, respectively. Three patients with secondary HPT were excluded from statistical analysis. **Results:** Among 87 patients 36 (41%) had positive imaging findings by visual analysis. Surgery for primary HPT was clinically indicated and performed in 19 patients, the remaining were followed-up biochemically. In patient-based analysis, FCH PET-CT was able to detect parathyroid adenoma in 89% of patients eligible for surgery (17/19). Two patients had biglandular disease, and one patient ectopic disease. In lesion-based analysis, FCH PET-CT showed a sensitivity of 86% (18/21). Semi-quantitative analysis of FCH-positive lesions exhibited that the mean SUVmax of parathyroid adenoma was trendwise higher in patients with surgical than in those with conservative follow-up (7.4±4.2, vs. 4.67±3.46). **Conclusion:** In this prospective study, FCH PET-CT showed promising results for the detection of parathyroid adenoma even in patients with normocalcemic pHPT. In those patients high at risk for osteoporotic fractures parathyroid imaging using FCH PET/

CT might guide successful surgical removal of parathyroid adenoma. **References:** None

OP-263

Early-phase SPECT/CT, as part of a hybrid dual-phase/double-tracer protocol, improves detection of rapid washout hyperfunctioning parathyroid glands

L. Lemos¹, P. Soeiro¹, R. Ferreira^{1,2}, G. Costa^{1,3}, J. Pedroso de Lima^{1,2,3};

¹Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL, ²Instituto de Ciências Nucleares Aplicadas à Saúde (ICNAS), Faculdade de Medicina, Universidade de Coimbra, Coimbra, PORTUGAL, ³Faculdade de Medicina, Universidade de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Rapid washout of the radiopharmaceutical is a cause of false negative studies in [^{99m}Tc]Tc-sestamibi parathyroid scintigraphy (PS), particularly in dual-phase protocols (with an early phase at 15–20 minutes and a late phase at 2–3 hours). While SPECT/CT imaging can improve diagnostic accuracy, the ideal timing of acquisition is not yet clear. This study aims to evaluate whether early-phase SPECT/CT improves detection of rapid washout hyperfunctioning parathyroid glands (HPG) as part of a hybrid dual-phase/double-tracer protocol. **Materials and Methods:** We reviewed the clinical charts of 122 patients (94 female, 28 male; mean age: 61.95±14.76) with hyperthyroidism who underwent PS, between March 2019 and March 2020. In that cohort of patients we used a new hybrid dual-phase/double-tracer protocol imaging acquisition protocol, with cervical SPECT/CT being performed in every patient, immediately after planar early-phase images. Digital subtraction was performed whenever possible, using the [^{99m}Tc]TcO₄⁻ and the early-phase [^{99m}Tc]Tc-sestamibi planar images. All scintigraphic studies were reviewed and classified in two groups: negative (no abnormal findings were observed in both phases) and positive (if findings suggesting HPG were detected in, at least, one of the two phases). In positive scans, the abnormal parathyroid gland was considered to display rapid washout of the radiopharmaceutical if it was not visible on late-phase images. Relevant demographic and clinical data were also collected, regarding biochemical parameters (PTH, calcium, phosphates, vitamin D, creatinine), other imaging studies, surgery and pathology reports. **Results:** Of the 122 studies analysed, 106 patients (86,9%) were referred for primary hyperparathyroidism, whereas 16 (13,1%) had secondary or tertiary hyperparathyroidism. 50 (41.0%) had positive studies, 8 (16.0%) of which showing rapid washout HPG (6 in primary hyperparathyroidism, 2 in secondary/tertiary hyperparathyroidism). Multiple HPG were reported in three patients, all of which with secondary/tertiary hyperparathyroidism. Patients with positive studies had significantly higher PTH (p<0.01) and calcium (p<0.01) levels than those with negative studies. We found no statistically significant differences in biochemical markers between

patients with rapid washout and delayed washout HPGs. Four patients with primary hyperthyroidism underwent surgery and the HPG was correctly located by scintigraphy in every case. **Conclusion:** In this series, the inclusion of early-phase SPECT/CT, as part of a hybrid dual-phase/double-tracer protocol, significantly improves the detection rates of rapid washout parathyroid glands. No predictive factors were found for rapid washout hyperfunctioning parathyroid glands in patients with primary or secondary/tertiary hyperparathyroidism. **References:** None

OP-264

Detection of hyperfunctioning parathyroid tissue with F18-fluorocholine PET/CT in patients with hyperparathyroidism

T. Nazerani Hooshmand¹, B. Pernthaler¹, A. Ntoumanoglou-Schuiki², P. Ofner-Kopeinig³, R. M. Aigner¹;

Aim/Introduction: Exact localization of a hyperfunctioning parathyroid tissue in hyperparathyroidism (HPT) is highly advantageous for an exact preoperative plan to acquire the best possible results. Recent studies show the high accuracy of F18-fluorocholine (FCH) PET/CT in finding parathyroid adenomas; however, there is no consensus for the optimal acquisition time after intravenous application of the tracer. The aim of our study is to determine a proper FCH PET/CT protocol and to find if there is any correlation between PET/CT results and laboratory parameters in patients with HPT.

Materials and Methods: Forty six patients with biochemical proven HPT were enrolled in this retrospective study. FCH PET/CT scan was performed and the acquisitions were conducted dynamically in the cervical region over 15 minutes, followed by static images of the neck and mediastinum at 15, 30, 45- and 60-minutes after tracer injection. The SUVmax (standardized maximum uptake value) of the suspected parathyroid lesion was measured in the dynamic and in all static images. The laboratory results of our patients including parathyroid hormone level, calcium and phosphate serum level and vitamin D levels were included in our database. **Results:** In 57% of patients (26/46) the suspected parathyroid lesion showed the highest tracer uptake at 45 minutes post injection with a SUVmax of $8,23 \pm 3,07$. In 22% of patients (10/46) the highest SUVmax was at 15 minutes post injection. There was no significant correlation between parathyroid hormone level, calcium and phosphate serum level and vitamin D and the SUVmax of the parathyroid lesions. **Conclusion:** Our study shows that the best acquisition time point for parathyroid gland is at the 45 minutes after tracer injection; however,

it is yet to be investigated if the dynamic phase is needed. Our study shows that the biochemical parameters such as parathyroid hormone level, calcium and phosphate serum level and vitamin D do not correlate with the intensity of the tracer uptake in hyperfunctioning parathyroid lesion.

OP-265

A Prospective GCP-Controlled Study of 60 Patients Regarding the Location of Hyperfunctioning Parathyroid Glands in PHPT Using 11C-Choline PET/CT vs. Dual Isotope SPECT/CT

J. Christensen¹, A. Ismail¹, M. Krakauer², F. N. Bennedbaek³, B. Zerahn¹, B. Kristensen¹, S. B. Søndergaard¹, L. T. Jensen¹;

¹Dept. of Nuclear Medicine, Herlev & Gentofte University Hospital, Herlev, DENMARK, ²Dept. of Nuclear Medicine, Herlev & Gentofte University Hospital, Gentofte, DENMARK, ³Dept. of Endocrinology, Herlev & Gentofte University Hospital, Herlev, DENMARK.

Aim/Introduction: In primary hyperparathyroidism (PHPT), one or more parathyroid gland(s) produce(s) excess parathyroid hormone (PTH), causing increased p-Ca²⁺. The only cure is surgical removal of the hyperfunctioning parathyroid gland(s) (HPGs). Preoperative location imaging is essential to insure minimally invasive surgery. The standard method is dual-isotope subtraction scintigraphy (SPECT/CT) using ^{99m}Tc-sestamibi/¹²³I-iodide. While accurate (sensitivity 93% (86%-97%), specificity 99% (97%-100%)) this method is time consuming. We compare the "standard method" to ¹¹C-Choline PET/CT, a faster method (10 minutes vs. up to 4 hours) with lower effective dose (6.6 mSv vs. 12.9 mSv) in a GCP-controlled prospective trial of 60 patients. **Materials and Methods:** Calculations of effect measures involve multiple observations per patient. Observations within patients are often positively correlated (i.e. the likelihood of a second HPG is higher than the first HPG). This may lead to biased estimates of sensitivity and specificity when correlation is ignored. More importantly, analyses ignoring correlation often yield misleadingly small estimated standard errors for sensitivity and specificity because observations are counted as independent. Thus, analyses of data that include multiple observations per patient require adjustment to account for possible correlation. We calculated effect measures at the patient level rather than using multiple observations per patient. Patients diagnosed with PHPT and referred to preoperative imaging are included in the present

study and undergo additional preoperative ^{11}C -Choline PET/CT. Number of HPGs, location relative to the thyroid gland (left/right and upper/middle/lower third/ectopic) are noted for each imaging modality and during surgery. Surgical results, confirmed by pathology and biochemistry serves as the gold standard. **Results:** The presented data is an interim analysis of the first 60 patients in an ongoing project. Patients are predominately female (75 %) with a mean age of 62 years (range 24–83). Sensitivities of dual isotope subtraction scintigraphy and ^{11}C -Choline PET/CT are 98% (90%–100%) and 100% (93%–100%) respectively. Calculations for specificities have been done, but are omitted. As all included patients have PHPT, they must have at least one HPG per definition, and no patient should be a “truenegative”. **Conclusion:** Patient-level analysis yields high sensitivities for both scintigraphy and PET/CT. Sensitivities were higher than previously found analysis at the gland level, because in the latter, every gland must be identified separately to count as true positive. These interim results are optimistic, but more statistical power is needed to warrant a change in recommended method. Project inclusion continues with next interim analysis at 100 patients. **References:** None

OP-266

Comparison between digital and analog ^{18}F -Fluorocholine PET/CT detection rate of parathyroid adenomas

M. Sizova, D. López-Mora, M. Estorch, F. Fuentes-Ocampo, S. Abouzian, A. Flotats, V. Camacho, J. Pérez García, I. Carrió; Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.

Aim/Introduction: To compare the detection rate of hyperfunctioning parathyroid tissue (HPT) between digital and analog PET/CT with ^{18}F -fluorocholine in patients with primary hyperparathyroidism (PHPT) and negative or inconclusive $^{99\text{mTc}}$ -MIBI scan. **Materials and Methods:** Forty-eight patients (35 females; 58 ± 14.8 years) with PHPT and negative or inconclusive $^{99\text{mTc}}$ -MIBI scintigraphy/SPECT/CT were prospectively included from January 2018 to June 2019. All patients consecutively underwent a dual imaging protocol (digital and analog PET/CT, in random order) on the same day, after a single injection of ^{18}F -fluorocholine. Three nuclear medicine physicians assessed the detection rate by identifying focal radiotracer uptake suspicious of HPT. **Results:** HPT was detected in 42/48 (88%) patients by the digital system, whereas it was detected in 32/48 (67%) patients by the analog system ($p < 0.01$). Parathyroidectomy was performed in 33/48 patients. HPT was confirmed in 30/33 (91%) patients by the digital system, whereas in 22/33 (67%) patients by the analog system ($p < 0.01$). All HPT suspected lesions that were resected and detected only by the digital system were $< 10\text{mm}$ ($7.5\text{ mm} \pm 1.3\text{ mm}$), while those detected by both systems were $> 10\text{mm}$ ($13\text{ mm} \pm$

3.8 mm). The elevated baseline preoperative parathyroid hormone plasma levels decreased 10 minutes after parathyroidectomy ($13.6 \pm 10.1\text{ pmol/L}$ vs. $2.9 \pm 2.5\text{ pmol/L}$). Fifteen patients are still waiting for parathyroidectomy. In 11/15 patients, focal radiotracer uptake suspicious HPT was detected, 10 detected by both systems and 2 detected only by the digital PET/CT ($p < 0.01$). In 4 patients neither the digital nor the analog PET/CT detected focal radiotracer uptake suspicious of HPT. **Conclusion:** In patients with PHPT and negative or inconclusive $^{99\text{mTc}}$ -MIBI scan, digital PET/CT offers a superior detection rate of HPT than the analog PET/CT, particularly in subcentimeter parathyroid adenomas. **References:** None

^{11}C -Methionine PET/CT in Patients with Primary Hyperparathyroidism and Inconclusive Pre-Operative Work-Up: Diagnostic Accuracy and Role of Semi-quantitative Analysis

D. Maccora¹, C. Caldarella², M. L. Calcagni^{1,2};

¹Istituto di Medicina Nucleare, Università Cattolica del Sacro Cuore, Rome, ITALY, ²Dipartimento di Diagnostica per Immagini, Radioterapia Oncologica ed Ematologia, UOC di Medicina Nucleare, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY.

Aim/Introduction: PET/CT using Carbon-11-Methionine (C-MET) is a promising method in detecting abnormal parathyroid glands in patients with hyperparathyroidism (HPT) and inconclusive standard diagnostic work-up. The first aim of the study was to evaluate which is the diagnostic role of C-MET in patients with primary HPT and inconclusive pre-operative imaging. Secondly, we aimed to investigate whatever C-MET semi-quantitative parameters may reflect biochemical and histological characteristics of involved glands. **Materials and Methods:** Patients with primary HPT, undergoing C-MET after an inconclusive pre-operative imaging and having a parathyroid surgery, were retrospectively included. Histological diagnosis, post-operative normalization of serum calcium and parathyroid hormone (PTH) were the reference standard. C-MET diagnostic performances were evaluated by visual assessment and semi-quantitative analysis. Parameters, as SUV_{max} , SUV_{peak} , SUV_{mean} , functional lesion volume (FLV) and total lesion activity (TLA), were measured for each detected lesion; SUV_{mean} , FLV and TLA were calculated on 40%–90% thresholds of SUV_{max} to define $\text{SUV}_{\text{mean}40-90}$, FLV_{40-90} and TLA_{40-90} . Results were correlated with patients' clinical-laboratory and histological data (calcium and PTH values; main size/weight of excised glands). Mann-Whitney test was used and P value < 0.05 was considered significant. **Results:** Thirty-eight patients were included. Median calcium and PTH values were 11.1 mg/dl [interquartile range (IQR) $10.6 - 11.5$] and 154.6 pg/ml (IQR $101.8 - 227.0$), respectively. C-MET

sensitivity, specificity and accuracy in detecting the correct side in the neck of the abnormal gland were 79%, 75% and 79%, while in detecting its correct position were 75%, 50% and 71%, respectively. A per-patient analysis showed sensitivity, specificity, accuracy of 85%, 75% and 84% in detecting the side, 84%, 50% and 79% in detecting the exact position, respectively. Clinical-laboratory and histological data were not significantly different according to C-MET performance. Calcium results were not significantly related to any C-MET semi-quantitative parameters ($P=ns$), while $SUV_{peak} FLV_{50-70}$ and TLA_{40-70} were significantly higher in cases with higher PTH results ($P<0.05$, respectively). The size of the excised gland showed a significant positive correlation with SUV_{max} , $SUV_{peak} FLV_{40-80}$ and TLA_{40-90} , its weight with SUV_{peak} , $SUV_{mean40-50}$, FLV_{40-80} and TLA_{40-90} ($P<0.05$, respectively). **Conclusion:** C-MET showed a good performance in detecting hyperfunctioning parathyroid glands in selected patients with inconclusive diagnostic work-up. Although clinical data did not guide in predicting C-MET performance, some semi-quantitative PET-derived parameters (i.e. $SUV_{peak} FLV_{50-70}$ and TLA_{40-70}) closely correlated with pre-operative PTH as well as with size and weight of the excised gland, thus reflecting some biochemical and histological characteristics of involved glands. **References:** None

OP-268

The value of PET/CT in patients with primary hyperparathyroidism and negative or inconclusive neck ultrasound and MIBI scintigraphy

D. Huic^{1,2}, A. Golubić¹, E. Pasini Nemir¹;

¹Department of Nuclear Medicine and Radiation Protection, University Hospital Centre Zagreb, Zagreb, CROATIA,

²School of Medicine Zagreb, Zagreb, CROATIA.

Aim/Introduction: Primary hyperparathyroidism (PHPT) is a common endocrine disorder and parathyroid surgery still represents the only curative approach. Preoperative localization of hyperfunctioning parathyroid glands is very challenging, but it is crucial for focused and minimally invasive parathyroid surgery. The aim of our study was to assess the value of ¹⁸F-fluorocholine positron emission tomography (PET/CT) in very selected group of patients with negative or inconclusive neck ultrasound and MIBI scintigraphy and history of hyperparathyroidism of several years. **Materials and Methods:** We performed PET/CT with 100-150 MBq of ¹⁸F-fluorocholine in 42 patients (female 36, male 6, mean age 57years) in 18 months' period. Low-dose PET/CT acquisition was done 15-30 minutes' post injection. The regions of neck and thorax were scanned, 3 min per bed position. **Results:** In 40 patients (95%) 42 foci of increased tracer uptake suggestive for hyperactive parathyroid gland have been found, single in 38 patients, and two in two patients. One patient was negative and the other one judged as false positive after surgery. Most often

localisation of the hyperactive parathyroid gland in the neck region was in the level of the lower pole of thyroid lobe (11 on the right side, 10 on the left. Less common we found lesions in the level of the upper pole of thyroid lobe (7 right, 5 left). Usually parathyroid glands in the neck were localised very deeply prevertebral. In 8 patients (19%) we found ectopic parathyroid gland in mediastinum. The average maximum diameter of the lesions was 8 mm (range 4-30 mm), and median SUV value was 6 (range 2-10,6). 17 patients underwent surgery, and 18 parathyroid glands were removed. Pathology confirmed parathyroid hyperplasia in 13 glands and adenoma in 5 cases. The mean PTH and Ca serum values postoperatively dropped significantly (PTH from 19,1 to 6 pmol/L; Ca from 2,8 to 2,4 mmol/L), and normalized in all patients. **Conclusion:** In conclusion, PET/CT with ¹⁸F-fluorocholine is very sensitive and simple method for localisation of hyperactive parathyroid glands in very demanding patients with the long history of primary hyperparathyroidism. The data about specificity will be more detailed when surgery will be completed in majority of our patients. **References:** None

Optimal Dose of ⁶⁸Ga-Satoreotide Trizoxetan as a PET Imaging Agent in Patients with Gastroenteropancreatic Neuroendocrine Tumours: Qualitative Analysis of PET Images

I. Virgolini¹, S. Bahri², H. Grønbaek³, A. Kjaer⁴, J. Czernin⁵, E. von Guggenberg¹, C. Powell⁵, S. McEwan⁶, C. G. Miller⁵;

¹Medical University Innsbruck, Department of Nuclear Medicine, Innsbruck, AUSTRIA, ²University of California, Los Angeles, CA, UNITED STATES OF AMERICA, ³Aarhus University Hospital, Aarhus, DENMARK, ⁴Rigshospitalet and University of Copenhagen, Copenhagen, DENMARK, ⁵Ipsen, Cambridge, MA, UNITED STATES OF AMERICA, ⁶Ipsen, Toronto, ON, CANADA.

Aim/Introduction: ⁶⁸Ga-satoreotide trizoxetan (also known as ⁶⁸Ga-IPN01070, ⁶⁸Ga-NODAGA-JR11, or ⁶⁸Ga-OPS202), a novel somatostatin receptor 2 (sstr2) antagonist, showed improved diagnostic performance as a PET imaging agent versus the agonist ⁶⁸Ga-DOTA-TOC in a single-centre study.¹ This analysis from the phase II study aimed to confirm the optimal dose range for peptide mass and radioactivity of ⁶⁸Ga-satoreotide trizoxetan based on quantitative maximum standardized uptake value (SUV_{max}) and other quality parameters. **Materials and Methods:** This international, open-label, factorial-design, phase II study investigated two

peptide mass dose ranges and three radioactivity ranges of ^{68}Ga -satoreotide trizoxetan (NCT03220217). 24 participants with well-differentiated metastatic sstr2-expressing gastroenteropancreatic neuroendocrine tumours were randomized to one of three study arms ($n=8$ per arm), each patient received two different peptide mass/activity range combinations at two consecutive visits 2–3 weeks apart with PET/CT images obtained at 60 ± 10 minutes post intravenous injection. Participants were allocated to 5–20 μg of peptide mass at visit-1 and 30–45 μg at visit-2, with one of three gallium-68 radioactivity ranges (40–80 [low], 100–140 [mid] or 160–200 [high] MBq) per visit. Comparative image quality was reported by independent blinded readers and the 5 most avid lesions in the liver and lymph nodes were selected for quantification (SUV_{max}). The reference tissue was either non-diseased liver parenchyma or aorta. The study design allowed for review of paired images of different activity doses. **Results:** The median SUV_{max} ratio (SUV_{max} lesion/ SUV_{mean} reference tissue) in the liver at low/mid/high activity was 9.9, 6.0 and 7.2 in the 5–20 μg subgroups, and 9.3, 8.4 and 7.0 in the 30–45 μg subgroups, respectively. The mean [median] signal-to-noise-ratios (SNR) in liver for low/mid/high activity were 3.9 [2.8], 4.9 [4.3] and 6.1 [4.5], respectively. There was no noticeable effect of peptide mass on SUV_{max} . Radioactivity evaluated as MBq/kg of participant bodyweight was weight independent. The comparative quality of the images was more often suboptimal in the low radioactivity range. No serious adverse events (AEs) and a total of 14 related Grade 1 or 2 AEs from 7 participants were reported. **Conclusion:** No safety concerns arose in this phase II study of ^{68}Ga -satoreotide trizoxetan, which confirmed the optimal dose of 150 ± 50 MBq delivered with a peptide mass range up to 50 μg , and will form the basis of a future development of a phase III program. **References:** 1. Nicolas et al. J Nucl Med. 2018 Jun;59(6):915–921.

^{18}F]AIF-NOTA-octreotide PET imaging: Pharmacokinetics, biodistribution, and head-to-head comparison with ^{68}Ga]Ga-DOTATATE in neuroendocrine tumour patients

E. Pauwels¹, F. Cleeren², T. Tshibangu², M. Koole¹, K. Serdons¹, J. Dekervele³, E. Van Cutsem³, C. Verslype³, K. Van Laere¹, G. Bormans², C. M. Deroose¹;

¹Nuclear Medicine, University Hospitals Leuven; Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM,

²Radiopharmaceutical Research, Department of Pharmacy and Pharmacology, KU Leuven, Leuven, BELGIUM, ³Digestive Oncology, University Hospitals Leuven, Leuven, BELGIUM.

Aim/Introduction: While gallium-68-labelled somatostatin analogue (SSA) PET is the current gold standard for somatostatin receptor imaging, its widespread use is hampered by practical, regulatory and economic

challenges associated with $^{68}\text{Ga}/^{68}\text{Ga}$ -generators. These challenges could be largely overcome by a fluorine-18-labelled alternative. This prospective trial aimed to evaluate pharmacokinetics, biodistribution and lesion targeting of ^{18}F]AIF-NOTA-octreotide (^{18}F]AIF-OC) and perform a first head-to-head comparison with ^{68}Ga]Ga-DOTATATE in neuroendocrine tumour (NET) patients. **Materials and Methods:** Six NET patients (5M/1F; age 48–74y) with a previous clinical ^{68}Ga]Ga-DOTATATE PET were included. After injection of 4 MBq/kg ^{18}F]AIF-OC, a 45-minute dynamic PET of a thoraco-abdominal region, containing several tumour lesions, was acquired, followed by 3 whole-body PET scans at 1h, 2h and 3h post-injection (PI). Pharmacokinetic analysis was performed using PMOD v3.9. Per patient, 4 to 6 target lesions were delineated on the dynamic scan (32 in total). For each lesion, the net influx rate K_1 was determined using the Patlak plot, with an image-derived input function retrieved from the radioactivity concentration in the descending thoracic aorta. The relation between K_1 and SUV_{mean} of the target lesions on the static scans was evaluated. Furthermore, normal organ uptake (SUV_{mean}), tumour uptake (SUV_{max}) and tumour-to-background ratio (TBR) and detection ratio (fraction of detected lesions; DR) with ^{18}F]AIF-OC and ^{68}Ga]Ga-DOTATATE were compared. **Results:** The median K_1 was 0.066 (0.012–0.126). Between K_1 and SUV_{mean} a moderate to good linear correlation was observed, somewhat decreasing over time ($R^2=0.73$ at 1h PI; $R^2=0.68$ at 2h PI; $R^2=0.60$ at 3h PI). Biodistribution of ^{18}F]AIF-OC was similar to ^{68}Ga]Ga-DOTATATE, except for the salivary glands, where ^{68}Ga]Ga-DOTATATE uptake was about 5-fold higher ($p=0.002$). In total, 242 lesions were detected with a high DR that was comparable for both tracers (86.0% for ^{68}Ga]Ga-DOTATATE at 30–45min PI vs. 83.1%, 90.1% and 91.7% for ^{18}F]AIF-OC at 1h, 2h and 3h PI; $p>0.05$). However, the DR for ^{18}F]AIF-OC was significantly lower at 1h PI, compared to 2h and 3h PI ($p=0.005$ and $p<0.001$). Mean tumour SUV_{max} was significantly lower for ^{18}F]AIF-OC at 1h and 2h PI ($p=0.016$ and $p=0.033$), but not at 3h PI ($p=0.065$). Moreover, SUV_{max} significantly increased with time from 10.7 ± 5.7 to 12.3 ± 6.5 and 13.1 ± 6.9 at 1h, 2h and 3h PI, respectively ($p=0.3$ for all). No significant differences were observed in TBR between ^{68}Ga]Ga-DOTATATE and ^{18}F]AIF-OC. **Conclusion:** ^{18}F]AIF-OC shows favourable kinetics and equivalent lesion targeting in NET patients compared to gallium-68-labelled SSA PET, warranting further head-to-head validation. **References:** None

Improving target volume delineation for 3D image-based dosimetry in Peptide Receptor Radionuclide Therapy

S. Berenato^{1,2}, E. Grassi³, F. Fioroni³, D. Finocchiaro^{3,4}, M. Iori³, G. Lewis², E. Spezi^{2,1};

¹Department of Medical Physics, Velindre Cancer Centre, Cardiff, UNITED KINGDOM, ²School of Engineering, Cardiff

University, Cardiff, UNITED KINGDOM, ³Medical Physics Unit, Azienda Unità Sanitaria Locale - IRCCS, Reggio Emilia, ITALY, ⁴Department of Physics, University of Bologna, Bologna, ITALY.

Aim/Introduction: To create an accurate map of the distribution of radiation dose deposition during radionuclide therapy it is important to measure the 3D activity after administration of the radioactive material [1]. In Peptide Receptor Radionuclide Therapy (PRRT) the total activity can be derived from sequential SPECT/CT scans. In this process, lesions are typically outlined on the scan showing the maximum uptake. This however does not reflect the nonuniform nature of activity distributions arising over time in the patient's anatomy. This can lead to a non-optimal definition of target volume and dose assessment. We describe a novel approach to the segmentation of the target volume based on 3D image-based dosimetry that takes into account the total activity accumulated over time.

Materials and Methods: 100 patients treated with PRRT were imaged 5 times with a SPECT/CT scanner, after therapeutic administration of ¹⁷⁷Lu-labeled peptides. Sequential scans were co-registered to the reference scan and used to calculate a personalised 3D dose map using the Raydose Monte Carlo code [2]. For each patient, lesions were segmented on the dose map using a variable threshold method. Dose and volume statistics were compared with those extracted from lesions manually contoured by expert clinicians on the SPECT with maximum uptake. Quantitative differences between the two methods were evaluated with the Jaccard conformity index (JCI) and Centre of Mass (CoM) distance. **Results:** 85.7% of the cases had a JCI lower than 0.5 and no cases had an index higher than 0.8. On average, a 0.29 conformity value was found. 71% of the cases had CoM shift between 0.3 and 1.5 cm. Some cases had a CoM shift up to 3.6 cm. 3D dose analysis showed an overestimation of absorbed doses in the 97% of the cases and an underestimation of the target volumes in 79% of the cases. According to Bland-Altman analysis, differences in doses and volumes were found to be statistically significant (p -value < 0.01). **Conclusion:** The novel approach described in this study provides visually accurate target volume delineations for PRRT which are based on the actual biodistribution of the administered radioactive compound. This method has the potential to minimise inter-observer variability and could be implemented as a standardised process to improve efficiency and accuracy of image-based treatment planning for radionuclide therapy. **References:** 1. Serum succinate as a marker of tumor metabolic burden in patients with 18F-FDG-PET positive sporadic or SDHB-mutated metastatic malignant pheochromocytomas/paragangliomas

⁶Endocrine Oncology, Gustave Roussy, Villejuif, FRANCE.

Aim/Introduction: 18F-FDG-PET/CT is a well-validated method for extension assessment (or for the follow-up) of metastatic malignant pheochromocytomas/paragangliomas (MPP). SDHB-mutated MPP are characterized by high 18F-FDG avidity and metastatic risk. On the other hand, SDHB mutations lead to succinate accumulation, making the serum succinate assay a potential tumor biomarker. Our objective is to determine whether the serum succinate levels reflect the metabolic tumor burden in 18F-FDG-PET/CT positive metastatic MPP patients according to their genetic status. **Materials and Methods:** This is a retrospective monocentric study on 32 patients with clinical, 18F-FDG-PET/CT and biological data available. 18F-FDG-PET/CT data were extracted using PET-VCAR software (GE Healthcare): TMTV (Total Metabolic Tumor Volume), TLG (Total Lesion Glycolysis) and SUVmax. MTV was measured setting a threshold of 40% of SUVmax. Serum succinate levels were quantified using a fully validated LC-MS/MS method (Xevo TQS, Waters). Spearman's rank correlation coefficient was used to test the correlation between PET markers and serum succinate levels. **Results:** Forty six 18F-FDG-PET/CT and succinate assays from 32 metastatic MPP patients (15 sporadic and 17 SDHB) were analyzed. Primary tumor site was abdominal, neck or adrenal for 13, 7 and 12 patients respectively. Twenty of the 46 18F-FDG-PET/CT and serum succinate assays were performed during locoregional or systemic treatment. In the sporadic group, median serum succinate level of 17 assays was 6,6 μ M (range 3,1-33,6) for a median TMTV, TLG and SUVmax of 69,6 cm^3 (range 0-3173,7), 662 (range 0-24196) and 9,5 (range 0-35,6) respectively. In the SDHB group, median serum succinate level of 29 assays was 17,9 μ M (range 5,5-274,9) for a median TMTV, TLG and SUVmax of 175,9 cm^3 (range 3,0-2409,4), 1126 (range 6-24724) and 22,0 (range 2,4-40,4) respectively. Strong and equivalent relationships were documented between the serum succinate level and TMTV ($r=0,75$) and TLG ($r=0,76$) in the overall study population. Moderate and equivalent relationship was observed between the serum succinate level and SUVmax ($r=0,6$). In the SDHB group,

patients with the highest tumor burden (3rd and 4th TLG quartiles ; range 1135-5129 and 5136-24725 respectively) showed significant increased succinate levels compared to the sporadic group ($p < 0.001$ and $p < 0.0001$ respectively). **Conclusion:** Serum succinate levels correlate well with TMTV and TLG and may be used as a marker of tumor metabolic burden in patients with 18F-FDG-PET/CT positive sporadic or SDHB-mutated metastatic MPP. This confirms its status as a potential biomarker of MPP. **References:** None

68Ga-DOTATOC PET/CT in patients with paraganglioma/pheochromocytoma. Interest of combination with other PET/CT methods according to a monocentric experience

C. Morvant, D. Druj, C. Ferron, M. Le Bras, E. Langlois-Mourrain, F. Toulgoat, E. Mirallie, K. Renaudin-Autin, P. Baumgartner, F. Kraeber-Bodere, C. Ansquer; University Hospital of Nantes, Nantes, FRANCE.

Aim/Introduction: ⁶⁸Ga-DOTATOC-PET/CT is recommended in patients with paraganglioma/pheochromocytoma (PGL/PHEO). Our retrospective study analyzed the sensitivity of ⁶⁸Ga-DOTATOC-PET/CT in PGL/PHEO patients explored in the University Hospital of Nantes between 2016 and 2019. **Materials and Methods:** Thirty three patients (16 men and 17 women), median age 50 years, with PGL/PHEO underwent a ⁶⁸Ga-DOTATOC-PET/CT in addition to morphological imaging (thoraco-abdomino-pelvic CT, head and neck MR-angiography or MR on another area) for initial staging or follow up. ¹⁸F-DOPA-PET/CT and ¹⁸F-FDG-PET/CT were also performed in 14 and 24 patients, respectively. Seventeen (52%) patients had localized PGL/PHEO and 16 (48%) metastatic or multifocal disease. Genetic mutations were identified in 13 (40%) patients (1 SDHA, 8 SDHB, 1 SDHC, 3 SDHD), not identified in 15 (45%) patients and indeterminate in 5 patients (15%). Uptake higher than physiological background was considered as pathological and was confirmed by the gold standard (histological proof or positivity of at least another imaging modality). **Results:** The 170 lesions identified by PET/CT in the 33 patients were all confirmed by the gold standard, corresponding to 46 primary tumors or local recurrences and 124 metastases. In the whole population, the per-patient sensitivities were 97% (32/33) with ⁶⁸Ga-DOTATOC, 96% (23/24) with ¹⁸F-FDG and 93% (13/14) with ¹⁸F-DOPA. The per-lesion sensitivities were 91% (155/170) with ⁶⁸Ga-DOTATOC, 90% (145/161) with ¹⁸F-FDG and 79% (44/56) with ¹⁸F-DOPA. A sub-analysis was performed in the 11 (33%) patients explored with the 3 tracers, 3 of them with localized disease and 8 with metastatic or multifocal disease. In this sub-group, the per-patient sensitivities were 91% (10/11) with each tracer and the per-lesion sensitivities were 77% (41/53) for ⁶⁸Ga-DOTATOC and ¹⁸F-DOPA and 83% for ¹⁸F-FDG (44/53). Twelve ⁶⁸Ga-DOTATOC false negative lesions were found in

6 patients, corresponding to 6 sub-diaphragmatic lesions (5 primaries and 1 lymph node), and 6 visceral metastases (lung = 5, liver = 1). These 6 patients presented with several mutation status : 1 SDHA, 1 SDHB, 1 SDHD, 2 not mutated, 1 indeterminate. Interestingly, among these 12 lesions, 5 were detected by ¹⁸F-DOPA-PET, 9 by ¹⁸F-FDG-PET and all of them by the combination of ¹⁸F-FDG and ¹⁸F-DOPA. **Conclusion:** Our study confirms the accuracy of ⁶⁸Ga-DOTATOC-PET/CT for the exploration of PGL/PHEO. Nevertheless, and as already reported with ¹⁸F-FDG and ¹⁸F-DOPA, ⁶⁸Ga-DOTATOC alone does not detect all the lesions. Best performances are obtained by combining nuclear imaging modalities, in particular in metastatic and multifocal disease. **References:** None

Fully hybrid 68Ga-DOTATOC PET/MRI in NET patients evaluation: assessment of synergic value of 68Ga-DOTATOC PET and MRI

P. Mapelli^{1,2}, G. Ironi³, F. Fallanca², S. Partelli^{1,4}, V. Bettinardi², F. Muffatti⁴, V. Andreasi^{1,4}, P. Scifo², R. Rigamonti², A. Savi², L. Gianolli², M. Falconi^{1,4}, F. De Cobelli^{1,3}, M. Picchio^{1,2};

¹Vita-Salute San Raffaele University, Milan, ITALY, ²Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, ³Radiology Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, ⁴Pancreatic Surgery Unit, Pancreas Translational & Clinical Research Centre, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim/Introduction: The simultaneous acquisition of ⁶⁸Ga-DOTATOC PET and functional MRI by using fully hybrid PET/MRI scanners represent an innovation in the field of molecular imaging with relevant implication in the field of Neuroendocrine Tumours (NETs). The aim of the present study is to evaluate the synergic value of fully hybrid ⁶⁸Ga-DOTATOC PET/MRI in the management of NETs. **Materials and Methods:** Forty-three patients with diagnosis or imaging suspicion of NET underwent ⁶⁸Ga-DOTATOC PET/MRI for staging (30 pts) or restaging (13 pts) purpose from September 2018 to November 2019. Whole-body PET/MRI scan started approximately 60 minutes after ⁶⁸Ga-DOTATOC injection, followed by a dedicated MRI protocol on the upper and/or lower abdomen. Using an axial LAVA-FLEX acquisition during contrast, two arterial phases and a portal venous phase before and after the injection of a gadolinium-based contrast agent have been performed. These sequences were followed by axial SSFSE and axial echo planar DWI. Axial and coronal breath-hold hepatobiliary phase (HBP) were finally performed. PET images were also acquired simultaneously to the diagnostic MRI. An experienced Nuclear Medicine Physician analyzed the ⁶⁸Ga-DOTATOC PET scans, while the diagnostic MRI exams have been reviewed by an expert Radiologist. For each ⁶⁸Ga-DOTATOC PET/MRI scan, an additional analysis combining

PET and MRI findings (concordant and/or discordant) was performed. **Results:** In 7/43 pts (16.2%; 5 in the staging group and 2 in the restaging group) discordances between PET and MRI were observed. Diagnostic MRI (at abdominal level) could not detect extra-abdominal lesions detected by whole body ⁶⁸Ga-DOTATOC PET (lung findings in 1/7 pts). In 3 staging patients, PET detected the presence of ⁶⁸Ga-DOTATOC uptake within the pancreas, in correspondence of small lesions (<8mm) not clearly identifiable on MRI images. Finally, MRI detected liver metastases not seen on ⁶⁸Ga-DOTATOC PET (2/7 pts; 1 in the staging group and 1 in the restaging group). In a MEN1 patient, both PET and MRI detected a major pancreatic lesion, with only PET identifying several additional uptakes within the pancreatic gland as site of additional NETs (histological examination confirmed multiple pancreatic NETs). **Conclusion:** In both staging and restaging phases of NETs patients, ⁶⁸Ga-DOTATOC PET and MRI provide synergic information. The major strength of PET is the ability to provide a whole-body assessment of receptor expression, also in small lesions hardly detected by MRI. On the other hand, MRI confirmed its undisputed role in liver disease detection and monitoring. **References:** None

OP-275

F-18 DOPA PET imaging in hyperinsulinemic hypoglycemia

K. Toplutas, L. Uslu-Besli, S. Asa, S. Sager, E. Karayel, H. Pehlivanoğlu, K. Sönmezoğlu;

Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul, TURKEY.

Aim/Introduction: Hyperinsulinemic hypoglycemia (HH) is a disorder developing due to focal or general insulin hypersecretion by pancreatic islet cells and is generally seen as insulinoma in adults and congenital hyperinsulinism in newborns. Focal and diffuse hyperplasia of the endocrine pancreas is involved in the etiopathogenesis and their differential diagnosis is important in planning surgical treatment. In this study, we evaluated patients who underwent F-18 DOPA (FDOPA)-PET with the indication of HH. **Materials and Methods:** Twelve HH patients, who were resistant or unresponsive to medical treatment and had negative or inconclusive radiological imaging results were referred to our department for FDOPA-PET. Ten patients (age range: 2 months-15 years) were children and two were young adults (age: 29 and 34 years). Dynamic PET imaging of the abdomen and whole-body imaging at 45-60 minutes post-injection were performed after FDOPA injection using either PET/CT or PET/MRI according to the patients' medical condition. Carbidopa premedication could not be used. **Results:** Among five children who had heterozygous ABCC8/KCN11 mutation suggesting focal disease, focal FDOPA uptake was detected in two and diffuse uptake was present in the remaining three. Islet cell

hyperplasia was histopathologically confirmed in one child with focal uptake who had focal pancreatectomy and no medication was needed during follow-up. The other child with focal uptake has not been operated yet and is still under investigation. Among five other children without genetic mutation, two had focal uptake and three had diffuse uptake. Of these, two with focal uptake had further imaging for preoperative evaluation and pancreatic lesion was confirmed in abdominal MRI in one of them. Patients with diffuse uptake were not operated. Both young adult patients had focal FDOPA uptake. One of these adults, who was previously diagnosed with insulinoma and had a history of pancreatectomy, underwent a second operation after FDOPA-PET and recurrence of insulinoma in the splenic hilum, which was in accordance with FDOPA PET, was histopathologically confirmed. Also, in the other adult patient, histopathology confirmed islet cell hyperplasia. While the patient with insulinoma continued medication, the other patient was followed without medication. **Conclusion:** FDOPA-PET imaging is the most promising method for the identification of preoperative lesions in HH patients who are resistant/unresponsive to medical treatment. In our cohort, FDOPA-PET was useful in identification of focal lesions and planning focal pancreatectomy, thus helped us to refrain from long-term side effects of subtotal pancreatectomy. **References:** None

OP-276

Early response assessment and prediction of overall survival after peptide receptor radionuclide therapy

D. Huizing, E. A. Aalbersberg, M. W. J. Versleijen, M. E. T. Tesselaar, I. Walraven, M. J. Lahaye, B. J. de Wit - van der Veen, M. P. M. Stokkel; Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Aim/Introduction: Response after peptide receptor radionuclide therapy (PRRT) can be evaluated using anatomical imaging (CT/MRI), somatostatin receptor imaging (⁶⁸Ga]Ga-DOTA-TATE PET/CT), and serum Chromogranin-A (CgA). The aim of this study is to assess the role of these response evaluation methods and their predictive value for overall survival (OS). **Materials and Methods:** Imaging and serum CgA levels were acquired prior to start of PRRT, 3 and 9 months after completion. Tumor size was measured on anatomical imaging and response was categorized according to RECIST and Choi criteria. ⁶⁸Ga]Ga-DOTA-TATE uptake was quantified in both the target lesions depicted on anatomical imaging and separately identified PET target lesions, which were either followed over time or newly identified on each scan. OS was calculated from PRRT start until death from any cause. The association of response determination methods and OS was assessed with univariate Cox regression analyses. **Results:** A total of 44 patients were included with a median follow-up of 31 months (IQR 26-36 months) and a median OS of 39 months

(IQR 32mo-not reached). Anatomical imaging analysis after 3 months was not associated with OS. Progressive disease after 9 months (according to RECIST) was significantly associated with worse OS compared to stable disease [HR 9.04 (95% CI 2.10-38.85)], however not compared to patients with response [HR 3.951, 95% CI 0.459-34.006]. According to the Choi criteria, progressive disease was also significantly associated with worse OS compared to stable disease [HR 6.10 (95% CI 1.38-27.05)] and compared to patients with response [HR 22.66 (95% CI 2.33-219.99)]. In some patients, new lesions were detected earlier with [⁶⁸Ga]Ga-DOTA-TATE PET/CT than with anatomical imaging. After 3 months, new lesions on [⁶⁸Ga]Ga-DOTA-TATE PET/CT which were not visible on anatomical imaging, were detected in 4/42 (10%) patients and in another 3/27 (11%) patients after 9 months. However, no associations between change in uptake on ⁶⁸Ga-DOTA-TATE PET/CT using any of the four quantification methods or serum CgA measurements and OS was observed. **Conclusion:** Progression on anatomical imaging after 9 months is associated with worse OS. In some patients, new lesions were detected earlier with [⁶⁸Ga]Ga-DOTA-TATE PET/CT than with anatomical imaging, however the numbers are too small for associations with OS. Overall, changes in [⁶⁸Ga]Ga-DOTA-TATE uptake, and serum CgA after PRRT were not predictive for OS in this series. **References:** None

OP-277

The role of ¹⁸F-FDG PET/CT in the prediction of overall survival of patients with GEP-NECs

M. Aly^{1,2}, H. L. Stokmo^{3,4}, S. M. Seraj¹, R. Ghorpade¹, A. J. Borja^{1,5}, X. Miao¹, G. O. Hjortland⁶, E. Malinen⁷, T. J. Werner¹, A. Alavi¹, M. E. Revheim^{1,3,4},

¹Department of Radiology, University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA, ²Department of Radiology, Asyut University Hospital, Asyut, EGYPT, ³Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, ⁴Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, NORWAY, ⁵Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA, ⁶Department of Oncology, Oslo University Hospital, Oslo, NORWAY, ⁷Department of Radiotherapy, Oslo University Hospital, Oslo, NORWAY.

Aim/Introduction: The clinical usefulness of ¹⁸F-FDG PET/CT is emerging in the evaluation and management of high-grade neuroendocrine neoplasms (NENs). A few studies have demonstrated the presence of increased glucose metabolism in NENs correlates with the aggressiveness of tumors and bad prognosis. Herein, we performed a study to evaluate the prognostic value of the volumetric and metabolic information derived from ¹⁸F-FDG PET/CT. **Materials and Methods:** Patient selection: This study includes 71 (40 males, 31 females) patients with median age 66

(range 31 - 80y) diagnosed with advanced neuroendocrine carcinoma who underwent a ¹⁸F-FDG PET/CT examination and a biopsy within 90 days (median -22, range -85 - 89d) of the PET-study. Image acquisition: ¹⁸F-FDG PET/CTs were performed on EARL-accredited (EANM Research Ltd) PET/CT systems (mCT 16, Siemens Medical Systems, Erlangen, Germany (n=63), Siemens Biograph 64/16 (n=6) and GE Discovery 690 (n=2)). The patients fasted for at least 6 hours and blood samples were obtained to document blood glucose levels (median 5.6, range 3.7 - 13.6 mmol/l) prior to intravenous administration of median 236 MBq ¹⁸F-FDG (range 154.7 - 400 MBq). Images were obtained approximately 60 min. post-injection (median 63, range 44 - 134 min). Image analysis: All the scans were analyzed using an adaptive thresholding system (ROVER software; ABX GmbH, Radeberg, Germany). Spherical or cylindrical masks were placed over the active malignant lesions, and the adaptive thresholding algorithm of ROVER delineated the boundaries of active lesions giving the metabolic tumor volume (MTV). Standardized uptake values (SUV) lik SUV_{mean} and SUV_{max}, in addition to partial volume corrected (pvc) SUV_{mean} and SUV_{max} were calculated by the software. Total lesion glycolysis (TLG) were calculated by the software by multiplying with SUV_{mean}. Global scores were calculated by summing all the patient lesions. The cut-off value for MTV dividing the patients into two groups was based on the median MTV (150.91 cm³). Overall survival (OS) for patients over- and under the cut-off value were compared using the Kaplan-Meier method, and the log rank test. **Results:** Median survival in the group with low global MTV was 694 days, compared to 226 days for the group with high global MTV. Global MTV under the cut-off value were significantly correlated to improved OS (X²=9.21, p=0.0024). Estimated 1-year OS was (X²=11.53, p=0.00068), and estimated 3-year OS was (X²=4.18, p=0.04). **Conclusion:** NECs with higher global MTV have poorer survival and hence indicate more aggressive disease. **References:** None

OP-278

Investigation of parameters impacting ⁶⁸Ga-DOTATOC PET image quality and quantification: a clinical and phantom study

M. Bernardini, C. Smadja, N. Ghazzar;
European Hospital Georges Pompidou, Paris, FRANCE.

Aim/Introduction: ⁶⁸Ga-DOTATOC PET/CT has emerged as a highly accurate imaging method for patients with neuroendocrine tumors (NETs). In our institution, we recently provided PET exams with ⁶⁸Ga-DOTATOC and we investigated the way to optimize the acquisition parameters and the differences of quantification between ¹⁸F-FDG, ¹⁸F-DOPA and ⁶⁸Ga-DOTATOC patient images. **Materials and Methods:** To investigate the influence of several parameters, as the delay after injection, injected activity, BMI and

acquisition time per bed position on 68Ga-DOTATOC PET exams, 24 patients were analyzed. Moreover, several 68Ga NEMA phantoms were acquired to explore the influence of positron energy and its pathway in water and air on the quantification, together with spatial resolution and volumes thresholding. **Results:** We did not find any correlation between SUV values and the delay after injection (varying from 48 min to 1h40), nor the injected activity (varying from 102 MBq to 198 MBq), neither the BMI (varying from 17 to 45). In the same way, the liver and sternum signal to noise ratio (S/N) did not show any correlation with the parameters cited above. When increasing time acquisition from 2min to 2min30sec per bed step, on 11 patients and 21 lesions analyzed, the signal globally decreases: SUVmax median value decreases of -3.6% for lesions (ranging from -15% to 42%), -4.7% for liver (varying from -10% to 6%) and -11.4% for sternum (ranging from -27% to -1%). NEMA phantoms analysis showed that the mean radioactive concentration (Bq/ml) outside spheres ranges from 10.3% (26.5ml sphere) to 20.3% (0.5ml sphere). Concerning the total activity (Bq) outside the spheres, it ranges from 24.6% (26.5ml sphere) to 139.2% (0.5ml sphere). **Conclusion:** The very high specificity of 68Ga-DOTATOC explains the absence of correlation between the signal quantification and the parameters that typically influence the F-18 FDG signal (injected activity, BMI, delay after injection), at the clinical values applied. SUV values decrease globally when the time per bed position increases, underlying the predominant effect of short half-life of Ga-68 (68 min) on quantification. Analysis of 68Ga-NEMA phantoms, showed lower recovery coefficient than F-18: mean radioactivity concentration in the edge of spheres ranging from 10.3% to 20.3% involves important amount of radioactivity detected out of the spheres, ranging from 24.6% to 139.2%. These results show that clinical volume thresholding and quantification methods applied for 18F-FDG or 18F-DOPA should be revised for 68Ga-DOTATOC exams. **References:** None

OP-279

Comparison between metastatic neuroendocrine tumours and carcinomas somatostatin receptor expression on ^{99m}Tc-EDDA/HYNIC-TOC SPECT/CT with immunohistochemical, histopathological and laboratory parameters

G. Sipka, Z. Besenyi, I. Farkas, T. Czékus, Z. Mikó, A. Bakos, S. Urbán, L. Pávics;

University of Szeged, Department of Nuclear Medicine, Szeged, HUNGARY.

Aim/Introduction: Neuroendocrine tumours can occur anywhere in the body, however these are treated as a common group because the cells of these neoplasms share multiple common features. The somatostatin receptor scintigraphy helps to visualize one of these feature, which

is especially essential in the advanced stages of these neoplasms. The aim of our study was to compare the somatostatin receptor expression of the pathological lesions from different origins on ^{99m}Tc-EDDA/HYNIC-TOC SPECT/CT images with other specific or aspecific histological, immunohistochemical and laboratory results to find any relevant correlations between these parameters. **Materials and Methods:** In our retrospective analysis, 38 histologically proven, advanced neuroendocrine tumour or carcinoma patients' (14 women, 24 men, mean age: 59 years) 53 ^{99m}Tc-EDDA/HYNIC-TOC SPECT/CT examinations were analysed. The detected pathological lesions somatostatin receptor expressions were standardly quantified and also a patient- and lesion-based semiquantitative assessment was performed. The obtained results were compared with each other and with the laboratory findings (Chromogranin-A, Neuronspecific enolase and other specific tumour markers), with histopathological results (Grade, Ki-67, TNM) and with immunohistochemistry reports (Chromogranin-A, Synaptophysin, CD56, Somatostatin receptor, SyntaxinA1, CK7, CK20, TTF-1, S100 and other markers). **Results:** In total 315 pathological lesions were detected on 53 ^{99m}Tc-EDDA/HYNIC-TOC SPECT/CT scans, which majority (235/315) located in the liver, lymph nodes and bones. The somatostatin receptor density quantification confirmed the different uptake between the neuroendocrine carcinomas and neuroendocrine tumours (Kruskal-Wallis, P<0,0001). The gastrointestinal tumours had higher somatostatin receptor expression, than other neuroendocrine malignancies (Mann-Whitney, P<0,0001). Most of the tumours were chromogranin-A, synaptophysin, and CD56 positive, but in addition to the widely known immunohistochemical parameters the CK7 (Mann-Whitney, P=0,0138) and TTF-1 negative (Mann-Whitney, P<0,0001), and moreover SyntaxinA1 (Mann-Whitney, P<0,0001), CK20 (Mann-Whitney, P=0,0128), S100 (Mann-Whitney, P=0,0067) and as expected the somatostatin receptor (Mann-Whitney, P=0,0001) positive lesions showed higher uptake. The somatostatin receptor density was not correlated between laboratory parameters and lesions. **Conclusion:** These data show that the ^{99m}Tc-EDDA/HYNIC-TOC SPECT/CT has the potential to differentiate between neuroendocrine tumours and carcinomas. Our study also confirms that the CK7, TTF-1 negativity and CK20, syntaxin A1, S100 positivity could be a good prognostic factor to predict the high somatostatin receptor expression. This correlation between certain immunohistochemical factors and somatostatin receptor expression may lead to a better understanding of the biochemical behaviour of the neuroendocrine tumours. **References:** None

OP-280

Normal pancreatic appearances of [⁶⁸Ga]Ga-DOTA-TATE

G. La Torre, S. Hughes;

University Hospital Birmingham, Birmingham, UNITED KINGDOM.

Aim/Introduction: [⁶⁸Ga]Ga-DOTA-TATE is a radiotracer for PET/CT imaging of neuroendocrine tumours (NETs). A thorough knowledge of the normal patterns of tracer uptake is needed to interpret these images accurately. Our study focuses on describing the normal patterns of pancreatic [⁶⁸Ga]Ga-DOTA-TATE uptake which is particularly important in pancreatic NETs (PNETs). **Materials and Methods:** We conducted a retrospective study of 163 consecutive routine [⁶⁸Ga]Ga-DOTA-TATE PET/CT scans carried out at the Queen Elizabeth Hospital Birmingham between 2017–2018. The patients with known PNETs were excluded. The normal appearance of the pancreas on the CT component of the PET/CT in the presence of pathologically confirmed NET elsewhere were interpreted as no evidence for second DOTA-TATE positive pancreatic pathology. We described the patterns of uptake in the anatomical regions of uncinata process, head, neck, body and tail of the pancreas defined by the regions correlating with the co-registered CT component. The pattern seen was recorded as being focal or diffuse. The maximum semi-quantitative uptake value (SUV_{max}) was recorded for qualitatively abnormal regions. **Results:** 27 patients had evidence of PNET or other pathology, these were removed from our analysis with a further 14 because images were not retrievable. 122 scans were analysed. 5.7% showed no detectable qualitative uptake. 18.0% showed whole pancreatic uptake in with diffuse patterns (highest SUV_{max}: 16.5). 41.8% of scans showed evidence of uncinata uptake (Focal:57%, Diffuse:43%, SUV_{max} Focal:65.6, Diffuse:24.1). 14.5% showed uptake in the head of the pancreas (Focal:10.5%, Diffuse:89.5%, SUV_{max} Focal:38.7, Diffuse:27.1); 4.5% showed uptake in the neck (Focal:37.5%, Diffuse:62.5%, SUV_{max} Focal:23.4, Diffuse:9); 21.2% in the body (Focal:10.5%, Diffuse:89.5%, SUV_{max} Focal:39.3, Diffuse:9.7) and 17.8% in the pancreatic tail (Focal:12.5%, Diffuse:87.5%, SUV_{max} Focal:92.7, Diffuse:17.7). Only 1 scan had evidence of 4 areas of uptake, 14 had 3 areas of uptake, 41 had 2 areas of uptake and 37 had only 1 area of uptake. Compared to previous studies, our results show a more complex pattern of normal uptake with both diffuse and focal regions of uptake. **Conclusion:** To the best of our knowledge, this is the most detailed description of probable normal patterns of pancreatic uptake of [⁶⁸Ga]Ga-DOTA-TATE. We show that normal uptake is not limited to the uncinata process and head of the pancreas, albeit the most common, and other important complex patterns are seen. We show that [⁶⁸Ga]Ga-DOTA-TATE PET/CT imaging may be a misleading tool for the local assessment of small PNETs without anatomical imaging. **References:** None

Channel 11

EPS-052

Identifying and quantification of cardiovascular calcification by 18F-NaF PET/CT in alkaptonuria patients

E. Alawadhi¹, S. Vinjamuri², J. A. Gallagher¹, R. Lakshminarayan³, J. Dillon¹;

¹Institute of Ageing & Chronic Disease, William Henry Duncan Building, the University of Liverpool, Liverpool, UNITED KINGDOM, ²Department of Nuclear Medicine Royal Liverpool University Hospital, Liverpool, UNITED KINGDOM, ³Liverpool Clinical Laboratories, Royal Liverpool & Broadgreen University Hospitals Trust, Liverpool, UNITED KINGDOM.

Aim/Introduction: Alkaptonuria is characterised by increased homogentisic acid (HGA) in the blood and tissues. The main pathophysiological event in alkaptonuria is the binding of an HGA-derived pigment to connective tissue, termed ochronosis. The ochronotic pigment can be deposited in the cardiovascular system causing severe cardiovascular involvement such as heart valve stenosis¹. Microcalcification and active calcification have been detected and identified using 18F-NaF PET/CT imaging². The study aimed to evaluate regional cardiac calcification by semi-quantifying the sodium fluoride uptake from PET images and attenuation coefficient from CT images as evidence of calcification in the main cardiac arterial regions within AKU patients. **Materials and Methods:** 18F-NaF PET/CT images from 40 AKU patients (24 males, 16 females) were analysed quantitatively in this study using HOROS software. Maximum standardised uptake value (SUV_{max}), maximum target-to-background ratio (TBR_{max}), and mean Hounsfield units (HU_{mean}) were generated from PET/CT images for the main cardiac arterial regions, including coronary and aortic arterial regions. SUV_{max}, TBR_{max}, and HU_{mean} from each region were correlated with gender and age using the Pearson correlation coefficient. **Results:** The average (±SD) SUV_{max} value of all measured coronary arteries was 1.39 ± 0.49, and for the aorta was 2.06 ± 0.84. The average TBR_{max} for the coronary arteries (1.80 ± 0.80) was significantly lower than the aorta TBR_{max} (2.7 ± 1.24, p < 0.005). The average HU_{mean} of all measured coronary arteries was 138.18 ± 139.41, and was 133.71 ± 143.48 for the aorta, with no significant differences (p > 0.05). Regional coronary arteries and aortic arteries 18F-NaF uptake values were not clearly correlated with age (p > 0.05), while HU_{mean} values were positively correlated with age (p < 0.05). Males had higher average coronary arteries SUV_{max} and TBR_{max} values compared to females (p = 0.036, p = 0.012). Almost similar aortic findings have been

noted between male and female subjects in all measured regions, with no significant confounding differences ($p > 0.05$). **Conclusion:** Quantitative assessment of cardiovascular molecular calcification by ^{18}F -NaF can be considered as a novel and practical tool for investigating the early vascular calcification in AKU patients. The findings from this initial study demonstrate the potential feasibility of using ^{18}F -F-NaF as a biomarker for in vivo quantification of molecular cardiovascular calcification as an early feature of cardiovascular atherosclerosis. **References:** 1.Hannoush, Hwaida, et al. Combined Thoracic Contrast-Enhanced CT with PET/CT in Assessment of Primary Cardiac Tumors in Adult Patients

E. Liu, T. Sun, S. Wang, Z. Chen, H. Dong, C. Liu, D. Shao, Z. Lian, Q. Xie, S. Wang; Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, CHINA.

Aim/Introduction: AIM ^{18}F -FDG PET/CT is a key molecular imaging modality to noninvasively assess and differentiate benign and malignant cardiac tumors. However, few benign cardiac tumors can be characterized by increased ^{18}F -FDG uptake, which makes differential diagnosis difficult. This study sought to retrospectively evaluate whether combined thoracic contrast-enhanced CT (CECT) with ^{18}F -FDG PET/CT helps in assessing primary cardiac tumors in adult patients, compared with CECT or PET/CT alone. **Materials and Methods:** A retrospective study was conducted using 109 consecutive patients with cardiac masses suspected by transthoracic echocardiography (TTE) and/or thoracic CT. All patients underwent ^{18}F -FDG PET/CT, followed by thoracic CECT on the same day. Visual qualitative interpretation and quantitative analysis were performed and diagnostic performance was evaluated using the receiver operating characteristic (ROC) analysis, with the area under the ROC curve (AUC) for multi-parameters. **Results:** A total of 46 patients with 46 tumors (29 benign, 17 malignant) were enrolled; 55.2% of benign tumors showed visually increased ^{18}F -FDG uptake. There were significant differences in the level of ^{18}F -FDG uptake and the degree of absolute enhancement between benign and malignant tumors ($P < 0.001$). The combination of two modalities (PET/CT and thoracic CECT) improved the specificity from 79% to 93%, the positive predictive value from 73% to 89%, and the accuracy of diagnosis from 85% to 93%. There were significant differences between PET/CT alone or thoracic CECT alone and combined modalities ($P = 0.034$ and $P = 0.026$, respectively). The combination with the optimal SUVmax cutoff value generated 94% sensitivity, 100% specificity, 97% negative predictive values, 100% positive predictive values, and 98% accuracy rates. **Conclusion:**

Combining thoracic CECT with ^{18}F -FDG PET/C significantly improved specificity and accuracy compared to CECT or PET/CT alone in detecting tumors. This combination of diagnostic imaging is effective in differentiating malignant from benign masses. **References:** None

V/Q scintigraphy and SPECT for the diagnosis of Chronic Thromboembolic Pulmonary Hypertension: Experience from a reference centre

D. Vega, P. Pilkington Woll, V. Godigna Guilloteau, A. Galiana Moron, S. Ruiz Solis, E. Martinez Albero, M. J. Tabuenca Mateo, M. D. Martin Ferrer, M. P. Sarandeses Fernandez, A. Gomez Grande, J. M. Estenoz Alfaro; Hospital 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: Our goal is to determine the diagnostic accuracy of the V/Q scintigraphy and SPECT in patients with suspected CTPH (Chronic Thromboembolic Pulmonary Hypertension) in our hospital. **Materials and Methods:** Patients with suspected CTPH referred from the CTPH multidisciplinary committee who later underwent ventilation/perfusion (V/Q) SPECT were analyzed retrospectively between the years 2018 and 2020. We registered the final diagnosis of each patient based on clinical management or surgical treatment/angioplasty performed, obtaining two groups: patients with CTPH and without CTPH. The results of V/Q SPECT were analyzed, considering as positive result the presence of perfusion defects of triangular morphology (with peripheral base) and not concordant with the ventilation study. Subsequently, we calculated the sensitivity (S), specificity (E), negative predictive value (NPV) and positive predictive value (PPV) of the V/Q scintigraphy and SPECT for the diagnosis of CTPH with the STATA statistical program. A sub-analysis was performed on 24 patients who had also undergone CTPA (CT Pulmonary Angiography) to compare the diagnostic accuracy of both tests. **Results:** A total of 45 studies were carried out, with a mean age of 65.6 years (from 31 to 95 years), 35.5% men and 64.5% women. Of these patients, 35.5% had CTPH as a definitive diagnosis. The statistical analysis determined that the diagnosis of CTPH with the V/Q SPECT obtained S:93%, E:96%, PPV:93% and NPV:96%. The results of the sub-analysis (CTPA VS SPECT) were:- CTPA: S: 83%, E: 91%, PPV: 90% and NPV: 84%. - SPECT: S: 100%, E: 91%, VPP: 92% and VPN: 100%. **Conclusion:** The performance of V/Q SPECT for the diagnosis of CTPH has a high diagnostic accuracy (similar to that described in the literature), therefore able to confirm it as the first-choice diagnostic test, increasing its importance when diagnosing accurately a pathology with significant morbidity and mortality. **References:** None

EPS-055**Nuclear medicine techniques for the assessment of cardiac sarcoidosis and cardiac amyloidosis. Preliminary results of a European survey**

P. Erba¹, R. Slart², A. Saraste³, O. Gheysens⁴, J. Bucnerius⁵, M. Dweck⁶, F. Hyafil⁷, A. Glaudemans⁸, H. Verberne⁸, M. Lubberink⁹, O. Gämperli¹⁰, G. Habib¹¹, A. Gimelli¹²;

Aim/Introduction: Despite nuclear imaging techniques have the potential to provide unique information in cardiac sarcoidosis/amyloidosis, an overview of the current clinical use in Europe is lacking. Therefore, we design a survey to evaluate the current clinical practice in imaging cardiac sarcoidosis/amyloidosis with nuclear techniques. In this abstract we present the results of the first round of the survey which was held between February 15 -April 15, 2020. **Materials and Methods:** none **Results:** Information was collected using an electronic questionnaire, consisting of 16 questions. Responses were obtained from 50 professionals, the majority of which were in the middle career stage working in center where < 10 patients with sarcoidosis and between 10-40 patients with amyloidosis are studied each year. Only a very few sites assessed > 40 patients per year. The large majority of the responders used nuclear imaging in patients with cardiac sarcoidosis/amyloidosis (40/50 (80%) and 46/50 (92%), respectively). The most common reasons for nuclear imaging in sarcoidosis were: staging of extracardiac disease, 2nd line imaging to establish the diagnosis in uncertain cases, and treatment response. [¹⁸F]FDG PET/CT, either whole body or cardiac, followed by MPI PET or SPECT were the most frequently

used technique. In case of cardiac amyloidosis, imaging was more often requested as either 1st line imaging test to establish a diagnosis or 2nd line imaging to establish the diagnosis in uncertain cases. Scintigraphy with bone-seeking radiopharmaceuticals was the most used imaging modality with ^{99m}Tc-DPD being used in almost 50% of the cases followed by ^{99m}Tc-HPD and ^{99m}Tc-PYP. Cardiac ¹²³I-MIBG was the second most used technique. The primary reasons not to study these patients were i) lack of referrals/interest from the referring clinicians and of proper equipment or radiopharmaceuticals; ii) lack of reimbursement and iii) use of echocardiography or MRI. Management of patients with cardiac sarcoidosis by a multimodality imaging team was present in less than 50% of the participating centers while it's slightly more common in case of amyloidosis. Almost all responders indicated willing to be involved in a European network registry/study, therefore underlying the interest for the topic. **Conclusion:** These preliminary results encourage the creation of coordinated European effort to promote clinical practice and research in cardiac sarcoidosis/amyloidosis. A second round of the questionnaire (June 2020), aiming at increasing the number of responders, will most likely strengthen the results. **References:** None

EPS-056**High Sympathetic Activity in Raynaud's Disease**

L. Lindberg¹, B. Kristensen¹, T. W. Hansen², P. Hasbak³, J. F. Thomsen⁴, E. Eldrup⁵, L. T. Jensen¹;

¹Department of Nuclear Medicine, Copenhagen University Hospital, Herlev Hospital, Herlev, DENMARK, ²Steno Diabetes Center Copenhagen, Gentofte, DENMARK, ³Department of Clinical Physiology, Nuclear Medicine & PET, Rigshospitalet, University of Copenhagen, Copenhagen, DENMARK, ⁴Department of Occupational and Environmental Medicine, Copenhagen University Hospital, Bispebjerg and Frederiksberg Hospital, Copenhagen, DENMARK, ⁵Department of Endocrinology, Copenhagen University Hospital, Herlev Hospital, Herlev, DENMARK.

Aim/Introduction: Raynaud's disease (RD) is characterized by episodic whitening of the fingers without an underlying cause. The disease is usually considered benign and of peripheral location. However, studies have indicated an increased sympathetic activity¹ as well as increased cardiovascular morbidity and mortality in patients with RD^{2,3}. Therefore, the aim of the study was to examine the sympathetic nervous system in patients with RD to elucidate a possible central nervous component of the disease. **Materials and Methods:** [¹²³I]MIBG heart scintigraphy was performed on 22 patients with RD. The diagnosis was verified by international consensus criteria. Early and late images were acquired. Regions of interest (ROIs) were drawn over the myocardium and the upper mediastinum, and the heart-to-mediastinum ratio (HMR_{late}) was calculated

upon analysis of the late images. Results were compared with results from 14 healthy subjects examined in a previous study. **Results:** The mean (SD) HMR_{late} in the patients with RD was 2.4 (0.4), and in the healthy subjects, it was 2.9 (0.4). The difference was statistically significant ($p = 0.0004$). Multiple linear regression analysis showed that a lower HMR_{late} was associated with higher age ($p = 0.03$) and the presence of RD (0.0002). Regression analysis including the patient group showed no association between HMR_{late} and severity of RD. **Conclusion:** The study supports the hypothesis that RD affects the central sympathetic nervous system, which seems to be overactive in these patients compared to healthy subjects. Although recommendations cannot be made based solely on results from the present study, more attention to the prevention of cardiovascular disease in RD might be advised. **References:** 1. The improvement of hibernating myocardium analyzed by gated ^{99m}Tc -sestamibi SPECT/CT and gated ^{18}F -FDG PET/CT in patients with ischemic cardiomyopathy were associated with the reversal of left ventricular remodeling after revascularization

Y. Lu¹, J. Cao², J. Tian¹, Y. Tian¹, W. Dong¹, M. Hacker³, R. Dong², X. Li¹, X. Zhang¹;

¹Department of Nuclear Medicine, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA, ²Department of Cardiac Surgery, Beijing Anzhen Hospital, Capital Medical University, Beijing, CHINA, ³Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: In this study, we aimed to evaluate the changes of hibernating myocardium after revascularization, and its association with the changes of cardiac function as well as left ventricular(LV) remodeling in patients with ischemic cardiomyopathy and severe heart failure (HF) after revascularization at different time points. **Materials and Methods:** Ischemic cardiomyopathy patients who were referred to revascularization underwent gated ^{99m}Tc -MIBI SPECT/CT myocardial perfusion imaging (GSPECT) and gated ^{18}F -FDG PET/CT metabolism imaging (GPET) pre-operation. 29 (age 56.7 ± 9.6 y, 26 male) patients with LV ejection fraction (LVEF, %) by GSPECT less than 35% were recruited, who performed followed-up GSPECT and GPET at different time points after revascularization. Total

perfusion defect (TPD, %), hibernating myocardium (HM, %), and infarcted myocardium (SCAR, %) were analyzed by 17-segment and 5 score system. GSPCT and GPET images were analyzed by QGS software, summed motion score (SMS), summed thickening score (STS), end-diastolic volume (EDV, mL), end-systolic volume (ESV, mL) and LVEF were obtained. Patients were divided into three groups according to the followed-up scan time (Group1 n = 6, at 3months, Group 2 n=7, at 6months, Group3 n=16, at 12months). The changes of TPD, HM, SCAR, SMS, STS, EDV, ESV, LVEF were evaluated, in addition, the correlation between the changes (Δ) of HM and function as well as remodeling parameters was analyzed by Pearson and Spearman rank correlation analysis. P value<0.05 was considered as statistical significance. **Results:** In comparison with pre-revascularization, both TPD ($27.9 \pm 16.5\%$ vs $19.1 \pm 15.7\%$, $p < 0.05$) and HM ($14.8 \pm 10.9\%$ vs $7.8 \pm 6.5\%$, $p < 0.05$) after revascularization were significantly improved in Group 3, LVEF were improved in Group 2 ($20.3 \pm 12.4\%$ vs $25.5 \pm 14.0\%$, $p < 0.05$) and Group 3 ($32.8 \pm 13.2\%$ vs $38.6 \pm 14.2\%$, $p < 0.05$). In addition, STS was decreased in Group 2 (29.8 ± 8.7 vs 25.5 ± 10.0 , $p < 0.05$) and Group 3 (20.9 ± 10.5 vs 17.3 ± 10.6 , $p < 0.05$). Besides, there was a significant correlation between Δ HM and Δ TPD ($r = 0.71$, $p = 0.001$), Δ HM and Δ SMS by GPET ($r = 0.386$, $p = 0.039$), and Δ HM and Δ EDV by GPET ($r = 0.374$, $p = 0.046$). While no correlation between Δ SCAR and these parameters. **Conclusion:** In patients with ischemic cardiomyopathy and HF, global function could be improved after revascularization. The improvement of hibernating myocardium was correlated with the improvement of myocardial perfusion, regional LV function and the reversal of LV remodeling after revascularization. Aim/Introduction: Coronary artery disease (CAD) represents one of the main causes of morbidity and mortality worldwide. The non-Mendelian heritable basis of common CAD presentations in middle to late adulthood, as well as the

significance of a positive family history, has been supported by clinical observations. Recently, based on genome-wide association studies (GWAS), several single nucleotide polymorphisms (SNPs) have reached genome-wide significance for CAD. In particular, the renin-angiotensin-aldosterone system (RAAS) has been reported to play an important role in the development of atherosclerosis. In the present study, we aim to investigate the correlations of RAAS-related SNPs with myocardial perfusion, as evaluated through myocardial perfusion single photon emission computed tomography (SPECT). **Materials and Methods:** The study sample consisted of 619 males and 191 females, referred to our departments for a clinically indicated stress-rest myocardial SPECT. Summed stress score (SSS), summed rest score (SRS), summed difference score (SDS), transient ischemic dilation (TID), and lung/heart ratio (LHR) were recorded. The following gene polymorphisms were studied: angiotensin-converting enzyme (ACE) insertion/deletion (I/D), angiotensinogen (AGT) M235T and T174M, angiotensin II type 1 receptor (AT1R) A1166C, angiotensin II type 2 receptor (AT2R) C3123A, and renin (REN) C5312T. **Results:** The heterozygotes or homozygotes on ACE D allele were 7.54 times more likely to have abnormal SSS and the AGT (T174M) heterozygotes were 5.19 times more likely to have abnormal SSS, while the AT1R heterozygotes had greater odds for having $SSS \geq 3$. The homozygotes of ACE D and the patients carried AT1R homozygosity of C allele had significantly higher values on TID. Further, the AGT (T174M) heterozygotes had higher values on TID. Finally, the homozygotes of ACE D and the heterozygotes of AT1R had significantly higher values on LHR. **Conclusion:** Among the polymorphisms studied, ACE D allele had the strongest association with abnormal myocardial perfusion. Genetic analysis combined with functional imaging may provide an efficient way to dissect the genetic basis of CAD. This approach could improve our ability to identify subjects at higher risk of developing CAD, and the use of additional prognostic parameters may improve patient risk stratification. **References:** None

EPS-059

Gated myocardial SPECT results in patients with chronic heart failure before and after cardiac contractility modulator implantation

A. Ansheles, V. Amanatova, T. Uskach, S. Tereschenko, V. Sergienko;

National Medical Research Center of Cardiology, Ministry of Healthcare, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Cardiac contractility modulation (CCM) is a relatively new method of non-drug treatment in patients with chronic heart failure (HF) without indications for cardiac resynchronization therapy. Myocardial perfusion SPECT has proved reproducibility in serial assessment of cellular left

ventricular (LV) perfusion with comparison of LV contractility in patients with HF. The purpose of the study was to assess gated myocardial SPECT data in patients with chronic heart failure before and after CCM device implantation. **Materials and Methods:** 28 patients with chronic heart failure due to LV dilation (12 - ischemic, 16 - non-ischemic, including 8 idiopathic and 8 - other non-ischemic, i.e. hypertensive or combined) underwent rest myocardial perfusion CT-AC SPECT with ^{99m}Tc -MIBI before Optimizer Smart implantable pulse generator installment and 6 months after. LV perfusion impairments were evaluated using summed rest score (SRS) parameter, gated SPECT analysis included end diastolic volume (EDV, ml) and LV ejection fraction (EF). **Results:** Before CCM mean EDV in the whole group was 253 ± 121 ml, EF - $23.4 \pm 9.5\%$, with no difference between ischemic and non-ischemic subgroups, while LV perfusion impairments were more severe in ischemic subgroup (mean SRS: 30.0 [22.0-34.0] vs 13.5 [7.5-24]). After 6 months of CCM device implantation mean EDV lowered (227 ± 102 ml) and LV EF increased ($28.7 \pm 11.2\%$), both insignificantly ($p=0.39$ and 0.14 , respectively). LV contractility increased predominantly in non-ischemic patients (mean Δ EF $+10.5 \pm 3.9$ units %), while patients with large perfusion defects detected by SPECT were mostly non-responders (mean Δ EF -4.9 ± 6.4 units %). Larger SRS values (higher than cut-off value of 14) predicted absent or worse LV EF response. Baseline SRS values correlated well with LV EF decrease ($r=-0.67$, $p=0.002$). **Conclusion:** We suggest that gated perfusion SPECT data allowed to identify areas of a viable (perfused but hypokinetic) myocardium in patients with LV dilation and low EF. Preserved perfusion with no severe focal impairments was a good prognostic factor for CCM response. Also, performing myocardial perfusion SPECT in the framework of preoperative preparation allowed to determine the most accurate electrode positioning at the viable interventricular septum zones. **References:** None

EPS-060

Stress gated blood pool SPECT: the prognosis of left ventricle repeated remodeling in 12 month after surgical correction of ischemic cardiomyopathy

V. Shipulin, K. Zavadovsky, S. Andreev, A. Pryakhin, V. M. Shipulin; Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: To assess the value of gated blood pool SPECT (GBPS) with dobutamine in the prognosis of left ventricular (LV) repeated remodeling after surgical treatment of patients with ischemic cardiomyopathy (ICM). **Materials and Methods:** A total of 30 patients with ICM [1] were enrolled. Prior to surgery patients underwent GBPS at rest and at stress (5/10/15 $\mu\text{g}/\text{kg}/\text{min}$ increasing doses of dopamine). The duration of each dosage was 5 minutes.

The values of LV volumes, global contractile function and dissynchrony were calculated. In the follow-up period (476 ± 36 days), patients were divided into two groups. Group 1 ($n=20$) - patients with repeated LV myocardial remodeling (an increase of LV end-systolic volume (LVESV) or decrease of $LVESV \leq 10\%$ according to 2D echocardiography in comparison to early postoperative period study). Group 2 ($n=10$) - reverse LV remodeling (reduction $>10\%$ in LVESV). **Results:** Stress study showed differences between groups in terms of stress-induced changes of LVEF (Δ LVEF): 2(2;8) vs. 11(5;2), $p=0.02$; LV dissynchrony - Δ PSD: 3(0;7) vs. -2(-9;3), $p=0.004$; Δ Entropy: 2(-1;6) vs. 0(-4;2), $p=0.01$, respectively. Multivariate logistic regression analysis showed that Δ LVEF (OR = 0,88; 95% CI 0,8; 0,97; $p = 0.008$), Δ PSD (OR=1,13; 95% CI 1,03; 1,25; $p=0.005$) and the number of coronary arteries with stenosis $> 75\%$ (CAS) (OR = 4.25; CI 1.57; 11.48; $p = 0.001$) were independent predictors of myocardial remodeling in the long term follow-up. The ROC analysis revealed that Δ PSD showed a sensitivity of 87% and a specificity of 64% (cut-off value >-1 ; AUC, 0.727), Δ LVEF had a sensitivity of 65% and a specificity of 82% (cut-off value ≤ 4 ; AUC 0.674) and CAS had a sensitivity of 84% and a specificity of 46% (cut-off value >2 ; AUC 0.691) in myocardial remodeling prediction. Based on multivariate logistic regression the prognostic model was estimated (including indices above and presence of diabetes mellitus). According to the ROC analysis, the AUC of this model (0.907) was significantly higher in comparison to AUC values of indices alone. **Conclusion:** In patients after surgical ICM correction, the values of Δ LVEF and Δ SDLV obtained with the preoperative stress GBPS are associated with the repeated left ventricular remodeling in the long-term follow-up period. **References:** 1. Shipulin V. M., Pryakhin A. S., Andreev S. L. et al. Surgical Treatment of Ischemic Cardiomyopathy: Current State of the Problem. *Kardiologija*. 2019;59(9):71-82. DOI: 10.18087//cardio.2019.9.n329

Patient Safety in MPI: Role of the Radiopharmacist in a Multidisciplinary Team

A. Jimenez-Heffernan, C. Salgado-Garcia, T. Aroui-Luquin, E. Sanchez de Mora, A. Amr-Rey, A. Ramirez-Navarro; Hospital Juan Ramon Jimenez, Huelva, SPAIN.

Aim/Introduction: To assess the radiopharmacist's role in a multidisciplinary team together with nuclear physicians and nurses, after a short period of specific training focused on the clinical contraindications of regadenoson and adenosine, in order to ensure the safe use of pharmacologic vasodilator stress agents in patients undergoing SPECT-MPI. **Materials and Methods:** We prospectively studied the safe use of regadenoson in 557 consecutive patients undergoing MPI (57.4% female, mean age: 67.2 ± 11.2 years, range: 32-90 years). Gender, age, medical history, medications, drug

allergies and contraindications for stress testing were registered together with the recommendations to the nuclear physician in charge. **Results:** The situations and contraindications found together with the corresponding recommendation to the nuclear physician were as follows: prior stroke or TIA 3.9%-consider carotid stenosis assessment; salicylates/sulfonamides allergy 3.8%- use ^{99m}Tc -sestamibi as the radiopharmaceutical; epilepsy/seizures 2.2%- reconsider test indication; risk factors for QTc interval prolongation 2.0%-extravigilance of ECG during test for QTc prolongation; systemic corticosteroid therapy for severe COPD 1.4%-do not perform test; acute exacerbation of COPD 1.1%-defer test until acute episode is over; severe asthma 0.7%-do not perform test; methylxanthine ingestion 0.4%-reassessment of patient's condition on the appointment day; other 6.5%-evaluation of other contraindications. No contraindications were detected in 78% of patients. **Conclusion:** Working in a systematic way, the radiopharmacist was able to detect a high number of issues related to the safe use of regadenoson in MPI studies, with one out of four patients presenting some drug interaction or clinical contraindication. The recommendations given by the radiopharmacist were well accepted by the nuclear physicians who changed their approach, thus contributing to increase the safety of patients referred for MPI. **References:** None

EPS-062

Added value of Myocardial Flow Reserve measurement during SPECT perfusion: correlation with invasive coronary angiography

M. Bailly¹, F. Thibault¹, M. Courtehoux², G. Metrard¹, D. Angoulvant², M. Ribeiro²;

¹CHR Orléans, Orleans, FRANCE, ²CHRU Tours, Tours, FRANCE.

Aim/Introduction: Myocardial blood flow (MBF) and flow reserve (MFR) measurement have been shown to improve diagnostic performances of coronary artery disease (CAD). Dedicated CZT cardiac cameras provide accurate evaluation of MBF and MFR. In this pilot study we correlated the results of SPECT myocardial perfusion imaging (MPI) and MFR measurement with invasive coronary angiography (ICA) findings. **Materials and Methods:** Patients referred for dynamic MPI for CAD screening between November 2018 and March 2020 and for whom coronary angiography was performed within 3 months were included. Symptoms and risk factors were collected. SPECT data were acquired on a CZT-based pinhole cardiac camera using a stress (251 ± 12 MBq) / rest (513 ± 25 MBq) one-day ^{99m}Tc -tetrofosmin protocol. Kinetic analysis was done with Corridor 4DM™ software using a 1-tissue-compartment model and converted to MBF using a previously determined extraction fraction correction. ICA was performed upon decision of the referring cardiologist and considered normal if no

stenosis > 30% or with impaired FFR was found. The results of ICA were compared to global MFR. **Results:** 35 patients (21 male, 14 female) were analyzed. MPI was visually normal in 25 patients, among them 16 had pathological ICA. Mean global MFR was 1.94 ± 0.77 . Global MFR was impaired (<2) in 25 patients; among them only 7 patients had abnormal visual MPI. This threshold could be considered as the optimal one and allowed a safe exclusion for asking an ICA: sensitivity 95.5%, specificity 69.2% and negative predictive value 99.3%, area under Receiver-Operator-Characteristic curve: 0.83. MFR is related to epicardial coronary arteries and to microvascular arteries; this can explain the limited specificity, with 4 patients having normal ICA but impaired MFR potentially due to microvascular dysfunction (diabetes with target organ damage such as proteinuria-). Only one patient had normal global MFR of 2.68, but abnormal ICA with severe stenosis on right coronary artery (inferior MFR was 1.68). **Conclusion:** Global MFR measured during MPI for CAD screening on CZT camera significantly enhances SPECT diagnostic performances and could be a safe exclusion or a strong motivation for asking an ICA. **References:** None

EPS-063

SPECT Myocardial Blood Flow and Calcium Scoring measurement in patients referred for Coronary Artery Disease screening

M. Bailly¹, F. Thibault¹, M. Courtehoux², G. Metrard¹, D. Angoulvant², M. Ribeiro²;

¹CHR Orléans, Orleans, FRANCE, ²CHRU Tours, Tours, FRANCE.

Aim/Introduction: Dedicated CZT cardiac cameras provide accurate measurements of absolute myocardial blood flow (MBF) and flow reserve (MFR). PET MBF studies using either Rb-82 or N-13-ammonia have shown that MFR was predictive of major adverse cardiovascular (CV) events. Coronary calcium score (CCS) is also predictive of CV events, especially in diabetic patients. In this study, we evaluated the results of SPECT global MFR measurement and CCS evaluation in patients referred for Coronary Artery Disease (CAD) screening. **Materials and Methods:** Patients referred for Myocardial Perfusion Imaging (MPI) for CAD screening between November 2018 and March 2020 were included in a prospective trial (CFR-OR). Clinical and CV risk factors were collected to classify patients in 3 groups: moderate, high and very high risk. HeartScore (SCORE) according to the European Society of Cardiology was calculated. SPECT data were acquired on a CZT-based pinhole cardiac cameras in listmode using a stress (251 ± 11 MBq) / rest (512 ± 23 MBq) one-day Tc-99m-tetrofosmin protocol. Kinetic analysis was done with Corridor4DM™ software using a 1-tissue-compartment model and converted to MBF using a previously determined extraction fraction correction. Low dose thoracic CT was acquired on the same day using another SPECT/CT camera in the same position and used for CCS evaluation. **Results:** 136 patients (60 male,

76 female) were included and classified in 3 clinical CV risk groups: 50 moderate, 36 high and 50 very high risk. Mean SCORE was 4 ± 3.1 %. Mean global MFR was 2.50 ± 0.74 ; 34 patients had impaired CFR (using a threshold of 2). MFR wasn't significantly different between the three groups of CV risk ($p=0.09$), but MFR was significantly reduced in high and very-high risk patients ($p=0.05$). CCS was not different according to risk categories ($p=0.32$). There was a significant inverse correlation between MFR and SCORE ($p=0.009$) and gender ($p=0.026$). Significant correlation was also found between CCS and SCORE ($p=0.001$) and gender ($p=0.05$). MFR was not correlated to CCS ($p=0.61$). Regarding CV risk factors, CCS was significantly higher in smokers ($p=0.05$), but no other significant correlation was found between MFR or CCS and dyslipidemia, hypertension, diabetes or family history of coronary artery disease (p at least 0.41). **Conclusion:** CCS and MFR measured during MPI for CAD screening are significantly correlated with SCORE and gender. MFR was significantly reduced in high and very-high risk patients. CCS and MFR however weren't correlated together. **References:** None

EPS-064

The Dark Side Of Atrial Uptake On 99mTc-3,3-Diphosphono-1,2-Propanedicarboxylic Acid (99mTc-DPD) Bone Scintigraphy In Patients With Cardiac Amyloidosis

R. Mei¹, I. Diemberger², R. Bonfiglioli¹, A. Paccagnella¹, F. Mattana¹, C. Gagliardi², G. Caponetti², S. Longhi², P. Massa², G. Saturi², M. Squazzotti², N. Galiè², S. Fanti¹;

¹Nuclear Medicine Policlinico S.Orsola-Malpighi, Bologna, ITALY, ²Cardio-Thoracic and Vascular Building, Department of Experimental, Diagnostic and Specialty Medicine, Bologna, ITALY.

Aim/Introduction: Bone scintigraphy with 99mTc-DPD is an excellent non-invasive diagnostic tool for cardiac amyloidosis, especially for the recognition of differential diagnosis between ATTR (amyloidosis with trans-tiretin deposition) and AL (amyloidosis with light-chains deposition). To date there is a lack of knowledge in recognizing atrial uptake (AU) and its possible clinical implications. We aimed to evaluate patterns of AU in patients with suspected or confirmed CA who undergone staging with 99mTc-DPD bone scintigraphy. **Materials and Methods:** Patients who had undergone bone scintigraphy with suspected or confirmed CA were retrospectively analyzed in the period 2016-2020. Inclusion criteria were: Perugini's score ≥ 1 , availability of clinical data, including comorbidities, laboratory exams, eventual supraventricular atrial disorders and echocardiographic anteroposterior atrial diameter. All planar and SPECT/CT images (when available) were revised by two experienced nuclear physicians; diffuse atrial and left ventricular uptake data were collected. Interobserver agreement (IA) analysis was performed (Cohen's k). Correlation between AU and supraventricular

rhythm disorders were evaluated with Pearson's chi square. **Results:** Sixty patients were finally selected (53M; 7F); mean age of 77 (+9.9). 48.3% of them had sinus rhythm, while 31 pts had different arrhythmias (permanent and paroxysmal atrial fibrillation 30% and 16.7%; atrial flutter 1.7%). Mean left anteroposterior atrial diameter was 46mm (+6.3mm). Out of 60, twenty-seven pts (45%) were still ongoing diagnosis pathway for amyloidosis (i.e. differential diagnosis between ATTRvs.AL), while 32 pts (55%) had ATTR and 1 with AL. An overall left ventricular cardiac uptake was observed in 60/60 by each two observers, with IA between mild versus moderate/severe uptake of 0.90 ($p < 0.0001$). AU was observed in planar images in 36/60 and 42/60 respectively by each two physicians, with an IA of 0.49 ($p < 0.0001$). SPECT/CT was performed in 17/60 pts; AU was observed in 14/17 and 15/17 pts respectively, IA=0.77 ($p = 0.001$). No significant correlation was observed between AU and current presence or history of supraventricular arrhythmias, nor with left atrial enlargement. **Conclusion:** Standard planar images of bone scintigraphy are a validated approach for detection and differentiation of CA. Our analysis evidenced limitations of this technique in identifying atrial involvement that can be at least mitigated by adoption of SPECT/TC scan. The association of AU with atrial enlargement and/or arrhythmias was not evidenced by our analysis but larger prospective studies systematically adopting SPET/TC are needed. Gaining insight into these possible relationships may help to better understand the real meaning of cardiac uptake, which still remains eclipsed. **References:** None

Electromechanical Decoupling Associated With Cardiac Transthyretin Amyloidosis. A Small Case Series Characterization of Left Ventricle Dyssynchrony Applying Gated-SPECT Phase Analysis

F. Ferrando-Castagnetto¹, C. G. Wakñe Corieñ², J. C. Rodríguez Gómez², K. Bayardo³, P. Romero Fernández², M. Pedrera Canal², I. Vilacosta⁴, A. Sánchez², F. Mut⁵, R. Ferrando³, M. Pérez Castejón², J. Carreras Delgado²;

⁴Instituto Cardiovascular, Hospital Clínico San Carlos, Madrid, SPAIN, ⁵Sevicio de Medicina Nuclear, Asociación Española Primera de Socorros Mutuos, Montevideo, URUGUAY.

Aim/Introduction: Myocardial amyloid deposition can alter the regional cardiac mechanics of the left ventricle (LV). Recent findings of Doppler tissue velocity imaging suggest that patients with early light-chain cardiac amyloidosis have increased segmental dyssynchrony compared to controls. (1) However, LV mechanical dyssynchrony (LVMD) has not

been assessed in transthyretin cardiac amyloidosis (ATTR). **Materials and Methods:** Consecutive patients with high clinical and imaging suspicion of ATTR and no coronary artery disease referred to bone-seeking scintigraphy during the last 6 months were included. Patients were studied using ^{99m}Tc-DPD and ^{99m}Tc-PYP with planar imaging and gated-SPECT/CT obtained 1-3 hours after injection. Peak amplitude (PA), phase standard deviation (PSD) and phase bandwidth (PBW) were calculated from phase histogram applying SyncTool (Emory Cardiac Toolbox®) and compared with normal values obtained with perfusion tracers as previously reported (2) and with a group of patients with normal gated-SPECT ^{99m}Tc-MIBI images (n = 24). The site of the onset of mechanical LV contraction (OMC) was detected in a digital video of contractile dynamics. **Results:** Six patients were included, 4 with ^{99m}Tc-DPD and 2 with ^{99m}Tc-PYP, all men, aged 70-89 years, LVEF = 41 + 18%. Two patients exhibited left bundle branch block in baseline ECG. The mean H/CL score was 2.83, all cases were graded as Perugini category 3. Patients with ATTR presented a marked LVMD (PA = 137.5 + 64.6, PSD = 57.1 + 21.9, PBW = 184.5 + 64.4 degrees (p -value < 0.05 for comparisons of PSD and PBW with both control groups). A multisite OMC was found in 33% of cases. **Conclusion:** Results of gated-SPECT phase analysis obtained using bone-seeking radiotracers suggest an underlying mechanical substrate of marked LVMD that could be correlated with a severe amyloid burden. This could be an unrecognized mechanism contributing to heart failure in ATTR subjects. However, phase histogram measures obtained with bone-seeking tracers should be validated by comparison with perfusion imaging tracers through large series, ideally on a per-patient, dual-isotope basis. **References:** 1) Migrino RQ, Harmann L, Woods T, et al. The Importance Of Monoclonal Proteins Determination For The Correct Diagnosis Of Transthyretin Cardiac Amyloidosis By [^{99m}Tc]Tc-diphosphonates

A. Roteta, D. Nogueira Souto, A. Andrés Gracia, L. Tardin Cardoso, P. Razola Alba, M. Delgado Castro, T. Escalera Temprado, E. Prats Rivera, M. Abós Olivares;
Clinic Hospital "Lozano Blesa", Zaragoza, SPAIN.

Aim/Introduction: To analyze the influence of the determination of free monoclonal proteins in blood and urine in the final diagnosis of Transthyretin Cardiac

Amyloidosis (TTRA). **Materials and Methods:** We have analyzed 200 [99mTc]Tc-diphosphonates scans: 192 performed on 190 patients under suspicion of TTRA and 7 patients with grade II-III radiotracer myocardial deposit as a casual finding (November/2013 - January/2020). Likewise, clinical and laboratory characteristics (heart failure, LVEF, proBNP levels, immunofixation in serum and/or urine for the detection of monoclonal chains and chronic renal failure) have been evaluated. A positive case has been considered for TTRAwT or senile (Score Perugini II-III scan, negative immunofixation in serum and/or urine, negative genetic study), positive case for hereditary TTRA (Score Perugini II-III scan, negative immunofixation and positive genetic study), positive case for secondary amyloidosis (positive immunofixation and presence of hematologic malignancy) and undetermined amyloidosis (immunofixation not performed or positive and absence of haematologic malignancies at follow-up). **Results:** 59 positive scans have been detected, 47 men (79.7%) and 12 women (20.3%). The mean age of the group of positives was 82.66 years, while that of the negatives was 72.15. The mean proBNP levels in the positives are 7561, compared to 5869 in the negative group. Immunofixation (serum and/or urine for detection of kappa or lambda monoclonal chains at 30 (50.8%) has been performed on these patients. Finally, 37.2% (22/59) resulted in ATTRwt, 3.4% (2/59) hereditary ATTR (genetic study: variant E54Q and mutation c.424> A (p.Val.122Ile) in exon 4 of TTR) and 1.7% (1/59) secondary amyloidosis. The remaining 34/59 (57.7%) cases were undetermined amyloidosis (6 positive immunofixation and 27 without monoclonal proteins determination). **Conclusion:** Determination of monoclonal bands in blood and urine is mandatory to correctly characterize cases of cardiac amyloidosis and, in presence of monoclonal bands, to assess the existence of underlying haematological malignancies. **References:** None

Left Ventricle Mechanical Response to Induced Ischemia In Patients With Narrow QRS and Normal Systolic Function Derived To Gated-SPECT

F. Ferrando-Castagnetto¹, M. Pedrera Cana², M. Ollarves Carrero², L. García Belaustegui², C. Real³, I. Vilacosta³, R. Ricca-Mallada¹, F. Mut⁴, R. Ferrando⁵, R. Lluber⁵, M. Pérez Castejón², J. Carreras Delgado²;

¹Departamento de Cardiología - CCVU, Hospital de Clínicas, FM, UdelaR, Montevideo, URUGUAY, ²Servicio de Medicina Nuclear, Hospital Clínico San Carlos, Madrid, SPAIN, ³Instituto Cardiovascular, Hospital Clínico San Carlos, Madrid, SPAIN, ⁴Servicio de Medicina Nuclear, Asociación Española Primera de Socorros Mutuos, Montevideo, URUGUAY, ⁵Departamento de Medicina Nuclear e Imagen Molecular, Hospital de Clínicas, FM, UdelaR, Montevideo, URUGUAY.

Aim/Introduction: Gated-SPECT phase analysis is a novel,

noninvasive and reliable method to quantify left ventricular mechanical dyssynchrony. However, the contributions of this technique as ancillary criteria to the diagnosis of induced myocardial ischemia have been scarcely evaluated. In this research, we characterized the contractile response of the left ventricle associated with post-stress myocardial ischemia in subjects without baseline electrical dyssynchrony. **Materials and Methods:** Phase histograms were obtained under basal and post-stress conditions in a sample of consecutive patients referred to gated-SPECT with normal systolic function and narrow QRS complex in 12-lead ECG. Gated-SPECT myocardial perfusion imaging with 99mTc-MIBI was performed following a two-days stress-rest protocol. Post-stress images were acquired 0.5 - 2.0 hours after exercise or vasodilator challenge. Patients in non-sinus rhythm, renal failure or mitro-aortic valve disease were excluded. The resting/post-stress changes (pre/post measurements) in phase standard deviation (PSD) and phase bandwidth (PBW) indices were compared between patients with and without myocardial ischemia on images. Continuous variables were expressed in means + SEM. The magnitude of these changes was evaluated using paired "t" test. **Results:** A total of 118 consecutive patients were included, 61% male, 68 + 12 years old; 46% of them completed a treadmill exercise protocol (Bruce). An increasing trend in the post-stress mechanical dyssynchrony indices was observed in patients with perfusion defects interpreted as ischemia, although not reaching statistical significance (PSDpre = 24.38 + 1.85, PSDpost = 26.36 + 2.12 degrees, p = 0.22; PBWpre = 73.04 + 6.17, PBWpost = 82.38 + 7.68 degrees, p = 0.08). The biggest change was observed in patients with reversible defects interpreted as ischemia and fixed defects compatible with infarct sequelae, either remote or perilesional (PBWpre = 79.11 + 9.37, PBWpost = 91.50 + 11.79 degrees, p = 0.06). **Conclusion:** Induced myocardial ischemia tended to be associated with increased dyssynchrony measured by gated-SPECT phase analysis obtained in post-stress images, especially in the subgroup of patients with myocardial scar. This response should be tested by acquiring immediate post-stress images and correlated with the amount (quantum) of ischemic burden, the extension of stenotic coronary lesions, and the presence of microvascular dysfunction. **References:** None

The Diagnostic Role Of ^{99m}Tc-DPD Scintigraphy In TTR Cardiac Amyloidosis And Its Corelation With Clinical And Radiological Findings, Our Experience

J. Cañadas Salazar¹, B. Lucas Velázquez², L. G. Díaz González², F. Gómez-Caminero López², P. García-Talavera-San-Miguel², A. C. Peñaherrera Cepeda², J. G. Villanueva Curto², S. López Puche², E. Martín Gomez², M. P. Tamayo Alonso²;

¹Sacyl, Salamanca, SPAIN, ²CAUSA, Salamanca, SPAIN.

Aim/Introduction: To evaluate the relation of ^{99m}Tc -DPD scintigraphy in patients with suspected TTR cardiac amyloidosis with clinical and radiological findings in echocardiogram and magnetic resonance imaging (MRI). **Materials and Methods:** 118 patients were reviewed from 2016 to 2020 (85 male / 33 female, with a mean age of 79 ± 9 years) with the suspicion of cardiac amyloidosis (AcTTR variant). A total body planar image and SPECT / CT hybrid imaging (acquisition of 90 views / 6s, reconstruction with an iterative method) using 740MBq of ^{99m}Tc -DPD, were performed. The interpretation of the images was carried out by visual assessment according to the Perugini scale, establishing those with grade 2 or 3 uptake as positive for AcTTR. Clinical and radiological parameters obtained by echocardiography or MRI were reviewed: ventricular function, hypertrophy, atrial dilation and enhancement. gadolinium late. **Results:** The scintigraphy was positive for AcTTR in 60/118 patients and all of them obtained the diagnosis of AcTTR based on this result and complementary non-invasive tests. In this subgroup of patients, heart failure was observed in 86%, atrial fibrillation in 70%, conduction disorders in 51%, and a pseudoinfarction pattern in 16%. Preserved left ventricular function was detected in 62%, ventricular hypertrophy in 100% and atrial dilation in 83%. Gadolinium MRI was performed in 42/60 patients, of which 38 (91%) showed a late enhancement pattern suggestive of amyloidosis. A genetic study was performed in 28 patients, 6 of them carrying an AcTTR-associated mutation. 58/118 patients with a negative scan for AcTTR were diagnosed with other cardiac diseases, the most frequent being valvular heart disease. **Conclusion:** In our experience ^{99m}Tc -DPD scintigraphy is a very useful technique in the non-invasive differential diagnosis of ATTR with a sensitivity and PPV of 100%, demonstrating its relationship and agreement with clinical alterations and structural parameters of cardiac imaging. **References:** None

OP-295**Introduction**

P. Fragoso-Costa; Clinic for Nuclear Medicine, University Hospital Essen, Essen, GERMANY.

OP-296**The effect of Artificial Intelligence (AI) on lung perfusion SPECT-CT segmentation analysis**

A. Willems van Beveren, G. T. Nauta, A. van Erp-Zeilstra, A. Heus, J. Pruijm; UMCG NGMB, Groningen, NETHERLANDS.

Aim/Introduction: The use of AI in nuclear medicine is

increasing. We tested an AI application in a group of severe COPD patients in order to assess the accuracy of segmentation and the consequences for the calculation of segmental lung perfusion. **Materials and Methods:** The data of 7 patients with COPD GOLD IV, that underwent a lung perfusion scan and SPECT CT with ^{99m}TcMAA because of intended lung volume reduction surgery, were fed to a newly developed Siemens AI application. The application was trained on approx. 8500 normal people, patients with lung cancer and patients with COPD. A 4-point Likert scale was used by 3 observers independently to assess the quality of the outlining by the system (0= bad match, 1= moderate match, 2= reasonable match, 3= good match): total overview of AI segmentation, pleural confection and the interlobular fissures. In case of discrepancies a radiology resident with subspecialisation in cardiothoracic imaging examined the results in addition. Also, the ratios of the left and right lung and as well the ratios of the respective inferior and the superior lobes from the AI application were compared to the static SPECT results. **Results:** In all but 1 delineation the segmentation by the system was considered to be reasonable to good. However, in 1 patient with a congenital absence of the right horizontal fissure the AI "created" a fissure from interlobular septae. The ratio between the right and left lung of the analysis suite application versus the static SPECT results were almost identical. However, the ratios between the left superior and inferior lobes, and between the right superior and inferior lung fields differed greatly from static SPECT: left 1% to 20% (mean 10%); right 3% to 34% (mean 17%). **Conclusion:** The AI application can reliably detect interlobular fissures in COPD GOLD IV patients although trained on normal thoracic CT scans. Introduction will most likely improve the accuracy of estimated perfusion of pulmonary lobes in lung perfusion scans. **References:** Lung Analysis suite 002_MI_RCCCA_S_LAS_V01, prototype User Guide, Siemens Healthineers, USA.

OP-297**The choice of colour scale for reconstruction of ⁶⁸Ga-PSMA-11 PET/CT images impacts upon diagnostic performance**

R. Schepers¹, C. Sachpekidis^{1,2}, J. Hünemann¹, K. P. Bohn¹, V. Fech¹, A. Rominger¹, A. Afshar-Oromieh¹, I. Alberts¹, C. Mingels¹;

¹Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,

²Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY.

Aim/Introduction: The aim of this study is to assess the lesion based inter-observer agreement between non-linear and linear colour scales of ⁶⁸Ga-PSMA-11 PET/CT in patients with recurrent prostate cancer. **Materials and Methods:** ⁶⁸Ga-PSMA-11 PET/CT scans for biochemical recurrence of prostate cancer (PCa) for 50 consecutive patients were

evaluated retrospectively. Scans were prepared in both a non-linear 'PET-rainbow' and a linear colour scale 'hot-metal new'. All images were reconstructed using Siemens SyngoVia. Two readers (one consultant and one junior resident), read all scans in a randomised order. Both were blinded to patient data, clinical details and each other's analyses. ^{68}Ga -PSMA-11-avid lesions were classified into benign and pathological in both colour scales. Confirmatory clinical follow-up was available for 68% of the patients. Only fusion PET/CT-datasets and stand-alone CT-images were analysed. The number of lesions (benign or pathological) was ascertained. Bland-Altman statistics (bias \pm 95% limits of agreement) was used to assess agreement in number of lesions between the two readers and the colour scales for benign lesions as well as for pathological lesions. **Results:** Both readers described greater numbers of pathological lesions in 'PET-rainbow' compared to 'hot-metal new' (junior reader 142 vs. 117, consultant 119 vs 112). Likewise, Bland-Altman analysis confirmed bias towards 'PET-rainbow' in the detection of pathological lesions (-0.50 ± 1.32). For the detection of benign lesions, no difference was seen (0.02 ± 2.48). We also found a difference between the consultant and junior reader, with a greater bias towards the junior reader for pathological lesions in 'PET-rainbow' (0.46 ± 1.25) than for 'hot-metal new' (0.10 ± 0.75). **Conclusion:** Greater numbers of pathological lesions were found in 'PET-rainbow' than in 'hot-metal new'. Likewise, Bland-Altman analysis confirmed a bias towards 'PET-rainbow' for pathological lesions, but not for benign. Emphasising that increased pathological lesion detection was not at cost of increased unspecific findings in 'PET-rainbow'. We found that the bias towards 'PET-rainbow' was greater for the junior reader, suggesting that 'PET-rainbow' was most beneficial for the less experienced physician. It can be shown from basic science that, non-linear colour scales aid lesion discrimination. We therefore suggest that ^{68}Ga -PSMA-11 PET/CT images shall be reconstructed in a non-linear colour scale as 'PET-rainbow' rather than in a linear colour scale like 'hot-metal new', owing to its improved performance. **References:** None

OP-298

Hand-foot contamination monitoring in hospital radiopharmacy laboratory: one-year data

K. Levänen¹, C. Lehtinen¹, M. Kullberg¹, N. Hänninen², J. Heikkinen²;

¹Department of Radiology and Nuclear Medicine, Social and healthcare joint authority of South Savo, Mikkeli, FINLAND, ²Department of Medical Physics, Social and healthcare joint authority of South Savo, Mikkeli, FINLAND.

Aim/Introduction: After the preparation of radiopharmaceuticals, contamination control is important in reducing unneeded doses to personnel or patients. A hand-

foot monitor is useful in detecting possible contaminations in gloves or shoes. In our facility, the hand-foot monitor was connected to cloud service, to allow real-time monitoring of the contamination measurements, in addition to easy record keeping and data collection. In this study, the collected data was analyzed to provide information about how common glove and shoe contaminations are and how they could be further prevented. **Materials and Methods:** Measurements were recorded for the duration of one year from February 2019 to February 2020. During that time, radiopharmacy laboratory was mainly used by four radiographers. After each of their visit to the lab, they measured the dose rate of their gloves and shoes with hand-foot monitor from eight target areas: right/left hand palm/back, right/left foot front/back. All the targets were measured simultaneously in one measurement instance. Radiographers identified their measurements by personal labels. Data was recorded by a cloud system connected to the monitor. **Results:** The threshold of contamination of clothes of personnel or the environment outside radio laboratory is defined as a dose rate of 4 Bq/cm² or more (Radiation and Nuclear Safety Authority STUK Finland). In total the four radiographers completed 237 measurement instances, of which in 16% cases (38 instances) the contamination threshold was exceeded in at least for one target area. Some activity in at least one target was detected in 73% of measurement cases (173 instances). Most common contamination target was right hand palm (87% or 33 of cases above threshold, 39% or 68 of cases of any activity). Foot contamination never exceeded the contamination threshold, though some activity was detected in 73% of measurement cases. When threshold was exceeded the average dose rate was 45 Bq/cm². Overall the average dose rate was 22 Bq/cm² (range from 0.01 to 248 Bq/cm²). Usually when one target was contaminated, some of the others were too. Average number of contaminated targets was 2.9 when threshold was exceeded, and 2.8 when any activity was detected. **Conclusion:** The contamination of the gloves and shoes in radiopharmacy laboratory of the hospital is common. Right hand was most commonly contaminated target, as the four radiographers were all right-handed. Based on the collected data, more precautions can be applied, e.g. changing the gloves more often in the laboratory. **References:** None

OP-299

Difficulties in achieving compliance with the dose limit requirements for the skin exposure of workers handling radiopharmaceuticals

J. Sabol¹, J. Hudzietzová², M. Fülöp³;

¹Department of Crisis Management, PACR, Prague, CZECH REPUBLIC, ²Faculty of Biomedical Engineering, CTU, Prague, CZECH REPUBLIC, ³Slovak Medical University, Bratislava, SLOVAKIA.

Aim/Introduction: The purpose of this paper is to summarize

the present regulatory requirements concerning compliance with the dose limit associated with the skin exposure of workers at Nuclear Medicine Departments. The difficulties in monitoring of the equivalent dose to skin in accordance with the definition of this quantity are highlighted. In addition, some results of monitoring are presented where appropriate correction factors converting ring dosimeters reading to the relevant personal dose equivalent approximate the equivalent dose at the location with the maximum exposure. **Materials and Methods:** More than 100 measurements were carried out at two nuclear medicine departments applying radiopharmaceuticals labelled with ^{18}F , ^{131}I , ^{11}C and ^{68}Ga . In each monitoring, 12 TLDs fixed on workers' hands were used. The readings of these dosimeters were compared with the personal equivalent dose $H_{\text{skin}}(0.07)$ corresponding to the location showing the maximum exposure, i.e. $H_{\text{skin,max}}(0.07)$, the value of which was correlated with the relevant dose limit 500 mSv/y. The correction factor, corresponding to the ratio of $H_{\text{skin,max}}(0.07)/H_{\text{skin}}(0.07)$, was assessed taking also into account specific handling techniques workers used. **Results:** The results of the correction factors was found to be in the range of 2–6 depending on the individual radionuclide handled and also on the worker's specific routine adopted in manipulating radiopharmaceuticals. In the case of ^{131}I , ^{11}C and ^{18}F , the mean value of this factor amounted to 2, 2.8 and 3.5, respectively. The highest value was observed for ^{68}Ga being close to 6. **Conclusion:** Our previous studies as well as the results presented by other authors indicate that nearly one in five workers in nuclear medicine might exceed the legal dose limit for skin. This is why it is important to pay attention to adopting a reliable approach to monitor the equivalent skin dose consistent with the definition of the relevant quantity. Since in most cases, the dosimeter is not located at the position with the maximum exposure, the use of the appropriate correction factor is the only way to ensure that the readings of routine dosimeters can be interpreted in terms of the equivalent skin dose. The results presented demonstrate that the difference between the reading of the dosimeter and actual equivalent dose may differ more than five times. This is a serious inconsistency in reliability of controlling of skin exposure based on routine monitoring where the position of the dosimeter has not up to now been normalized. **References:** None

OP-300

Reduction of [^{18}F]-FDG activity applied is feasible in clinical routine for 3D TOF PET/CT scanner: A retrospective patient study

J. Pilz, L. Hehenwarter, G. Rendl, G. Schweighofer-Zwink, C. Pirich;
Department of Nuclear Medicine and Endocrinology,
University Hospital Salzburg, Paracelsus
Medical University, Salzburg, AUSTRIA.

Aim/Introduction: Phantom studies demonstrated that PET imaging data using a reduced acquisition time of 57s per bed position still fulfil international EARL criteria. Therefore, we investigated PET/CT studies of oncological patients with standard and reduced PET acquisition times. This study aimed to evaluate the equivalence of acquisition times of 75 and 57 seconds per bed position translating into an activity reduction from 4MBq to 3MBq per kg bodyweight (bw) **Materials and Methods:** 96 patients (60 men, 36 women, age 27–87, mean \pm SD 65 \pm 11.6 years) with melanoma, lung or head and neck cancer were divided into three different bw classes (<75kg, 75–100kg, >100kg) and underwent a standard whole-body or skull base-to-thigh [^{18}F]-FDG PET/CT examination using the Philips Ingenuity TF PET/CT scanner. The [^{18}F]-FDG activity applied was equal to 4MBq per kg bw (MBq range 246–479, mean \pm SD 345.3 \pm 71.1). Retrospectively, PET list-mode data were recalculated gaining a second PET study per patient with a reduced acquisition time of 57s instead of 75s per bed position. PET/CT data were reconstructed using a 3D OSEM TOF algorithm. Blinded patient data were analysed by two nuclear medicine physicians. The number of PET-positive lesions per body region (head and neck, thorax, abdomen, bone, extremity) and image quality (grade 1–5) were evaluated. Standardised uptake values (SUVs) were calculated with the help of 3D volume of interests in order to be able to compare the PET-positive lesions in the standard as well as the recalculated PET/CT study with reduced acquisition time. Statistical analyses were performed by equivalence testing using the R software version 3.6.3 and Bland-Altman Plots were created with graph pad prism version 6. PET-positive lesions were confirmed histologically or by clinical follow-up. **Results:** Lesion detection rate per patient's body region matched in > 98% comparing 57s and 75s datasets. Overall subjective image quality was assessed as even or superior in 80 and 69%, respectively. Equivalence was established in 214 PET-positive lesions (164 malignant: mean $\text{SUV}_{\text{max}} \pm$ SD of 7.9 \pm 4.0, 50 benign: mean $\text{SUV}_{\text{max}} \pm$ SD of 6.0 \pm 3.3) matched per patient between the 75s and 57s PET studies for SUV_{max} (mean of differences: 0.008411, equivalence bounds \pm 0.0974, 90% CI -0.047–0.063, $p=0.00405$). **Conclusion:** This retrospective patient study demonstrates that an activity reduction of [^{18}F]-FDG from 4MBq to 3MBq per kg bw beyond the current EANM guidelines is feasible in clinical routine employing a 3D TOF PET/CT. **References:** None

Dose reduction in FDG-PET by reconstruction optimization using resolution modelling

A. Tegelaar - Kuiper¹, S. Koenders^{1,2}, D. Koopman¹, P. G. Sanches³,
B. N. Vendel¹, H. Arkies¹, J. A. van Dalen⁴;
¹Department of Nuclear Medicine, Isala Hospital, Zwolle,
NETHERLANDS, ²Technical Medical Centre, University of
Twente, Enschede, NETHERLANDS, ³Health Systems, Philips

Benelux, Eindhoven, NETHERLANDS, ⁴Department of Medical Physics, Isala Hospital, Zwolle, NETHERLANDS.

Aim/Introduction: Image quality of FDG-PET greatly depends on administered tracer dose and applied reconstruction settings. Especially by lowering the number of updates (iterations \times subsets) and applying resolution modelling (RM) in iterative reconstructions, noise can be reduced while maintaining lesion's uptake value. Our aim was to determine the FDG-dose reduction that can be obtained using RM-reconstruction, compared to a high-resolution reconstruction without RM. **Materials and Methods:** Using the NEMA image quality phantom with fillable spheres (diameters 10–37mm), FDG-PET imaging (Vereos, Philips Healthcare) was performed using a sphere-to-background ratio of 10. We applied multiple reconstructions using updates ranging from 12 to 39 and RM (point-spread-function: 1 iteration; 4 regularizations). No post-smoothing filter was applied in order to maximize contrast recovery coefficients (CRCs) of the spheres. Reconstructed images were compared to a reference high-resolution reconstruction using 39 updates without RM nor filtering, as previously determined to maximize CRCs. The RM-reconstruction with similar CRCs and background noise as compared to our reference was applied to FDG-PET data of 10 consecutive oncology patients. Extra reconstructions simulating dose reductions up to 40% using clipped list-mode data were made. We measured maximum SUVs of reported lesions and the noise in the liver to verify our phantom results and to determine the maximum dose reduction without significantly altering SUVs or noise. Furthermore, three expert readers scored the image quality on a four-point scale (bad, moderate, good, excellent). **Results:** Reducing the number of updates resulted in both lower CRCs and noise. The reconstruction with 15 updates and RM had similar CRCs compared to our reference without RM. Applying this RM-reconstruction to patient data provided similar SUVs and an average noise reduction of 32%, as compared to the reference reconstruction. RM-reconstructions using 15 updates and simulating 40% dose reduction still showed similar SUVs and also similar noise levels, as compared to the reference. Expert readers scored the image quality of all RM-reconstructions using 15 updates to be at least 'good' and to be equal or even better compared to our reference. **Conclusion:** An FDG-dose reduction of 40% can be obtained when using iterative reconstruction with 15 updates and RM, compared to a high-resolution reconstruction without RM. For each PET/CT-facility it is recommended to investigate optimal reconstruction settings when using RM. Specifically, it gives the opportunity to minimize noise by reducing the number of updates without altering SUVs. **References:** None

Optimal Balance between Patient Comfort, Received Dose and Image Quality for Block Sequential Regularized Expectation Maximization Reconstruction and Digital PET/CT

D. Klagyvik¹, F. Nagy², A. Ács-Nagy¹, P. Szabó¹, I. Gara², A. Forgács², Á. K. Krizsán²;

¹ScanoMed Nuclear Medicine Centers, Budapest, HUNGARY,

²ScanoMed Nuclear Medicine Centers, Debrecen, HUNGARY.

Aim/Introduction: The present study focuses on a quantitative and qualitative comparative evaluation of clinical whole-body ¹⁸F-FDG images acquired on a SiPM-based digital PET/CT scanner using Block Sequential Regularized Expectation Maximization reconstruction (BSREM). The aim of this study was to find the optimal reconstruction parameter β value for the reduced injected activity examination protocol, without the degradation of image quality. **Materials and Methods:** Whole-body ¹⁸F-FDG patient scans including wide range of BMIs (19.7 - 36.8) were acquired with 1.5 min/bed positions. Two reconstruction algorithms were compared in case of ¹⁸F-FDG studies with oncological indications. Patients were divided into two separate groups: „Low dose” and „Normal dose” radiopharmaceutical injection protocol. The two groups were divided into further subgroups according to their body habitus: BMI=20, 25, 30, 35. The „Normal dose” group included 8 patients receiving 3.0, 3.5, 4.0 MBq/kg, while in the „Low dose” group 8 patients receiving 2.0, 2.5, 3.0 MBq/kg for BMIs \leq 20, between 20 and 30, $>$ 30 respectively. The Whole Body PET images were created with various β values of 500, 1000, 1500, 2000. In addition to the four BSREM reconstruction, one TOF OSEM reconstruction was performed per patient with a total of 80 reconstructions. Evaluation of the reconstructed images in terms of ranking the overall image quality was performed by an experienced nuclear medicine physician and quantitatively analysed with fix 40 mm VOIs on the liver in each cases. **Results:** It can be clearly stated that „Low-dose” injected activity protocol using higher β values resulted in better image quality, i.e. higher contrast and reduced noise. Medical reading revealed that β value 1000 resulted excellent image quality for all BMI categories except Low-dose injected patient with BMI=30, (preferred β value was 500) and showed similar qualitative result for both injected activity protocols. Liver VOI analysis revealed that SUV mean ranged between (1.87–2.88), and (St.Dev./Mean)² values were significantly lower compared to conventional (TOF OSEM with PSF correction) reconstructions for both injected activity protocols. **Conclusion:** Q.Clear image reconstruction could provide good image quality performance when using β value 1000 at short total acquisition times for better patient comfort, even in case of low injected activity protocols. According to the most important result of this study, it is feasible to reduce the amount of injected activity and increase the β

value for the proper quality of Whole Body ^{18}F -FDG PET/CT images. **References:** None

OP-303

Image quality performance of Block Sequential Regularized Expectation Maximization and digital PET/CT with the Kyoto IB-10 brain phantom

A. Ács-Nagy¹, D. K. Klagyvik¹, F. Nagy², P. Szabó¹, I. Garai², Á. K. Krizsán²;

¹ScanoMed Kft., Budapest, HUNGARY,

²ScanoMed Kft., Debrecen, HUNGARY.

Aim/Introduction: This study focused on the evaluation of the image quality performance of a SiPM-based digital PET/CT scanner using Block Sequential Regularized Expectation Maximization reconstruction (BSREM, also called as Q.Clear) for ^{18}F -FDG Brain images. **Materials and Methods:** All phantom measurements were performed on a GE Discovery MI PET/CT system. We used the Kyoto IB-10 phantom that includes a linearity and an anthropomorphic compartment. 5 chambers of linearity compartment was filled with ^{18}F -FDG with the following activity concentrations: 2.13, 5.22, 12.68, 26.84, 53.06 kBq/ml, while one chamber was filled with water only. The anthropomorphic phantom compartment was filled with ^{18}F -FDG solution in a 3.67 ratio for grey/white matter. Single bed position PET scans with 5 minutes acquisition time durations were performed for both Kyoto IB-10 phantom compartments. BSREM reconstruction β values were varied between 100 and 4000 using increments of 100 for both phantom compartments, while in case of the anthropomorphic compartment additional reconstruction series were performed with β values from 20 to 200 with increments of 20. **Results:** Following the image reconstructions, Standard Deviation/Mean values were calculated for Volume of Interests (VOIs) applied on all chambers of the linearity compartment images. This evaluation revealed that image noise reaches a minimum at 400 β value for lower activity concentrations and 200 β value for higher activity concentrations, while significant image degradation and spill over occurs above 2000 β value. In addition, the activity concentration in the water-only compartment (caused by the spill-over effect) reaches minimum in Standard Deviation/Mean around β value of 1000. For optimal reconstruction in case of brain studies these limitations should be also taken into consideration. The anthropomorphic compartment was evaluated with calculating the mean activity concentration ratios using VOIs on the gray matter, thalamus, putamen, caudate nucleus region compared to the VOI applied on the white matter region. These ratios are monotonously increasing towards the lower β values, and reaches the real activity concentration ratio for grey/white matter at β value of 80. **Conclusion:** The Kyoto IB-10 phantom set gave us opportunity to comprehensively evaluate imaging

performance and quantitative accuracy of digital PET/CT technology with BSREM reconstruction for brain ^{18}F -FDG studies. Definition of optimal BSREM β value for ^{18}F -FDG PET/CT images still remain a complex topic. The optimal noise values appear between 200 and 400 β values, while the reconstructed activity concentration ratios are close to the real ratio at β value of 80. **References:** None

OP-304

A Comparative Study Between Conventional & Digital PET-CT For Detection of Lymph Node Metastases in Patients with High-Risk Prostate Cancer Using ^{18}F -Flourocholine

M. Björsdorff¹, J. Oddstig², A. Bjartell³, C. Puterman⁴, H. Kjölhede⁵, E. Trägårdh⁶;

¹Department of Translational Medicine, Malmö, SWEDEN,

Sahlgrenska University Hospital, University of Gothenburg, Gothenburg, SWEDEN, ⁶Clinical Physiology and Nuclear

Medicine, Skåne University Hospital and Wallenberg Center for Molecular Medicine, Lund University, Malmö, SWEDEN.

Aim/Introduction: In 2017, new digital PET-CT technology were installed at Skåne University Hospital, Sweden. The diagnostic performance for detection of lymph node metastases for digital PET-CT compared with conventional technology remains largely unknown. The aim was to compare the diagnostic performance of conventional and digital PET-CT for detecting pelvic lymph node metastases in patients with high-risk prostate cancer (PCa) referred to for ^{18}F -flourocholine (FCH) PET-CT, using histopathology as reference method. **Materials and Methods:** 176 high-risk PCa patients were included, examined on either the conventional Philips Gemini TF PET-CT, (n= 91) or on the digital GE Discovery MI PET-CT (DMI) (n= 85). Patients were referred for initial staging of high-risk prostate cancer. All were injected with 4 MBq/kg FCH and the PET data was collected one hour after injection. The medical reports regarding lymph node metastases were compared to the medical report from histopathology after extended pelvic lymph node dissection for calculation of sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV). **Results:** The examinations performed on Philips Gemini showed 72 patients (72.9%) having no lymph node metastases and 19 patients (20.8%) having suspected lymph node metastases. 31 patients (34%) had lymph node metastases on histopathology. The sensitivity, specificity, PPV and NPV for Philips Gemini were 29.0%, 83.3%, 47.4% and 69.4%, respectively. The examinations performed on DMI showed 44 patients (51.8%) having no

lymph node metastases and 41 patients (48.2%) having suspected lymph node metastases. 21 (25%) had lymph node metastases on histopathology. The sensitivity, specificity, PPV and NPV for DMI resulted in 61.9%, 56.3%, 31.7% and 81.8% respectively. The area under the ROC curve was 0.56 for Philips Gemini and 0.59 for DMI. **Conclusion:** The present study showed similar overall accuracy (ROC analysis) but large differences in sensitivity, specificity, PPV and NPV between conventional and digital PET-CT. Potential reasons for the differences needs further investigations. **References:** None

OP-305

A PET Technologist's Role in Imaging Research

D. Ribeiro, R. Janisch;

Invicro, A Konica Minolta Company, London, UNITED KINGDOM.

Aim/Introduction: Positron Emission Tomography (PET) is best known for its contribution in cancer diagnostics and follow up, however, this imaging modality can also be used in research. Common applications in research span from investigation of neurodegenerative and psychiatric diseases to drug development. The aim of this project is to provide an overview of PET technologist's role in the field of imaging research. **Materials and Methods:** Research sites with an in situ cyclotron and manufacturing capabilities are able to produce a broader range of isotopes and radiopharmaceuticals than the ones used clinically and, after undergoing preclinical trials, they can be used in human research studies. These studies must be conducted in accordance with the International Council for Harmonisation (ICH) Good Clinical Practice (GCP) and the guiding principles of the 2013 Declaration of Helsinki [1]. Unlike clinical scans, most research scans are acquired in a dynamic format for 90 minutes or longer, which poses unique challenges in movement correction, and are often processed with analytic rather than iterative reconstructive algorithms, as accurate quantification is paramount [2]. **Results:** Biodistribution and imaging studies that use tracers for which the pharmacokinetics cannot be described by 2-tissue compartment models, require arterial blood sampling and analysis. Usually, the first 15min after tracer administration provide information regarding initial peak radioactivity and blood clearance. Discrete blood samples thereafter are used for investigation of whole-blood-to-plasma radioactivity concentration and metabolites. Ethical concerns must always be weighed particularly in situations of lack of understanding, inappropriate consent or lack of an impartial interpreter. PET Technologists may also be involved in providing practical and technical perspectives on imaging protocols and reviewing associated documentation, writing PET-related study documentation and Standard Operating Procedures, accurately maintaining records to a very high standard of GCP compliance, performing internal

audits and actively assisting in external audits. **Conclusion:** As the field of medical imaging technologies continues to develop, it's important to demonstrate that the roles and responsibilities of PET Technologists have evolved alongside. PET Technologists form a vital part of a team and with appropriate training and competency assessments, these multidisciplinary teams make valuable contributions to research. **References:** [1] Vijayanathan A, Nawawi O. FAPI PET/CT: Tracer- biodistribution in patients with head and neck-, lung-, pancreatic- and colorectal- cancer

F. Staudinger¹, J. Schlittenhardt¹, T. Lindner¹, H. Rathke¹, M. Röhrich¹, S. Körber^{2,3,4}, J. Debus^{2,3,4}, C. Kratochwil^{5,6}, U. Haberkorn^{1,6,7}, F. Giesel^{1,6,8};

¹Department of Nuclear Medicine, Heidelberg University Hospital, Heidelberg, GERMANY, ²Department of Radiation Oncology, Heidelberg University Hospital, Heidelberg, GERMANY, ³National Center for Tumor diseases (NCT), Heidelberg, GERMANY, ⁴Heidelberg Institute of Radiation Oncology (HIRO), Heidelberg, GERMANY, ⁵Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY, ⁶Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, ⁷Translational Lung Research Center Heidelberg (TLRC), German Center for Lung Research (DZL), Heidelberg, GERMANY, ⁸Clinical Cooperation Unit Radiation Oncology, German Cancer Research Center (DKFZ), Heidelberg, GERMANY.

Aim/Introduction: Fibroblast activation protein inhibitor (FAPI)-positron-emission tomography (PET) / computed tomography (CT) is a promising staging tool for detecting a variety of solid cancers. Here we describe the in vivo biodistribution of the FAPI-tracer head and neck-, lung-, pancreatic- and colorectal- cancer patients. **Materials and Methods:** A mean of 245 MBq (range 111-336 MBq) ⁶⁴Ga-FAPI-02/-04/-46 and ¹⁸F-FAPI-74 was administered and PET/

CT imaging was acquired at 1h post injection (p.i.). FAPI-PET/CT was performed in a cohort of 81 patients (median age 63 years) including 20 patients with head- and neck-cancer, 18 patients with lung-cancer, 21 patients with pancreatic-cancer and 22 patients with colorectal-cancer. Normal organ distribution and tumor uptake were semi-quantitatively evaluated based on the standardized uptake values (SUV)_{max} and SUV_{mean} at the 1h time-point. **Results:** The overall SUV_{max} average at 1h in primary tumors was 12,93; in lymph node metastases it was 9,82; in distant metastases 8,32. Thus, due to rapid kidney clearance of non-tumor-bound tracer and moderate nonspecific uptake in normal organs, promising tumor-to-background-ratios could be achieved: tumor/bloodpool: 7; tumor/muscle: 9; tumor/fat: 24; tumor/spinal: 18. A direct quantitative comparison of the different tumor entities presented no significant differences in the SUV_{max} of primary cancers (p=0,38), lymph node metastases (p=0,117) and distant metastases (p=0,212). **Conclusion:** The present study demonstrates that FAPI-PET/CT can achieve equal or even superior results in patients with head and neck-, lung-, pancreatic- and colorectal-cancer compared to gold standard imaging modality for staging/-restaging cancer stratification. Due to a low background activity in normal tissue, there was a high tumor-to-background ratio in most lesions. The high contrast tumor delineation of FAPI indicates potential usefulness for multiple clinical applications. **References:** None

OP-308

FAPI-74 PET/CT Using Either ¹⁸F-AIF or Cold-kit ⁶⁸Ga-labeling: Biodistribution, Radiation Dosimetry and Tumor Delineation in Lung Cancer Patients

F. Giesel¹, S. Adeberg¹, M. Syed¹, T. Lindner¹, L. Jiménez-Franco², F. Staudinger¹, E. Tonndorf-Martini¹, S. Regner¹, S. Rieken³, R. El Shafie¹, M. Roehrich¹, P. Flechsig¹, A. Kluge⁴, A. Altmann¹, J. Debus¹, U. Haberkorn¹, C. Kratochwil¹;

¹University Hospital Heidelberg, Heidelberg, GERMANY, ²ABX CRO advanced pharmaceutical services, Dresden, GERMANY, ³University Hospital Goettingen, Goettingen, GERMANY, ⁴ABX advanced pharmaceutical services, Dresden, GERMANY.

Aim/Introduction: ⁶⁸Ga-FAPI-2/4/46 have already been proposed as promising PET-tracers. However, the short half-life of ⁶⁸Ga (T_{1/2} 68 min) creates problems with manufacture and delivery. ¹⁸F (T_{1/2} 110 min) labeling would result in a more practical large scale production and a cold-kit formulation would improve the spontaneous availability. The NOTA-chelator ligand FAPI-74 can be labeled with both ¹⁸F-AIF (Aluminum-Fluoride) and ⁶⁸Ga. Here we describe the in-vivo evaluation of ¹⁸F-FAPI-74 and a proof-of-mechanism of ⁶⁸Ga-FAPI-74 labeled at ambient temperature. **Materials and Methods:** In ten patients with lung cancer PET-scans were acquired at 10 min, 1h and 3h after administration of 259±26 MBq ¹⁸F-FAPI-74. Physiological biodistribution and

tumor uptake were semi-quantitatively evaluated based on SUV at each time-point. Absorbed doses were evaluated using OLINDA/EXM 1.1 and QDOSE dosimetry software with the dose calculator IDAC-Dose 2.1. Identical methods were used to evaluate one exam after injection of 263 MBq ⁶⁸Ga-FAPI-74. **Results:** The highest contrast was achieved 1 h p.i. in primary tumors, lymph node and distant metastases with SUV_{max} >10, respectively. The effective dose per 100 MBq administered activity of ¹⁸F-FAPI-74 was 1.4±0.2 mSv and for ⁶⁸Ga-FAPI-74 it was 1.6 mSv. Thus, the radiation burden of a diagnostic ¹⁸F-FAPI-74 PET-scan is even lower than that of PET-scans with ¹⁸F-FDG and other ¹⁸F-tracers; ⁶⁸Ga-FAPI-74 is comparable to other ⁶⁸Ga-ligands. FAPI-PET/CT supported target volume definition for guiding radiotherapy. **Conclusion:** High contrast and low radiation burden of FAPI-74 PET/CT favors multiple clinical applications. Centralized large-scale production of ¹⁸F-FAPI-74 or decentralized cold-kit labeling of ⁶⁸Ga-FAPI-74 allows flexible routine use. **References:** None

OP-309

Reversing cold tumor microenvironment with targeted alpha-therapy

J. Perrin, M. Capita, S. Gouard, C. Maurel, C. Louvet, M. Lancien, F. Bruchertseifer, A. Morgenstern, M. Chereil, J. Gaschet, Y. Guilloux; INSERM, Nantes, FRANCE.

Aim/Introduction: Actual cancer therapies are facing numerous challenges towards tumor cell destruction: tumor microenvironment involves immunoregulatory cells and cytokines, which prevent anti-tumoral immune response. Therapeutic combination could be the key to turn these « cold » tumor microenvironment into « hot » ones: more vascularised and infiltrated with immune cells. To this end, this project focus on combining targeted alpha-therapy (TAT) and adoptive T-cells transfer (ACT). **Materials and Methods:** This therapeutic combination was conducted in a Multiple Myeloma (MM) murine model using a 5T33-OVA MM cell line expressing the CD138 antigen and H₂K^b/OVA₂₅₇₋₂₆₄ complexes grafted subcutaneously to C57BL6/KalwRij mice. TAT was delivered through intravenous injection of a ²¹³Bismuth radiolabelled anti-CD138 antibody. To further reinforce its efficiency, TAT was combined with an ACT of tumor specific OT-1 T-cells. This therapeutic combination resulted in a significant tumor growth delay and improved survival, compared to ACT or TAT alone (Ménager and al. 2015). Based on these results, the aim of this project was then to understand the impact of TAT on the “cold” tumor microenvironment and on ACT efficacy. Tumor infiltrated cells were analysed by flow cytometry to identify in situ immune populations, and cytokines production were assessed by RT-qPCR on tumor fragment. **Results:** Although OT-1 T cells infiltrated the tumor after ACT, only combination with TAT resulted in regulatory CD4 T cell drop and

production of IL-2 and IFN γ within the tumor. Furthermore, OT-1 T cells motility was increased on TAT treated tumor slices as observed by ex vivo time lapse. **Conclusion:** Combining TAT and ACT appears to turn this “cold” tumor model into a “hot” one with regulatory T cells depleted, proportion and motility of tumor-specific CD8 T cells increased and IL-2 and IFN γ produced in the tumor. Next, we aim to investigate impact of this combination on metabolism and hypoxia in tumor microenvironment. **References:** ADDIN Mendeley Bibliography CSL_BIBLIOGRAPHY Ménager, J. et al. (2015) ‘Combining α -radioimmunotherapy and adoptive T cell therapy to potentiate tumor destruction’, *PLoS ONE*, 10(6), pp. 1–14. doi: 10.1371/journal.pone.0130249. <![endif]-->

PET Imaging of PD-L1 Expression in NSCLC: Pharmacokinetic Comparison of an Antibody and its Fab Fragment

A. Bouleau¹, H. Nozach², M. Richard¹, S. Dubois², G. Torquet¹, B. Kuhnast¹, B. Maillère², V. Lebon¹, C. Truillet¹;

¹Université Paris-Saclay, CEA, CNRS, Inserm, BioMaps, Service Hospitalier Frédéric Joliot, Orsay, FRANCE, ²Département Médicaments et technologies pour la santé, SIMoS, Université Paris-Saclay, CEA-Saclay, Gif-sur-Yvette, FRANCE.

Aim/Introduction: The interaction of programmed death ligand 1 (PD-L1) with its receptor PD-1 on T-cells promotes tumour cell immuno-escape. In solid cancers, including non-small cell lung cancer (NSCLC), the PD-L1⁺ status, assessed via immunohistochemistry (IHC) on tumour biopsies, was associated with the efficacy of PD-1/PD-L1 immunotherapy. However, IHC ignores spatial and temporal dynamics of PD-L1 expression within and across lesions of a patient. Immuno-PET with radiolabelled antibody-based PD-L1 ligands provides non-invasive whole-body visualization of PD-L1 expression, and may thus help to improve patient stratification and response monitoring for PD-1/PD-L1 immunotherapy. To select the most appropriate PET imaging tool to assess in vivo PD-L1 expression, for obtaining high-contrast images at early time points, we compared the pharmacokinetics (PK) of an anti-PD-L1 IgG and its Fab fragment radiolabelled with ⁸⁹Zr in NSCLC xenograft models. **Materials and Methods:** A cross-species anti-PD-L1 antibody C4 and its Fab fragment (50 kDa), with nanomolar affinities for human and mouse PD-L1, were developed. PK and biodistribution of the ⁸⁹Zr-labelled IgG C4 and Fab C4 were evaluated with PET/CT imaging in nude mice bearing subcutaneous human NSCLC xenografts with different PD-L1 expression levels. **Results:** Specific tumour uptake of ⁸⁹Zr-IgG C4 and ⁸⁹Zr-Fab C4 was observed in PD-L1⁺ H1975 xenografts, with the highest tumour-to-muscle ratio (TMR) at 50 h post-injection (pi) for ⁸⁹Zr-IgG C4 (TMR = 8.3 \pm 0.6) and at 4 h pi for ⁸⁹Zr-Fab C4 (TMR = 4.7 \pm 0.5). ⁸⁹Zr-Fab C4 uptake was significantly lower in PD-L1⁻ A549 xenografts (TMR = 2.9 \pm 0.2 at 4h) as compared to PD-L1⁺

H1975 xenografts (P = 0.004). Uptakes correlated to PD-L1 expression levels in tumour tissues determined by flux cytometry. **Conclusion:** The Fab C4 achieved maximum TMR quickly (4 h pi), although it was lower (\approx 2x) than the IgG C4 maximum TMR (48 h pi). The faster Fab tumour diffusion allows tracer injection and imaging on the same day. It would reduce patient radiation exposure with the use of shorter-lived isotopes like ¹⁸F. ⁸⁹Zr-Fab C4 was mainly cleared via the urinary tract, resulting in high kidney signal, whereas ⁸⁹Zr-IgG C4 was excreted through the hepatobiliary route. PK and biodistribution of the fragment scFv C4 (30 kDa) will be assessed in the same NSCLC H1975 xenograft model. Murine 3D imaging-based dosimetry analysis will also be performed for the ⁸⁹Zr-IgG C4 and its fragments. **References:** Truillet C, et al. Imaging PD-L1 expression with ImmunoPET. *Bioconjug Chem.* 2018; 29: 96-103.

OP-311

⁹⁰Y-NM600 Combined with Bempedgesleukin (NKTR-214) Improves Response to Immune Checkpoint Inhibition in a Syngeneic Murine Model of Head and Neck Cancer

J. Grudzinski¹, A. Bates¹, R. Hernandez¹, G. Sosa¹, E. Nystuen¹, S. Emma¹, E. G. Sumiec¹, A. Pieper¹, R. Patel², E. Aluicio-Sarduy¹, J. Engle¹, I. Marsh¹, B. Bednarz¹, J. Weichert¹, Z. Morris¹;

¹University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA, ²University of Pittsburgh, Pittsburgh, PA, UNITED STATES OF AMERICA.

Aim/Introduction: Combining low-dose targeted radionuclide therapy with a CD122 agonist like NKTR-214, which exhibits greater serum half-life, more preferential CD8⁺ T cell and NK cell activation, and improved tolerability compared to native IL-2, is one possible approach to improving low response rates of immunotherapies in unresectable recurrent or metastatic head and neck squamous cell carcinoma (HNSCC). The aim of this study was to test whether NKTR-214 and ⁹⁰Y-NM600 increases the response to anti-CTLA-4 immune checkpoint blockade in an immunologically “cold” and spontaneously metastatic MOC2 syngeneic mouse model of HNSCC. **Materials and Methods:** C57BL/6 female mice (n = 4) bearing MOC2 tumors were administered 9.25 MBq of ⁸⁶Y-NM600, and longitudinal static microPET/CT scans were acquired at 3, 24, 48, and 72 h post-injection. Region-of-interest analysis of the images afforded dosimetry estimation of ⁹⁰Y-NM600 using Monte Carlo simulation. In therapy studies, mice bearing subcutaneous MOC2 tumors (n = 8; 100 mm³) received combinations of NKTR-214, ⁹⁰Y-NM600, and anti-CTLA-4. 3.7 MBq of ⁹⁰Y-NM600, estimated to deliver a tumor dose of 8 Gy (2.17 Gy/MBq), was administered i.v. on Day 1 followed by anti-CTLA-4 (200 μ g) i.p. injections on days 4, 7, and 10. NKTR-214 (16 μ g) was given i.v. on days 6, 15, and 24 post administration of ⁹⁰Y-NM600. Tumors from a subgroup of treated mice were collected at Day 14 for

flow cytometry analysis. Survival and tumor growth were tracked until Day 60. **Results:** Imaging confirmed selective uptake and retention of NM600 in MOC2 tumors and gradual clearance from normal tissues. Absorbed doses per ^{90}Y -NM600 injected activity of 3.15, 1.52, and 0.65 Gy/MBq were estimated for the tumor, spleen, and muscle, respectively. In the MOC2 tumor model, 62.5% of mice treated with the combination of ^{90}Y -NM600, NKTR-214, and anti-CTLA4 experienced complete tumor response, and these mice showed no observable primary or metastatic disease 60 days after treatment initiation. No mice receiving single or dual therapy combinations exhibited complete tumor response ($p < 0.01$). Treatment with NKTR-214 and ^{90}Y -NM600 resulted in increased tumor infiltration by CD8+ T cells. Interestingly, ^{90}Y -NM600 triggered increased expression of the IL2-beta receptor, CD122, on tumor infiltrating CD8+ T cells, indicating a sensitization of T-cells for NKTR-214. **Conclusion:** NKTR-214 combined with ^{90}Y -NM600, and anti-CTLA-4 resulted in complete and durable tumor response in a murine model of HNSCC. Low-dose TRT may enhance the effect of NKTR-214 by increasing the expression of the IL2-beta receptor on tumor infiltrating T-cells. **References:** None

Aim/Introduction: This study evaluated the usefulness of micro-positron emission tomography (micro-PET) with ^{18}F -fluorodeoxyglucose (^{18}F -FDG) in assessing response to anti-programmed death 1 (PD-1) monoclonal antibody pembrolizumab in triple-negative breast cancer (TNBC) cell MDA-MB-231 xenograft and to investigate whether the molecular mechanism involves hypoxia-inducible factor 1- α (HIF1 α). **Materials and Methods:** Methods: Five-week-old female BALB/c nude mice received subcutaneous injections of 5×10^6 MDA-MB-231 cells in 100 μL of saline at the right dorsal flank. Fourteen days after tumour implantation, the mice were randomly assigned to a treatment group receiving anti-programmed death 1 (PD-1) monoclonal antibody pembrolizumab (200 μg /per mouse) or a control group receiving saline three times per week intraperitoneally for 21 days. The status of the nude mice, tumor growth rate and size changes in both groups were observed. ^{18}F -FDG microPET scan was performed before and after treatment to calculate the maximum tumor uptake rate per gram (%ID/gmax) for efficacy evaluation. At the end of the experiment,

animals were sacrificed, and tumour tissues were collected for weighing and immunohistochemistry for Ki-67, cysteine proteinase 3 (Caspase-3), HIF1 α , glucose transporter-1 (GLUT1), and lactate dehydrogenase A (LDHA). The lactic acid production of xenografts was investigated with enzymic method. The mRNA expression and the protein expression levels of glycolytic metabolic enzymes in xenografts were detected by real-time PCR and western blotting. **Results:** Results: Compared with PBS-control group, tumors derived from pembrolizumab treatment group had decreased glucose uptake as shown by ^{18}F -FDG microPET imaging ($P < 0.01$). Furthermore, compared with the tumors in the PBS-control group, tumors in mice treated with pembrolizumab were smaller and lighter ($P < 0.05$). IHC analysis of tumours revealed that pembrolizumab reduced Ki-67, HIF1 α , GLUT1, and LDHA protein levels and increased Caspase-3 expression. Lactic acid analysis of the tumor masses further confirmed that pembrolizumab decreased lactate production. Real-time PCR and western blotting showed that under pembrolizumab treatment, the protein and mRNA expression levels of HIF1 α and its downstream glycolytic metabolic enzymes such as GLUT1, HK2 and LDHA were significantly inhibited. **Conclusion:** Conclusion: The anti-programmed death 1 (PD-1) monoclonal antibody pembrolizumab has a significant inhibitory effect on the growth of TNBC MDA-MB-231 transplanted tumors. ^{18}F -FDG PET plays an important role in the early evaluation of pembrolizumab for TNBC. The molecular mechanism may be related to the pembrolizumab-induced HIF1 α /Glut1 pathway. **References:** None

Immune-checkpoint blockade enhances ^{225}Ac -PSMA617 efficacy in a mouse model of prostate cancer

K. Lueckerath, K. Current, C. E. Mona, L. Nyiranshut, F. Hikmat, C. G. Radu, J. Czernin;
University of California Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Radionuclide therapy (RNT) may increase tumour immunogenicity. We aimed at exploiting this effect by combining PSMA-targeted RNT with immunotherapy in a mouse model of prostate cancer (PC). **Materials and Methods:** C57BL/6 mice bearing syngeneic RM1-PGLS tumours were treated with ^{225}Ac -PSMA617 (30 kBq, i.v.), an anti-PD-1 antibody (10 mg/kg, i.p., q3d for 4 doses) or both. Therapeutic efficacy was assessed by tumour volume measurements (computed tomography), time to progression (TTP) and survival. **Results:** PSMA-RNT or anti-PD-1 alone tended to prolong TTP (isotype control 25d; anti-PD-1 33.5d, $p=0.0153$; RNT 30d, $p=0.1038$) and survival (control 28d; anti-PD-1 37d, $p=0.0098$; RLT 32d, $p=0.1018$). Combining PSMA-RNT and anti-PD-1 significantly improved disease control compared to either monotherapy. TTP was

extended to 47.5d ($p < 0.0199$ vs. monotherapies), and survival to 51.5d ($p < 0.0251$ vs. monotherapies). In mice with smaller tumours, complete responses were observed with RNT/anti-PD-1. Complete-responders were immune to tumour re-challenge. **Conclusion:** PSMA-RNT and PD-1 blockade synergistically improve therapeutic outcomes in our PC model and might facilitate generation of an immunological memory. Thus, RNT might aid the conversion of PC into immunological “hot” tumours. Together, our data support the evaluation of RNT/immunotherapy combination regimens for PC patients. **References:** None

PD-L1 targeted Ga-68-PET imaging in human lung adenocarcinoma xenografts

J. Notni, K. Steiger, N. G. Quigley, F. Richter, W. Weichert;
Technical University of Munich, Munich, GERMANY.

Aim/Introduction: Immune checkpoint therapy with PD-L1 targeted antibodies is characterized by low response rates and high costs. Therefore, eligible cancer patients must be carefully selected, while selections are based on tumoral PD-L1 status. At present, such decisions rely on histological analysis of biopsies, which however are characterized by low reliability due to small volume of specimen and a high degree of heterogeneity of PD-L1 expression. Consequently, non-invasive mapping of PD-L1 expression could significantly improve patient management. **Materials and Methods:** The peptidic PD-L1 ligand WL12 [1] was decorated with the Ga-68-chelator TRAP employing Click Chemistry (CuAAC) as described [2]. The resulting Ga-68 labelled compounds were evaluated in H2009 (human lung adenocarcinoma) xenografted SCID mice employing dynamic (90 min) and static (60 and 120 min p.i.) PET as well as biodistribution (60 min p.i.). PD-L1 expression in tumors and organs was determined by immunohistochemistry. **Results:** In analogy to the clinical picture observed in lung cancer patients, subcutaneous H2009 tumors were characterized by a low and heterogeneous PD-L1 expression density (overall approx 20% of positive tumor cells, with large regional differences). Nevertheless, Ga-68-TRAP-WL12 showed a high and persistent tumor accumulation (approx. 7 %ID/g). Comparably low uptakes in liver (6.1 %ID/g), lung (5.0 %ID/g), and blood pool (2.2 ± 0.6 %ID/g) resulted in favorable tumor/organ ratios (T/liver: 1.2; T/lung: 2.4; T/blood: 3.4, 60 min p.i.). Dynamic PET data indicated no significant washout from tumor but a strongly decreasing activity in blood and organs, resulting in an increase of image contrast over time. **Conclusion:** Conjugation of a hydrophilic Ga-68-TRAP chelate to the lipophilic WL-12 peptide yielded a renally excreted PET tracer with higher overall hydrophilicity and less non-specific uptake, as compared to other radiolabelled WL-12 derivatives [1,3]. Ga-68-TRAP-WL12 is characterized by a high PD-L1 detection sensitivity. Thus, it appears suitable

for PET-based patient selection of possible responders to PD-L1 immune checkpoint therapy, potentially enhancing the overall performance of PD-L1 directed personalized cancer therapy regimen. **References:** [1] R. A. De Silva et al., *Mol Pharmaceutics* 2018;15:3946. [2] Baranyai Z, et al., *Dalton Trans.* 2015;44:11137-11146. [3] Lesniak WG, et al., *Mol. Imaging* 2019;18:1536012119852189.

OP-315

Imaging tumour CD8+ T-cell infiltrates following radioimmunotherapy in an immunocompetent mouse model

B. Cornelissen¹, G. Dias¹, E. O'Neill¹, C. Bristow¹, F. Salazar², R. Tavare², N. Sibson¹, A. Wu²;

¹University of Oxford, Oxford, UNITED KINGDOM, ²City of Hope, Duarte, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Combination of irradiation (IR) and immunotherapy (IT) has been shown to be an effective regime for cancer therapy in certain settings. This approach however requires optimized IR and IT regimes. To measure the effects of anti-CTLA-4 on CD8+ T-cell infiltrates in multiple lesions in the same individual during radiotherapy, we used SPECT imaging with a radiolabelled anti-CD8-cys-diabody (α -CD8-CDb). **Materials and Methods:** Female immunocompetent Balb/c mice were inoculated with murine CT-26 cancer cells on the left and right lower flank. Fourteen days after, only the right-hand side tumours were irradiated (4Gy). On day 15, half of the mice were administered a therapeutic dose of anti-CTLA4 antibody (250 μ g). α CD8-CDb was labelled with ¹¹¹In through maleimide-DTPA. [¹¹¹In] In-mDTPA- α CD8-CDb (1.9 MBq, 10 μ g) was administered intravenously on day 21, and SPECT/CT images acquired on day 22 (MILabs VECTor^{CT}). Tumours and organs were excised, weighed and measured on a gamma counter. Flash frozen tumours were sectioned and processed for autoradiography, and stained with a rat anti-CD8 antibody. **Results:** Tumour growth was not significantly different within the studies time frame comparing the irradiated (right, RT) and the non-irradiated (left, LT) tumours. SPECT/CT images showed uptake of the [¹¹¹In]In-anti-CD8-CDb in spleen, kidneys, tumours and lymph nodes. The axillary and brachial nodes were clearly visible with the [¹¹¹In]In-anti-CD8-CDb, while any signal from inguinal nodes was overshadowed by tumour location. IR + α CTLA4-treated mice showed a greater uptake of ¹¹¹In in the non-IR tumour compared to the IR tumour, contrary to mice that did not receive anti-CTLA4. Heterogeneity within tumours was evident from autoradiographs and immunohistochemistry staining, showing the presence of CD8 in the tumours. **Conclusion:** In vivo CD8 expression was assessed post irradiation and α CTLA4 treatment using a radiolabelled anti-CD8-cys-diabody. The differences between the uptake of [¹¹¹In]In-anti CD8-CDb in LT and RT between the IR only and

combo group suggest further investigation to the effects of α CTLA4 in T-cell infiltrate recruitment. Further analysis is underway to relate the amount of staining to the amount of [^{111}In]In-anti CD8-CDB. **References:** Tavaré R, Escuin-Ordinas H, Mok S, et al. An Effective Immuno-PET Imaging Method to Monitor CD8-Dependent Responses to Immunotherapy. *Cancer Res.* 2016;76(1):73-82.

Development of [^{18}F]AIF-NODA-CTHRSSVC for imaging M2 macrophages with PET

B. Fernandes¹, I. F. Antunes², C. M. M. Jecke³, E. F. J. de Vries², P. H. Elsinga²;

¹UMCG, Groningen, NETHERLANDS, ²University of Groningen, University Medical Center Groningen (UMCG), Groningen, NETHERLANDS, ³Graduate Program in Biomedical Gerontology, School of Medicine, Pontifical Catholic University of Rio Grande do Sul (PUCRS), Porto Alegre, BRAZIL.

Aim/Introduction: Macrophages are specialized cells that play an important role in the immune system and the tumor microenvironment. Macrophages can be activated into the pro-inflammatory M1 phenotype or the anti-inflammatory M2 phenotype¹. Since these phenotypes have opposing effects, it is important to be able to discriminate them, e.g. by PET imaging. The haptoglobin-hemoglobin scavenger receptor (CD163) is selectively expressed by the M2 macrophage phenotype. CTHRSSVC is a peptide that binds to the CD163 receptor. In this study, the peptide was radiolabeled with fluorine-18 and evaluated as a novel agent PET imaging of M2-type macrophages. **Materials and Methods:** NODA-CTHRSSVC was labeled with [^{18}F]AIF²⁺. The labeling conditions were optimized using different concentrations of NODA-CTHRSSVC (15, 30, 60, and 90 $\mu\text{g}/\text{mL}$) and reaction times. The logD and in vitro stability were determined. In Balb-c mice, dynamic PET scans were acquired and ex vivo biodistribution was performed at 30, 60, and 90 minutes post-injection. **Results:** Radiolabeling of NODA-CTHRSSVC with [^{18}F]AIF²⁺ gave the highest conversion after 20 minutes of reaction using 90 μg of precursor in 1 mL of sodium acetate pH 4.5 (29.3 \pm 6.5%). If 30 μg or less precursor was used, the conversion dropped to <11%. Under the optimal conditions, [^{18}F]AIF-NODA-CTHRSSVC was obtained in a radiochemical yield of 9.2 \pm 4.9% after HPLC purification and formulation. The product had a purity of 96.4 \pm 2.5% and a molar activity of 281 \pm 388 GBq/ μmol . In the formulation solution, [^{18}F]AIF-NODA-CTHRSSVC was stable at least for 2 hours. The PET imaging and ex vivo biodistribution studies in balb/c mice showed the highest tracer uptake in kidneys, bladder, duodenum, liver, and spleen. The tracer showed fast clearance mainly via kidneys due to its high hydrophilicity (Log D = -4.6). Moreover, low bone uptake was observed, suggesting little defluorination or release of [^{18}F]AIF²⁺. **Conclusion:** [^{18}F]AIF-

NODA-CTHRSSVC was successfully labeled and is stable in vitro. The radiotracer shows fast renal clearance and accumulation in organs with high amounts of resident M2 macrophages (liver, spleen). Further validation in an in vivo immune disease model is warranted. **References:** 1. Silva et al. *Int J Mol Sci.* 2016;17(9).

Multimodal assessment of test-retest reliability using functional PET, ASL and BOLD imaging in a complex visuo-spatial motor task

L. Rischka¹, G. M. Godbersen¹, V. Pichler², P. Michenthaler¹, S. Klug¹, M. Klöbl¹, V. Ritter¹, W. Wadsak², M. Hacker², S. Kasper¹, R. Lanzenberger¹, A. Hahn¹;

¹Department of Psychiatry and Psychotherapy, Medical University of Vienna, Vienna, AUSTRIA, ²Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Cerebral glucose metabolism is commonly assessed to examine disease status and cognitive processes. The recent introduction of functional PET (fPET) enabled the quantification of glucose metabolism at rest and task within a single measurement[1], showing high signal-to-noise ratio and task sensitivity[2]. However, for clinical applicability, new methods also require testing for a stable longitudinal performance. We therefore investigated the test-retest reliability of fPET, using a complex visuo-spatial motor task. In a multimodal approach, ASL and BOLD contrast imaging were acquired within the same session as fPET, enabling a direct comparison. **Materials and Methods:** Twenty healthy subjects underwent two measurements on a hybrid PET/MR scanner, approximately 4 weeks apart. The radiotracer [^{18}F]FDG was administered in a bolus+constant infusion protocol. After 8 minutes of rest, a visuo-spatial motor task was carried out in two difficulty levels (2 easy, 2 hard, 6 minutes) each followed by 5 minutes of rest. ASL was acquired at rest and simultaneously with fPET during one easy and one hard period. Immediately after fPET, BOLD imaging was carried out in a block design with the same difficulty levels (12x30 sec, 10 sec rest). Cerebral glucose metabolism (influx constant K_1) was assessed with a general linear model and the Gjedde-Patlak plot. Cerebral blood flow (CBF) and BOLD changes were estimated with standard procedures[2,3]. Functional regions of interest were defined as the intersection of group t-maps in the hard condition ($p < 0.05$ FWE corrected voxel level), across

all three modalities. Finally, intraclass correlation ($ICC_{3,1}$), median coefficient of variation (CoV) and DICE coefficient were estimated for each difficulty. **Results:** The intersection revealed task changes in the frontal eye field, intraparietal sulcus and occipital cortex. Highest reliability was achieved with K_1 at rest (CoV: 4.6–5.8%, ICC: 0.87–0.89). Although reliability decreased during task performance (CoV: 15.7–40.6%), this was similar to CBF (CoV: 9.5–38.7%) and higher than BOLD (CoV: 16.0–66.2%). BOLD imaging exhibited the highest DICE coefficient (0.8) compared to CBF (0.7) and K_1 (0.6). **Conclusion:** Task-specific changes can be detected with all three modalities. However, fPET achieved similar or even superior test-retest reliability compared to well-established modalities. Since fPET is still novel, further optimisation procedures will also enhance its reliability. We therefore suggest fPET as valuable tool for application in clinical routine, enabling the assessment of metabolic dynamics in a reasonable time frame of 30 minutes for enhanced diagnosis. **References:** [1]Hahn (2016) J.Nucl.Med 57:1933–1940 [2]Rischka (2018) Neuroimage 181:323–330 [3]Wang (2005) Radiology 235:218–228

Improvement of FDG PETCT and MRI concordance in Temporal Lobe Epilepsy Pre-surgical Assessment using Statistical Parametric Mapping Z-scores

M. Kershaw¹, H. Amada², L. Yiping³, V. Sawlani⁴, S. Hughes⁴;

¹University of Birmingham, Birmingham, UNITED KINGDOM,

²Sandwell and West Birmingham NHS Trust, Birmingham,

UNITED KINGDOM, ³Fudan University, Fudan, CHINA, ⁴University

Hospitals Birmingham, Birmingham, UNITED KINGDOM.

Aim/Introduction: This study evaluates the diagnostic performance of statistical parametric mapping (SPM) analysis of PET-CT in temporal lobe epilepsy (TLE). Our aim is to increase consistency in image reporting and increase confidence in the surgical evaluation of TLE patients. **Materials and Methods:** Thirty-eight patients with TLE who underwent MRI and PET-CT imaging at the Queen Elizabeth Hospital in Birmingham were included in this study. Images were interpreted by visual assessment by radiologists. Quantitative analysis for PET-CT was performed using SPM. Statistical analyses performed include the Kruskal-Wallis and Game Howell tests, analysis of Receiver Operating Characteristic (ROC) curve and Cohen's κ statistics. **Results:** The standardised uptake value (SUV) ratio for left temporal epilepsy, non-epilepsy and right temporal epilepsy were -1.06 ± 1.01 , 0.08 ± 0.79 , 0.39 ± 0.73 respectively, exhibiting significant difference between the three groups ($p < 0.01$). In the left/non-left group, the area under curve (AUC) was 0.881 while the cut-off value to separate left temporal epilepsy from non-epilepsy and right temporal epilepsy was -0.305 with 89.7% sensitivity and 88.9% specificity. In the right/non-right group, the AUC was 0.792 while

the cut-off value to separate left temporal epilepsy from non-epilepsy and right temporal epilepsy was 0.190 with 83.3% sensitivity and 81.3% specificity. When patients were divided into three groups based on SUV ratio (left temporal epilepsy, non-epilepsy and right temporal epilepsy), there was good inter-method agreement between MRI and SUV ratio ($\kappa = 0.63$, 95% CI, 0.42–0.85). **Conclusion:** These results indicate that PET-CT-based SUV ratios may have promising diagnostic value in future clinical practice. **References:** None

OP-319

Clinical impact of digital vs conventional healthy control databases for semi-quantitative analysis of brain 18F-FDG PET scans

de Marseille, UMR 7249, Institut Fresnel, Marseille, FRANCE.

Aim/Introduction: Digital PET cameras offer clear improvements in brain 18F-FDG PET image quality as compared to conventional PET cameras. However, the clinical impact of such image quality enhancements on the semi-quantitative analysis (SQA) of brain 18F-FDG PET scans remains unknown. The aim of this study was to evaluate performances of digital PET SQA of brain 18F-FDG PET scans over conventional PET cameras. **Materials and Methods:** Twenty-seven patients with moderate to severe Alzheimer's disease (AD) with cerebro-spinal fluid confirmation and 22 age and gender-matched healthy patients (H) without any neurological antecedent were included. They had a brain 18F-FDG PET on a digital PET camera (Vereos, Philips®) with SQA in comparison to two normal age and gender-matched healthy control databases acquired respectively with a digital PET (n=20, Vereos, Philips®) and a conventional PET (n=19, Biograph 6, Siemens®) cameras. Results are presented at the group-level, and with visual analyses at the individual level for the positive diagnosis of AD by a consensual analysis of 3 experimented readers, using SPM T-maps representations. SQA involved an inclusive AD mask and the sensitive-motor cortex as reference for the intensity normalization. **Results:** At the group level, digital database SQA showed more marked hypometabolism in AD (+22 cm³ at $p < 0.001$ for the voxel, corrected for the expected

cluster volume) and less extensive hypometabolism in H (-2 cm³) when compared to conventional database SQA. At the individual level, accuracy of digital database SQA was higher than those of conventional database SQA (78 vs. 65%, $p < 0.01$, at $p < 0.005$ for the voxel, corrected for the expected cluster volume), with lower specificity (64 vs. 91%) but much higher sensitivity (89 vs. 44%). **Conclusion:** There is an urgent need to develop digital PET databases for brain 18F-FDG PET SQA as it is associated with improved accuracy of AD diagnosis, in particular higher detection sensitivity, as compared to conventional database SQA. **References:** None

OP-320

Understanding gender pattern differences in 11C-Methionine PET Glioma patients with radiomics analysis

L. Papp, S. Rasul, M. Weber, M. Grahovac, T. Beyer, M. Hacker, T. Traub-Weidinger;
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: PET-tracer uptake in glioma patients may vary with gender and histological subgroups. Here, we study gender differences in Glioma histological subgroups by the means of imaging patterns and radiomics analysis. **Materials and Methods:** 56 11C-MET-PET positive cases were included. Each case underwent semi-automated tumour delineation (Hybrid 3D, Hermes Nuclear Diagnostics, Sweden) as well as a normal background definition in the contra-lateral region. PET voxel values were normalized to the mean of the respective background to provide TBR values. Extraction of 50 radiomic features from each TBR-normalized VOI was performed. Matched-size male-female cohorts with similar characteristics (histology, WHO stage, age, IDH mutation status) were categorized to Astrocytoma (n=14, Oligodendroglioma (n=16), Oligoastrocytoma (n=14) and Glioblastoma multiforme (n=12) subgroups according to the WHO 2007 classification system. Radiomics feature weighting was performed based on establishing gender prediction models by ensemble learning in all the four pairwise subgroups. The three most prominent radiomic features in each of the four subgroups were analyzed to identify gender differences in each subgroup. **Results:** All subgroups demonstrated TBR heterogeneity differences, with Glioblastoma multiforme having the most prominent textural feature pattern differences within gender. The Oligoastrocytoma subgroup was an exception, where the most prominent feature to differentiate genders was sphericity-based, followed by textural features. **Conclusion:** Our pairwise radiomic analysis indicates that significant heterogeneity pattern differences are present between gender in glioma patients. Our results may support why Oligoastrocytoma presented a challenge in the interpretation according to the WHO 2007 system. Even though the WHO 2016 system eliminates the term

Oligoastrocytoma, our results imply that future classification systems shall also consider a gender specificity. **References:** None

OP-321

Age correction has only minor impact on the diagnostic accuracy of the specific binding ratio in dopamine transporter SPECT in the diagnosis of parkinsonian syndromes

I. Apostolova¹, H. Schmitz-Steinkrüger¹, C. Lange², L. Frings³, S. Klutmann¹, S. Hellwig³, P. T. Meyer³, R. Buchert¹;
¹University Hospital Hamburg Eppendorf, Hamburg, GERMANY, ²Charité - Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, GERMANY, ³Medical Center - University of Freiburg, Faculty of Medicine, Freiburg, GERMANY.

Aim/Introduction: Several studies in healthy volunteers covering a wide age range consistently demonstrated an age-related decline of the [¹²³I]FP-CIT specific binding ratio (SBR) in the striatum and striatal subregions with healthy aging of about 5% per decade. However, age explains less than 10% of the SBR variability in healthy volunteers aged 50y and older. Therefore, the necessity of age correction of the SBR to support interpretation of [¹²³I]FP-CIT SPECT in clinical routine is still a matter of debate. The present study tested the impact of age correction on the diagnostic SBR performance in three different settings. **Materials and Methods:** Research setting: The putaminal SBR of 210 healthy controls (HC) and 446 Parkinson's disease (PD) patients of the Parkinson's Progression Marker Initiative (PPMI) was downloaded from the PPMI homepage. Clinical setting A: 186 patients with neurodegenerative PS and 186 patients with non-neurodegenerative PS were recruited retrospectively from one clinical site. The putaminal SBR was obtained by hottest voxels analysis of SPECT images reconstructed by filtered backprojection. Clinical setting B: 84 patients with neurodegenerative PS and 38 patients with non-neurodegenerative PS were recruited retrospectively from another clinical site. The putaminal SBR was obtained by applying anatomical standard ROIs (AAL atlas) to iteratively (OSEM) reconstructed SPECT images. The minimum of left and right putamen SBR was used in all settings. Age correction was based on linear regression of the minimum putamen SBR with age as independent variable in the HC subjects / patients with non-neurodegenerative PS, separately in each setting. The area (AUC) under the ROC curve for identification of PD / neurodegenerative PS was used as performance measure. **Results:** The AUC without/with age correction was 0.982 (95%-CI: 0.971-0.992) / 0.980 (0.971-0.990) in the research setting, 0.949 (0.927-0.972) / 0.945 (0.921-0.969) in clinical setting A, and 0.965 (0.937-0.993) / 0.974 (0.950-0.998) in clinical setting B. Only the small loss of AUC by age correction in clinical setting A was

statistically significant (DeLong $p = 0.029$, research setting: $p = 0.600$, clinical setting B: $p = 0.220$). **Conclusion:** These findings do not support age correction of the specific [123I]FP-CIT binding ratio in the etiological diagnosis of parkinsonian syndromes. **References:** None

KINGDOM, ²Uppsala University, Uppsala, SWEDEN,

³Hermes Medical Solutions, Stockholm, SWEDEN, ⁴Hermes

Medical Solutions, London, UNITED KINGDOM, ⁵Imperial

College London, London, UNITED KINGDOM.

Aim/Introduction: 18F-Florbetaben PET/CT estimates beta-amyloid plaque density in patients with cognitive impairment under evaluation for Alzheimer's disease. Quantitative analysis can be performed using BRASSv4.0 software, with an automated PET only registration method, utilising an adaptive template based on principal component analysis to register PET data to a regional template. This approach could be beneficial as spatial normalisation of amyloid images is challenging due to different cortical uptake patterns in positive and negative scans. The aim of this work was to assess the ability of BRASSv4.0 software to quantify and aid identification of positive and negative 18F-Florbetaben scans. **Materials and Methods:** Patients ($n=194$) who underwent 18F-Florbetaben PET scan for a minimum 20 minutes were included in this study. Brain beta-amyloid was quantified using BRASSv4.0 software and compared with the final clinical report. The binary result and brain amyloid plaque load (BAPL) sub-group classification were identified in the double reported and independently reviewed clinical report (reference standard). The two experienced clinicians reached a consensus in cases of disagreement. Regional values from BRASSv4.0 were normalised using the Pons region as reference to give regional amyloid uptake ratios (SUV_R). The mean SUV_R value across all regions was calculated (mean SUV_R). A coefficient within the linear registration model which correlated with amyloid load was identified for all scans ($A\beta$ -index). ROC curves were used to evaluate the most useful regions for accurate diagnosis, and threshold values were determined which minimised errors in diagnosis (false positive and false negative scans). **Results:** Of 194 18F-Florbetaben scans, 100 were classified as negative (BAPL1) and 94 as positive (8 BAPL2, 86 BAPL3). The optimum threshold for $A\beta$ -index and mean SUV_R was found to be 0.041 (AUC 0.989) and 0.74 (AUC 0.982) respectively for all data. Region-wise the left and right anterior cingulate, left and right frontal cortex, left and right lateral temporal cortex had best separation

between the positive and negative cohorts. Optimal SUV_R thresholds were found to be 0.79 (AUC 0.972, 0.962), 0.77 (AUC 0.985, 0.978) and 0.73 (AUC 0.985, 0.972) respectively. **Conclusion:** BRASSv4.0 performed well for 18F-Florbetaben scans giving very good agreement with the final clinical report and could be utilised to aid identification of positive and negative scans. A threshold value for mean $SUV_R=0.74$ (sensitivity 97%, specificity 96%) and $A\beta$ -index=0.041 (sensitivity 94% specificity 97%) is suitable for classification of typical 18F-Florbetaben studies. As shown, high sensitivity and specificity were obtained when adopting these recommended thresholds. **References:** None

Aim/Introduction: 18F-Florbetaben PET/CT is widely used to access amyloid burden in the central nervous system. Data analysis is usually based on static late acquisition (90 min. pi.). However, refinement with kinetic parameters extracted from dynamic acquisitions and compartmental analysis may be useful. This work aims to evaluate the correlation between late image SUVR and BP, DVR and K (parametric images) obtained from the kinetic compartmental analysis. **Materials and Methods:** Data from twenty-five patients with cognitive impairment (14 females and 11 males, mean age 68 ± 11 years, 11 amyloid positive and 14 amyloid negative) were retrospectively studied. Dynamic PET/CT scans were 45 minutes long and started immediately post-injection of 291 ± 24 MBq of 18F-Florbetaben. Late acquisitions started 90 minutes post-injection for 20 minutes. All studies were acquired in the Philips Vereos Digital PET/CT. Four kinetic methods were used: simplified reference region method (SRTM2), modified reference region method (MRTM2), Logan plot and Patlak plot. The parametric images BP-SRTM2, BP-MRTM2, DVR-Logan and K-Patlak were extracted from the dynamic acquisitions using the respective kinetic models. All images (including late acquisitions) were registered to Montreal Neurological Institute (MNI) space using deformable geometric transformations. Cerebellar gray matter was the reference region used both for kinetic models and SUVR computation. Voxelwise within subject and regional correlations were accessed between SUVR

images and the four parametric images. **Results:** Mean brain voxelwise within subject correlation between SUVR images and BP-SRTM2, BP-MRTM2, DVR-Logan and K-Patlak parametric images were 0.91 ± 0.04 , 0.94 ± 0.02 , 0.85 ± 0.09 and 0.78 ± 0.09 , respectively. Regarding the voxelwise regional correlation between SUVR images and the kinetic parametric images, similar correlation patterns were obtained in all cases. However, the following variations were found: higher correlations between the SUVR image and BP-SRTM2 and BP-MRTM2 images; very high correlation ($r > 0.90$) in most of the brain cortex; fair correlation ($0.4 < r < 0.7$) around the ventricles and fissures. **Conclusion:** Good voxelwise within correlation was obtained between SUVR images and all parametric images. The inferior correlation obtained with the K-Patlak does not mean worse performance than the BP, since there is no ground true of the real amyloid burden. They may measure different things. Regional voxelwise correlation, in general, was very high for most of the brain. The inferior correlation around the ventricles and fissures may be explained by imperfection of the image registration and the variability among the subjects in terms of brain atrophy in these regions. **References:** None

Dual-time-window dynamic [^{18}F]MK-6240 PET protocols for improved quantification in longitudinal studies and stroke patients

G. D. Kolinger¹, D. Vázquez García¹, R. Boellaard^{1,2}, T. G. Lohith³, E. D. Hostetler³, C. Sur³, A. Struyk³, M. Koole⁴;

¹Medical Imaging Center, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS, ²Department of Radiology and Nuclear Medicine, Amsterdam University Medical Centers, location VU Medical Center, Amsterdam, NETHERLANDS, ³Merck & Co., Inc., Kenilworth, NJ, UNITED STATES OF AMERICA, ⁴Department of Nuclear Medicine and Molecular Imaging, KU Leuven, Leuven, BELGIUM.

Aim/Introduction: Kinetic modeling of [^{18}F]MK-6240 brain uptake requires long dynamic PET scans up to 2 h due to slow kinetics in regions with high tau load. Therefore, dual-time-window (DTW) protocols were evaluated to reduce the total acquisition time and make [^{18}F]MK-6240 PET procedures more tolerable for patients. **Materials and Methods:** A plasma input two-tissue compartment model (2TCM) was fitted to 90min dynamic [^{18}F]MK-6240 PET scans using individual metabolite corrected plasma input functions from three healthy control (HC) and five mild cognitive impairment/Alzheimer's Disease (MCI/AD) subjects showing various levels of specific tracer binding. The 2TCM fit parameters were then used to simulate various 120 min time activity curves (TAC). Additional TACs for target regions based on PET-Braak stages were generated by varying the relative influx rate ($R1 = K1/K1_{\text{ref}}$ changes; range: -50% to 50%) while keeping $K1/k2$ constant to mimic

changes of blood flow and blood brain barrier functionality. Using cerebellar cortex as reference tissue, distribution volume ratios (DVR) were estimated with the reference Logan model (RefLogan). Standardized uptake value ratios (SUVR) were calculated for the 90-120min interval. To simulate different DTW protocols, four break intervals were introduced in the TACs: 20-90min, 30-90min, 40-90min and 50-90min. Breaks in the simulated DTW-TACs were filled using linear interpolation. DVRs from DTW-TACs were compared with 120min TACs. **Results:** For the HC subjects, DVR bias was less than 2.5% for all break intervals. For the MCI/AD subjects, DTW with 20-90min break had an average DVR bias up to 7% while shorter breaks resulted in less than 2.5% DVR underestimation. In terms of $K1$ changes, average SUVR bias ranged from -5.3% to 11% (regional standard deviation (SD) up to 14%), while 30-90min DTW DVR bias ranged from -5.9% to 1.3% (SD < 4% for all regions). **Conclusion:** The DTW protocol with 30-90min interval using RefLogan and cerebellar cortex as reference tissue is suitable for clinical routine allowing to estimate tracer influx rate in addition to binding parameter DVR. Compared to 90-120min SUVR, a 30-90min DTW quantification is less susceptible to reduced $K1$ values which can be expected in stroke patients and potentially in longitudinal MCI/AD studies. (This project is partially funded by European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 764458.)

Optimizing of the white matter reference region for synaptic density imaging with [^{11}C]UCB-J PET

N. Mertens¹, L. Michiels^{2,3}, B. Lacroix⁴, J. Mercier⁴, R. P. Maguire⁴, R. Lemmens^{2,3}, K. Van Laere¹, M. Koole¹;

¹Nuclear Medicine and Molecular Imaging, University Hospital and KU Leuven, Leuven, BELGIUM, ²UZ Leuven/KU Leuven, Neurology, Neurosciences, Experimental Neurology, Leuven, BELGIUM, ³VIB, Center for Brain & Disease Research, Laboratory of Neurobiology, Leuven, BELGIUM, ⁴UCB Pharma, Braine-l'Alleud, BELGIUM.

Aim/Introduction: [^{11}C]UCB-J PET, targeting synaptic vesicle glycoprotein 2A (SV2A), has been widely used as in vivo proxy for synaptic density. For non-invasive quantification, subcortical white matter (centrum semiovale - SO), restricted to white matter (WM) with only very limited partial volume effects (PVE), has been proposed as reference region (=method 1)[1]. However, in brain disorders with WM pathology this region reduces the potential to exclude pathological WM without affecting statistics. Therefore, we considered more expanded subcortical WM (=method 2) and cerebellar WM (=method 3) as candidate reference tissues while using a partial volume correction (PVC). **Materials and Methods:** 10 healthy volunteers (8M/2F; 27.6 ± 10.0 yrs)

underwent a 90-min dynamic [^{11}C]UCB-J PET/MR scan (GE Signa) with full arterial sampling under baseline and dosing conditions using a compound with selective affinity for SV2A. Six subjects received a second post dose scan. Cerebellar WM and SO were obtained by 3-tissue class segmentation of T1-weighted MR. WM standardized uptake values (SUV;60-90min post injection) in both regions was estimated by a four-tissue compartment model including white and gray matter within and outside of the predefined regions and applying Gaussian smoothing to mimic limited PET resolution. SUV of method 2 and 3 was compared to method 1. Baseline and post dose SUV was evaluated for displacement for both new methods. SUVR-based occupancy was compared with occupancy using full kinetic modeling. **Results:** PVC with a 6mm Gaussian filter resulted in no significance difference between baseline and post dose SUV in method 2, while a significant difference was detected in method 3 ($p < 0.05$). For the latter, increased smoothing of 7.5mm resulted in similar baseline and post dose SUV. For these filter settings, SUV was similar when using method 2 ($p > 0.05$; bias: $2.2\% \pm 7.8\%$) while higher bias was observed in method 3 ($p < 0.001$; bias: $-29.3\% \pm 22.5\%$). Bland-Altman revealed SUVR-based occupancies in line with method 1 [1] for method 2 ($p > 0.05$; bias: $3.5\% \pm 9.2\%$) and method 3 ($p > 0.05$; bias: $-2.3\% \pm 10.3\%$) but a higher variation in method 3. **Conclusion:** PVC allows the use of a more extensive and robust subcortical WM reference region (method 2) for non-invasive [^{11}C]UCB-J quantification, while the use of cerebellar WM (method 3) seems to be more challenging as it may produce bias. **References:** M. Reliability of occipital reference region in [^{23}I]-FP-CIT SPECT

T. Noponen^{1,2}, E. Jaakkola³, E. Mäkinen³, M. Eklund³, S. Nuutila³, K. Lindholm³, J. Joutsa³, M. Seppänen^{1,4}, V. Kaasinen³;

¹Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND, ²Department of Medical Physics, Turku University Hospital, Turku, FINLAND, ³Department of Clinical Neurosciences, Turku University Hospital and University of Turku, Turku, FINLAND, ⁴Turku PET Centre, Turku, FINLAND.

Aim/Introduction: Dopamine transporter (DAT) imaging using [^{23}I]-FP-CIT SPECT is a routine clinical method to examine patients with suspected Parkinson's disease (PD). Currently there is, however, no straightforward method to estimate the reliability of reference region values for specific binding ratio (SBR) calculations. In this study the stability of counts-per-voxel values of occipital cortex in DAT imaging were investigated. **Materials and Methods:**

[^{23}I]-FP-CIT SPECT imaging was carried out for 89 patients with clinically uncertain parkinsonian syndrome. The injected activity was 185 MBq and the imaging was started 3 h after injection with GE Infinia II Hawkeye or Siemens Symbia T6 SPECT/CT scanner using LEHR collimators. To prevent thyroid uptake, potassium perchlorate was given 30-60 min before the injection. Data were acquired using 120 projections with 30-s time per projection and matrix size of 128x128. The data were reconstructed with 3D OSEM based iterative algorithm including Chang's attenuation, collimator and Monte-Carlo-based scatter correction and Gaussian post-filtering. Regional specific-binding ratios (rSBR) were calculated with Brass software (Hermes Medical Solutions, Sweden). The patient data were automatically registered with the template volume using a traditional nine parameter transformation. Before registration the data were resampled to the template size and after the registration slices with zero intensity were removed. Then six constant size striatal volume-of-interests (VOIs) (the right and left anterior putamen, the right and left posterior putamen, the right and left caudate nucleus) and the reference occipital VOI were transferred from the template volume to the patient image. Average counts-per-voxel values of occipital reference VOIs and the correlation of those values with the striatal rSBRs were analyzed. **Results:** The occipital reference VOIs included in average 8200 ± 189 (mean \pm sd) voxels. The occipital mean (\pm sd) counts-per-voxel value was 116.4 ± 1.3 , sd being 1.1% of the mean. The correlation coefficients between occipital cortex counts-per-voxel values and rSBRs ranged from 0.00 to 0.14 meaning non-significant correlations ($p = 0.19 - 0.96$). **Conclusion:** Average occipital counts-per-voxel values in [^{23}I]-FP-CIT imaging have a low variation between patients. Non-specific [^{23}I]-FP-CIT binding in occipital cortex is therefore very constant and occipital cortex can be used as a reliable reference region in [^{23}I]-FP-CIT imaging. These findings also suggest that average counts-per-voxel values are useful as a quality control measure, e.g., to estimate the success of radiopharmaceutical injection in [^{23}I]-FP-CIT imaging in clinical routine. **References:** None

Multicenter intensity harmonization of dopamine SPECT studies without previous in-site scanner calibration

J. Silva-Rodríguez¹, A. Moscoso², A. Niñerola-Baizán³, J. Cortés⁴, B. Aradas-Cabado⁴, Á. Ruibal⁴, P. Aguiar¹;

¹Health Research Institute of Santiago de Compostela, Santiago de Compostela, SPAIN, ²Wallenberg Centre For Molecular and Translational Medicine, Gothenburg, SWEDEN, ³Nuclear Medicine Department, Hospital Clinic, Barcelona, SPAIN, ⁴Nuclear Medicine Department, University Hospital of Santiago de Compostela, Santiago de Compostela, SPAIN.

Aim/Introduction: Specific binding ratios (SBR) used for the

semiquantification in DAT-SPECT are largely dependent on the scanner, the used collimator, and the acquisition and reconstruction parameters [1]. Conventionally, SBRs are harmonized by calculating calibration factors for different camera-collimator combinations using physical phantoms [2]. Nevertheless, the harmonization of SBRs through image postprocessing is of great interest for several applications [3]. In this work, we study the feasibility of different implementations histogram matching (HM) as a post-processing only harmonization method. **Materials and Methods:** Striatum SBRs were quantified for 183 healthy controls (HC) and 470 Parkinson's Disease (PD) patients DAT-SPECT images acquired at 6 different gammacameras. HC SBRs variations across scanners were evaluated for unprocessed images and for four different implementations of HM: Conventional HM (HM), exact HM (EHM), bi-histogram HM (BiHM) and LogPow HM (LpHM). Potential changes in spatial information due to the image processing were assessed by evaluating the preservation of asymmetry and caudate-to-putamen ratios (CPRs) for the different methods on PD patients. Binary classification (HC vs. PD) for each of the proposed methods and for the unprocessed images was evaluated by calculating receiver operating curves (ROC). **Results:** While the median voxel-wise standard deviation for the original images was 13.6%, the evaluated methods reduced it to 4.5% (EHM), 5.5% (HM), 6.6% (LpHM) and 8.2% (BiHM). When focusing on SBR values, EHM and LpHM were able to eliminate all the significant difference between scanners (on 1 vs. 1 comparisons). EHM was the only method altering asymmetry values ($p < 0.001$) while all the methods presented significant changes on the CPRs (LpHM provided the best preservation). In terms of classification, EHM, HM and LpHM provided great improvements (AUC= 0.91-0.94) in comparison with unharmonized images (0.77). **Conclusion:** HM is a suitable methodology for the harmonization of HC and PD DAT-SPECT images, both visually and in terms of SBR. Of the tested implementations, LpHM was the most promising method both in terms of classification and spatial feature preservation. **References:** [1] Tossici-Bolt L, Dickson JC, Sera T, et al. Aim/Introduction: Quantification has been proposed as an aid to improve the accuracy and confidence of visual interpretation of amyloid PET scans of patients with suspected Alzheimer's disease (AD). However, the limited spatial resolution of PET scanners may hamper the diagnostic capacity of amyloid PET. This study assesses the impact of partial volume correction (PVC) on the diagnostic capacity of quantitative amyloid PET against clinical and biomarker-assisted diagnostic criteria for AD. **Materials and Methods:** A total of 864 participants from ADNI cohort (185 healthy controls (HC), 90 subjects with significant memory concern, 443 subjects with mild cognitive impairment, 146 patients with AD dementia) were included in this study. AV45-PET, T1-MRIs, CSF Abeta1-42, p-tau, and clinical diagnosis were available for all participants. PVC was done using a region-based method (Rousset et al, *JNM*, 1998). Global cortical amyloid was quantified for both non-PVC and PVC PET images normalized to the whole cerebellum as reference region. Optimal diagnostic cut-offs were calculated on the PVC and non-PVC corrected images using a Gaussian Mixture Model (GMM) by selecting the mean of the 'normal' Gaussian plus 2 standard deviations. Receiver Operating Curve (ROC) analysis was conducted for global SUVR to discriminate HC vs. AD dementia (clinical diagnosis of AD), as well as participants with Low vs. High pTau/Abeta1-42 ratios (cutoff=0.11, biomarker-assisted AD definition). The area under the curve (AUC) was measured, as well as the sensitivity at 90% specificity (Sens@90%Spec). **Results:** After applying PVC, global SUVR of the subjects with high amyloid level increased 12.73%±5.59% which is due to recovering the cortex signal spilled out to the white matter, while global SUVR of subjects with low amyloid burden decreased 26.11%±11.97% due to reducing activity contamination spilled in the cortex from the white matter regions. The optimal SUVR cutoff for clinical diagnostic classification decreased from 1.02±0.12 to 0.88±0.06 after PVC. In the ROC analysis, AUC for differentiating between HC and AD dementia significantly improved from

0.83(95%Confidence Interval: 0.78-0.87) to 0.87(0.83-0.91) ($p < 0.0001$) and the sensitivity at 90% specificity increased from 54.8% to 68.5%. Accordingly, the optimal SUVR cutoff for biomarker-assisted diagnostic classification decreased from 1.03 ± 0.08 to 0.89 ± 0.1 after PVC. For predicting high pTau/Abeta1-42 ratio, PVC significantly improved the AUC from 0.81(0.79-0.84) to 0.84(0.81-0.86) ($p = 0.003$) and the Sens@90%Spec was improved from 65.6% to 68.7%. **Conclusion:** Our results show that PVC can improve the diagnostic capacity of amyloid PET quantification using both clinical and biomarker-assisted criteria. These results suggest that quantification using PVC can serve as an aid to the visual interpretation of amyloid PET scans for diagnostic purposes. **References:** None

Matched-pair comparison of ^{68}Ga -PSMA-11 and ^{18}F -rhPSMA-7 PET/CT in patients with primary and biochemical recurrent prostate cancer

I. Rauscher¹, M. Krönke¹, A. Wurzer², H. Wester², W. Weber¹, M. Eiber¹;

¹Department of Nuclear Medicine, Technical University of Munich, Klinikum rechts der Isar, Munich, GERMANY, ²Department of Pharmaceutical Radiochemistry, Technical University of Munich, Klinikum rechts der Isar, Munich, GERMANY.

Aim/Introduction: ^{18}F -labeled prostate-specific membrane antigen (PSMA)-ligand positron emission tomography/computed tomography (PET/CT) is increasingly used for prostate cancer imaging due to several major principal advantages (image contrast/noise, logistics, positron range) compared to ^{68}Ga -PSMA-11. We aimed to evaluate frequency of non-tumor related uptake and tumor positivity comparing ^{68}Ga -PSMA-11 and recently introduced ^{18}F -rhPSMA-7 (providing low urinary excretion) in patients with both primary and recurrent prostate cancer (PC). **Materials and Methods:** This retrospective matched-pair comparison included 160 ^{18}F -rhPSMA-7 PET/CT and 160 ^{68}Ga -PSMA-11 PET/CT studies both for primary staging ($n=33$) and biochemical recurrence ($n=127$) matched by various clinical variables. All PET/CTs were reviewed by two nuclear medicine physicians in consensus. First, all PET positive lesions, defined as focal uptake above surrounding background and not physiological distribution, were identified. Then, lesions suspicious for PC were differentiated from lesions attributed to benign origin based on known pitfalls and information from CT. For each region, SUVmax of the lesion with the highest PSMA-ligand uptake was noted. Tumor positivity rates were determined and SUVmax were compared separately for ^{68}Ga -PSMA-11 and ^{18}F -rhPSMA-7. **Results:** In total, ^{18}F -rhPSMA-7 PET and ^{68}Ga -PSMA-11 revealed 532 and 293 PSMA-ligand positive lesions, respectively. The absolute number of lesions attributed to benign origin was 3.3 times higher for ^{18}F -rhPSMA-7 PET compared to ^{68}Ga -PSMA-11 PET (351 vs. 105 lesions, respectively), whilst the distribution of their etiology was relatively similar (46%, 27%, 20% in ^{18}F -rhPSMA-7 vs. 30%, 40%, 20% in ^{68}Ga -PSMA-11 for ganglia, unspecific LN and bone lesions, respectively). All primary tumors were positive in ^{18}F -rhPSMA-7 and ^{68}Ga -PSMA-11 ($n=33$ each) while a slightly higher number of metastatic lesions was observed with ^{68}Ga -PSMA-11 in primary staging (16 for ^{18}F -rhPSMA-7 and 21 for ^{68}Ga -PSMA-11). In biochemical recurrence a similar number of malignant lesions (132 for ^{18}F -rhPSMA-7 and 134 for ^{68}Ga -PSMA-11) were detected. SUVmax of all malignant lesions was significantly higher ($p < 0.01$) in ^{18}F -rhPSMA-7 PET (SUVmax 26.7 ± 28.8 for ^{18}F -rhPSMA-7 PET and 17.9 ± 18.7 for ^{68}Ga -PSMA-11 PET, respectively) while SUVmax of the urinary bladder was significantly lower in ^{18}F -rhPSMA-7 PET (SUVmax 3.8 ± 1.9 for ^{18}F -rhPSMA-7 PET and 11.2 ± 14.0 for ^{68}Ga -PSMA-11 PET, respectively). **Conclusion:** While tumor positivity rate is consistently high for ^{18}F -rhPSMA-7, a considerably higher number of lesions with increased PSMA-ligand uptake attributed to benign lesions is present compared to ^{68}Ga -PSMA-11. However, after adequate reader training, physicians should be well equipped to distinguish likely malignant lesions from those that are most probably benign, while fully exploiting the logistical advantages of ^{18}F -labeled PSMA-ligands. **References:** None

OP-333**Prospective Single Institution Study of F18-DCFPyL PET/CT in Biochemically Recurrent Prostate Cancer: An Analysis of Lesions Detection and Localization**

A. Iagaru, H. Song, H. Duan, C. Harrison, K. Guja, N. Hatami, B. Franc, J. Nguyen, F. Moradi, C. Mari, G. Davidzon;
Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: F18-DCFPyL, a promising PET agent targeting prostate specific membrane antigen (PSMA), is prospectively evaluated in a single academic center for detecting recurrent lesions in prostate cancer patients with biochemical recurrence (BCR). **Materials and Methods:** We prospectively enrolled 170 men (49–91 years old, mean \pm SD: 69.6 \pm 8.0) with biochemical recurrence (PSA median 2.27 ng/mL, range 0.12 to 698.4) after primary definitive treatment with prostatectomy (67%), radiotherapy (33%) or both (22%). All patients were scanned using a SiPM-based PET/CT (GE Discovery MI). The F18-DCFPyL positive lesions compatible with prostate cancer were evaluated by two independent readers. Impact of F18-DCFPyL PET/CT on patient management was recorded from clinical chart review. **Results:** F18-DCFPyL PET/CT had an overall positivity rate of 84% (142 scans), which increased with higher prostate specific antigen (PSA) levels (ng/mL): 67% (PSA<0.5), 71% (0.5 \leq PSA<1), 93% (1 \leq PSA<2), 93% (2 \leq PSA<5) and 98% (PSA \geq 5), respectively. In the cohort who underwent prostatectomy, F18-DCFPyL PET/CT had higher positivity rate in patients with shorter PSA doubling time (PSAdt) (95% in PSAdt 0–3 months vs. 56% in PSAdt > 12 months, P<0.01). No difference of F18-DCFPyL positivity rate was observed in post-radiation patients with different PSAdt, nor were there differences between patients with low grade (Gleason 6) or higher-grade prostate cancer (Gleason 7–10). 21 patients (12%) had lesions in the prostate bed only and 50 patients (29%) had oligometastatic disease (1–3 lesions), making them candidates for locally targeted therapy. We identified a total of 1573 F18-DCFPyL positive lesions, including 57 lesions in the prostate bed, 316 pelvic and 506 extra-pelvic lymph nodes, approximately 594 osseous lesions, including 5 patients with diffuse osseous metastases, and 100 lesions in other organs (most commonly in the lungs). 105 out of 170 patients (62%) had change in treatment after F18-DCFPyL PET and, most noticeably, 57 of these patients (34% total) had lesions only localized on F18-DCFPyL PET/CT despite negative conventional imaging. **Conclusion:** F18-DCFPyL PET/CT holds great potential to be a “one-stop shop” diagnostic tool in the work-up of BCR prostate cancer, with high (62%) impact on the management of these patients. **References:** None

OP-334**The role of ⁶⁴Cu-PSMA PET/CT in the early diagnosis of prostate cancer recurrence: preliminary results on a prospective cohort of 127 patients**

S. Annunziata, R. Sciuto, S. Rea, A. Annovazzi, R. Pasqualoni, S. Bergomi, L. Romano, C. Mazzone, S. Di Traglia, G. Sanguineti;
IRCCS Regina Elena National Cancer Institute, Rome, ITALY.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) positron emission tomography/computed tomography (PET/CT) emerged as an accurate imaging method for prostate cancer (PC). Until now, the most investigated PSMA tracers are labelled with ⁶⁸Ga. Recent studies on small series have demonstrated the potential of ⁶⁴Cu-labeled PSMA in patients with recurrent PC. ⁶⁴Cu-PSMA may also offer the possibility of pre-therapeutic dosimetry in the theragnostic approach. The aim of this study is to investigate the diagnostic role of ⁶⁴Cu-PSMA PET/CT in a large prospective cohort of PC patients with early recurrence of disease. **Materials and Methods:** The study was approved by the local Ethical Committee as a prospective trial on a cohort of 162 patients with PC biochemical recurrence (BCR). The primary endpoint was to verify the diagnostic accuracy of ⁶⁴Cu-PSMA PET/CT compared to ¹⁸F-Choline PET/CT in the early identification of PC recurrence with low values of prostate specific antigen (PSA). All patients underwent to ⁶⁴Cu-PSMA-617 and ¹⁸F-choline PET/CT in a maximum time of two months. ⁶⁴Cu-PSMA and ¹⁸F-Choline results were compared and verified by histology, other imaging, or on follow-up. Thereafter, patients underwent to secondary treatment (target radiotherapy or surgery as appropriate). The clinical impact of ⁶⁴Cu-PSMA was discussed in a multidisciplinary setting. **Results:** A preliminary analysis was performed on 127 patients. At the time of ⁶⁴Cu-PSMA PET/CT, PSA values ranged from 0,17 ng/ml to 3,2 ng/ml with a median value of 0,76 ng/ml. Patient-based PET/CT sensitivity was of 57% for ¹⁸F-choline and of 89% for ⁶⁴Cu-PSMA, respectively. ⁶⁴Cu-PSMA PET/CT identified 209 lesions while ¹⁸F-choline PET/CT identified 122 lesions, showing ⁶⁴Cu-PSMA higher sensitivity (41% more identified lesions than ¹⁸F-choline). Small local recurrence (up to a minimum of 3 mm) were identified by ⁶⁴Cu-PSMA in 60% of cases, while only 20% identified by ¹⁸F-Choline. Node metastasis sensitivity was of 15% and 35% for ¹⁸F-Choline and ⁶⁴Cu-PSMA, respectively. Moreover 15% of bone lesions showed by ⁶⁴Cu-PSMA PET/CT were missed by ¹⁸F-choline. ⁶⁴Cu-PSMA specificity was higher than ¹⁸F-Choline, differentiating aspecific nodal and bone uptake in more than 5% of cases. ⁶⁴Cu-PSMA PET/CT changed clinical management in more than 90% of cases, guiding treatment choice and target therapy. **Conclusion:** ⁶⁴Cu-PSMA PET/CT is an accurate imaging tool in a large prospective cohort of patients with early recurrence of PC, showing higher sensitivity than ¹⁸F-Choline PET/CT and

significantly impacting on further clinical management. A future role of ^{64}Cu -PSMA as theragnostic agent is worth exploring. **References:** None

In-vivo D'Amico score for predicting low-vs-high risk and biochemical recurrence in prostate patients from PET/MRI with machine learning

L. Papp, C. P. Spielvogel, D. Krajnc, M. Grahovac, T. Beyer, M. Hartenbach, M. Hacker;
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Combined PET/MR imaging is a useful approach to localize and characterize prostate cancer lesions. Nonetheless, the pre-operative diagnosis of prostate cancer is still performed by the D'Amico score, which builds on clinical stage, PSA and biopsy-based Gleason scoring. Our goal was to establish an in-vivo D'Amico score for post-operative and biochemical risk predictions utilizing PET/MRI risk scores provided by machine learning (ML) as the replacement of biopsy-derived risk scores. **Materials and Methods:** This study included 74 multi-parametric prostate PET/MRI cases with ^{18}F -FMC, ^{18}F -FMC+ ^{68}Ga -PSMA^{HBED-CC} (dual-tracer) PET, and T2, ADC, iAUC, KEP, Ktrans and Ve MRI images. Based on annotated, full-mount histopathological slices, 120 lesions representing different Gleason patterns were delineated and annotated as of the histopathological data (Hermes Nuclear Diagnostics, Sweden). Extraction of 56 radiomics features from PET/MR image sets was performed for all 120 lesions. Ensemble learning was utilized to build lesion-specific low ($\leq G3$) vs. high ($\geq G4$) as well as benign ($< G3$) vs malign ($\geq G3$) risk probability predictors (LH and BM respectively). The summed LH and BM prediction probabilities across the two largest lesions were categorized as +3 (BM+LH>T & LH>BM), +2 (BM+LH>T & LH<BM) and +1 (BM+LH<T) risk score, as the replacement of the biopsy Gleason +3, +2 and +1 risk scores in the D'Amico scheme. 1000-fold Monte Carlo (MC) cross-validation was performed to estimate the performance of the in-vivo D'Amico score. For all the MC folds, T=0.3 and T=0.9 were selected based on the first MC fold training data analysis to predict in-vivo D'Amico post-operative low-high risk (IPR) and in-vivo biochemical recurrence (IBCR) no-yes scores respectively. **Results:** IPR prediction performance values were SENS 83%, SPEC 88% and ACC 84% compared to reference D'Amico SENS 74%, SPEC 94% and ACC 80%. The IBCR performance values were SENS 100%, SPEC 81% and ACC 86% compared to reference D'Amico SENS 78%, SPEC 65% and ACC 69%. **Conclusion:** We have presented a novel in-vivo D'Amico score utilizing PET/MRI-derived ML risk values to predict post-operative risk as well as biochemical recurrence in prostate patients. Our results indicate that such predictions can be improved alternatives of the gold-standard D'Amico score system. **References:** None

OP-336

The impact of 18F-Choline (FCH) PET/MRI on PSA response in patients with oligometastatic prostate cancer (PCa)

L. Evangelista¹, G. Cassarino¹, C. Lacognata², S. Da Pozzo², D. Cecchin¹, P. Zucchetta¹;
¹University of Padua, Padua, ITALY,
²Hospital of Padua, Padua, ITALY.

Aim/Introduction: Oligometastatic disease (OMD) in PCa represents a clinical condition that significantly influences the optimal choice of treatment. PET/MRI with radiolabeled PSMA and Choline (FCH) has showed a high detection rate in patients with an early (i.e. PSA levels ≤ 1 ng/mL) recurrence of PCa. The aim of the study was to assess the impact of FCH PET/MRI on PSA response in patients with oligometastatic PCa. **Materials and Methods:** We retrospectively analyzed a cohort of 108 patients who underwent FCH PET/MRI for biochemical recurrence of PCa. The inclusion criteria were: 1) PSA ≤ 1 ng/mL at PET time; 2) OMD defined as < 5 lesions at PET/MRI scan; and 3) available follow-up data of at least 6 months after PET. T2-weighted turbo spin-echo, T1-vibe after contrast enhancement, T2-haste, T1-vibe fat saturated and diffusion weighted image (DWI) sequences were used for the MRI component. PET images were acquired using a dedicated (>20 min) acquisition of the pelvis, followed by a whole-body scan. Attenuation correction was performed using a mu-map obtained from a MR sequence with a 2-point Dixon fat and water separation for a segmentation into 4 tissue classes (air, lungs, fat, and soft tissue). All images were revised jointly by two nuclear medicine physicians and a radiologist. **Results:** Out of 108 patients, 67 (62%) were eligible. Fifty-five patients presented with OMD at PET/MRI. Nine patients were lost at follow-up. In 46 patients sixty lesions were detected: 39 in the prostatic fossa (20 at MRI and 19 at PET/MRI), 20 in local and distant lymph nodes (2 at MRI, 12 at PET and 6 at PET/MRI) and 1 lesion in bone visible only at MRI. Twenty-six (57%) patients were treated with radiotherapy (RT), 9 (20%) with hormonal therapy (HT), 3 (6%) with a combined therapy (RT+HT) and 8 (17%) underwent a PSA surveillance. At follow-up, PSA levels decreased in 35 (76%) patients mostly in those undergoing RT or RT+HT. In the subset of patients with a reduction of PSA levels, PET/MRI detected more lesions than MRI alone (87% vs 71%). **Conclusion:** FCH PET/MRI showed an higher detection rate than MRI alone in oligometastatic PCa patients, with a PSA ≤ 1 ng/mL. Therefore, It could be used as a tool to optimize treatments in OMD. **References:** 1. Kranzbuhler et al. J Nucl Med 2020; 61:194-201 2. Evangelista et al. Nuclear Med Comm 2018; 39:260-7.

OP-337**Clinical utility of PET/CT with ¹⁸F-FSU880 in patients with biochemical recurrence after curative treatment of prostate cancer**

Y. Nakamoto, Y. Shimizu, T. Ishimori, T. Otani, T. Saga;
Kyoto University, Kyoto, JAPAN.

Aim/Introduction: We have developed a new ¹⁸F-labeled compound, called ¹⁸F-FSU880 [1], for targeting prostate-specific membrane antigen with higher affinity, and our feasibility assessment has been already reported [2]. The purpose of this study was to investigate the clinical utility of PET/CT with ¹⁸F-FSU880 for detecting suspected recurrent lesions in biochemical recurrence after curative treatment of prostate cancer. **Materials and Methods:** A total of 14 male patients (58-79 yr, mean 69 yr) were assessed who had undergone curative treatment for prostate cancer by surgery (n=8) or radiation therapy (n=6), who had been suspected of having recurrence due to increase of serum PSA level (0.266 - 11.74 ng/mL), and for whom conventional imaging was inconclusive. All patients were scanned using a combined PET/CT scanner twice one hour and three hours after administration of ¹⁸F-FSU880. PET/CT images were interpreted visually. Quantitative values in suspected lesions and physiological uptake were evaluated. **Results:** FSU880-PET/CT demonstrated positive findings in 8 of 14 patients (57%); however, one patient was finally diagnosed to have hemangioma in the rib, i.e. false positive. Other suspected findings, suggesting bone metastasis (n=2), lymph node metastasis (n=5), lung metastasis (n=1), and local recurrence (n=1) in seven patients were considered recurrence/metastasis, based on clinical follow-up. The detection rates for suspected lesions were comparable between 1-hr and 3-hr post-injection, while maximum standardized uptake value (SUVmax) tended to be higher in 3-hr images (5.3-26.5) than in 1-hr post-injection (2.7-15.2). Positive results were obtained in all patients when their PSA levels exceeded 2 ng/mL. Physiological uptake was seen in lacrimal glands (mean SUVmax at 1h, mean SUVmax at 3h = 9.4, 11.8), parotid glands (12.1, 15.4), submandibular glands (12.2, 16.0), sublingual glands (6.3, 7.3), liver (5.3, 6.8)*, spleen (4.1, 3.3), renal cortex (21.2, 22.9), and duodenum (7.4, 10.9), and they increased over time except in the spleen. *: SUVmean **Conclusion:** Our preliminary data suggest that ¹⁸F-FSU880 would be a new promising tracer for detecting metastasis/recurrence in patients with biochemical recurrence of prostate cancer. **References:** [1] Harada N, Kimura H, Onoe S, et al. Synthesis and biologic evaluation of novel ¹⁸F-labeled probes targeting prostate-specific membrane antigen for PET of prostate cancer. *J Nucl Med.* 2016; 57: 1978-1984. OP-338**Impact of Targeted Molecular Imaging with ¹⁸F-PSMA-1007 and ⁶⁸Ga-PSMA-11 PET/CT in Multimodal Evaluation of Local Recurrence of Prostate Cancer**

L. Dronka^{1,2}, M. Radzina^{1,2}, M. Tirane^{1,2}, L. Zemniece¹, M. Kalnina^{1,3}, L. Roznere^{2,3}, I. Briede⁴, V. Lietuvielis⁵, A. Freimanis⁵, E. Vjaters⁶;
¹Institute of Radiology, Pauls Stradins Clinical University Hospital, Riga, LATVIA, ²Riga Stradins University Radiology Research Laboratory, Riga, LATVIA, ³Riga Stradins University Nuclear Medicine Clinic, Riga, LATVIA, ⁴Center of Patology, Pauls Stradins Clinical University Hospital, Riga, LATVIA, ⁵Center of Urology, Riga East University Hospital, Riga, LATVIA, ⁶Center of Urology, Pauls Stradins Clinical University Hospital, Riga, LATVIA.

Aim/Introduction: Recurrent prostate cancer (PCa) can be assessed by magnetic resonance imaging (MRI) and positron emission tomography (PET/CT). The aim was to compare the diagnostic tools - MRI, ⁶⁸Ga-PSMA-11 and ¹⁸F-PSMA-1007 PET/CT for evaluation of local recurrence. **Materials and Methods:** In this prospective study were included 54 patients (32 patients underwent ⁶⁸Ga-PSMA-11 PET/CT and 22 patients - ¹⁸F-PSMA-1007 PET/CT) with biochemical recurrent PCa (with PSA ≥0.2 ng/ml) who were previously treated with radical prostatectomy and/or radiation therapy of prostate bed. The probability of a ⁶⁸Ga-PSMA-11 or ¹⁸F-PSMA-1007 PET/CT scan suggestive of pathology was compared with the MRI Imaging results. The results of MRI and PET/CT were compared using reference standard that was based on clinical data of patient and/or results of histology material and/or follow-up information. **Results:** Total 54 patients were divided in two groups - ⁶⁸Ga-PSMA-11 and ¹⁸F-PSMA-1007 group. Mean patient age in groups - 63±7 vs. 66±7 years, age range 49-81 vs. 52-77. Mean PSA value at the time of the studies were 2.27 ng/ml vs. 1.97 ng/ml, median PSA 1.07 ng/ml vs. 0.86 ng/ml. Median Gleason score 7 vs. 7, range 5-10 vs. 5-9. PSA median doubling time 4.63 months vs. 5.73 months. PET/CT ⁶⁸Ga-PSMA-11 local recurrence findings were in 38% (n=12/32) patients, in MRI - 37 % (n=11/30). The mean SUVmax value of recurrent local lesions was 5.3. Against the standard of reference, sensitivity, specificity, accuracy, PPV and NPV for local recurrence of PET/CT were 63.6 %; 73.7%; 77.8; 58.3% and 77.8%, respectively. MRI reached 90.9%; 94.7%; 92.3%, 90.9% and 94.7% respectively. In PET/CT ¹⁸F-PSMA-1007 group local recurrence findings were detected by PET/CT in 41 % (n=9/22), in MRI - 30% (n=6/20). The mean SUVmax value of recurrent local lesions was 7.1. Sensitivity, specificity, accuracy, PPV and NPV for ¹⁸F-PSMA-1007 PET/CT and MRI were 100%, 92.9%, 95.5%, 88.9%, 100% and 62.5%, 91.7%, 80%, 83.3%, 78.6%, respectively. **Conclusion:** Our comparative study results revealed ¹⁸F-PSMA-1007 PET/CT as superior diagnostic tool to MRI and ⁶⁸Ga-PSMA-11 PET/CT for evaluation of local recurrence. Low urinary background clearance of ¹⁸F-PSMA-1007 provide higher diagnostic value

of PET/CT in evaluation of the prostate bed and pelvis in recurrent PCa patients. **References:** None

OP-339

Parameters Predicting [¹⁸F]PSMA-1007 scan Positivity and Type and Number of Detected Lesions in patients with Biochemical Recurrence of Prostate Cancer

N. Ahmadi Bidakhvidi¹, A. Laenen², S. Jentjens¹, C. M. Deroose¹, K. Van Laere¹, C. Berghen³, K. Haustermans³, S. Joniau⁴, W. Everaerts⁴, K. Goffin¹;

¹Nuclear Medicine, University Hospitals Leuven, Leuven, BELGIUM, ²Interuniversity Institute for Biostatistics and Statistical Bioinformatics, Leuven, BELGIUM, ³Radiation Oncology, University Hospitals Leuven, Leuven, BELGIUM, ⁴Urology, University Hospitals Leuven, Leuven, BELGIUM.

Aim/Introduction: Biochemical recurrence of prostate cancer (PCa) after primary treatment with curative intent occurs in 30-50% of patients within 10 years. Detection of the site of recurrence using PSMA-PET/CT is important to guide further treatment. The aim of this study was to evaluate the positivity rate of [¹⁸F]PSMA-1007-PET/CT in patients with biochemically recurrent PCa and identify parameters that predict [¹⁸F]PSMA-1007-PET/CT positivity and the type and number of identified lesions. **Materials and Methods:** This monocentric retrospective study included 137 PCa patients with biochemical recurrence who underwent one or more [¹⁸F]PSMA-1007-PET/CT scans between August 2018 and June 2019. [¹⁸F]PSMA-1007-PET/CT was considered positive if at least one PET-positive lesion was identified (focal non-physiological tracer uptake above local background with high suspicion of malignancy). PET-positive lesions were classified as local recurrence, lymph node, bone or soft tissue metastases. A maximum of 10 PET-positive lesions per lesion type were analysed. We evaluated the influence of serum PSA, PSA doubling time and velocity, Gleason score, neo-adjuvant treatment, primary treatment, PSA after radical prostatectomy (RP), adjuvant radiation therapy (RT), salvage therapy (surgery or RT), ongoing/prior androgen deprivation therapy (ADT), injected activity and tracer uptake-time on scan positivity and type and number of detected lesions using logistic regression analysis (binary outcomes) and Poisson models (count-type outcomes). **Results:** We included 175 [¹⁸F]PSMA-1007-PET/CTs after RP (78%), RT (9%), ADT (7%), brachytherapy (5%) and high intensity focused ultrasound (1%) as primary treatment. Median PSA and PSA velocity at moment of PET/CT were 1.6 ng/ml and 0.10 ng/ml/month, respectively. Positivity rate was 80%. PSA velocity and PSA at moment of PET/CT were significant predictors of scan positivity and were also significantly correlated with the number of detected lymph nodes, bone and soft tissue metastases. Salvage therapy was a significant negative predictor of local recurrence. Higher Gleason score was a positive predictor of the number of

bone and soft tissue metastases. Increased PSA level after RP was significantly correlated with the number of bone metastases. Ongoing/prior ADT was significantly correlated with detection of bone metastases and the number of lymph node/soft tissue metastases. The other parameters were not correlated with scan positivity or number/type of detected lesions. **Conclusion:** [¹⁸F]PSMA-1007-PET/CT showed a high positivity rate in patients with biochemically recurrent PCa. PSA velocity and PSA value at moment of scan were significant predictors of scan positivity. Together with parameters of the patient's PCa history, they also predicted the number of detected metastases. **References:** None

OP-340

Management impact and detection rate of 18F- Prostate-Specific Membrane Antigen (18F-PSMA) PET/CT imaging for biochemically recurrent prostate cancer

E. Panagiotidis, A. Paschali, A. Klampatsas, A. Pipintakou, A. Makridou, V. Chatzipavlidou; Theagenio Cancer Center, Thessaloniki, GREECE.

Aim/Introduction: To determine the impact on clinical management of patients with biochemical recurrence (BCR) of prostate cancer using 18F- Prostate-Specific Membrane Antigen (18F-PSMA) with positron emission tomography-computed tomography (PET-CT). **Materials and Methods:** Sixty-eight (68) patients (pts) had management plans documented at a multidisciplinary meeting before 18F-PSMA PET-CT. Three group of patients underwent PET-CT scans 90-min post-injection of 18F-PSMA (mean 171 ± 31.2 MBq), 47 pts had radical prostatectomy, (Group 1), 1 pts had implementation of radioactive I125 (Group 2) and 20 pts had radiotherapy in the prostatic bed (Group 3) (median age 71years, range : 50-82). Post-scan management plans, TNM score, Gleason score, prostate-specific antigen (PSA), PSA velocity and PSA doubling time (PSAdt) were recorded. **Results:** In total, 262 pathological lesions depicted by PET/CT. 32/68 (47%) pts had management changed. Patients with PSA < 4 µg/L had more frequent management changes (18/32, 56.25%) compared with PSA > 4 µg/L (14/32, 43.75%). Forty out of 68 (59%) scans were positive. Positivity rate increased with PSA level (PSA < 0.5 µg/L, 0%; PSA 0.5-1.0 µg/L, 25%; PSA 1.0-5.0 µg/L, 59%; PSA 5.0-10.0 µg/L, 93%), PSAdt of < 6 months (59% vs 46%) and Gleason score > 8 (81% vs 53%). **Conclusion:** 18F-PSMA PET-CT influences clinical management in significant numbers of patient with biochemical recurrent prostate cancer. Therapeutic alteration is associated with PSA and Gleason score, despite lower scan positivity rates at low PSA levels < 0.5 µg/L. **References:** None

OP-341**18F-Choline PET/CT in the evaluation of high-risk prostate cancer outcome: an explorative study on radiomics feature classification for prediction of disease progression**

P. Alongi¹, A. Stefano², A. Comelli³, R. Laudicella⁴, G. Arnone⁵, S. Barone⁵, M. Midiri⁵, G. Russo²;

¹Istituto San Raffaele G. Giglio, Cefalù PA, ITALY, ²Institute of Molecular Bioimaging and Physiology, National Research Council (CNR), Cefalù PA, ITALY, ³Department of Electrical and Computer Engineering, Georgia Institute of Technology, Atlanta, GA, UNITED STATES OF AMERICA, ⁴Department of Biomedical and Dental Sciences and of Morpho-functional Imaging, Nuclear Medicine Unit, University of Messina, Messina, ITALY, ⁵University of Palermo, Palermo, ITALY.

Aim/Introduction: The aim of the study was to investigate the potential application of texture analysis of Cho-PET/CT images in prostate cancer and to propose a model incorporating a new machine-learning radiomics model to select PET imaging features able to predict disease progression in prostate cancer (PCa) in patients with the same class of risk at re-staging. **Materials and Methods:** We retrospectively analyzed 94 high-risk PC patients who underwent restaging Cho-PET/CT after first-line therapy. Follow-up data about clinical, laboratory and radiological exams were recorded for a time of 24 months after PET. PET studies and related structures containing volumetric segmentation using an active contour method were imported in LifeX toolbox to extract 51 imaging features from each lesion by defining subgroups as follow: primary or local relapse; lymph-nodal disease; bone metastasis; whole sample). In addition, PSA and Gleason score features were considered (51+2=53 features). Due to the redundancy, heterogeneity and uncertainty of the information represented by radiomics features, a novel statistical system based on correlation matrix and point-biserial correlation coefficient has been implemented for feature reduction and selection, while Discriminant Analysis (DA) was used as a method for feature classification in a whole sample (all lesions in 94 patients) and in sub-group analysis for T, N and M. **Results:** The most Cho-PET avid lesions (for T, N and M = 134 lesions) were examined for texture analysis in the whole group (N=94): 53 features were extracted for each lesion for a total of 7102. After statistical reduction and selection in the whole group, 2 features (HISTO_Entropy_log10; HISTO_Energy_Uniformity)) resulted able to discriminate the occurrence of disease progression at follow-up, obtaining the best performance in DA classification and improving the FU status assessment (Sensitivity 47.11%, Specificity 76.54%, Precision 46.78%, and Accuracy 67.66%). In the sub-group analysis, the same method demonstrates the best performance in DA classification for T (N=38) in 3 features (SUVmin; SHAPE_Sphericity; GLCM_Correlation)

with Sensitivity 91.59%, Specificity 84.06%, Precision 79.14, and Accuracy 86.99%, for N (N=44) in 2 features (HIST= Energy Uniformity; GLZLM_SZLGE) with Sensitivity 68.09%, Specificity 91.42%, Precision 83.00%, and Accuracy 82.59%, and for M (N=52) 2 Features (HISTO_Entropy_log10 - HISTO_Entropy_log2) with Sensitivity 64.39 %, Specificity 74.60 %, Precision 40.55 %, and Accuracy 72.52 %. **Conclusion:** The presented artificial intelligence model demonstrated to be feasible and potentially useful to select Cho-PET features for T , N and M with valuable association with High-Risk PCA patients' outcomes. **References:** None

OP-342**PET metabolic tumor volume as a prognostic factor in childhood rhabdomyosarcoma: a cohort study**

H. Fayolle¹, N. Jehanno², V. Cances-Lauwers³, M. Castex⁴, D. Orbach⁵, P. Payoux⁶, A. Hitzel¹;

¹Nuclear Medicine Department, CHU Purpan, Toulouse, FRANCE, ²Nuclear Medicine Department, Institut Curie, Paris, FRANCE, ³Epidemiology and Public Health department, Toulouse, FRANCE, ⁴Pediatric Hemato-oncology Department, Toulouse, FRANCE, ⁵IREDO Oncology Center, PSL University, Institut Curie, Paris, FRANCE, ⁶ToNIC, INSERM, Toulouse, FRANCE.

Aim/Introduction: Childhood rhabdomyosarcoma (RMS) is a rare and serious disease in which evaluation at diagnosis is essential for therapeutic management. We studied the prognostic value of the metabolic tumor volume measured from a pre-treatment 18F-FDG PET scan in this disease. **Materials and Methods:** This multicenter study examined the prognosis accuracy of the metabolic tumor volume at diagnosis of patients with RMS from the last ten years, for overall survival and progression-free survival. Then we looked at of other prognostic parameters such as SUVmax, SUVpeak or bone lysis. **Results:** A total of 101 patients were included in 6 French university hospitals. In univariate analysis a metabolic volume greater than 200 cm³ was predictive of overall survival ((HR = 3.47 [1.79; 6.74], p <0.001) and progression-free survival (HR = 3.03 [1.51; 6.07], p=0.002). SUVmax, SUVpeak and bone lysis were prognostic of overall survival (p=0.005, p=0.004 and p=0.007) and progression-free survival (p=0.029, p=0.019 and p=0.015). In the multivariate analysis a metabolic volume greater than 200 cm³ was predictive of overall survival (HR= 2.642 [1.272;5.486], p=0.009) and progression-free survival (HR=2.707 [1.322;5.547], p=0.006) after adjustment for confounding factors including SUVmax, SUVpeak and

bone lysis. **Conclusion:** 18F-FDG PET imaging is currently used for RMS disease staging. In our study, a metabolic tumor volume greater than 200 cm³, SUVmax, SUVpeak and bone lysis in the pre-treatment assessment were poor prognostic factors for overall survival and progression-free survival. Children presenting tumors with a metabolic volume of more than 200 cm³ had approximately 2.6 and 2.7 times the risk of death and progression, respectively, after adjusting for confounding factors. It should be worth validating the prognostic advantage of measuring the metabolic volume on a larger patient population. **References:** 1. OP-343

Risk Stratification Using 18 FDG PET/CT In High Risk Neuroblastomas :Is It Comparable With 131I-Metaiodobenzylguanidine (MIBG)

C. Bongulwar, S. Shah, N. Purandare, A. Agrawal, V. Rangarajan; Tata Memorial Hospital, Mumbai, INDIA.

Aim/Introduction: Radioiodinated metaiodobenzylguanidine (mIBG) is an established imaging modality in neuroblastoma. Semiquantitative scoring -SIOOPEN [International Society of Pediatric Oncology Europe Neuroblastoma Group] and Modified Curie using radiolabelled MIBG are used for prognostication in high risk neuroblastomas. The present study aims to use 18F -fluorodeoxyglucose (FDG) for semiquantitative scoring and compares it with mIBG scores thereby validating it for risk stratification. **Materials and Methods:** Data of 90 patients were retrospectively analyzed diagnosed to have stage IV high risk neuroblastoma. MIBG scans were assessed according to the SIOOPEN and the modified Curie scoring method. Similarly 18 F FDG PET/CT scans were also scored using the semi quantitative systems. The paired scans were compared at initial staging and end of induction therapy. A Curie score of ≤ 2 and > 2 and a SIOOPEN score ≤ 4 and > 4 (best cutoff) described in previous studies was used to classify these scans into low and high risk and subsequently correlated with the clinical course of the disease. **Results:** At initial staging there was a statistically significant difference between the Curie-FDG

scores of (10.94 ± 10.0) as compared to mIBG score of (7.99 ± 9.00) with an increase of 2.94 with $p=0.001$. Also for SIOOPEN -FDG scores of (20.00 ± 26.00) against mIBG (11.72 ± 20.00) with a difference of 8.27 and $p=0.12$. At end of induction therapy there was no statistically significant difference ($p > 0.01$) between the Curie FDG and MIBG scores. Using the standard cut off values for Curie and SIOOPEN scores 18 patients show discordance out of which 6 patients (33%) showed disease progression or death. **Conclusion:** Modified CURIE score and SIOOPEN score using 18F FDG shows an incremental value over MIBG score and can be correlated with the clinical outcome of the disease. The Modified Curie and SIOOPEN score can be validated using 18 F FDG PET/CT establishing their role in risk stratification. **References:** Borris decoralis et al Boris Decarolis, Christina Schneider, Barbara Hero, Thorsten Simon, Ruth Volland, Frederick Roels, Markus Dietlein, Frank Berthold, and Matthias Schmidt Iodine-123 Metaiodobenzylguanidine Scintigraphy Scoring allows Prediction of Outcome in Patients With Stage 4 Neuroblastoma: Results of the Cologne Interscore Comparison Study 2013 -JCO Matthey KK, Edeline V, Lombroso J, et al: Correlation of early metastatic response by 123I metaiodobenzylguanidine scintigraphy with overall response and event-free survival in stage IV neuroblastoma. *J Clin Oncol* 21:2486-2491, 2003

OP-344

Comparison of 18F-FDG PET/CT with Anatomic Imaging Methods in Pediatric Neuroblastoma

M. Engin, A. Arcay, Z. G. Kiprak, C. N. Dundar Caglayan, G. G. Bural, A. Boz;

Akdeniz university faculty of medicine nuclear medicine department, Antalya, TURKEY.

Aim/Introduction: Neuroblastoma is the most common extracranial malignant solid tumor in the pediatric age group and ranks high among the causes of cancer-related death in children with a rate of approximately 15% (1). Performing appropriate imaging modalities during staging and follow-up would lead to selection of appropriate treatment protocols and improve patient survival. In this study, it was aimed to compare the effectiveness of 18F-FDG PET/CT imaging with anatomical imaging methods (CT, MRI) in patients with neuroblastoma. **Materials and Methods:** We enrolled 15 pediatric patients (7 girls, 8 boys; age range 1-10 years) with histopathologically proven neuroblastoma, who had both FDG PET/CT and anatomical imaging (CT or MRI) between November 2015 and March 2020 for staging and restaging. Twenty FDG PET/CT studies were compared with the findings of anatomical imaging methods (CT, MRI). Equivocal findings were correlated with clinical and follow-up imaging. **Results:** Of the 20 FDG PET/CT images included in the study, 11 were for

staging, 6 for treatment response evaluation, and 3 for restaging. All primary tumors were detected by both FDG PET/CT and anatomical imaging methods. In 8/20 (40%) examination bone and bone marrow metastases and in 5/20 (25%) examination, cervical, supraclavicular, mediastinal, anterior diaphragmatic and pelvic metastatic lymph nodes were detected by only FDG PET/CT. Findings suggesting pulmonary infection on anatomical imaging in one patient were evaluated in favor of metastasis on FDG PET/CT, and lesions were compatible with metastasis in accordance with clinical and follow-up findings. In one patient, the findings interpreted in favor of metastatic lung nodules with FDG PET/CT resulted in diagnosis of infection in accordance with anatomical imaging methods, clinical and laboratory findings. In four patients; liver metastasis, millimetric metastatic abdominal and pelvic lymph nodes, millimetric lytic bone metastases, spinal canal invasion and adrenal recurrence detected on CT or MRI, could not be detected with FDG PET/CT. **Conclusion:** In the pediatric patients diagnosed with neuroblastoma, ^{18}F -FDG PET/CT is superior to the anatomical imaging methods in the detection of bone, bone marrow and distant lymph node metastases. In a few cases, with small lesion size and extra-adrenal organ metastases, anatomical imaging methods may be required as a complementary examination. For the detection of the primary tumor site, there was no difference between ^{18}F -FDG PET/CT and anatomical imaging methods. **References:** 1-Park J.R., Eggert A., and Caron H.: Neuroblastoma: biology, prognosis, and treatment. *Pediatric Clin North Am* 2008; 55: pp.97-120

OP-346

SIOPEN SCORING vs 3 Simplified Scoring Systems in Pediatric Patients with HR-NB-1 and L2-NB

C. Olianti¹, A. Martini¹, R. Di Dato¹, M. Allocca¹, A. Tondo², H. Gauthier³;

¹University Hospital of Florence, Florence, ITALY,

²University Hospital Meyer of Florence, Florence,

ITALY, ³Oscar Lamberet Center, Lille, FRANCE.

Aim/Introduction: SIOPEN scoring system SIOPEN-SS (12 anatomical body segments with a 0-6 scale and 72 as maximal score) is used to semiquantify metastatic tumor load (TL) in HR-NB to stratify patients with good versus poor response to therapy (1): a cut-off score ≥ 3 was the most useful predictor across trials to define good responders and a tumor load at staging 0-23 correlates with a better EFS vs 24-47 and 48-72. We tested the ability of 3 simplified methods to define TL and response to therapy. **Materials and Methods:** To compare the SIOPEN-SS and the three proposed Simplified Scoring System (SSS), 14 pediatric patients HR-NB-1 and 14 intermediate or low risk-NB referred to Nuclear Medicine for I-123 MIBG scintigraphy (January 2009 - February 2019) were investigated by 123I-MIBG

scans for staging, response to therapy, after surgery, after radiotherapy, off-therapy for a total of 92 planar whole-body plus SPECT scans. The studies included 9 F and 19 M (mean age 4.14 \pm 2.85 years at the first scintigraphy). SSS1 analyzes three great sector: neural, body and arms, with the same SIOPEN 0-6 scale, SSS2 analyzes three great sector: neural, body and arms, with a simplified 0-4 scale, SSS3 analysis 12 body segments as SIOPEN scoring, with a simplified 0-2 scale. Total number of discrete lesions is also reported. **Results:** Obviously statistical analysis showed a huge correlation between SIOPEN and three SSS scorings : Rho Spearman : 1.000, 0.988 and 0.982 between SIOPEN and respectively SSS1, SSS2 and SSS3 ($p < 0.000$). Graphical representation of SSS 1, 2 and 3 versus SIOPEN-SS taken as gold standard, shows an exponential trend of values with a plateau towards 24 in SSS3, towards 12 in SSS2 and a linear correlation in SSS1 ($R^2_{\text{linear}} = 0.993$). Regression Analysis with estimate of curves shows a logarithm trend for SSS2 and a hyperbolic trend for $1/\text{SSS2}$ vs SIOPEN. **Conclusion:** SSS1 and SSS3 don't bring a real advantage respect SIOPEN-SS cause the first has the same grading in lesions-extension characterization, and the second has the same numbers of segments. Otherwise the SSS2 seems bring a real benefit in terms of simplification both for number of segments and grading of lesion-extension without a significant lost of accuracy for each patient. SSS2 should be tested on a selected larger cohort of HR-NB, to verify prognostic impact respect SIOPEN scoring system. **References:** 1) Eur J Nucl Med Mol Imaging. 2018 February; 45:292-305, DOI 10.1007/s00259-017-3829-7

OP-347

Do SUV values reflect completely accurate results especially in pediatric cases?

O. Ozmen¹, S. Beykan², E. Tatci¹;

¹University of Health Sciences Atatürk Chest Diseases

and Thoracic Surgery Training and Research

Hospital, Ankara, TURKEY, ²Klinik fuer Nuklearmedizin

Universitaetsklinikum Wuerzburg, Wuerzburg, GERMANY.

Aim/Introduction: In FDG PET/CT studies, SUV is a useful parameter in distinguishing malignant lesions from benign lesions and evaluating the treatment response in cancer patients. SUVs are mainly depend on patients' weight and injected activity, however, in practice there are several sources of bias and variance of calculation. The variety might be critical especially pediatric patients due to significant change in weight and brain volume. The aim is to analyze the patient-specific FDG uptake in brain and liver of pediatric and adult patients. And investigate the correlation of the SUVweight and SUVlbm of liver between pediatric and adult patients **Materials and Methods:** Images of 53 pediatric (23F,30M age:3-17y , weight:12-97kg , injected activity: 90-519 MBq) and 25 adult patients (7F,18M

age:22-86y, weight:60-104 kg, injected activity:310 - 565 MBq) who underwent FDG PET/CT imaging for oncological purposes were evaluated retrospectively. Pediatric patients were investigated in three groups as 3-7 years, 8-12 years, 13-17 years. The percentage injected activities (A%) in brain, bladder, liver and whole-body are calculated for all patients. In addition, Liver SUVweight and SUVlbm were calculated for all patients. **Results:** A% of brain per injected activity was higher in pediatric patients approximately as a factor of 8 (for 3-7 years), 5 (for 8-12 years), and 2 (for 13-17 years) in compare to adults. This is highly related to brain volume. The difference between liver SUVweight and SUVlbm were 20% for adult and patient group-iii whereas the difference was $\pm 2\%$ for others. There is little to no gender dependent correlation on liver SUV values in the pediatric patient groups 3-7year and 8-12year whereas $\pm 12\%$ difference was observed for other patients. Adult liver SUVs were lower than pediatric patients 57% for 3-7 years, 43% for 8-12 years and 26% for 13-17 years. **Conclusion:** In compare to adults, for pediatric patients, majority of the injected activity accumulated in the brain since brain-to-Whole-body volume ratio in pediatric patients are higher than adults. This directly resulted in lower SUV for other tissues and tumors which may be confusing for the physician. In pediatric patients adults based reference SUVs should be carefully take into account for diagnostic evaluation. **References:** None

¹⁸F-FDG-PET/MR Semiquantitative Response Assessment Methods in Paediatric Hodgkin Lymphoma Patients

S. Gusella¹, A. Spimpolo², S. Berti³, F. Menegatti³, C. Campi^{4,5}, M. Pillon⁶, C. Giraudo⁷, D. Cecchin³, P. Zucchetta³;

¹Nuclear Medicine Unit, Ospedale di Bolzano, Bolzano, ITALY,

²Nuclear Medicine Unit, Department of Medicine, PhD Student International PhD Program in Arterial Hypertension and Vascular Biology, University of Padova, Padua, ITALY, ³Nuclear Medicine Unit, Department of Medicine, University of Padova, Padua, ITALY, ⁴Department of Mathematics "Tullio Levi-Civita", University of Padova, Padua, ITALY, ⁵Padova Neuroscience Center, University of Padova, Padua, ITALY, ⁶Clinic of Paediatric Haematology-Oncology, Department of Women's and Children's Health, University of Padova, Padua, ITALY, ⁷Institute of Radiology, Department of Medicine, University of Padova, Padua, ITALY.

Aim/Introduction: Deauville score (DS) has proved to be a reliable qualitative method for ¹⁸F-FDG-PET-based response assessment in paediatric Hodgkin Lymphoma (HL). PET/MR is a recommended imaging modality for paediatric patients, thanks to its lower radiation exposure in comparison with PET/CT. A number of semiquantitative measures might be derived, whose consistency is still to be validated. The aim of our study was to evaluate the correlation between commonly used semiquantitative

parameters, such as Δ SUVmax, Δ SUVpeak and qPET with DS and response categories (CMR, PMR, NMR, PMD) in paediatric HL patients undergoing ¹⁸F-FDG-PET/MR scans both at baseline (sPET) and at interim (iPET). **Materials and Methods:** We retrospectively evaluated 30 consecutive paediatric HL patients who underwent n. 60 ¹⁸F-FDG-PET/MR investigations (sPET and iPET) at Our Institution. All PET images were analysed using a research-dedicated software. Spherical VOIs were manually drawn on the 6 hottest lesions of sPET and on areas of residual uptake of iPET images. After isocontouring with a fixed 41%-of-SUVmax threshold, lesion Δ SUVmax and Δ SUVpeak were calculated. In order to derive the qPET parameter, liver uptake was used according to Hasenclever et al.¹ Each parameter was calculated using bw-, bsa-, and lbm-SUV values. Treatment response categories (CMR, PMR, NMR and PMD) were determined according to the Lugano criteria and correlation with the above-mentioned parameters was calculated. Kruskal-Wallis nonparametric test was used to compare median values of each semiquantitative parameter both in the different DS and response categories subgroups. **Results:** Two out of thirty HL patients (M:F=12:18, age range: 8-18) were excluded since no iPET residual uptake areas were present or brown fat activation impaired VOIs positioning. The SUV normalization method did not influence the qPET capacity of differentiating between DS3, DS4 and DS5, and between PMR and CMR categories ($p < 0.01$). Similar results were obtained for Δ SUVmax and Δ SUVpeak even if more intra-group variability was observed ($p \leq 0.01$). **Conclusion:** In paediatric HL patients undergoing ¹⁸F-FDG-PET/MR at interim, qPET proved to reliably differentiate among DS and response categories. The use of different SUV normalization methods did not significantly affect the qPET performance. **References:** 1. Hasenclever D, Kurch L, Mauz-Körholz C, et al. qPET - a quantitative extension of the Deauville scale to assess response in interim FDG-PET scans in Lymphoma. OP-349

Assessment of prognostic value of baseline ¹⁸FDG PET/CT metabolic parameters (SUV max, MTV and TLG) and treatment response on ¹⁸FDG PET/CT scan in patients of Langerhan Cell histiocytosis

M. Pereira, S. Shah, A. Puranik, A. Bedmutha, A. Agrawal, N. Purandare, V. Rangarajan;
Tata Memorial Hospital, HBNI, Mumbai, INDIA.

Aim/Introduction: To assess prognostic value of baseline FDG PET/CT metabolic parameters (SUV max, MTV and TLG) and treatment response on FDG PET/CT scan in patients of Langerhan Cell histiocytosis (LCH) **Materials and Methods:** Between August 2010 and March 2019, 36 paediatric patients with LCH were treated with chemotherapy in our institution and their baseline and post chemotherapy

PET/CT scans were reviewed. The SUV max, MTV and TLG parameters of LCH lesions were recorded. These PET parameters were correlated with disease free survival. Also post chemotherapy PET-CT scans were reviewed for treatment response into categories based on visual scoring (good response: uptake \leq liver; no response : uptake $>$ liver). The treatment response on FDG PET/CT was correlated DFS. Follow-up time was analyzed from the last day of chemotherapy to the date of the last follow-up, recurrence, or death. DFS rate was calculated using Kaplan-Meier analysis stratified according to cut-off value (median value) and compared using the log-rank test. **Results:** At a median follow-up time of 27 months (range, 1 to 100 months), the disease-free survival (DFS) rate was 83.4% respectively. Baseline PET parameters, SUV max, MTV and TLG of LCH lesions showed no statistically significant correlation with DFS ($p=0.8$, $p=0.9$, $p=0.5$ respectively). Of the 36 patients of LCH, 8 patients (22%) developed recurrence, from which 5 patients had complete response and 3 showed stable or progressive disease post treatment. Hence correlation of treatment response on PET-CT with clinical outcome of patients did not achieve a statistical significance ($p = 0.1$). **Conclusion:** None of the baseline PET-CT parameters were an independent prognosticator of disease free survival. Treatment response on FDG PET/CT did not correlate with clinical outcome in patients with LCH. **References:** None

OP-350

Correlation between ^{18}F -DOPA PET/CT findings and genetic mutation analysis in patients with persistent hyperinsulinemic hypoglycemia

S. Sagar, N. Damle, R. Sharma, K. Reddy, T. Subudhi, V. Jain, C. Bal, M. Tripathi, M. Jana;
AIIMS, Delhi, INDIA.

Aim/Introduction: Persistent hyperinsulinemic hypoglycaemia is a rare but life threatening disease of infancy and childhood. ^{18}F -DOPA PET/CT has been shown to be a useful modality in the localization of focal pancreatic lesions in these patients. We aimed to assess the role of ^{18}F -DOPA PET/CT in such patients at our institution. **Materials and Methods:** ^{18}F -DOPA PET/CT scans and clinical details of 22 children with clinical diagnosis of hyperinsulinemic hypoglycemia were reviewed. Scans were acquired at 5 min post-injection of 2-3 mCi of ^{18}F -DOPA on dedicated PET/CT scanners (Biograph mCT, Siemens Inc and Discovery PET/CT, GE). Abdominal spot images over 1-2 bed positions were acquired. Additionally, genetic mutation status was correlated to the scan findings in some children. **Results:** In this ethically approved study, out of 22 children (9 female and 13 male), 14 were infants. The age of the children ranged from 1 month to 8 years. Sixteen children had undergone gene analysis, 13 were positive for ABCC8, 1 for

GLUD-1, 1 for GCK mutations and 1 had not showed any mutation. ^{18}F -DOPA PET/CT scan showed 5 focal pancreatic lesions in 5 children (1 in each), two focal lesions in 1 child and diffuse pancreatic uptake in 16 children. Of the 13 ABCC8 mutation positive children, ^{18}F -DOPA PET scan showed focal pancreatic lesion in 5 (38.4%) and diffuse uptake in 8. Of the 7 children who inherited ABCC8 paternal monoallelic recessive mutation, 5 (71.4%) were having focal pancreatic lesions on ^{18}F -DOPA PET scan. One child with GLUD-1 mutation showed multifocal pancreatic uptake, 1 with GCK mutation showed diffuse pancreatic uptake and one child with no mutation on gene analysis showed mild diffuse uptake on PET scan. However, in 6 children with unknown mutation status, ^{18}F -DOPA scan showed diffuse uptake. Two patients underwent surgery and are thriving on regular food without any complications post-surgery 19 and 8 months back respectively. Both the patients have paternally inherited ABCC8 gene mutation. All the remaining 20 patients are being managed medically with 17 patients maintained on octreotide and rest 3 maintained on diazoxide medication. **Conclusion:** ^{18}F -DOPA PET/CT is a useful modality for localising focal pancreatic lesions in children with persistent hyperinsulinemic hypoglycemia. The detection rate is significantly higher in patients with ABCC8 paternal monoallelic recessive gene mutation. ^{18}F -DOPA PET scan driven by genetic analysis appears to be useful in planning the management of children with hyperinsulinemic hypoglycemia. **References:** None

OP-351

Risk of structural persistent disease in pediatric patients with low or intermediate risk differentiated thyroid cancer

M. Manganelli¹, M. Klain¹, E. Zampella¹, F. Volpe¹, L. Piscopo¹, M. De Risi¹, M. De Risi¹, V. Gaudieri¹, C. Nappi¹, A. D'Antonio¹, S. Limone¹, L. Pace², A. Cuocolo¹;

¹Department of Advanced Biomedical Sciences, University Federico II of Naples, Naples, ITALY, ²Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, ITALY.

Aim/Introduction: In pediatric patients with differentiated thyroid cancer (DTC), the risk of recurrence is high and the indication for post-operative ^{131}I administration is still debated. Aim of this study was to assess the risk of structural recurrence in pediatric DTC patients at low-intermediate risk. **Materials and Methods:** We retrospectively evaluated 69 pediatric patients with DTC, treated with surgery and ^{131}I . The patients were classified as low, intermediate or high risk of recurrence according to the American Thyroid Association (ATA) guidelines. We excluded 8 patients with positive serum anti-thyroglobulin antibody and 7 patients with post-operative ATA high risk, leaving 54 subjects. Follow-up was performed. The need of additional therapy or the observation of structural disease persistence, defined

as defined by histology or imaging procedures, were considered as end-point. Annualized event rate (AER), was calculated. Hazard ratios were obtained by Cox regression analyses. Disease free survival analysis was performed by Kaplan-Meier method. **Results:** Follow-up was available in 45 subjects. During a mean time of 64 ± 53 months, 15 structural events occurred (33% cumulative event rate). The patients with events had higher pre-therapy thyroglobulin values (82 ± 21 vs. 13 ± 18 , $P < 0.001$), as well as a higher prevalence of age ≤ 14 years (53% vs. 23%, $P < 0.05$) and intermediate ATA risk (80% vs. 30%, $P < 0.01$), as compared to those without events. A TSH stimulated thyroglobulin value > 10 ng/ml before post-operative RAI therapy resulted the best trade-off in predicting the occurrence of events. The occurrence rate of structural events was higher in patients with thyroglobulin > 10 (AER 15% vs. 0.5%) and those at intermediate risk (AER 11% vs. 1.5%) (both $P < 0.01$). At multivariate analysis, a thyroglobulin level > 10 ng/ml resulted the only independent significant prognostic factor of structural recurrence ($P < 0.001$). At Kaplan Meier analysis, the worst prognosis was observed in patients with a serum thyroglobulin level > 10 ng/mL in both ATA risk and age categories (both P for trend < 0.001). **Conclusion:** In this retrospective series of pediatric patients with ATA low or intermediate risk DTC treated with surgery and RAI, post-operative elevated thyroglobulin values (> 10 ng/mL) have a high independent prognostic impact independently from age and ATA risk. The detection of a high serum thyroglobulin value could improve the post-surgical risk stratification and indicate RAI treatment. **References:** None

OP-352

Renogram Image Features and the Reproducibility of Differential Renal Function Measurements

A. Brink¹, M. Levin¹, E. Libhaber², M. D. Mann¹;

¹Red Cross War Memorial Children's Hospital, Department of Paediatrics, University of Cape Town, Cape Town, SOUTH AFRICA, ²School of Clinical Medicine and Health Sciences Research Office, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, SOUTH AFRICA.

Aim/Introduction: The reproducibility of differential renal function (DRF) measurements on ^{99m}Tcmercaptoacetyltryglycine (^{99m}TcMAG3) is good in most children. There is however a group with poor reproducibility which could affect clinical decision making. Factors, such as age and glomerular filtration rate (GFR), have been implicated as causes for poor reproducibility. The aim of this study is to investigate image features associated with the reproducibility of DRF measurements. **Materials and Methods:** The image features and reproducibility of the DRF estimates of cohort 1 (n=127) was used to identify the factors associated with reproducibility. The associations between these image features and reproducibility were then tested

in a second cohort (n=227). The DRF measurements were calculated using the area under the curve method (AUC) and the Rutland Patlak method (RP). The images were visually inspected to categorise the categorical variables and processed to obtain the values of the continuous variables. The variables investigated included age and measured/ estimated GFR. The association between each variable and the reproducibility of DRF measurement was tested with univariate linear regression. The results of the univariate linear regression were used to plan the multiple linear regression combinations. All possible combinations were tested with multiple linear regression. **Results:** The R²-values for goodness-to-fit for the multiple regression models ranged from 0.35 to 0.49 for AUC and 0.33 to 0.45 for RP in cohort 1 and they ranged from 0.17 to 0.22 for AUC, and 0.17 to 0.22 for RP in cohort 2. One variable, left kidney to background ratio, was significant in all the multiple linear regression combinations ($p < 0.05$). Age, right kidney to background ratio, right renal margins well defined, right renal margins poorly visualised and time visualisation right calyces were significant in most of the combinations analysed. The reproducibility of DRF measurement was decreased when the kidney to background ratio was < 2 . **Conclusion:** The variables which predicted reproducibility for the measurement of DRF on ^{99m}TcMAG3 renograms using AUC and RP methods were left kidney to background ratio, right kidney to background ratio, right renal margins well defined, age and time visualisation right calyces. Consideration should be given to incorporating the kidney to background ratio into the renal processing screen display as a valuable quality control step. The DRF values should be interpreted with caution if the kidney to background ratio is < 2.0 . **References:** None

OP-353

DMSA renal investigations performed with a 360° whole-body CZT SPECT camera as compared with the conventional method based on planar images from an Anger camera

A. Bahloul, L. Imbert, G. Karcher, P. Marie, A. Verger;

Nancy University Hospital, Vandoeuvre Les Nancy, FRANCE.

Aim/Introduction: The whole-body Veriton™ CZT-camera (Spectrum Dynamics Medical) is equipped with 12 swiveling high-resolution detectors regularly spaced over 360 degrees and covering an axial field-of-view of 32 cm. These detectors may be placed in close proximity with the abdomen for adults or children and SPECT recordings may additionally be focalized on the kidney area. This study aimed to assess the results of DMSA renal scintigraphy recorded with the 360° CZT-SPECT system, as compared with results provided by conventional planar images from an Anger camera (Ecam, Siemens Healthineers). **Materials and Methods:** A total of 21 patients, with an age range from 6 months to

85 years (mean: 21±23 years) and who were referred for DMSA scintigraphy, were selected. The protocol involved conventional planar images on an Anger camera, equipped with a conventional high-resolution parallel hole collimator, immediately followed by an abdominal SPECT recording obtained with the CZT camera and with the addition (n=13) or not (n=8) of a focalized recording on the kidney area. Routine acquisition and reconstruction parameters were used for both cameras. The count sensitivity and the relative renal functions from right and left kidneys were compared between the two cameras, as well as the rate of visual detection of renal sequelae made by two experimented nuclear physicians. **Results:** Marked enhancements in count sensitivity were observed with the CZT-SPECT recording, as compared with the conventional planar recording, with mean relative increases of 70% and 180% for the recordings planned respectively without or with the use of a kidney focus. A close correlation was documented between the relative kidney functions determined with the CZT-SPECT and those obtained with the conventional camera ($y=0.92x+3.9$; $R^2=0.98$) with a mean relative difference of only $2.2\pm 1.9\%$ between the two modalities. The visual identification of renal sequelae was concordant in 19 of the 21 patients (90%) and on the basis of additional clinical and imaging data, the 2 discordant cases were ultimately considered as corresponding to an accurate diagnosis for the CZT-camera and not for the Anger-camera (one false-positive result and one false-negative result for the latter). **Conclusion:** Results from the DMSA scintigraphy recorded with this CZT-SPECT camera are highly concordant with those from the conventional planar method, but with the advantages of: (i) high diagnostic quality provided by the 3-dimensional CZT-SPECT images and (ii) high count sensitivity using CZT-SPECT, a property that might allow reduction in scan recording times and/or injected activities. **References:** None

Spatial relationship between brain tumor regions assessed by 11C-Methionine and perfusion weighted imaging (PWI) in neuro-oncological lesions assessed by fully hybrid PET/MRI

P. Mapelli^{1,2}, P. Scifo², M. Barbera³, F. Fallanca², A. Castellano^{1,3}, V. Bettinardi², R. Menichini², A. Savi², L. Gianolli², N. Anzalone^{1,3}, M. Picchio^{1,2};

¹Vita-Salute San Raffaele University, Milan, ITALY, ²Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, ³Neuroradiology Unit and CERMAC, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim/Introduction: The aim of this analysis is to investigate the spatial relationship between PW-MRI maps and MET-PET in brain tumors by using a fully integrated PET/MRI system.

Materials and Methods: Ten patients (13 lesions) with primary or secondary cerebral neoplastic diseases, characterized by Gd enhancement, underwent simultaneous 11C-MET PET/MRI. MR protocol included T1w, T2w, FLAIR, DWI, DCE and DSC PWI sequences with double Gd bolus injections and a 3D T1w post-contrast scan. Simultaneous MET-PET acquisition lasted 20 minutes on brain level. ZTE-based attenuation correction was used to account for the head bone. After the assessment of the optimal co-registration of PW-MRI and MET-PET over 3D post-contrast T1w images, a neuro-radiologist and a nuclear medicine physician manually defined the segmentation of the lesions using PMOD software. MRI lesions (Gd-VOIs) and PET lesions (PET-VOIs) have been defined on T1w enhancement and on the PET images, respectively. PET-VOIs were used to measure SUVmax, MTV and SUVmean for each lesion seen on MET-PET. Ktrans, Vp and rCBV maps have been calculated using OLEA software and the Gd-VOIs have been used to mask Ktrans, Vp and rCBV maps. DICE coefficient for each lesion of each patient was calculated to measure the overlap between the corresponding VOIs on PET and Gd-enhanced MRI. The Center of Masses (CoM) of each masked map (Ktrans, Vp, CBV and MET-PET) have been localized and the distances between MET-PET CoM and PWI CoMs have been calculated. **Results:** Eleven/13 lesions showed both Gd-enhancement and MET-PET uptake (mean SUVmax: 4,5; range: 2,5-10,8; mean SUVmean: 2,7; range: 1,5-6,5; MTV: 21,7, range: 0,5-94,6). Mean DICE index between PET and Gd-VOIs of the lesions was moderate (0.58 ± 0.15). PET-VOIs were significantly larger than Gd-VOIs (median PET-VOI: 47 cc; range 9.9-2499; median Gd-VOI: 33cc; range 4,4-1097). The distances between PWI-CoMs and PET CoM were: mean Ktrans-PET distance = $2,79 \text{ mm} \pm 2,60$; mean Vp-PET distance = $2,82 \text{ mm} \pm 2,32$, mean rCBV-PET distance = $3,81 \text{ mm} \pm 3,52$, without statistical difference between distances of PWI-CoMs from PET. **Conclusion:** Areas defined by MET-PET and Gd-MRI seem to be able to characterize different tumour aspects (metabolic active lesions within not-enhancement and vice-versa) with moderate overlapping. Although heterogeneous histology of the lesions included in this study may have hampered the analysis, no statistical difference between distances of PWI-CoMs from PET-CoM have been observed. Our findings suggest that MET-PET

and PW-MRI provide complementary information on brain tumor biology. **References:** None

OP-356

Photopenic defects in gliomas with amino-acid PET and relative prognostic value: a multicentric ¹¹C-Methionine and ¹⁸F-FDOPA PET experience

A. Verger¹, T. Zaragori¹, A. Castello², E. Guedj³, A. Girard⁴, N. Galldiks⁵, N. Albert⁶, E. Lopci⁷;

¹Department of Nuclear Medicine and Nancyclotep Imaging Platform, CHRU Nancy, Nancy, FRANCE, ²Nuclear Medicine Department, Humanitas Clinical and Research Hospital, Milan, ITALY, ³Department of Nuclear Medicine, Assistance Publique Hôpitaux de Marseille, Timone University Hospital, Marseille, FRANCE, ⁴Department of Nuclear Medicine, Eugène Marquis Center, Rennes 1 University, Rennes, FRANCE, ⁵Dept. of Neurology, Faculty of Medicine and University Hospital Cologne, University of Cologne, Cologne, GERMANY, ⁶Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: As an adjunct to MRI, amino-acid PET is currently recommended in newly-diagnosed gliomas. Among negative amino-acid PET scans at initial diagnosis, photopenic defects in gliomas have been reported with ¹⁸F-FET PET, associated to a more aggressive clinical course as compared to isometabolic gliomas. In line with this emerging concept, we aimed to explore photopenic defects in newly diagnosed glioma patients and their prognostic value using the other two widely used amino-acid radiotracers, ¹¹C-MET and ¹⁸F-FDOPA. **Materials and Methods:** Patients with newly diagnosed glioma and ¹¹C-MET or ¹⁸F-FDOPA negative PET were retrospectively selected in this European multicentric study. Photopenic defects were identified visually and semi-quantitatively using mean tumor-to-brain ratios (TBR_{mean}), extracted from FLAIR MR image volumes. Progression free survival (PFS) calculation was based on the RANO criteria. **Results:** 32 ¹¹C-MET and 26 ¹⁸F-FDOPA PET scans with amino-acid PET-negative gliomas were selected. Out of these 58 patients examined gliomas 16 ¹¹C-MET and 10 ¹⁸F-FDOPA PET scans with photopenic defects were identified, exhibiting lower TBR_{mean} as compared to isometabolic gliomas ($P < 0.001$). Gliomas with photopenic defects had not significantly different PFS than isometabolic gliomas in the whole-population ($P = 0.40$), but shorter PFS in the subgroup of WHO grade II IDH-mutant astrocytomas (median PFS, 35 vs. 68 months; $P = 0.047$). **Conclusion:** Photopenic defects observed with ¹¹C-MET and ¹⁸F-FDOPA are able to delineate subgroups of patients with poorer outcome for patients with WHO grade II IDH-mutant astrocytomas. **References:** Albert NL, Weller M, Suchorska B, et al. Aim/Introduction: Gliomas, the most common primary brain tumours, have poor prognosis. The prognostic evaluation is a crucial step in the therapeutic strategies planning. Aim: to investigate the prognostic value of ¹¹C-methionine PET/CT (MET-PET) in patients with suspected glioma recurrence. **Materials and Methods:** We retrospectively analysed MET-PET of 67 patients (40 males; age: 48 ± 15 years) with a histological diagnosis of glioma (37/67 high-grade) performed for suspected recurrence at MRI. A 15min brain static acquisition was performed 20min after ¹¹C-methionine injection (185-200MBq). MET-PET images were qualitatively and semi-quantitatively analysed. After PET-MR images co-registration, regions of interest were manually drawn over the lesion (T) and contralateral normal cortex (N). SUVmax, SUVmean, SUVratio (SUVmaxT/SUVmeanN) were calculated. Mann-Whitney test was used to compare parameters between groups. ROC analysis was performed to determine the optimal parameters' threshold. Progression-free and overall survival (PFS, OS) were calculated from the MET-PET date using Kaplan-Meier method and compared using log-rank test. **Results:** MET-PET was positive in 46/67 (68.7%) patients. The overall median follow-up was 19 months. The one-year PFS and OS rates were 42% and 75% respectively. During follow-up, recurrence occurred in 3/21 and 43/46 patients with negative and positive MET-PET, respectively; death occurred in 1/21 and 22/46 patients with negative and positive MET-PET, respectively. Negative MET-PET patients had significant better PFS ($p < 0.0001$) and OS

($p=0.0013$) than positive MET-PET patients. Recurrence patients (46/67) showed higher SUVmax (median: 3.36vs1.1; $p<0.0001$), SUVmean (1.76vs1.1; $p=0.0009$) and SUVratio (3.38vs2.13; $p<0.0001$) than non-recurrence patients (21/67). The optimal thresholds indicating recurrence patients were: SUVmax >3.01 ($S=67\%$; $Sp=81\%$; $p=0.0002$), SUVmean >1.58 ($S=65\%$; $Sp=81\%$; $p=0.0002$), SUVratio >2.39 ($S=80\%$; $Sp=71\%$; $p<0.0001$). Patients with SUVmax >3.01 , SUVmean >1.58 and SUVratio >2.39 had significant worse PFS ($p<0.0001$, $p=0.0001$, $p<0.0001$, respectively). No significant differences in PFS between high-grade and low-grade glioma patients were found. Deceased patients (23/67) showed higher SUVratio (median: 3.76vs2.43; $p=0.0045$) than alive patients (44/67). No significant difference in SUVmax and SUVmean between deceased and alive patients was found. The optimal threshold indicating alive patients was SUVratio <3.67 ($S=52\%$; $Sp=84\%$; $p=0.0014$). Patients with SUVratio <3.67 and low-grade glioma had better OS ($p=0.0005$, $p<0.0001$, respectively). **Conclusion:** In patients with suspected glioma recurrence, qualitative and semiquantitative evaluation of MET-PET were able to predict both disease progression and survival, unlike the histological grade tumour. This clinically relevant finding highlight the better ability of functional imaging to reflect the tumour cells' behaviour, compared to grade tumour. Future PET studies with more sophisticated analysis, including dynamic quantitative parameters or machine learning-driven approaches, could identify new prognostic factors. **References:** None

OP-358

Clinical value of ^{18}F -FET-PET/CT in pediatric patients with central nervous system tumors

O. Kertels¹, J. Krauß², C. M. Monoranu³, S. Samnick⁴, A. Dierks⁴, A. K. Buck⁴, B. Bison⁵, C. Lapa⁶;

¹Institute of Diagnostic and Interventional Radiology, University Hospital Würzburg, Würzburg, GERMANY, ²Department of Neurosurgery, University Hospital Würzburg, Würzburg, GERMANY, ³Department of Neuropathology, Institute for Pathology, University of Würzburg, Würzburg, GERMANY, ⁴Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, ⁵Department of Neuroradiology, University Hospital Würzburg, Würzburg, GERMANY, ⁶Department of Nuclear Medicine, University Hospital Augsburg, Augsburg, GERMANY.

Aim/Introduction: Positron emission tomography/computed tomography (PET/CT) with O-(2-[^{18}F]fluoroethyl)-L-tyrosine ([^{18}F]FET) is a well-established tool for the non-invasive assessment of brain tumors. However, data on its diagnostic utility and impact on clinical management in children and adolescents is limited. **Materials and Methods:** 21 children and young adults (13 males; mean age, 9.3 ± 5.2 years; range, 1-19 at initial diagnosis) with both [^{18}F]FET-PET/CT as well as cranial magnetic resonance imaging (cMRI)

were retrospectively analyzed. Five patients presented with newly diagnosed brain tumors, in the remaining sixteen, tumor recurrence after resection and/or radio-chemotherapy was suspected. Beyond its diagnostic accuracy, impact of PET imaging on clinical decision making was assessed. Histopathology ($n=12$) and/or clinical and imaging follow-up ($n=9$) served as reference. **Results:** [^{18}F]FET-PET/CT was rated correctly in 16 out of 21 patients with a very good inter-reader consensus with $\kappa = 0.83$. [^{18}F]FET-PET/CT had an impact on further treatment decisions in 17 out of 21 patients with avoidance of invasive surgery or biopsy in seven patients, exact biopsy guidance in five patients, change of further treatment in another three patients and confirmation of the diagnosis in two patients. **Conclusion:** [^{18}F]FET-PET/CT can provide important additional information for treatment decisions in pediatric and adolescent patients with CNS tumors. **References:** None

OP-359

Primary diagnosis of low-grade glioma: ^{18}F -FET or ^{18}F -FCH PET? A pilot study

M. Hodolic¹, A. Golubic², A. Misir Krpan³, M. Zuvic², M. Baucic³, G. Mrak⁴, J. Nemir⁴, D. Huic²;

¹Nuclear Medicine Department, Faculty of Medicine and Dentistry, Palacký University Olomouc, Olomouc, CZECH REPUBLIC, ²Department of Nuclear Medicine and Radiation Protection, University Hospital Centre Zagreb, Zagreb, CROATIA, ³Department of Oncology, University Hospital Centre Zagreb, Zagreb, CROATIA, ⁴Department of Neurosurgery, University Hospital Centre Zagreb, Zagreb, CROATIA.

Aim/Introduction: Gliomas, as one of the more commonly diagnosed primary brain tumours, are associated with variable survival, in part linked with their histological type. The diagnosis of low grade gliomas (LGG) is challenging, as results of radiological imaging modalities can often be inconclusive or equivocal. Functional imaging modalities have been introduced to provide additional metabolic information. O-(2-[^{18}F]fluoroethyl)-L-tyrosine (^{18}F -FET) is PET radiopharmaceutical approved for the characterisation of glioma-suggestive brain lesions. ^{18}F -FET displays a high tumour-to-background ratio and minimal accumulation in inflammatory lesions. Because of low uptake in healthy brain parenchyma, fluoromethyl-(^{18}F)-dimethyl-2-hydroxyethyl-ammonium chloride (^{18}F -FCH) has also been used for diagnosis of LGG in some European nuclear medicine units. The objective of this pilot study was to investigate the diagnostic accuracy of ^{18}F -FET and ^{18}F -FCH PET in patients with primary LGG. **Materials and Methods:** Eleven patients aged 21-80 years with MRI-suspected LGG were involved in this study. Patients underwent both ^{18}F -FET and ^{18}F -FCH PET/CT within one week. Brain PET/CT was performed according to standard protocol: 20 minutes after intravenous injection of 185 MBq of ^{18}F -FET and 185 MBq of ^{18}F -FCH PET. Surgery

and histological diagnoses were performed in the next two weeks. **Results:** Eleven out of 11 patients with suspected LGG underwent MRI, ^{18}F -FET and ^{18}F -FCH PET/CT. All patients had LGG according to MRI. In all PET positive patients, tumour location on MRI was consistent with region of PET/CT positivity. Nine out of 11 patients with suspected LGG had final histological diagnosis after the surgery. Two out of 11 patients included in this study did not undergo surgery or biopsy for histological confirmation. Both had negative ^{18}F -FET and negative ^{18}F -FCH PET scan, so they declined surgery and multidisciplinary tumour board recommended follow-up. Seven lesions positive on ^{18}F -FET PET and negative on ^{18}F -FCH PET scan were diffuse astrocytoma (grade II), ganglioma (grade I) and anaplastic astrocytoma (grade III) by pathohistology. Two lesions positive on ^{18}F -FET PET and positive on ^{18}F -FCH PET scan were glioblastoma multiforme (grade IV) by pathohistology. **Conclusion:** Preliminary results on a small patient sample suggest appropriate radiopharmaceutical should be chosen before performing PET/CT scan in patients with newly diagnosed LGG. ^{18}F -FET is more accurate radiopharmaceutical than ^{18}F -FCH in detection of LGG, while increased lipid synthesis seems to correlate with higher grade and more aggressive gliomas. **References:** None

OP-360

Is there a need for premedication with Carbidopa for static and dynamic ^{18}F -FDOPA PET imaging of brain tumors?

M. Bros, T. Zaragori, F. Rech, M. Blonski, L. Taillandier, A. Verger;
Centre Hospitalier Régional Universitaire
de Nancy, Nancy, FRANCE.

Aim/Introduction: ^{18}F -FDOPA is a PET amino-acid tracer recommended in brain tumor imaging for glioma assessment. There is currently no evidence-based recommendation for the use in this clinical setting of a premedication with Carbidopa, an inhibitor of peripheral DOPA metabolism, which increases ^{18}F -FDOPA availability during acquisitions. This study aimed to determine the impact of this premedication on conventional quantitative parameters used in the ^{18}F -FDOPA PET imaging of brain tumors. **Materials and Methods:** Ninety-four patients having undergone a ^{18}F -FDOPA PET for newly-diagnosed glioma, among which 72 also had dynamic acquisitions, and whom respectively 56 and 40 patients were premedicated with 100 mg of Carbidopa, were retrospectively included. Mean Standardized Uptake Values (SUVmean) were calculated on static images, as well the Time-To-Peak (TTP) and curve slope dynamic parameters, on the reference striatum and on the tumors regions. These previous quantitative parameters were also evaluated through ratios to the background. **Results:** In patients with Carbidopa premedication, significant higher values for SUVmean, longer TTP and more

increasing slope curves were observed in the striatum as compared to quantitative parameters obtained in patients without any premedication (respective values of 3.04 vs. 2.50; 29.9 vs. 28.9 min; and 1.9 vs. 0.7 SUV/h, $p \leq 0.01$). All these differences were no more documented after using ratios to the background (1.82 vs. 1.80; 30 vs. 29.1 min; and 1.1 vs. 1.3 h^{-1} , $p > 0.29$). In tumors regions, significant higher SUVmean values (2.75 vs. 2.25, $p < 0.01$) and a tendency to a longer TTP (14.6 vs. 10.9, $p = 0.06$) were also observed in patients with Carbidopa premedication, but no significant difference remained after using ratios to the background (1.67 vs. 1.66; 8.1 vs. 11.1 min, $p > 0.13$), no differences being observed between the two groups of patients regarding the tumor molecular status ($p > 0.31$). **Conclusion:** The effects of Carbidopa, mainly observed for static parameters, are no more documented after using ratios to the background parameters used in clinical routine. This potentially limits the added-value of this costly and not always easily available premedication in ^{18}F -FDOPA PET imaging of brain tumors. **References:** Law I, Albert NL, Arbizu J, et al. OP-361

Multicentre evaluation of the clinical impact of ^{18}F -FDOPA brain PET in the management of high grade gliomas

J. Darcourt¹, J. Gal¹, R. Schiappa¹, V. Bourg², L. Taillandier³, F. Le Jeune⁴, L. Collombier⁵, A. Kas⁶, A. Verger³;

¹Centre Antoine Lacassagne - UCA, Nice, FRANCE, ²CHU - UCA, Nice, FRANCE, ³CHRU, Nancy, FRANCE, ⁴Centre Eugène Marquis, Rennes, FRANCE, ⁵CHU, Nîmes, FRANCE, ⁶CHU Hôpital Pitié-Salpêtrière, Paris, FRANCE.

Aim/Introduction: ^{18}F -FDOPA PET is one of the nuclear medicine recommended methods for response assessment after initial treatment of high-grade gliomas (HGG) improving the differential diagnosis between tumour progression/recurrence and treatment-related changes. We present the preliminary results of a prospective multicentre trial to evaluate its practical clinical impact in this situation. **Materials and Methods:** 94 patients (mean age 54.7) followed after initial HGG treatment were included in 6 different centres. When MRI was not fully conclusive, a ^{18}F -FDOPA PET-CT static acquisition was performed (10-20 min post injection of 2-3 MBq/kg of ^{18}F -DOPA) within 28 days. PET and MRI images were coregistered. Images were visually analysed comparing tumour uptake to striatal activity (Lizarraga scale). They were considered positive when tumour uptake was equal or superior to striatal uptake. PET results were included in the clinical management of patients as follows. Multidisciplinary Neuro Oncology Board (MNOB)

meetings considered first clinical and MRI data (including perfusion and spectrometry) without knowledge of PET data and proposed a first diagnosis and a preferred treatment option (MNOB1). Then, 18F-DOPA PET images were shown and diagnosis and management were reconsidered for final decision (MNOB2). The role of PET data was evaluated by assessing the number of changes in patients' management decisions and, when unchanged, by the level of confidence in the final decision assessed on a 3 levels scale. **Results:** 78 patients were discussed once during MNOB meetings and 16 several times (2 to 3) leading a total of 115 studied cases. Between MNOB1 and MNOB2, diagnosis was changed in 18 cases (15.6%); leading to upstaging in 14 (12.6%) and downstaging in 4 (3.6%); management was changed in 27 cases (23.5 %). When management was unchanged, the confidence in final decision increased in 73 cases (82.9%), was unchanged in 14 cases (15.9%) and decreased in 1 cases (1.1%). **Conclusion:** This study confirms the usefulness of 18F-DOPA brain PET to differentiate progression/recurrence from treatment-induced changes during the follow-up of HGG. TEP-DOPA results modified patient's management in 23.5 % of the cases and improved the decision's confidence in most of the other cases. **References:** None

Evaluation of PSMA expression in high grade gliomas using ⁶⁸Ga-PSMA PET/CT

A. Kumar¹, S. T. ArunRaj¹, M. P. Yadav¹, S. Ballal¹, R. Kumar¹, D. Khan¹, A. Hemrom¹, K. P. Haresh², S. Gupta², N. A. Damle¹, A. Garg³, M. Singh⁴, M. Tripathi¹, C. Bal¹;

¹Department of Nuclear Medicine and PET/CT, All India Institute of Medical Sciences, New Delhi, INDIA, ²Department of Radiation Oncology, All India Institute of Medical Sciences, New Delhi, INDIA, ³Department of Department of Neuroimaging & Interventional Neuroradiology, All India Institute of Medical Sciences, New Delhi, INDIA, ⁴Department of Neurosurgery, All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Evaluation of Prostate Specific Membrane Antigen (PSMA) expression in high grade gliomas using Glu-NH-CO-NH-Lys-(Ahx)[Ga-68(HBED-CC)](Ga-68 PSMA 11) positron emission tomography (PET) for its potential theranostic application- with the background that recurrent high grade gliomas (HGG) and brainstem (BSG) gliomas have limited therapy options. **Materials and Methods:** Twenty-seven patients (M:F=16:11, Age:20-60, Median=37years) with recurrent HGG (Grade III and IV of WHO classification) on follow up MRI after treatment completion and five BSG patients (M:F=1.5:1, Age:5-18, median=11) with residual disease after treatment were prospectively evaluated using Ga-68 PSMA PET/CT. Images were acquired on Biograph-mCT scanner (Siemens Inc.) 45-60minutes after intravenous administration of 3-5mCi of Ga-68 PSMA-11. Scans were evaluated qualitatively by two experienced Nuclear

medicine physicians and analysed semiquantitatively using SUVmax of the target lesion, contralateral hemisphere [Target to contralateral ratio (TCR) for HGG], parotid and centrum semiovale (CS) [Target to CS ratio for BSG]. For HGG correlation of tumor MIB-index with SUVmax tumor and TCR, difference in SUVmax values in patients with positive and negative mutations for IDH and p53 were evaluated. **Results:** Twenty-seven patients with recurrent HGG included 10 grade III and 17 grade IV gliomas with median MIB index of 18% (8-20%, IQR). All had recurrent lesions reported on MRI and showed increased radiotracer uptake on PSMA PET/CT (100% detection rate) with median SUVmax of 6.2 (IQR- 3.9-8.5), median SUVmean of 3.36 (IQR- 2.7-3.7) and median TCR of 35.1 (IQR, 22.1-51.9). Median recurrent lesion to parotid SUVmax ratios were 0.34 (IQR, 0.27-0.54). Two glioblastoma multiforme patients had maximum lesion to parotid ratio (>1). No significant correlation with tumor MIB index and the uptake values was noted. Significantly high SUVmax and TCR values were observed in IDH wild type gliomas (p value of 0.02). Significant difference in distribution of SUVmax was also observed between positive and negative p53 gene mutations. Among 5 patients of brain stem glioma one was midbrain glioma and 4 were diffuse intrinsic pontine glioma with median SUVmax of 4.4 (IQR- 3.5-7.9), median SUVmean of 3.0 (IQR- 2.5-4.4) and median T/CSR of 33.9 (IQR-29.8-176.0). **Conclusion:** High TCR of recurrent HGG and high TCSR of BSG on Ga-68 PSMA PET/CT suggest potential for theranostics with Lu-177 PSMA-617 however tumor to parotid ratios will be the limiting factor limiting patient eligibility for therapy. Significantly high SUVmax and TCR values observed in IDH wild type gliomas suggest PSMA expression to be a potential biomarker for poor prognosis. **References:** None

OP-363

Imaging of androgen receptor by [¹⁸F]-FDHT PET/CT in patients with GBM

O. Shamni¹, N. Zalcman¹, A. Mordechai¹, S. Moscovici¹, C. Alexandre¹, Y. Shoshan¹, T. Shahar², H. Charbit¹, M. Guterma¹, I. Paldor¹, E. Mishani¹, A. Lossos¹, M. Orevi¹, I. Lavon¹;
¹Hadassah medical center, Jerusalem, ISRAEL, ²Shaare Zedek medical center, Jerusalem, ISRAEL.

Aim/Introduction: Glioblastoma multiforme (GBM) is the most malignant form of brain tumor and is associated with a median overall survival of 14.6 months. The androgen receptor (AR) is a member of the steroid hormone receptor superfamily which function through their ability to regulate the transcription of specific genes, some of which can promote cancer cell survival and growth. The 16β-18F-fluoro-5α-dihydrotestosterone ([¹⁸F]-FDHT) PET tracer has been used clinically in metastatic prostate cancer patients and permits the detection and relative quantification of the AR. Recently we showed that AR is overexpressed in

vast majority of GBM specimens. Ninety-three percent of the GBM samples showed AR RNA overexpression and 56% demonstrated AR-protein induction. Inhibition of AR signaling with FDA approved AR antagonists induced dose-dependent death in several glioblastoma cell lines and significantly reduced the growth of human glioblastoma in a xenograft mouse model. The aim of this study was to evaluate whether [¹⁸F]-FDHT PET can be employed to detect and quantify AR expression in GMB patients, and enable selection of candidates who might benefit from AR antagonist therapy. **Materials and Methods:** Twelve patients suspected of having GBM underwent dynamic (first 30 min) and whole-body static (later 60-80 min) [¹⁸F]-FDHT PET/CT (296-370 MBq) scans, 2-4 days prior to the surgery or biopsy. Tumor tissues were collected for pathology and AR-protein expression levels were measured by western blot analysis. AR expression levels were compared to [¹⁸F]-FDHT uptake (SUV_{mean} and SUV_{max}) and a correlation between AR-protein expression and [¹⁸F]-FDHT tumor uptake was calculated. **Results:** At 60 min after injection, 7 of the 12 patients showed significantly higher tumor accumulation of [¹⁸F]-FDHT, compared to reference tissue ($(SUV/Control)_{mean}$: 1.3-2.6 fold, $(SUV/control)_{max}$: 1.3-3.4 fold). The AR protein expression from the specimen was measured. In 6 of the 7 patients who had higher tumor accumulation of [¹⁸F]-FDHT, the AR protein expression was also increased, in comparison to the AR protein expression of normal brain tissue (1.4-2.3 fold higher). Pearson correlation coefficient for the $(SUV/Control)_{mean}$ at 60 min after the injection versus AR protein expression was calculated and showed a high positive correlation $r=0.88$ ($p < 0.002$). **Conclusion:** The findings indicate that [¹⁸F]-FDHT PET/CT can be used as a screening tool for selecting GBM patients who are candidates for therapy with AR antagonists. In addition, [¹⁸F]-FDHT PET/CT could possibly be employed to monitor treatment response and/or progression during the course of AR antagonist therapy. **References:** None

Hypoxia characterization in high-grade glioma: complementary role and spatial relationship of 18F-FAZA PET/CT, perfusion and diffusion brain MRI

P. Mapelli^{1,2}, P. Scifo², A. Castellano^{1,3}, F. Fallanca², G. Conte³, V. Bettinardi², A. Savi², E. Incerti², A. Coliva², A. Compierchio², N. Anzalone^{1,3}, L. Gianolli², M. Picchio^{1,2};

¹Vita-Salute San Raffaele University, Milan, ITALY, ²Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, ³Neuroradiology Unit and CERMAC, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim/Introduction: Definition of complementary value of 18F-FAZA PET/CT, perfusion and diffusion weighted MRI in assessing functional status of high-grade glioma (HGG), by assessing the mutual spatial relationship of co-

registered PET and MR acquisitions. **Materials and Methods:** Prospective study including 20 pts with HGG. Eighteen/20 pts underwent pre-treatment 18F-FAZA PET/CT. SUV was derived for each 18-FAZA PET scan. All pts also underwent MRI (FLAIR, T2w, 3D-T1w pre- and post-contrast, diffusion and perfusion images); however, only 11/20 have been considered for analysis with 18F-FAZA in this preliminary work. FAZA-PET, MR Perfusion and Diffusion images were firstly co-registered to 3D-T1 MR. Ktrans, Vp and CBV maps were calculated from Dynamic contrast enhanced (DCE) and Dynamic Susceptibility contrast (DSC) MR images. Mean Diffusivity (MD) was calculated from Diffusion Tensor MR (DTI). 18F-FAZA SUV maps were divided by the muscle value uptake to calculate defined maps. A threshold of tumour-to-muscle (T/M)>1.2 was used to define FAZA-based VOIs (VOIsFAZA). By using these VOIsFAZA, Spearman correlations between FAZA SUV and perfusion parameters have been calculated for each subject. A second VOI has been defined in pw-maps and MD based on the Gd-enhanced regions on 3D T1 post contrast images (VOIsGd). Then, the spatial coordinates of center-of-mass (CoM) of VOIsGd in each parametric map (Ktrans, Vp, CBV, MD, FAZA) were found and relative distances were calculated for each patient. **Results:** With a T/M threshold of 1.2 for FAZA SUV and the 3D T1 Gd-enhancement, mean values \pm SD of the volumes were: 12.4 ± 12.3 cc for VOIsFAZA and 26.6 ± 22.1 cc for VOIsGd, respectively. Tumour volumes were different between the two modalities ($p < 0.004$). Using FAZA and VOIsGd, mean values of Dice and Jaccard coefficients were 0.588 ± 0.166 and 0.434 ± 0.165 ; volume overlap was 0.612 ± 0.254 . CoMs of pw-maps and MD in the VOIsGd, were in different positions depending on the map. The relative distances from FAZA CoMs of some MR CoMs were correlated: Ktrans and Vp ($p=0.000$), Vp and CBV ($p=0.002$), Vp and MD ($p=0.007$) and CBV and MD ($p=0.002$). No differences in the distances were found between the different CoMs, neither normalizing with the volume extension. **Conclusion:** FAZA PET and Gd-MR enhancement provide different information on tumour hypoxia as indicated by the low similarity indexes; the similar relative distances of MR CoMs from FAZA CoM suggest that all MR parameters are more correlated among them compared to FAZA. This suggests that FAZA PET and MRI provide complementary information in HGG patients. **References:** None

EPS-069

Clinical Significance of Extra-thyroid ^{99m}Tc-Perchnetate

Uptake before Initial Radioiodine Therapy for Differentiated Thyroid Carcinoma

B. Long^{1,2,3}, L. Yao^{1,2,3}, H. Yi^{1,2,3}, S. Chen^{1,2,3}, S. Jin^{1,2,3}, X. Ye^{1,2,3}, C. Lou⁴;

¹Institute of Cancer and Basic Medicine (ICBM), Chinese Academy of Science, Hangzhou, CHINA, ²Department of Nuclear Medicine, Cancer Hospital of the University of Chinese Academy of Sciences, Hangzhou, CHINA, ³Department of Nuclear Medicine, Zhejiang Cancer Hospital, Hangzhou, CHINA, ⁴Department of Nuclear Medicine, Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.

Aim/Introduction: ^{99m}Tc-pertechnetate scanning is commonly used to evaluate thyroid remnants before the initial radioiodine (RAI) therapy for differentiated thyroid carcinoma (DTC). However, extra-thyroid ^{99m}Tc-pertechnetate uptake is rarely reported. This study aimed to investigate the clinical significance of extra-thyroid ^{99m}Tc-pertechnetate uptake before the initial RAI therapy for DTC. **Materials and Methods:** We retrospectively analyzed 4930 RAI-treated DTC patients. Thirty-eight cases of extra-thyroid ^{99m}Tc-pertechnetate uptake were selected. The clinical features, location, location count, and extra-thyroid ^{99m}Tc-pertechnetate uptake distribution were analyzed, combined with the uptake rate, stimulated thyroglobulin (sTg) level, post-therapy whole-body scan, and curative effect. **Results:** Sixty-five extra-thyroid ^{99m}Tc-pertechnetate foci were detected in 38 patients. The patient proportions with abnormal uptake in the lymph nodes, lungs, and bones were 68.4%, 10.5%, and 10.5%, respectively. The corresponding uptake rates were 0.2%, 0.2%, and 0.8%. The uptake rate was significantly lower in the lymph nodes than in the bones ($Z = -2.722$, $p = 0.019$). The uptake rate and sTg were positively correlated ($r = 0.36$, $p = 0.027$). ¹³¹I uptake was found in 36 cases at the technetium uptake site, and the number of iodine uptake foci was significantly higher than that of ^{99m}Tc-pertechnetate uptake foci. The sTg value and pathological staging significantly differed between the excellent and nonexcellent response groups ($Z = 2.947$, $p = 0.003$, and $Z = 2.348$, $p = 0.019$, respectively). **Conclusion:** In most cases, extra-thyroid ^{99m}Tc-pertechnetate uptake before RAI therapy for DTC indicated metastasis with specific clinical features, which may have prognostic value for the judgment of the iodine uptake function and RAI therapy plan. **References:** None

EPS-071

Association between clinical and tumor features with postoperative thyroglobulin in pediatric papillary thyroid cancer

T. Tian, B. Liu;

West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: Postoperative pre-ablation stimulated thyroglobulin (s-Tg) has the capability of predicting the

clinical outcomes in children and adolescents with thyroid cancer. However, the exact reason for the prevalence of elevated pre-ablation s-Tg in certain thyroid cancer patients without distant metastasis is unknown. The aim of our study was to systematically investigate the associations of pre-ablation s-Tg with clinical and tumor characteristics in children and adolescents with papillary thyroid cancer.

Materials and Methods: A retrospective analysis of 93 children and adolescents without initial distant metastases who underwent remnant ablation was performed. Pre-ablation s-Tg after thyroid hormone withdrawal and clinical and histopathologic characteristics, according to American Thyroid Association pediatric initial risk classification system, was assessed. **Results:** The median age was 18 years, and the majority were female (79.6%). The pre-ablation s-Tg ranged from 0.02–902.00 ng/mL, with a median of 9.2 ng/mL. Forty-five (48.4%) patients presented elevated pre-ablation s-Tg (> 10 ng/mL). In multi-variate analyses of clinical and tumor characteristics, high-risk stratification and high neck uptake (>2%) were the independent predictive factors for the presence of elevated pre-ablation s-Tg. **Conclusion:** Children and adolescents with high-risk stratification and high neck uptake are likely to present a high level of pre-ablation s-Tg after surgery. Our study confirms that pre-ablation s-Tg is a useful biomarker for monitoring post-operative residual disease in pediatric thyroid cancer. **References:** 1. Radiation dose to family members during hospitalization of pediatric thyroid cancer patients treated with radioactive iodine

H. Tissot¹, T. Henry¹, A. Cosse², L. Lamartina³, M. Terroir¹, J. Hadoux³, D. Hart⁴, E. Baudin³, M. Schlumberger⁵, N. Guilabert², S. Leboulleux¹;

¹Nuclear Medicine Department, Gustave Roussy, Villejuif, FRANCE, ²Service de Radioprotection, Gustave Roussy, Villejuif, FRANCE, ³Endocrine Oncology, Gustave Roussy, Villejuif, FRANCE, ⁴Department of Head and Neck Oncology, Thyroid Surgery Unit, Gustave Roussy, Villejuif, FRANCE, ⁵Departments

of Nuclear Medicine and Endocrine Oncology, Gustave Roussy and University Paris-Saclay, Villejuif, FRANCE.

Aim/Introduction: Radioactive iodine (RAI) is often used for the treatment of pediatric thyroid cancer (TC). Given the young age of the patients, support from family members (FM) is often needed during hospitalization. RAI is a source of radiation exposure to FM that should be minimized. A dose constraint of 5 mSv per episode is deemed reasonable according to the International Atomic Energy Agency. The aim of this retrospective monocentric study was to evaluate the radiation dose received by FM accompanying pediatric patients treated with RAI in our center. **Materials and Methods:** Prior to hospitalization for RAI administration, FM were given an operational dosimeter to be carried when present in the hospital room. The following radiation protection recommendations were given: entering the room was allowed from RAI administration until discharge (72 hours post treatment). We encouraged multiple FM to visit a given patient, but only one relative at a time was allowed in the room; staying in the room was allowed for one person. Radiation exposure of 28 FM from 17 pediatric patients (median age 12 years, 13 females, 7 with distant metastases) treated with RAI (median 131-I activity: 2265 MBq; range: 967–3745) between 2014 and 2019 was recorded. **Results:** The median time during which a pediatric TC was accompanied by a FM was 20h17 (range: 3h10–64h20). During the first 24h following RAI administration, the median time spent by each FM in the room was 4h05 min (range: 51min–20h29). During the first night, 12 FM stayed in the room, 9 during the 2nd night and 10 the 3rd night. Four FM stayed 3 nights in the room. Each RAI treatment was associated with a median cumulative radiation dose for the entire family of 74.5 μ Sv (range: 8–545). The median cumulative radiation dose to each of the 28 FM during their entire stay at the hospital was 66 μ Sv (range: 2–374), and the median duration of time spent in the room was 16h35 (range: 0h51–59h50). The median cumulative radiation dose to each FM was 93 μ Sv during the 1st night (range: 25–229), 30 μ Sv during the 2nd night (range: 6–98) and 9 μ Sv during the 3rd night (range: 3–110). **Conclusion:** Levels of radiation received by family members who stay and sleep in the hospital room of pediatric TC patients treated with RAI were low. This should permit relatives to stay with their child even during the nights whenever needed. **References:** None

Aim/Introduction: Differentiated Thyroid Cancer (DTC) is one of the most frequent malignancies, especially among women and young adults. Radioiodine therapy (RAIT) is performed to achieve full ablation of thyroid remnants after thyroidectomy. However, persistence or recurrence of DTC after RAIT is observed in around 12.5% of patients, often requiring subsequent therapy. The aim of our study was to evaluate the predictive value of post-therapeutic dosimetry and thyroglobulin measurements to identify patients at risk for persistent or recurrent DTC post RAIT. **Materials and Methods:** This monocentric retrospective study enrolled patients with DTC treated with RAIT between January 2010 and October 2019. All patients were iodine-naive, non-metastatic and RAIT was realized after thyroid hormone withdrawal. Patients with positive anti-thyroglobulin antibodies were excluded. All patients performed two post-therapeutic planar scintigraphies centered on the neck area for intended dosimetry using identical acquisition parameters 24–48 hours and 120–168 hours after RAIT. Thyroglobulin (Tg) concentrations were measured the day 0 of RAIT (Tg₀) and after therapy at the same time-points as post-therapeutic scintigraphy (Tg₁). Tg₁/Tg₀ ratios were calculated, for each patient the highest ratio reached at different post-therapeutic Tg was considered for analysis. Absorbed energy to the remnants (AER) was measured in mJoules (mJ) using anterior planar scintigraphy and normalized for Tg₀. Persistence or recurrence of DTC was defined at one-year follow-up after RAIT either as nonstimulated Tg level ≥ 0.2 μ g/L or stimulated Tg level ≥ 1.0 μ g/L, positive thyroid bed uptake observed at WBS or suspicious finding on neck ultrasonography with pathological confirmation. **Results:** Out of 103 patients, 24/103 (26.2%) presented persistent or recurrent DTC at 1-year follow-up. Median Tg₀ was significantly higher (28.0 μ g/L vs 3.2 μ g/L, $p < 0.0001$) and Tg₁/Tg₀ ratio were significantly lower (2.7 vs 11.9, $p < 0.0001$) in the recurrence group as compared to the complete ablation group, ROC analysis of Tg₀ and Tg₁/Tg₀ ratio showed an AUC of 0.86 (CI95%=0.78–0.94) and 0.75 (CI95%=0.63–0.86) respectively. Median normalized AER was significantly lower in the recurrence group compared to the complete ablation group (6.7 mJ/ μ gTg/L vs 71.4 mJ/ μ gTg/L, $p < 0.0001$). ROC analysis of normalized AER showed an AUC of 0.86 (CI95%=0.76–0.97). A cut-off value of < 20 mJ/ μ gTg/L AER predicted persistent or recurrent DTC with a sensitivity and a specificity of 85.2% and 86.8% respectively (PPV=70%, NPV=94%). **Conclusion:** Post-therapeutic dosimetry and circulating Tg evaluation before and after RAIT allows more precise risk stratification of DTC after ablative radioiodine

therapy. **References:** None

EPS-074

Is endogenous TSH-stimulation associated with more violent cell destruction during radioiodine therapy than exogenous TSH?

I. Lopo¹, P. Lapa^{1,2}, G. Costa^{1,2}, J. Pedroso de Lima^{1,2,3};

¹Serviço de Medicina Nuclear do Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL,

²Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL, ³Instituto de Ciências Nucleares Aplicadas à Saúde (ICNAS), Coimbra, PORTUGAL.

Aim/Introduction: Thyroglobulin (Tg) is release into the blood along with thyroid hormones. This physiologic leak is amplified by situations that promote cell destruction, like radioiodine therapy (RAI-T). It is therefore reasonable to think that the increase in serum Tg, during the days following iodine administration, may reflect the magnitude of the target cell death. In RAI-T for differentiated thyroid carcinoma (DTC), patient's preparation can be done either by thyroid hormone withdraw or by exogenous administration of rhTSH. With this study, we aim to compare the magnitude of the variation of TSH-stimulated Tg (stTg) between the two preparation methods. **Materials and Methods:** A total of 107 patients with DTC, admitted in our Department for the first RAI-T (January/2016-December/2019), were selected. During hospitalization for RAI-T, we collected two blood samples to measure stTg level: stTg0h (just before the radioiodine administration) and stTg48h (48 hours after radioiodine). The RAI-T variation of serum stTg was defined as the ratio between stTg48h and stTg0h (stTg-ratio). All patients were considered to have an adequate TSH stimulation and were negative for serum Tg-autoantibodies. According to the method of TSH stimulation, patients were divided in two groups: endogenous (n=47; 43.93%) vs exogenous with rhTSH (n=60; 56.07%). During follow-up, and according to the established criteria based on international guidelines, each patient was then classified as responder or no-responder to the initial treatment. Relevant demographic and clinical data available were collected (age, gender, histology, TNM-classification, radioiodine administered activity). Using SPSS for statistical analysis, a comparison between the stTg-ratio in both groups (Mann-Whitney U test) and the association between the TSH stimulation method and the therapeutic response (Chi-square test) were evaluated. **Results:** Statistically significant higher values of stTg-ratio were found in the group of patients prepared with endogenous-TSH (p<0.001). No difference was found between the two groups regarding to gender, tumour histology and TNM-classification. Patients in exogenous group were older (p=0.002) and were exposed to a higher radioiodine activity (p=0.002) compared to endogenous one. Responders

rate were slightly better in patients prepared with thyroid hormone withdraw (p=0.046). **Conclusion:** Our results suggest that endogenous stimulation of TSH is associated with a more intense release of tissue-stored-Tg into the blood, indicating faster or more extensively cell destruction than the exogenous TSH-stimulation, impacting in some way the responder's rate. **References:** None

EPS-075

Long-term outcome of RAI remnant ablation in low-risk differentiated thyroid cancer patients

A. Tupalli, B. Mangu, A. Hemrom, N. Mohan, C. Bal;

All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Post definitive surgery for thyroid carcinoma, all patients are stratified into low, intermediate, or high-risk categories, which helps in surveillance and therapeutic management decisions. If the significant remnant is present post-surgery, radioactive iodine (RAI) ablation was indicated earlier. This retrospective cohort study was designed to assess the long-term outcomes, namely, the recurrence rate and overall survival (OS) in low-risk DTC patients. **Materials and Methods:** The cohort of DTC patients at our center is being meticulously followed in Thyroid Clinic, Department of Nuclear Medicine, AIIMS, New Delhi since 1967. In our previous 3 randomized control trials since 1990, we had recruited 1080 (149 +509 +422) low-risk DTC patients for remnant ablation. The data of 390/1080 patients who were administered ≤ 30 mCi of ¹³¹I were analyzed for long term outcomes, i.e., recurrence, OS, and prognostic factors. **Results:** Out of 390 patients, 300 were females, and 90 were males. The median follows up period was 122.6 months. The recurrences were developed in 4/390 (1%) patients. The median time to recurrence was 77.5 months, ranging from 54 to 108 months. Two patients had loco-regional failures, 1 had pulmonary recurrence alone, and 4th one had both pulmonary and skeletal recurrences. The patient who had a recurrence in lungs and bones received 150 mCi RAI therapy, on scan proved to have TENIS, thus was put on TKI (Sorafenib). Initial serum Tg was >300 ng/ml, and subsequently, become biochemical and radiological disease-free at the end follow-up. The patient who had a recurrence in the lungs alone did not respond to RAI therapy, and TKI continued on progression but still surviving with the disease at last contact. Out of 2 Patients who had cervical lymph nodal recurrence, surgery could not be performed due to co-morbid conditions; one progressed even after RAI therapy, and TKI and other person lost to follow up immediately after recurrence. None of the low-risk patients died even after recurrence. No associated factors could be found for recurrence. Until now, no secondary hematological malignancy or any other solid organ malignancy has been observed. **Conclusion:** The results are very reassuring. In ATA low-risk

DTC patients, with a median follow up of 10 years, loco-regional and distant failure combined is 1%, who had received remnant ablation less than or equal to 30 mCi of ^{131}I . **References:** None

EPS-076

Prognostic factors for patients with low-risk differentiated thyroid cancer after surgery and the first ^{131}I therapy

M. Xiao^{1,2}, H. Xingmin^{1,2}, L. Baoping^{1,2};

¹The First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA, ²Henan Medical Key Laboratory of Molecular Imaging, Zhengzhou, CHINA.

Aim/Introduction: Radioactive iodine (RAI) therapy for thyroid remnant ablation is used to treat differentiated thyroid carcinoma (DTC). This study aimed to evaluate the prognostic factors for patients with low-risk DTC after surgery and adjuvant RAI therapy. **Materials and Methods:** From March 2015 to October 2017, patients with low-risk DTC who underwent ^{131}I therapy after total thyroidectomy were retrospectively analyzed. Multivariate logistic regression analyses were performed using eight variables, including age, gender, pathological type, size of primary tumor, lymph node metastasis, interval between surgery and ^{131}I therapy, thyroid-stimulating hormone (TSH) and stimulated postoperative thyroglobulin (sPOTg) levels before ^{131}I therapy. The predictive value of the independent associated factors on prognosis was assessed by receiver operating characteristic (ROC) curve. **Results:** A total of 158 patients were included in the study, 94 (59.5%) of them were disease free after the first postoperative ^{131}I therapy. There were no statistical differences in any of the variables between the disease free group and persistent disease group except that of TSH and sPOTg levels before ^{131}I therapy ($P < 0.05$). Multivariate analysis showed that sPOTg level was an independent prognostic factor (OR=1.100, 95%CI: 1.056-1.146, $P < 0.001$). The area under ROC curve was 0.806 (95%CI: 0.739-0.873). The corresponding sensitivity and specificity of sPOTg level was 92.2% and 58.5%, respectively. **Conclusion:** sPOTg is a prognostic factor for patients with low-risk DTC who received surgery and adjuvant ^{131}I therapy, and it may be a clinically useful marker. **References:** None

Radioiodine-131 therapy during preimplantation period of pregnancy: Evaluation of uterus exposition of a patient with differentiated thyroid carcinoma

C. Happel¹, D. Gröner¹, M. Borowski², M. Fiebich³, B. Schulze⁴, A. Sabet¹, W. T. Kranert¹, F. Grünwald¹;

¹University Medical Center Frankfurt, Department of Nuclear Medicine, Frankfurt, GERMANY, ²Städtisches Klinikum Braunschweig GmbH; Institut für Röntgendiagnostik und Nuklearmedizin, Braunschweig, GERMANY,

³Technische Hochschule Mittelhessen Gießen; Institut für Medizinische Physik und Strahlenschutz, Gießen, GERMANY, ⁴Genetische Beratung und Diagnostik; Kaiserstraße 6; Frankfurt am Main, Frankfurt, GERMANY.

Aim/Introduction: To protect the unborn life, pregnancy is an absolute contraindication for radioiodine-131 therapy (RIT). Therefore, ruling out pregnancy by beta hCG pregnancy testing (PT) can be considered mandatory prior to RIT. However, a sufficient amount of hCG can at the earliest be proven in a blood sample seven days after fertilization, resulting in a given time gap of proof. **Materials and Methods:** A 39-year-old patient with differentiated papillary thyroid cancer (DTC) was treated with RIT. The patient declared not to be pregnant and the PT performed upon administration was negative. Subsequently, 3.721 MBq of radioiodine-131 were administered orally. One month after discharge pregnancy was detected. Conception was dated about 5 days prior to the administration of radioiodine-131 by the gynecologist. Therefore, a reasonable recommendation concerning the further course of the pregnancy was requested. **Results:** Radiation dose to the uterus was estimated according to the 2019 revised DGMP report No. 7 [1]. It subdivides the human development into preimplantation period (0-10d p.c.), organ building period (10d-8w p.c.) and fetal period (3-9m p.c.). A radiation exposure (>100 mSv) during the preimplantation period leads to either cessation of pregnancy or regular implantation (all-or-nothing effect). No other detriments are to be expected during this period. In the presented case the exposure likely occurred during this period. However, an exposition during the organ building period might lead to severe malformations. As, within the given uncertainty, conception might be more than 10d before dose application and from the fact that the exposure lasted for a longer period, dose to the uterus was calculated. The dose to the uterus was calculated to be 283 mSv, using a conversion factor of 76 $\mu\text{Gy}/\text{MBq}$ as stated in [1]. This dose is clearly above the threshold for anatomic malformations, growth disturbance and mental retardation, which is expected to be 100 mGy. After genetic counseling and detailed discussion with the patient the pregnancy was continued until a healthy child was delivered. **Conclusion:** The DGMP report is an indispensable guideline for nuclear medicine physicians, medical physicists and gynecologist to assess the uterus dose of pregnant women, who were exposed to radiation [1]. Additionally, detailed genetic counselling is indispensable. The dose consideration and the resulting potential consequences for the health of the child show the importance of a reliable PT prior to RIT. **References:** Pränatale Strahlenexposition aus medizinischer Indikation. Dosisermittlung, Folgerungen für die Ärztin/den Arzt und Schwangere. DGMP-Bericht Nr.7; Überarbeitete und ergänzte Neuauflage 2019; ISBN 978-3-00-064613-3.

EPS-078**Variation of serum thyroglobulin during the first radioiodine therapy: a prognostic marker in patients with thyroid carcinoma?**I. Lopo¹, P. Lapa^{1,2}, G. Costa^{1,2}, J. Pedroso de Lima^{1,2,3};¹Serviço de Medicina Nuclear do Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL,²Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL, ³Instituto de Ciências Nucleares Aplicadas à Saúde (ICNAS), Coimbra, PORTUGAL.

Aim/Introduction: In patients with differentiated thyroid carcinoma (DTC), serum thyroglobulin (Tg) is extensively used for postoperative initial risk stratification and for disease monitoring, during life-long follow-up. Low Tg levels are expected to be associated with better outcome. However, a few days after radioiodine therapy (RAI-T), a dramatic transient serum Tg level elevations could be observed, reflecting benign/malignant thyroid tissue destruction. Our aim is to evaluate the value of the variation of TSH-stimulated Tg (stTg) during the first RAI-T, as prognostic marker. **Materials and Methods:** We review the clinical chart of all patients with DTC submitted to the first RAI-T in our Department, between January-2016 and December-2019. During hospitalization for RAI-T, a dual time stTg measurements were performed: stTg0h (just before the radioiodine administration) and stTg48h (48 hours after radioiodine administration). The variation of serum stTg was defined as the ratio between stTg48h and stTg0h (stTg-ratio). All patients were negative for serum Tg autoantibodies. Based on therapeutic responses at follow-up, and according to ATA guidelines, patients were divided in two groups: excellent or indeterminate/incomplete responses. To evaluate the association between stTg-ratio and therapeutic responses, a Mann-Whitney U test and ROC curve were performed. All relevant clinical data available were collected, either those known at the RAI-T (histology, TNM-classification, TSH-stimulation method, post-therapy whole-body scan) or those registered later, during the follow-up (Tg level and neck ultrasound, performed 6-30 and 4-36 months after RAI-T, respectively). **Results:** One hundred and eight patients were enrolled (mean age 52.4±15.5 years; 75.0% women; 89.8% papillary carcinoma; TMN: T1=27.8%, T2=24.1%, T3=47.2%, T0=0.9%). Statistical analysis showed that stTg-ratio was significantly higher in the group of 66 patients (61%), with excellent RAI-T response, than in the group of indeterminate/incomplete RAI-T response ($p<0.001$). However, when grouping for the TSH-stimulation method, just thyroid hormone withdrawal ($n=48$ patients; 44%) showed association between stTg-ratio and therapeutic response ($p=0.001$). For this group, a ROC curve analysis predicted an optimal stTg-ratio cutoff value of 2.41, with a sensitivity of 88.6% and specificity of 76.9% for an excellent response (AUC=0.813, 95%CI

0.669-0.957; $p=0.001$). **Conclusion:** Our study suggest that when endogenous TSH stimulation is used, stTg-ratio is a potential predictor of response to the initial RAI-T, pointing to an excellent result if higher than 2.41. **References:** None

EPS-079**Efficacy of a 740 MBq Single Fixed Radioactive Iodine Dose for Subclinical Hyperthyroidism Treatment and Implications of Pretreatment Thyroid Antibodies Levels**

F. Cañete, P. Garrastachu, X. Boulevard, L. Romero, M. Mangas, A. Cabrera, R. Delgado-Bolton, R. Ramírez;

Centre for Biomedical Research of La Rioja (CIBIR), Logroño, SPAIN.

Aim/Introduction: There is an emerging role for I-131 in the treatment of so-called subclinical hyperthyroidism[1]. Our study first aimed to evaluate the efficacy of a fixed dose of 740MBq of I-131 in subclinical hyperthyroidism treatment and to assess the secondary effects frequency. A second aim is to see if there is any correlation between previous elevated thyroid antibodies and final thyroid function status. **Materials and Methods:** We retrospectively studied patients with normal thyroid hormone levels and suppressed thyroid-stimulating hormone concentrations persistent for at least six months, with no previous antithyroid drugs treatment, recent Tc-99m pertechnetate thyroid scan (to discard low thyroid uptake) and neck ultrasound, treated with a fixed dose of 740MBq of I-131. Clinical and thyroid function test were periodically reviewed thereafter for a minimum period of eight months. Also, 36 patients had antithyroid peroxidase and antithyroid stimulating antibodies tests previous to radioiodine treatment. The elevation of any or both of them was considered as positive, and normal or negative values were considered negative. Chi-square test was used for the comparison between categorical variables. A $p<0.05$ was considered statistically significant. **Results:** 62 patients (21%males, 79% females; age: 70±11,8, 45-94 years) treated from October 2009 to November 2015 met inclusion criteria. Of this group, 85% were toxic multinodular goiter and 15% single hyperfunctioning adenoma. 100% of our patients achieved response, out of which 32% finally became hypothyroid and 68% euthyroid. After a clinical following mean period of 4 years and 7 months (range 8 months to 8 years and 8 months), only one patient (1.6%) presented secondary effect, which was transient gastritis. The majority of patients with negative antibodies (74%) were euthyroid and most of those with positive antibodies (89%) became hypothyroid after radioiodine treatment ($p=0,001$). **Conclusion:** Using a fixed dose of radioactive iodine dose of 740MBq for treating toxic multinodular goiter and single hyperfunctioning adenoma subclinical hyperthyroidism, successful treatment can be achieved in 100% of the patients, with very low (1.6%) side effects rate. Furthermore, there is a good correlation between elevated thyroid antibodies previous radioiodine treatment

and getting hypothyroid status after it. Normal or negative antibodies pretreatment leads to euthyroidism. **References:** [1] Stokkel MP, Handkiewicz Junak D, et al. EANM procedure guidelines for therapy of benign thyroid disease. *Eur J Nucl Med Mol Imaging*. 2010 Nov;37(11):2218–28.

Assessment of preoperative imaging techniques in patients with primary hyperparathyroidism treated in an unique endocrine surgical unit

I. Saura Lopez, M. J. Ribelles Segura, I. Blanco Saiz, L. Paruta Araez, M. I. Morales Lozano, J. García Torres, N. A. Rudic Chipe, F. Gomez Sainz, M. Díaz Tobarra, Á. O. Rabines Juarez, E. Anda Apiñaniz, H. Gomez Herrero, A. Echegoyen Silanes, A. Camarero Salazar, P. Salvador Egea, E. Goñi Gironés; Navarra Hospital Complex, Pamplona/Iruña, SPAIN.

Aim/Introduction: Because the only treatment of primary hyperparathyroidism (pHPT) is the surgery management, evidence-based recommendations enhance the appropriate and effective practice in reference hospitals. We want to evaluate the records of our unit in order to check that the results of our team are within the current standards. The aim of this study was to determine the diagnostic performance of [^{99m}Tc]Tc-MIBI SPECT/CT and ultrasonography (US) for preoperative localization of parathyroid adenoma. **Materials and Methods:** Retrospective study of 152 patients with a median (interquartile range, IQR) of age 63 (52–71) and 80.3% women, from August 2016 to December 2019 in Complejo Hospitalario de Navarra. All patients underwent [^{99m}Tc]Tc-MIBI dual-phase scintigraphy with early SPECT/CT and US prior to surgery. In doubtful cases, L-[methyl-¹¹C]-methionine PET/CT and/or CT were added. Sensitivity and positive predictive value (PPV) were calculated. Histopathology was used as reference value. **Results:** Preoperative laboratory data were median (IQR) of calcium 11 mg/dL (IQR 10.7–11.5), PTH 181 pg/mL (IQR 144–249) and 25-hydroxyvitamin D 18 ng/mL (IQR:13–26). More than one surgical criterion was found in 26 cases (17.1%) and the most frequent surgical procedure was minimally invasive parathyroidectomy (121 cases; 79.6%). Parathyroid lesion was successfully removed in 142 (93.4%) patients, corresponding 139 (91.4 %) to adenomas (5 double), 2 hyperplasias and 1 carcinoma. Sensitivity and PPV were 83% and 94% for [^{99m}Tc]Tc-MIBI; 74% and 95% for US, respectively. Parathyroid [^{99m}Tc]Tc-MIBI scintigraphy had reported the accurate surgical location in 116 (76.7%) patients (102 eutopic and 14 ectopic), whereas US located in 100 (68.5%) patients (94 eutopic and 6 ectopic). The difference was statistically significant ($p = 0.03$). Both, [^{99m}Tc]Tc-MIBI and US were concordant in the precise localization of the lesion in 94 (61.8%) patients, corresponding to adenoma 88 (93.6%). The remaining 58 (38%) patients in whose there were discordant results or both failed results were explored

with PET/CT (36 cases) and/or CT (14) being diagnostic 10 and 11 patients, respectively, thereby achieving the correct excision of the pathological gland in 54/58 (93.1%) patients. **Conclusion:** [^{99m}Tc]Tc-MIBI scintigraphy shows significantly higher sensitivity and accuracy than US in anatomical presurgical localization in primary hyperparathyroidism. The combined use of both techniques provides the necessary information for the surgical decision in most patients. However, radioguided surgery should be considered in the subgroup of patients in which, despite the addition of other available diagnostic tests, removal of the adenoma is not achieved. **References:** None

EPS-081

¹¹C-methionine PET/CT for the evaluation of patients with recurrent or persistent secondary hyperparathyroidism after surgery and negative or inconclusive ^{99m}Tc-MIBI scintigraphy

A. Damian^{1,2}, A. Quagliata¹, S. San Roman³, E. Silvera², M. Rodriguez Taroco¹, N. Niell^{1,2}, R. Castro¹, R. Silvariño³, O. Alonso^{1,2}; ¹Uruguayan Centre of Molecular Imaging (CUDIM), Montevideo, URUGUAY, ²Centro de Medicina Nuclear e Imagenología Molecular, Hospital de Clínicas, UdelaR, Montevideo, URUGUAY, ³Centro de Nefrología, Hospital de Clínicas, UdelaR, Montevideo, URUGUAY.

Aim/Introduction: Persistent or recurrent secondary hyperparathyroidism (sHPT) after parathyroidectomy is a complex clinical scenario and constitutes a diagnostic and therapeutic challenge. Few studies have assessed the additional value of ¹¹C-methionine PET/CT in the evaluation of patients with primary hyperparathyroidism and negative MIBI scans that previously underwent surgery. However, no study has explored the diagnostic performance of this modality in patients with sHPT. Thus, the objective was to evaluate the detection capability of ¹¹C-methionine PET/CT in these patients. **Materials and Methods:** We included 16 patients (5 women, median age 57.5 years, range 39–72 years) with chronic renal failure, persistent or recurrent sHPT after surgery and a negative or inconclusive dual-phase ^{99m}Tc-MIBI scintigraphy. PET/CT was acquired 10 minutes after the administration of a dose of approximately 400 MBq of ¹¹C-methionine. SUV_{max}, SUV parathyroid/cervical soft tissue and SUV parathyroid/thyroid index were calculated for each positive lesion. **Results:** ¹¹C-methionine PET/CT was positive for the detection of hyperfunctioning parathyroid tissue in 14 patients (87.5 %). Three patients (18.8%) had multiple gland foci. Serum PTH ranged from 288 to 3000 pg/mL (median 1450 pg/mL). In eleven patients (68.8%) the hyperfunctioning tissue was located in the neck and in three patients (18.8%) it was located in the mediastinum. Lesion size measured on axial CT ranged from 6 to 25 mm (median 9 mm). Median SUV_{max} of the

positive lesions was 3.7 (range from 2 to 7.1), while median SUV parathyroid/cervical soft tissue index was 2.6 (range from 1.7 to 4), and median SUV parathyroid/thyroid index was 1.4 (range 1 to 2.85). Four of the patients underwent a second or third parathyroidectomy after PET. **Conclusion:** ^{11}C -methionine PET/CT may provide valuable information for the localization of hyperfunctioning parathyroid tissue in patients with persistent or recurrent sHPT after surgery. **References:** None

F18-choline PET/CT in primary hyperparathyroidism when conventional tests are negative or inconclusive

J. Atance García de la Santa, D. Zamudio Rodríguez, R. Pérez Pascual, J. J. Ardila Mantilla, Y. K. Henao Celada, M. Baquero Oliveros, M. I. Gómez Fernández, A. Rotger Regí, C. M. Durán Barquero, A. Marí Hualde, J. E. Orcajo Rincón, J. C. Alonso Farto, S. Vargas Martín; Hospital Universitario Gregorio Marañón, Madrid, SPAIN.

Aim/Introduction: To assess the sensitivity of F18-choline PET/CT for parathyroid adenoma detection in patients with primary hyperparathyroidism (PHPT) and negative or inconclusive Tc99m-MIBI scintigraphy (planar and SPECT/CT) result. **Materials and Methods:** Prospective study of a series of patients with PHPT and previous negative or inconclusive results in conventional tests. All patients underwent F18-choline PET/CT; the result was scored as positive, inconclusive or negative. The number of uptake foci and their sites were recorded. The result of the F18-choline PET/CT guided the surgical procedure (selective parathyroidectomy or bilateral cervical exploration). The results were compared with the pathological findings. **Results:** 46 patients were included: 30 (65.2%) with a negative and 16 (34.8%) with an inconclusive previous Tc99m-MIBI scintigraphy result. 9 of them had a persistent/recurrent PHPT despite previous parathyroid surgery (8 after a negative and 1 after an inconclusive Tc99m-MIBI scintigraphy result). 38 (82.6%) F18-choline PET/CT were scored positive, 2 (4.4%) inconclusive and 6 (13%) negative, showing 45 cases of uniglandular disease, including 2 ectopic localizations and 1 case of multiglandular (2 foci) disease. 16 patients have already undergone surgery. In 14 patients (87.5%) a positive F18-choline PET/CT result guided surgery: 9 selective parathyroidectomies (64%) and 5 bilateral cervical explorations. The PHPT of these 14 patients was solved after surgery (their levels of PTH and calcium decreased) and pathological findings was adenoma in everyone of them (14 true positives). 1 patient with a positive F18-choline PET/CT result underwent a bilateral cervical exploration in another hospital regardless of this result. In this patient the PHPT persisted after surgery and no adenoma was found in the pathological

examination. 1 patient with a negative F18-choline PET/CT result underwent bilateral cervical exploration, with resolution of the PHPT, and was considered 1 false negative. With current data, sensitivity and positive predictive value were both 93%. **Conclusion:** Preoperative F18-choline PET/CT appears to have a high sensitivity and positive predictive value for parathyroid adenoma detection in patients with PHPT and negative or inconclusive conventional tests. Bilateral cervical exploration could be avoided in up to 60% of patients. **References:** None

EPS-083

Pre-surgical imaging tests in the diagnosis of primary hyperthyroidism in adverse scenarios: low weight adenomas and concomitant thyroid disease

L. Paruta Araez, I. Blanco Saiz, M. Ribelles Segura, M. Morales Lozano, J. García Torres, M. Díaz Tobarra, I. Saura López, N. Rudic Chipe, A. Rabines Juárez, F. Gomez Sainz, B. Alvarez Galán, P. Caballero García, A. Goikoetxea Urdiain, A. Camarero Salazar, E. Goñi Gironés, P. Salvador Egea; Complejo Hospitalario de Navarra, Pamplona, SPAIN.

Aim/Introduction: BACKGROUND: Parathyroid scintigraphy and ultrasonography are the routine preoperative localization procedures. However, when thyroid disease coexists and the lesion has low weight, their diagnostic accuracy is possibly diminished. AIM: To analyze the factors that influence in the success of localization with $^{99\text{m}}\text{Tc}$]Tc-MIBI SPECT/CT and ultrasound in the primary hyperthyroidism. **Materials and Methods:** Retrospective descriptive review of 152 patients from Aug 2016 to Dec 2019 with primary hyperparathyroidism and surgical criteria. $^{99\text{m}}\text{Tc}$]Tc-MIBI dual phase scintigraphy (early SPECT/CT) and cervical ultrasonography were the pre-surgical methods of localization in all patients; $^{99\text{m}}\text{TcO}_4$] thyroid scintigraphy (planar and SPECT-CT acquisition) was added in doubtful cases. Different results and statistics parameters were compared. Data were recorded for the following study variables: gender, age, gland weight (mg), calcemia (mg/dL), preoperative PTH (pg/mL) and 25-hydroxyvitamin D (ng/mL), associated thyroid nodular disease, previous cervical surgery and results of imaging techniques performed. **Results:** The study included 122 (74.8%) females. The median age was 63 y/o (IQR: 52-71). BMI over 30 was registered in 34 (22.4%). Median pre-surgical calcium was 11 mg/dL (IQR:10.7-11.5), median PTH 183 pg/mL (IQR:144-251), and median 25-hydroxyvitamin D 18 ng/mL (IQR:13-26). Neither $^{99\text{m}}\text{Tc}$]Tc-MIBI SPECT/CT nor ultrasound found statistically significant difference in the location of the lesion with respect to sex, age, BMI, calcium, PTH and 25-hydroxyvitamin D levels. In $^{99\text{m}}\text{Tc}$]Tc-MIBI SPECT/CT negative patients the media weight of the lesion was 602.9 mg (95%CI 389.3-816.5), whereas

in those positive was 1147.4 mg (95%CI 962.6–1332.1), $p=0.002$. This regard was not significant on ultrasound. MIBI localization was not significantly affected by concomitant thyroid nodular pathology, meanwhile ultrasound was diminished, although in the limit of statistical significance ($p=0.05$). Considering 84 (55.2%) patients with underlying nodular thyroid pathology, ultrasound was positive in 56 (66.7%), doubtful or negative in 28 (33.3%); while [^{99m}Tc] Tc-MIBI SPECT/CT was positive in 72 (85.7%) and doubtful or negative in 12 (14.3%). The addition of the thyroid scan was conclusive for the diagnosis of adenoma in 12 of these patients and to exclude it in 5, who in the absence of this test would have been misclassified. **Conclusion:** The only factor significantly related with the diagnostic accuracy to [^{99m}Tc] Tc-MIBI SPECT/CT is the weight of the gland. Underlying nodular thyroid pathology causes a decreased of the ultrasound detection rate, not so in the [^{99m}Tc]Tc-MIBI SPECT/CT thanks to the added value of thyroid scan. **References:** None

EPS-084

Brown Tumors Secondary To Tertiary Hyperparathyroidism Masquerading As A Lytic Or Sclerotic Skeletal Metastases On Preoperative/ Postoperative 18F-FDG PET/CT: A Case Report

C. Engur, T. Ones, N. Filizoglu, S. Kesim, S. Ozguven, K. Oksuzoglu, H. T. Turoglu, S. Inanir, T. Y. Erdil;
Marmara University Pendik Training and Research Hospital,
Department of Nuclear Medicine, Istanbul, TURKEY.

Aim/Introduction: Tertiary hyperparathyroidism (THPT) develops from secondary hyperparathyroidism in cases when the secretion becomes autonomous. Brown Tumors are rare skeletal lesions of hyperparathyroidism that may mimic cancer metastasis. In this case report, we discuss the FDG PET/CT findings of a patient with tertiary hyperparathyroidism with multiple Brown Tumors which mimics osteolytic/osteoblastic metastases. **Materials and Methods:** We report a case of a patient who was diagnosed with tertiary hyperparathyroidism that evaluated with two FDG PET scans with an interval of 23 months in the preoperative and postoperative period. **Results:** Thorax CT imaging of this patient was revealed multiple lytic lesions evaluated in favor of bone metastasis and FDG PET/CT (first scan) was performed to detect the primary focus. In the first PET scan intense hypermetabolic lytic/destructive multiple lesions were observed in the skeleton. When these lesions were evaluated together with the patient history, the diagnosis was in favor of multiple Brown Tumors secondary to tertiary hyperparathyroidism. After this first PET scan parathyroidectomy was performed. Twenty-three months after the surgical procedure the patient evaluated with new PET scan for another reason. The second PET scan revealed multiple sclerotic bone lesions in the skeleton (which were

described as intensely hypermetabolic lytic/destructive lesions previously). **Conclusion:** Although they are benign lesions giant cell reparative granuloma, aneurysmal bone cyst, giant cell tumor of bone and osteoclast-like giant cell containing lesions of bone show increased FDG uptake in favor of malignancy. These benign lesions contain giant cells and/or histiocytes derived from monocyte-macrophage group and provide their energy mostly by glucose metabolism. Brown tumors contain mononuclear cells and fibroblasts that derived from the same cell group. They provide their energy as the same way. Radiologic characteristics of 18F-FDG PET/CT between Brown Tumors and skeletal metastases are similar and it should be kept in mind that Brown Tumors can imitate both osteolytic and osteosclerotic metastases depending on the surgical history especially in patients with diagnosed tertiary hyperparathyroidism. **References:** None

EPS-085

Evaluation of Primary Hyperparathyroidism in Hormone Receptor- Positive Breast Cancer Patients Using [^{99m}Tc] Tc-MIBI SPECT/CT and Ultrasound

M. Punda, P. Petranovic Ovcaricek, V. Gladic Nenadic, I. Sisko Markos, M. Franceschi, T. Jukic;
UHC Sestre Milosrdnice, Zagreb, CROATIA.

Aim/Introduction: Breast cancer (BC) patients receiving advanced specific anti-neoplastic treatments are at increased risk for cancer treatment-induced bone loss. The guidelines recommend bone mineral density (BMD) testing by dual-energy X-ray absorptiometry (DXA) and exclusion of secondary causes for low BMD such as primary hyperparathyroidism (PHPT). The number of studies that describe PHPT in BC patients are scarce and show conflicting results. Several reports documented an increased frequency of PHPT in BC patients, particularly associated with the use of aromatase inhibitors (AIs) in hormone receptor-positive breast cancer (HRBC). Hence, we aimed to determine the prevalence of PHPT among our HRBC patients to provide better clinical insight into this condition. **Materials and Methods:** We examined 169 HRBC patients referred to our Osteoporosis Clinic Unit between January 2014 and November 2019. BMD by DXA, serum PTH, serum calcium and thyroid function was assessed in all patients. The patients with biochemical evidence of PHPT and no evidence of bone metastasis underwent dual-phase [^{99m}Tc]Tc-MIBI SPECT/CT parathyroid scintigraphy, a high-resolution ultrasound (US) and ultrasound-guided fine-needle biopsy with measurement of PTH levels in the needle washout (FNB-PTH). **Results:** Six (3.6%) patients had biochemically proven PHPT (mean \pm SD: serum PTH 154.6 \pm 78.82 pg/mL, serum calcium 2.70 \pm 0.14 mmol/L) and low BMD (mean T-scores of -2.23 at the lumbar spine and -1.35 at the femoral neck). The patients aged 58.6 \pm 9.24

years (mean, \pm SD) were evaluated for PHPT 26.5 months (median, range 11–180 months) after BC diagnosis. The subjects previously underwent postoperative radiotherapy (6/6 patients), chemotherapy (2/6 patients) and five out of 6 patients were taking AIs for a median time of 15 months (range 4–24 months). One patient has completed tamoxifen treatment for recurrent BC. The longest US-diameter of parathyroid lesions was 10.5 ± 3.39 mm. PHPT was confirmed in 6/6 patients based on concordant [^{99m}Tc]Tc-MIBI SPECT/CT, US and FNB-PTH findings: 4 patients underwent surgery for a single parathyroid adenoma, in one patient surgery was canceled due to advanced age and severe comorbidities, and one patient with asymptomatic disease was advised to closer follow-up. Three patients had co-existing Hashimoto thyroiditis and 2 patients had nodular goiter. **Conclusion:** We found PHPT in 3.6% of our HRBC patients which is consistent with the increased prevalence of PHPT observed in several reports (2.88–7%) compared to the adult female population without BC (<1.5%). Among cancer-treated HRBC patients with low BMD and hypercalcemia a careful diagnostic evaluation is required to rule out PHPT. **References:** None

The Increase In The Activity Of Technetium-99m, Isolated From The Routine Activity Generator

A. Rogov, E. Stasyuk;

National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Currently, more than 80% of all radionuclide studies are performed using radiopharmaceuticals based on technetium-99m. To obtain the isotope installations called technetium generators are used. Organization of ^{99}Mo production by the reaction of radiative capture (n, γ) using enriched molybdenum-98 at research reactors widespread in Russia and in the world. This technology has virtually no waste, but the resulting product has a low specific activity 6-10 Ci/g. The use of such low active materials for the production of generators requires the use of columns of increased size, which increases elution profile of generators and as a consequence, to a decrease in the volume activity of eluted preparation of technetium-99m. **Aim:** To investigate the factors influencing the elution characteristics of

generators of technetium-99m, manufactured by neutron irradiation of enriched molybdenum oxide 98. **Materials and Methods:** Elution of technetium-99m from generators in the form of sodium pertechnetate solution was carried out by pumping of 0.9% solution of NaCl (eluent) in portions of ~2 ml into 10 ml vials through columns followed by measuring the activity of ^{99m}Tc on the radiometer RIS-01A. Based on these results, the dependence of changes of the yield of ^{99m}Tc on the volume of passed eluent, as well as dependence of changes of elution yield from the adsorbed mass of molybdenum-98 for different volumes of the eluent are developed. Changes in the activity of adsorbed ^{99}Mo along the length of chromatographic column was determined by single-channel pulse-height analyzer Strahlungsmessgerät 20 046 (Germany) by scanning the columns above the detector with collimator. **Results:** We show that with an increase of molybdenum mass elution profile of generator becomes narrower. For example, for the complete elution of ^{99m}Tc from generator with adsorbed weight of 0.070 g it is necessary to pass 16-17 ml of eluent through its column and 8-9 ml will be enough at a weight of 0.177 g. Accordingly, even at the same total activity of ^{99m}Tc eluted from generators the volumetric activity of the preparation will be about 2 times higher in the latter case than in the first. **Conclusion:** The width of elution profile of generators depends on the adsorbed mass of molybdenum. At the same time, with its increase the profile of generators becomes narrower, reaching a minimum at a certain limiting mass. **References:** National Research Tomsk Polytechnic University

TEPS-02

Research To Create A Miniature Generator Of Technetium-99m

A. Rogov;

National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Radiopharmaceuticals based on short-lived technetium-99m (^{99m}Tc) radionuclides are used for diagnostic studies in many areas of medicine. Most of the global market is for chromatographic generators based on fission products of uranium-235. Their manufacture requires a high activity of ^{99}Mo (200 Ci / g), produced by environmentally hazardous technologies. The proposed possibility of obtaining ^{99}Mo by radiation capture (n, γ) when molybdenum-98 is exposed to the neutron field of a nuclear reactor. The described technology has virtually no waste, and the resulting product has a low specific activity of ^{99}Mo at 7-9 Ci / g. In this regard, it becomes necessary to use a large amount of ^{99}Mo , about 150-190 mg. This necessitates the use of a large amount of sorbent, aluminum oxide. **Materials and Methods:** Mo aluminum oxide capacity has a saturation limit of 22-25 mg per gram of sorbent. The

required activity of the obtained technetium-99m product is possible only when 190 mg of Mo is adsorbed onto the surface of the sorbent. In this case, it is necessary to use from 7.6 to 8.6 g of sorbent. Such conditions require an increase in the size of the column and the device delivered to the clinic (technetium-99m generator). **Results:** Studies of the possibility of creating a sorption generator of technetium-99m in a reduced form were carried out in a number of experiments to increase the sorption capacity of aluminum oxide. Depending on the initial (production) and subsequent processing of the sorbent, it becomes possible to prepare a sorbent capacity of Mo, approximately equal to 34 mg / g This is achieved through the use of a set of measures for the preparation of the sorbent and methods of densifying the structure of the active centers of the sorbent. These conditions increase the capacity of the sorbent from a solution containing ⁹⁹Mo. **Conclusion:** By reducing the required volume of the sorbent by 26.4%, there is a decrease in the weight of the sorbent and the device itself. The mass of the used sorbent is reduced to 5.6 g from the starting position of 8.6 g. This allows to reduce the columns and frames of the generator. As a result of research, the design of the compact technetium-99m generator and a number of methods used for their manufacture were designed. **References:** None

TEPS-03

Development methods for ^{99m}Tc-labeled nanocolloidal preparations

V. Sadkin¹, E. Nesterov¹, V. Skuridin¹, E. Stasyuk¹, A. Rogov¹, N. Varlamova¹, R. Zelchan²;

¹National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, ²Cancer Research Institute, Tomsk National Research Medical Center, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: The work considers the problem of obtaining nanocolloid radiopharmaceuticals (RPs) and studying their functional suitability for diagnosing sentinel lymph nodes (SLN) in cancer patients. **Materials and Methods:** All the reagents were purchased from Sigma-Aldrich ACS grade and used without further purification. Technetium-99m was obtained from chromatographic ⁹⁹Mo/^{99m}Tc generator «^{99m}Tc-GT-TOM» produced by Tomsk Polytechnic university (TPU) - Tomsk, Russia. **Methods use:** Method for preparation of ^{99m}Tc labeled nanocells. Determination of the size of ^{99m}Tc labeled colloidal particles. Thin-layer chromatography (TLC) procedure. Determination of the functional suitability of preparations for scintigraphic detection of SLN. **Results:** As a result of the studies, the composition of the reagents and the conditions for the synthesis of three nanocolloid RPs were determined. An experimental dependence of the change in the content of ^{99m}Tc (VII) impurities on the concentration of tin (II) was established and its minimum amount (0.175 mg/ml) was determined to reach a RHP greater than 94%.

In this case, the yield of the target colloid with particle sizes of 50 ± 100 nm is 42 - 76%. Preliminary tests of the developed preparations on experimental animals showed that accumulation of RP in lymph nodes is practically not observed, although the sizes of colloidal particles are in the required range. Increase in the speed of "transportation" of colloids through the lymphatic system was achieved by the introduction of gelatin in the composition (2.5-4 mg/ml). In addition, there was an increase in the yield of the colloid with particle sizes of 50-100 nm to 76-97% with radiochemical purity of the preparations of 94-95%. **Conclusion:** Repeated studies in experimental animals have shown that all synthesized nanocolloid preparations provide a good level of accumulation in the SLN. Thus, the level of accumulation of RP "^{99m}Tc-DTPAmod" and RP "^{99m}Tc-Fe@C(ADT)" in the SLN is 1.5% and 1.71% respectively. At the same time, the accumulation level of the preparation based on aluminum oxide is 8.6% of the total input activity, which is several times greater than all known analogues. **References:** None

TEPS-04

Sedimentation of Radioactive-labelled Colloid During Transport

M. Rode Pedersen, B. Hoyer Mathiasen;
Hospital Lillebaelt, Vejle, DENMARK.

Aim/Introduction: At our department we use a Tc-99m-labelled pharmaceutical containing human serum albumin nano-colloid, requiring suspension prior to extraction. After daily preparation, we deliver a multi-dose vial to a collaborating hospital. Due to recent requirements from the Danish Health Authorities, the pharmaceutical now has to be transported in prepared syringes, instead of the glass vial. The aim of our study was to investigate whether the radioactive nano-colloid would sediment in the syringes during different settings, to determine if the required practice would be feasible in regards to product quality. **Materials and Methods:** The study was conducted over the course of four days under different settings; Day 1: Syringes placed horizontal without air, Day 2: Syringes placed vertically without air, Day 3: Syringes placed horizontally with air, Day 4: Syringes placed vertically with air. Each day, two syringes containing 0.8 mL of the pharmaceutical was prepared into 1 mL syringes, with a concentration of 100 MBq/mL at time of preparation. The syringes containing air, was suspended prior to acquisition. Distribution of radioactivity within the syringes was imaged and analyzed after four and six hours. Each acquisition was done on a Siemens Symbia Intevo SPECT/CT scanner, as a five minute static acquisition. Images were analyzed using a ROI-tool from Hermes Medical Solutions, by dividing the image into 12-14 ROIs and plotting them into a graphic display. **Results:** By analyzing the number of counts in each ROI, we were able to graphically show the distribution of radioactive

nano-colloid the syringes at 4 and 6 post-preparation. In each setting, it showed a rapid increase in activity, after which the graph stabilized, before a rapid decrease, thus indicating a homogenous distribution throughout the syringe. The graphs showed that the distribution of radioactive nano-colloid was homogenous in all instances, regardless of orientation or suspension. Furthermore, the measurement of activity in the syringes before and after imaging indicated the nano-colloid does not adhere to the inside of the syringes, as only 10 % of activity remains after discharge, which corresponds to the syringe tip. **Conclusion:** Our study could not provide evidence that orientation or suspension of syringes has any effect on the distribution of radioactive nano-colloid. We were not able to prove, that the nano-colloid would sediment, even after 4 or 6 hours. Thus, we assess that the transport of prepared syringes containing radioactive human serum albumin nano-colloid, is feasible and without risk of sedimentation. **References:** None

TEPS-05

Review of the radiosynthesis preparation of ^{68}Ga -labelled PSMA in a fully automated system - a routine procedure

M. Paula, C. Capelo, A. Fonseca, L. Ribeiro, H. Duarte;
Ipo Porto, Porto, PORTUGAL.

Aim/Introduction: The PET imaging of the prostate-specific membrane antigen (PSMA) using (^{68}Ga)Ga-PSMA-HBED-CC) has gained highest clinical impact. The application of ^{68}Ga -labeled peptides has considerable interest for cancer imaging due to the physical characteristics of ^{68}Ga and the availability of reliable GMP-compliant $^{68}\text{Ge}/^{68}\text{Ga}$ generators. Although ^{68}Ga -labeled PSMA individual doses can be purchased it is economically and strategically important to have the possibility of synthesizing the radiopharmaceutical on-site. In 2016 we present the data of our initial experience with the firsts radiosynthesis of ^{68}Ga -labeled HBEC-CC-PSMA ; after 4 years we propose to review what has become a routine procedure in our Nuclear Medicine Department. **Materials and Methods:** In the radiolabeling we used a cassette based automated synthesis module; the $^{68}\text{Ge}/^{68}\text{Ga}$ generator, elution solvent HCl 0.1M. Preconcentration: SCX cartridge, elution with NaCl/HCl mixture (3 ml) Labelling buffer: sodium acetate/hydrochloric acid buffer pH 4.5+/-0.1 (400 μl) Precursor amount: 10-20 μg ; Reaction time/Incubation: 5 min at 95°C at pH ~4 Purification with C-18 light, product elution from C18 cartridge with ethanol/water solution (50%) into product vial and dilution with saline. All patients had a histopatological confirmation of prostate cancer and/or increased values of PSA. PSMA images were acquired with a mCT FlowMotion continuous bed motion PET/CT equipment. **Results:** Between October 2015 and February

of 2020, we performed 390 synthesis of (^{68}Ga) Ga-PSMA-HBED-CC) and PET/CT imaging in about 1164 patients. We had better results achieving higher specific activity labelling using precursor amount > 10 μg , the synthesis time was 14+/-3min. The success rate of the synthesis was very high, just 10 of them had failure. **Conclusion:** The radiosynthesis of ^{68}Ga) Ga-PSMA-HBED-CC as described it prove to be a method fast and reliably over the past 4 years and it has become a routine procedure in our department. Is suitable for being used in Nuclear Medicine Departments for clinical use with high reproducibility and robustness. One of the biggest challenge is manage the validity of the Ge / Ga generators, which is 9-12 months and the activity obtained by synthesis gradually decreases. Since our first syntheses in 2016, little or nothing has changed in the process, which has been more significant is the operator's ability to solve problems faster and more effectively with the synthesis module or the generator or even problems with the computer programs. **References:** None

TEPS-06

Contribution of Information Technology systems in the planning of radiopharmaceuticals purchase: an ongoing experience

M. Maccagnani, A. Farina, R. Bonfiglioli, C. Malizia, S. Fanti;
Azienda Ospedaliero-Universitaria S.Orsola-Malpighi, Bologna, ITALY.

Aim/Introduction: The application of the best practice in radiopharmacy has required to Nuclear Medicine Centers, to implement quality assurance systems to allow complete traceability of their activities. In many cases, Information Technology System(NMIS) was employed to manage the required documentation. The aim of this work was to investigate the possible use of NMIS database in the planning of radiopharmaceuticals purchase in order to move from short term (3-months) planning to long term (1-year) planning. **Materials and Methods:** The NMIS for they use need and collect a variety of data that is possible to infer and analyze to describe the macroscopic profile of both main and side activities in radiopharmacy. The information about each warehouse movement of the radiopharmaceutical in use was extracted in monthly step for the period 2016-2018 and used to plan the purchase activity for the year 2019. Especially, we extract the data about purchase, use and expire of every radiopharmaceuticals in use. As a first step, the average of the products used annually was calculated and a value equal to 10% was set to resize the minimum amounts always available in the radiopharmacy warehouse. Secondly, the average of the products purchased annually was calculated and the value obtained, increased by 5%, was set as standard annual order. Then the value divided over the 12 months according to the scheduled activity to plan the arrive in the radiopharmacy. These values have been

approximated to multiples of the minimum purchasable quantity. The quantities calculated so far, theoretically, allow to always have sufficient products in the radiopharmacy warehouse to cope with both radiopharmaceutical labelling and/or supply problems without interfering with the scheduled activity. **Results:** 2019 was a year of transition between the supply management method and therefore not decisive to evaluate the effectiveness of the change. However, data analysis shows some interesting effects: 1) both the supply and warehouse volumes of the radiopharmaceuticals were sufficient to guarantee the diagnostic activities; 2) a widespread drop in the number of expired radiopharmaceuticals without being used; 3) a drop in spending on radiopharmaceuticals from €1,369,617.75 to €1,150,781.17, with saving around 16%. **Conclusion:** The use of NMIS was appropriate in the management of purchases of the radiopharmaceuticals. In light of these positive data, the same calculation method for supplies was applied for 2020, with a prediction of savings between 5%–7% compared to 2019. Due to the ongoing health emergency, expenditure data for the first quarter of 2020 was not available yet, therefore early verification was not possible. **References:** None

TEPS-07

Normal values of ^{201}Tl myocardial uptake at stress using a CZT SPECT and IQ-SPECT

A. Matsumoto¹, S. Yoshimura¹, S. Tomiguchi², S. Shiraishi³, Y. Nakamura⁴, H. Sakamoto²;

¹Graduate School of Health Sciences, Kumamoto University, Kumamoto, JAPAN, ²Faculty of Life Sciences, Kumamoto University, Kumamoto, JAPAN, ³Kumamoto University, Hospital, Kumamoto, JAPAN, ⁴Division of medical technology, Kumamoto University, Hospital, Kumamoto, JAPAN.

Aim/Introduction: A cadmium zinc telluride (CZT) single-photon emission-computed tomography (SPECT) device (CZT SPECT: NM530c:GE) and IQ-SPECT (Siemens) have higher count sensitivity than a conventional NaI SPECT device. Both SPECT devices are therefore feasible to investigate the myocardial perfusion quantitatively. Stress ^{201}Tl myocardial uptake (myocardial uptake index: MUI) presumed to be useful index for the diagnosis of coronary arterial disease (CAD). The aim of this study was to assess the normal values of MUI obtained by CZT SPECT and IQ-SPECT. **Materials and Methods:** 7 patients using a CZT camera (Discovery NM 530c, GE) and 11 patients using IQ-SPECT without coronary arterial stenosis (normal subjects) performed stress ^{201}Tl SPECT-myocardial perfusion imaging (MPI) were enrolled. MUI was calculated by dividing estimated radioactivity of whole left ventricular myocardium by injected dose. Estimated activity was obtained by multiplying SPECT counts by Cross Calibration Factor (CCF). No attenuation correction or scatter correction

was performed on the reconstructed images. **Results:** CCF was 5.05 for CZT SPECT and 0.50 for IQ-SPECT, respectively. The mean of MUI value using the CZT SPECT was 6.0%, and that using the IQ-SPECT was 10.7%. Scaling factor may be one of the factors of difference in normal values of MUI between CZT SPECT and IQ-SPECT. **Conclusion:** It should be careful that the normal value of MUI on IQ-SPECT is higher than that on CZT-SPECT in the quantitative evaluation of myocardial blood flow. **References:** None

TEPS-08

Usefulness of CT attenuation correction for $^{201}\text{Tl}/^{123}\text{I}$ -BMIPP dual-isotope myocardial SPECT on CZT camera

S. Yoshimura¹, S. Tomiguchi², F. Sakamoto³, T. Matsubara⁴, S. Shiraishi⁴;

¹Graduate School of Health Sciences, Kumamoto University, Kumamoto, JAPAN, ²Faculty of Life Sciences, Kumamoto University, Kumamoto, JAPAN, ³Faculty of Life Sciences, Kumamoto University, Kumamoto, JAPAN, ⁴Kumamoto University, Hospital, Kumamoto, JAPAN.

Aim/Introduction: Dual-isotope myocardial single-photon emission-tomography (SPECT) using ^{201}Tl and ^{123}I -BMIPP is better to undergo with a CZT camera than with a conventional NaI camera because of high energy resolution on CZT camera. Precise assessment on ischemic myocardium can be performed by combining the information of fatty acid metabolism from ^{123}I -BMIPP SPECT with that of myocardial perfusion from stress ^{201}Tl myocardial SPECT. The myocardial uptake ratio of ^{123}I -BMIPP / ^{201}Tl (BM/TL ratio) is considered to be a useful index for evaluation the myocardial ischemia. The effectiveness of CT attenuation correction (CT-AC) for quantitative assessment has not been fully studied on the CZT camera. The aim of this study was to evaluate the usefulness of CT attenuation correction for diagnosing a coronary arterial disease (CAD) using stress ^{201}Tl / rest ^{123}I -BMIPP dual-isotope myocardial SPECT on CZT camera. **Materials and Methods:** 26 patients underwent dual-isotope myocardial SPECT combining stress ^{201}Tl with rest ^{123}I -BMIPP studies on CZT camera (NM530c:GE) were enrolled. They were 10 patients with CAD and 16 without CAD, respectively. In 10 patients with CAD, 2 patients have a coronary arterial stenosis of more than 75% luminal diameter (severe CAD patients). BM/TL ratio was obtained by dividing ^{123}I -BMIPP myocardial uptake at rest by ^{201}Tl myocardial uptake at stress. Each uptake calculated from myocardial counts corrected cross calibration factors divided by injected dose. The diagnostic performance for CAD was evaluated by ROC analysis. **Results:** BM/TL ratio is significantly higher in patients with CAD than those without CAD. However, BM/TL ratio in severe CAD patients showed higher value than that in patients without CAD. The AUC of ROC curve was 0.83 without CT-AC and 0.90 with CT-AC, respectively. The AUC increase in 0.98 with CT-AC excluding

severe CAD patients. **Conclusion:** CT-AC is useful to diagnose the CAD using the BM/TI ratio on stress ^{201}Tl / rest ^{123}I -BMIPP dual-isotope myocardial SPECT. BM/TI ratio is considered to be the useful index for diagnosing CAD patients with mild coronary arterial stenosis. **References:** None

TEPS-09

Studies on Decision of the Cut-off Standardized Uptake Values for Normal Bones and Bone Metastases in the Vertebrae in ^{18}F -fluoride PET/CT and ^{18}F -FDG PET/CT

R. Ono¹, N. Fujita^{1,2}, Y. Ito¹, T. Tada¹, R. Murayama¹, H. Ikeda³, Y. Ochi³, M. Nishio³, Y. Tsutsumi², T. Odagawa¹, M. Tamura¹, S. Abe², K. Kato³;

¹Department of Radiological and Medical Laboratory Sciences, Nagoya University Graduate School of Medicine, Nagoya, JAPAN, ²Department of Radiological Technology, Nagoya University Hospital, Nagoya, JAPAN, ³Department of Integrated Health Science, Nagoya University Graduate School of Medicine, Nagoya, JAPAN.

Aim/Introduction: For the detection of bone metastases, ^{18}F -fluoride PET/CT and ^{18}F -FDG PET/CT are used as imaging modalities and standardized uptake value (SUV) is often used besides visual image interpretation. According to previous studies, different vertebral regions have different normal SUVs. If the cut-off SUVs for normal bones and bone metastases in the cervical to lumbar vertebrae are established, they can be used for the assessment of bone metastases in the vertebrae. The aim of this study is to determine the cut-off SUVs for normal bones and bone metastases in the cervical to lumbar vertebrae in ^{18}F -fluoride PET/CT and ^{18}F -FDG PET/CT. **Materials and Methods:** Our study subjects were 24 patients who underwent ^{18}F -fluoride PET/CT and ^{18}F -FDG PET/CT within 2 months at our Hospital. We measured SUVmax and SUVpeak from the vertebral bodies of the cervical, thoracic, and lumbar vertebrae, and calculated the mean \pm standard deviation of SUVmax and SUVpeak in the cervical, thoracic, lumbar, and cervical-lumbar vertebrae. We analyzed differences between SUVs of normal bones and bone metastases by Mann-Whitney U test. We calculated the cut-off values and area under the curve (AUC) with its associated 95% confidence interval (95%CI) of SUVmax and SUVpeak using the receiver operating characteristic curve (ROC) analysis. **Results:** SUVs of bone metastases were significantly higher than those of normal bones in the cervical, thoracic, lumbar, and cervical-lumbar vertebrae in ^{18}F -fluoride PET/CT and ^{18}F -FDG PET/CT. In ^{18}F -fluoride PET/CT, the cut-off SUVmax (AUCs) of the cervical, thoracic, lumbar, cervical-lumbar vertebrae were 9.3 (0.96), 10.0 (0.89), 13.4 (0.96), and 10.0 (0.92), respectively, and the cut-off SUVpeak (AUCs) of those were 8.4 (0.95), 8.5 (0.87), 10.9 (0.95), and 8.4 (0.91), respectively. In ^{18}F -FDG PET/CT, the cut-off SUVmax (AUCs) of those were 2.4 (0.77), 3.0 (0.66), 3.1 (0.77), and 3.0 (0.71), respectively, and the cut-

off SUVpeak (AUCs) of those were 2.0 (0.77), 2.2 (0.64), 2.4 (0.69), and 2.1 (0.69), respectively. **Conclusion:** In order to differentiate bone metastases from normal bones in the cervical to lumbar vertebrae with the cut-off values, both SUVmax and SUVpeak are useful in ^{18}F -fluoride PET/CT, and SUVmax is useful in ^{18}F -FDG PET/CT. **References:** None

TEPS-10

Improved TEW method estimating primary photons in the energy tail in ^{201}Tl SPECT-MPI on CZT camera

K. Yoshimura¹, S. Tomiguchi², S. Shiraishi³, F. Sakamoto², R. Kamezaki³;

¹Graduate School of Health Sciences, Kumamoto, JAPAN, ²Faculty of Life Sciences, Kumamoto, JAPAN, ³Kumamoto University Hospital, Kumamoto, JAPAN.

Aim/Introduction: A tailing effect has been observed in energy spectrum of ^{201}Tl using a CZT camera (NM-530c;GE) for single-photon emission-tomography myocardial perfusion imaging(SPECT-MPI). Scatter photons in the tail of energy spectrum is overestimated by scatter correction using TEW method because primary photon also includes in the tail. On the other hands, scatter correction has been performed if the primary photons or scatter photons in the tail is estimated. The aim of this study was to investigate the usefulness of scatter correction method of a combination of the TEW method and the model of primary photons in the tails by simulation. **Materials and Methods:** All simulations with a CZT detector fitted with a single pinhole collimator were executed using SIMIND developed by Ljungberg M. et al. First, we simulated a scatter-free point source energy spectrum at distances of 19 cm~24 cm from the detector and energy windows were set on 50-64keV (scatter window including tail effect), 64-77 keV(narrow main window for ^{201}Tl), and 64-86.1keV (wide main window for ^{201}Tl), respectively. Next, the scatter-free count ratio of the scatter window to the main window at each distance (primary photon fraction in the scatter window) was calculated and averaged. The modelling of primary photon fraction in the scatter windows at various distance was then fitted by the Gaussian function. SPECT-MPI images were reconstructed by ML-EM algorithm using this modeling. Finally, digital myocardial phantom filled with ^{201}Tl was reconstructed without scatter correction, with conventional TEW and improved TEW method, respectively. Average count ratio of myocardium to ventricular cavity (myocardial S/N) and coefficient of variation (CV) of counts in the myocardium (count uniformity) were evaluated. **Results:** In both narrow and wide main energy windows, myocardial S/N of new TEW method improved approximately 1.2 times greater than that of the conventional TEW method and 1.5 times greater than that without scatter correction. CV decrease in about 30% in both windows as compared with conventional TEW method. CV in the narrow main energy window was

6% lower and that in wide energy window was 6% higher than that without scatter correction. **Conclusion:** Improved TEW method is superior to conventional TEW method with higher myocardial S/N. The narrow main energy window shows better count uniformity in the myocardium than the wide main energy window. **References:** None

Nuclear Medicine Dynamic Cardiac Phantom Implemented by 3D Printing Technique

H. Park¹, J. Lee²;

¹Shingu University, Seongnam, KOREA, REPUBLIC OF,

²Songho University, Hoengseong, KOREA, REPUBLIC OF.

Aim/Introduction: The static phantom of international standard is widely used in the field of nuclear medicine. Although the heart is a moving organ, only a fixed situation can be reproduced and evaluated, so a study on the dynamic situation is necessary. More research is necessary to address these challenges. **Materials and Methods:** This study used 3D printing techniques to design dynamic cardiac phantom. It also intended to reproduce the images through dynamic cardiac flow to confirm the usefulness of the proposed technique. The frame of dynamic cardiac phantom was produced based on the international standard phantom and a nuclear medicine dynamic cardiac phantom was produced based on the myocardium implemented by 3D printing technique. In this way, we compared the quantitative and qualitative properties of the static and the dynamic cardiac phantom, as well as the clinical and the dynamic cardiac phantom images. **Results:** In the quantitative analysis of the static and the dynamic cardiac phantoms, the SRS (Summed Rest Score) indicated 5.80 ± 0.45 points in static cardiac phantom, 3.40 ± 0.89 points in 10 stroke rate, 2.40 ± 0.55 points in 20 stroke rate, and 1.40 ± 0.55 points in 30 stroke rate in dynamic cardiac phantom. The SRS was the highest in the static cardiac phantom, followed by SRS in the order of 10, 20 and 30 stroke rate in the dynamic cardiac phantom ($P < 0.05$). The TPD (Total Perfusion Deficit) was the highest in the static cardiac phantom, followed by TPD in the order of 20, 10 and 30 stroke rate in the dynamic cardiac phantom. The Adjusted Man-Whitney test was conducted to determine which groups showed significant differences between the static and dynamic cardiac phantom 30 stroke rates, with a very significant difference of < 0.0001 , but no significant difference between the static and dynamic cardiac phantom 10 and 20 stroke rates, respectively, was found to be 0.899. **Conclusion:** The potential for clinical application of the proposed method was confirmed in the dynamic cardiac phantom implemented with 3D printing technique. It is believed that the objective information secures the reliability of the inspection equipment and it contributes to improve the value of diagnosis of nuclear medicine. **References:** None

TEPS-12

Phantom analysis in hybrid imaging

S. Rep, S. Kotar;

University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: The distribution of radiopharmaceuticals in the body after administration can be demonstrated with two tomography methods. The first is a single-photon emission computed tomography and the second positron emission tomography, which (in combination with computer tomography) enables the viewing of physiological and morphological information from the body. The purpose of research is qualitatively and quantitatively evaluating the contrast-to-noise ratio (CNR) and the signal-to-noise ratio (SNR) in PET/CT and SPECT/CT images obtained with a NEMA body phantom.

Materials and Methods: The NEMA body phantom was filled with ^{99m}Tc and ¹⁸F FDG in ratios of 1 : 2, 1 : 4, and 1 : 8. Phantom imaging was done with SPECT/CT and PET/CT. The obtained scintigrams were evaluated qualitatively and quantitatively by using the OASIS processing software. The SNR was quantitatively evaluated for the background of phantoms and CNRs for assessing the spheres according to the background. SPSS 21 software was used for analysis.

Results: Quantitative analysis of spheres in the NEMA body phantom shows spheres with diameters of 17, 22, 28 and 37 mm in ratios of 1 : 2, 1 : 4, and 1 : 8 on SPECT/CT. In a ratio 1 : 8, SPECT/CT also shows spheres with diameters of 13 mm. All spheres in the NEMA body phantom are visible on the PET/CT at ratios of 1 : 4 and 1 : 8, and at a ratio of 1 : 2 only spheres with diameters of 17, 22, 28, and 37 mm are visible. The quantitative value of the SNR for the background was higher in PET/CT according to SPECT/CT. A comparison of CNR for PET/CT and SPECT/CT showed a significant difference between the two methods ($p = 0.002$). For both methods, the SNR value is higher in relation to the height of the ratio and shows a good correlation between ($r = 0.85$ and $p < 0.001$). **Conclusion:** The results of the analysis between SPECT/CT and PET/CT methods showed a better SNR and CNR ratio in the PET/CT image method compared to SPECT/CT. **References:** Lee TC, Alessio AM, Miyaoka RM, Kinahan PE (2016). TEPS-13

Evaluation of the Usefulness of SPECT Brain Phantom Based on 3D printing

H. Park¹, Y. Lee², H. Lee¹, J. Lee³;

¹Shingu University, Seongnam, KOREA, REPUBLIC

OF,²Kismits, Seoul, KOREA, REPUBLIC OF,³Songho University, Hoengseong, KOREA, REPUBLIC OF.

Aim/Introduction: Although an experiment was shown that 3D printing material such as ABS(acrylonitrile butadiene styrene) and PLA(polylactic acid) showed a possibility to replace the PMMA(Polymethylmethacrylate) which is normally used for phantom, a lot of experiment haven't been performed to compare the usefulness of these 3D printing materials and PMMA in nuclear medicine. In this experiment, SPECT(Single-photon emission computed tomography) brain phantom which was made with 3D printing material and 3D printing technology was used for it to evaluate the applicability of it. **Materials and Methods:** The information from the original phantom using CT(computed tomography) were obtained. The acquired file was printed by the SLA(Stereo lithography apparatus) method of ABS materials. SPECT-CT was used to obtain images. We filled the both Phantom with a solution mixed with 1 mCi ^{99m}Tc in 1 liter of water and acquired images in accordance with the standard protocol. Using Image J, the SNR(signal to noise ratio) for each slice of the image was obtained. As a reference images, AC(Attenuation correction) images were used. For the analysis of acquired images, ROI(region of interest) was set in the white matter and gray matter sections of each image, and the average Intensity Value within the ROI were compared. **Results:** The 3D printed phantom had 5.43 average SNR and the original phantom had 5.32 average SNR. It showed that the 3D printed phantom had 0.1 higher SNR. However, white matter and gray matter of the original phantom had 9.59 and 32.64 intensity value while the 3D printed phantom had 13.32 intensity value for white matter and 42.98 for gray matter. The ratio of intensity value of them was 1:3.4 for white matter and gray matter of the original phantom and 1:3.2 3D printed phantom. **Conclusion:** Therefore, if calibration value is applied, it is believed that contributing effective examination of quality control and cost reduction. Since there were technical limitations and we used only one radioactive isotope, solving the technical problem and variety radioactive isotope would be required for further study. **References:** None

TEPS-14

Implementation of an automatically quantification package (Hone Graph) for phantom-based image quality assessment of bone SPECT: computerized self-classification of detectability using a novel index

H. Ichikawa^{1,2}, T. Shibutani², M. Onoguchi², K. Kawakami³, K. Nagatake⁴, T. Ito⁵, T. Kato¹;

¹Department of Radiology, Toyohashi Municipal Hospital, Toyohashi, JAPAN, ²Department of Quantum Medical Technology, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, JAPAN, ³Products Marketing Dept., FUJIFILM Toyama Chemical Co., Ltd., Tokyo, JAPAN,

⁴Quality Assurance Dept., FUJIFILM Toyama Chemical Co., Ltd., Tokyo, JAPAN, ⁵Department of Radiology, Saiseikai Yokohamashi Tobu Hospital, Yokohama, JAPAN.

Aim/Introduction: We have already developed a custom-design thoracic bone scintigraphy-specific phantom (hereafter referred to as "SIM²bone phantom") to assess image quality in bone SPECT imaging. The purpose of this study was to develop and demonstrate the validity of an automatically assessment system for imaging technology in bone SPECT. **Materials and Methods:** We were able to make more realistic phantom configurations of the thorax, spines, mediastinum, lung and bone metastases. SIM² bone phantom was constructed with an elliptical shape with a major axis of 310 mm, a minor axis of 210 mm, and a height of 320 mm. The vertebral body and reference section were constructed in a cylinder shape with a diameter of 36 mm, and height of 207 and 35 mm, respectively. Spherical lesion with diameters of 13, 17, 22 and 28 mm inserted in the vertebral body. The developed software was fully automatically calculated quantitative indexes (e.g. contrast-to-noise ratio, % coefficient of variance, % detectability equivalence volume, sharpness index, etc.). The repeatability and reproducibility of each index was assessed and compared between automatically and manually methods. A detectability score (DS) was defined four observation types to score the hot spherical lesions with the following value and was classified with the quantitative indexes by using decision tree analysis. The DS of lesions is 1) poor, 2) average, 3) adequate, 4) excellent. The validity of DS was assessed by comparison with visual analysis. **Results:** The repeatability and reproducibility of the software were excellent, and the automatically classified DSs exhibited an almost perfect agreement with those of classified by three expert board-certified nuclear medicine technologists. Decision tree analysis produced seven terminal groups, and four quantitative indexes were used for classifying the DS. Percentage agreement between Hone Graph and experienced, moderately experienced and inexperienced were almost perfect agreement, substantial and moderate, respectively. **Conclusion:** The software could automatically classify the detectability of hot lesion in the SIM2 bone phantom using the quantitative indexes, which were calculated by itself. It is suggested that this software is excellent in convenience or repeatability in order to fully automatically perform from analysis after data input to output result. **References:** None

¹²⁵I Radiation protection

J. Bartl, R. Bartlova;

Masaryk Memorial Cancer Institute, Brno, CZECH REPUBLIC.

Aim/Introduction: Radionuclide source ¹²⁵I is

intended for medical use for its introduction into close proximity to the tumor centre for its precise localization and subsequent operative extirpation. **Materials and Methods:** Type-approved small closed radionuclide sources (Iodine grain IsoAid ¹²⁵I) in localization needles. Package of iodine grain is taken from the supplier by radiation worker of the Pharmacy Department and in a shielded container is placed in a reserved place. Prior to the planned administration of iodine grains, the radiological assistant of the Radio Diagnostics (RD) Department will take a predetermined number of sources (maximum 3 pcs per day) that inserts into the portable shielded container and deposits it in the storage area behind the mammographic intervention room. The individual iodine grain is applied by the radiologist directly on the mammographic intervention scan to the patient's breast tissue. After implantation of the grain, the patient goes to the operating room of Surgical Department. Iodine grains are removed from the patient's breasts during radio-guided surgery. The extirpated node with iodine grain is transported from the operating room by elevator for pathological samples to the pathology site. After the removal of the grain by the pathologist and after purification in the formaldehyde solution, all iodine grains from the same working day are handed over to the supervising person on the Nuclear Medicine (NM) Department, who puts them in the transport shielded container, which is transferred to the storage areas of the NM Department. Here is stored in the form of solid waste for the period of release limits compliance, and then released into the environment within municipal waste. **Results:** The staff for handling of ionizing sources are trained in occupational safety and radiation protection by supervising persons of RD and NM Departments. The patient's written informed consent to the application of radionuclide grain and its familiarity with other procedures and behavior during application is prepared by the supervising person and the head of RD Department. Pathologists are not guided as radiation workers. Prior to the start of this work, must be demonstrably trained by the supervising person of NM Department in radiation protection and occupational safety with this type of radionuclide. **Conclusion:** The employees of RD and NM Departments for handling of ionizing sources are radiation workers equipped with full-body OSL personal dosimeters, finger thermo luminescent dosimeters (TLD) and electronic direct reading personal dosimeters. Pathologists are equipped with finger TLDs. **References:** None

Simultaneous myocardial Tc-99m/I-123 imaging using a cadmium-zinc-telluride camera: Validation of triglyceride deposit cardiomyopathy diagnosis

T. Niimi¹, M. Sugimoto¹, K. Unno¹, S. Yoshida²;

¹Nagoya Daini Red Cross Hospital, Nagoya, JAPAN,

²Nagoya University, Nagoya, JAPAN.

Aim/Introduction: Simultaneous myocardial Tc-99m/I-123 (Tc/I) imaging using a cadmium-zinc-telluride (CZT) camera allows for the concomitant evaluation of the processes targeted by the two radioisotopes with reduced radiation exposure. Recently, attention has been paid to myocardial scintigraphy with I-123-β-methyl iodophenyl-pentadecanoic acid (¹²³I-BMIPP) as a diagnostic imaging method for triglyceride deposit cardiomyopathy (TGCV). Among the features of ¹²³I-BMIPP scintigraphy, the washout rate is a major diagnostic criterion (less than 10%) in addition to myocardial perfusion and metabolism. To validate a CZT camera's (D-SPECT) response to TGCV diagnosis, simultaneous myocardial Tc/I imaging results were quantitatively evaluated. **Materials and Methods:** The impacts of cross-talk and reconstructed image contrast were quantified by measuring the contrast-to-noise ratio (CNR) and transmural defect contrast in the left ventricle wall (C_{TD}) induced by the difference in energy for combinations of Tc/I using a cardiac phantom. The collected data were reformatted by reconstruction without scatter correction and reorientation. We also verified the appropriate dose ratio, including the cross-talk rate of the energy spectra of both nuclides. The washout rate of I-123 was calculated using a cardio-hepatic phantom filled with clinically simulated proportions of I-123 for each organ. After acquiring the early images, the delay images were acquired 4 times with any time interval for the calculation of the washout rate (with decay correction). **Results:** The C_{TD} values of Tc/I were 91% for Tc-99m and 95% for I-123 in the anterior wall without scatter correction. Regarding the inferior wall, the C_{TD} was approximately 20% lower than that of the anterior wall. No notable difference was confirmed in the CNRs of the anterior and inferior walls. Higher Tc/I dose ratios for Tc-99m resulted in lower cross-talk rates for I-123, and Tc-99m exhibited a cross-talk rate of about 5% at 3 times the dose of I-123. The mean error of the washout rate for the combination of the data of the five measurements was 3%. **Conclusion:** The D-SPECT system features a difference in detectability between the anterior and inferior walls; however, it is capable of performing high-quality simultaneous dual-isotope imaging using Tc/I to facilitate TGCV diagnosis. The criteria for TGCV diagnosis using the D-SPECT system should be judged based on a washout rate error of 3%. **References:** None

TEPS-17

Effect of Reconstruction Parameters on Lu-177 SPECT Imaging

Y. Parlak, D. Goksoy, C. Sezgin, G. Mutevelizade;

Celal Bayar University, Faculty of Medicine, Department of Nuclear Medicine, Manisa, TURKEY.

Aim/Introduction: Lutetium-177 is a radionuclide used for the treatment of the neuroendocrine tumors, bone pain from metastatic disease, and prostate cancer. For lesion dosimetry based ^{177}Lu , resolution and reconstruction parameters are critical and should be considered. In this study, ^{177}Lu was evaluated of activity quantification and reconstruction parameters for different combinations on planar and SPECT imaging. **Materials and Methods:** A uniform “body phantom” was used with 6 lesions (6900 ml; distance; 10 mm to 35 mm) and filled with 444 MBq ^{177}Lu -water. First, the calibration factor of the gamma camera was calculated using a point source with known radioactivity. The phantom was scanned by positioning in the center of the gamma camera (GE, Infinia) gantry. Planar images were acquired for 10 min 256 x 256 matrix at a single bed position and multiple time points. The SPECT acquisition parameters were performed for 120 projections, 30 s per projection, a non-circular step-and-shoot acquisition orbit and 128 x 128 matrix. Projection data were acquired using two gamma rays of 113 ± 15 keV with a 6% abundance factor and 208 ± 15 keV with an 11% abundance factor using a parallel-hole medium-energy general-purpose (MEGP) collimator. The concentration of activity in the signal-to-background ratio was performed by manually drawing regions of interest (ROIs). All images were reconstructed with OSEM 3D, Flash 3D and filtered back-projection algorithms for different combinations. **Results:** The gamma camera calibration was calculated as 7.1 cps/MBq from planar scans. All reconstructions were processed in terms of the signal to background ratio in each sphere. According to the analyzes, the highest SNRs were calculated as 2.97, 3.4, 3.61 for OSEM, FBP and Flash 3D reconstructions, respectively. The SNR obtained with the Flash 3D algorithm were found statistically different ($p < 0.05$). **Conclusion:** The accuracy of activity determination was evaluated for ^{177}Lu imaging studies. Our results indicate that the methods used in this study allow for accurate determination of ^{177}Lu activity, and also suggest that standardizing reconstruction settings decreases inter-system variability for quantification of ^{177}Lu . This has an important role in dosimetry studies **References:** None

A comparison of the results of myocardial perfusion analysis software for ischemia diagnosis between each coronary artery branch area

T. Iimori¹, H. Miyauchi², T. Sada¹, T. Umezawa¹, K. Sawada¹, Y. Masuda¹, Y. Kuwabara², T. Uno³, Y. Kobayashi²;

¹Department of Radiology, Chiba University Hospital, Chiba, JAPAN, ²Department of Cardiovascular Medicine, Chiba University Graduate School of Medicine, Chiba, JAPAN, ³Department of Diagnostic Radiology and Radiation Oncology, Chiba University Graduate School of Medicine, Chiba, JAPAN.

Aim/Introduction: The results of stress myocardial perfusion single-photon emission computed tomography (SPECT), can be quantitatively evaluated by calculating the grade of ischemia or infarction using a myocardial perfusion analysis software. CardioREPO provided by FUJIFILM Toyama Chemical Co., Ltd. is a myocardial perfusion analysis software, and various verification studies have been performed regarding its ischemia diagnostic ability. However, there are few reports of its verification of ischemia diagnostic capability based on the coronary artery branch region^{1,2}. The concordance rates of CardioREPO results, quantitative perfusion SPECT (QPS) scores, and coronary angiographic findings were evaluated for each coronary artery branch (right coronary artery: RCA, left anterior descending: LAD, and left circumflex: LCX). **Materials and Methods:** Sixty-two patients who underwent both technetium-99m-methoxy-isobutyl-isonitrile myocardial perfusion SPECT and coronary angiography were evaluated. Using stress myocardial perfusion SPECT, the total value of the regions corresponding to the RCA, LAD, and LCX was calculated based on CardioREPO and QPS from the myocardial data divided into 17 segments. 1) The correlation coefficient was calculated for each coronary artery branch based on CardioREPO and QPS from the calculated scores. 2) When coronary angiography showed vascular stenosis of 75% or greater, the region was defined as “with ischemia.” Based on these results of coronary angiography, the ischemia diagnostic ability of CardioREPO and QPS was evaluated using the receiver operator characteristic (ROC) curves. **Results:** 1) Correlation between CardioREPO results and total defect score of QPS The rank correlation coefficients for each coronary artery governing region were determined in all regions of the RCA, LAD, and LCX. 2) Results of ROC analysis of coronary angiography, CardioREPO, and QPS Although there was no difference between CardioREPO and QPS in terms of the summed stress score, the results of the analysis for each coronary artery branch showed that CardioREPO had a higher area-under-the-curve value than that of the QPS in all coronary artery branch regions. **Conclusion:** In this study, the evaluation of coronary branch ischemia using CardioREPO was shown to be useful. **References:** 1). Immediate adverse effects recorded in patients with neuroendocrine tumors undergoing treatment with ^{177}Lu -oxodotatrid, using Lysine and Arginine at a

slower rate of infusion. Nursing management

S. Lopez Gandul, E. Albuixech, J. Arcos, S. Garcia, F. Hernando, M. Iniesta, E. Lopez, L. Lozano, Y. Samadi, C. Sanchez, I. Garlito, D. Villasboas, A. Garcia, J. Castell; Hospital Universitari Vall d'Hebrón, Barcelona, SPAIN.

Aim/Introduction: To record the immediate adverse effects (IAEs) in cancer patients undergoing treatment with ¹⁷⁷Lu-oxodoteotride, using amino acid formula Lysine and Arginine, by Metabolic Therapy Unit staff. **Materials and Methods:** Thirty-four patients (9 women and 25 men, 22±83 age) with gastroenteropancreatic neuroendocrine tumors and paragangliomas, underwent treatment with ¹⁷⁷Lu-oxodoteotride in our Metabolic Therapy Unit (July 2016 to April 2020). Protocol: intravenous premedication with Ondasentron (8mg) and Pantropazol (40mg); was followed by a continuous perfusion of amino acid Lysine and Arginine formula (1500cc /6hours). 30 minutes into the aminoacid perfusion, ¹⁷⁷Lu-oxodoteotride (200mCi/7400MBq) was administered using intravenous infusion pumps (lasting up to 1 hour in some cases, to avoid some adverse reactions). The hospital protocol establishes the administration of four doses of ¹⁷⁷Lu-oxodoteotride every 2 months, depending on the patients evolution and response to treatment. IAEs were recorded during the administration of amino acid formula. **Results:** Thirty-four patients underwent eighty-nine ¹⁷⁷Lu-oxodoteotride treatments and 16,8% had IAEs (nausea 5, vomiting 3, abdominal pain 1, diarrhea 2, headache 1, flushing 1, dizziness 1 and muskuloeskeletal pain 1). **Conclusion:** According to our experience, the use of our protocol of administration of Lysine and Arginine administrated at a slower infusion rate significantly reduces the appearance of IAEs in patients with ¹⁷⁷Lu-oxodoteotride treatment. **References:** None

Incidental suspicious COVID-19 findings in asymptomatic patient during ¹⁸F-FDG PET/CT follow-up

M. Paula, A. Fonseca, C. Marques, L. Ribeiro, S. Sequeira, H. Duarte; Ipo Porto, Porto, PORTUGAL.

Aim/Introduction: Although nuclear medicine procedures are unlikely to have a role in the primary diagnosis of COVID-19, there may be incidental detection found in PET/CT patients with history of neoplastic disease. These findings have implications in the hospital daily routines. Furthermore in addition, it is our task as Nuclear Medicine Technologists to know and follow the institution's guidelines for safely dealing with patients suspected of having COVID-19 infection, protecting staff and other patients. **Materials and Methods:** A 41-year-old woman with a 1-year history of breast cancer underwent a follow-up ¹⁸F-FDG PET/CT during COVID-19 outbreak. After the PET/CT acquisition abnormalities in parenchyma lung have been reported.

It was suspected that the changes presented on CT could be related to infection by COVID-19. At the end of the examination, the patient was treated as potentially infected with COVID-19 and was referred to a COVID-19 diagnosis area that was created at the institution to assist patients who, during examinations or consultations, present suspicious criteria of infection. **Results:** The PET/CT was report as "No evidence of hypermetabolic lesions. Hyperactivity in poorly defined peripheral pulmonary densifications scattered in the right lung of probable nature inflammatory (infectious? iatrogenic?)...". The patient was forwarded, according to the rules instituted in our hospital, to the department responsible for testing patients with suspected COVID-19. The patient remained in the hospital until the test result was obtained, which in this case was a negative test for COVID-19. **Conclusion:** The CT patterns of respiratory infection in PET / CT has been described as subcapsular densifications attributed to recent RT. Nonspecific symptoms or asymptomatic patients that present suspicious images should be quickly tested and monitored for SARS-CoV-2 nucleic acid. The COVID-19 infection changed the way we work. The health system and professionals must be alert and should aim to provide safe patient care, workplace safety and well-defined rules for dealing with suspected cases that may occur according to the National and International recommendations. **References:** None

TEPS-21

The impact of SARS-Cov-2 emergency in the activity of the Nuclear Medicine Department, a single-center experience

M. Maccagnani, A. Farina, R. Bonfiglioli, S. Fanti; Azienda Ospedaliero-Universitaria S.Orsola-Malpighi, Bologna, ITALY.

Aim/Introduction: The SARS-Cov-2 emergency was declared in Italy on January 31th. It progressed in steps until March 11th, when all the Italian territory was involved in extremely severe restrictive measurements. The emergency had a substantial impact on all the activities of the hospital. The aim of this work was to investigate the real effect of this restriction on the management of the patients and on the volume of examinations performed in our Nuclear Medicine Center (NMC). **Materials and Methods:** Nuclear medicine diagnostic methods are classified as second-level, and thus the NMC was not directly involved in the confirmation of SARS-CoV-2 infections. However, access to the NMC by positive cases cannot be excluded. Moreover, both oncological and non-oncological pathologies may present with the same symptoms of COVID-19, and the etiopathogenesis of the infection does not ease the rapid identification of possible infects patients. For this reason, the NMC first step was the creation of a "checkpoint",

surveilled by a nuclear physician and a nurse, where all the outpatients were taken the temperature and examined about COVID-19-like symptoms. Secondly, the NMC medical team assessed all the scheduled examinations until the end of April and postponed the non-urgent exams. The same approach was put in place for all the exams carried out in collaboration with other specialists due to the change in their volume of activities. In collaboration with the Clinical Hygiene Department, new and more precise procedures were prepared regarding the reception and admittance of patients in the diagnostic areas, their discharge, the cleaning and disinfection of furniture and equipment in between examinations. In the same way, some patients contacted the ward expressing the will to postpone, or cancel, the exams already scheduled. **Results:** As a result, there was a significant drop in the activities carried out in the NMC compared to the same period (March–April) of the previous year: - 27% of PET activity (from 2038 to 10495 exam) and -40% of conventional nuclear medicine activity (from 1050 to 629 exams). **Conclusion:** In conclusion, the decrease in activity was a key factor to safeguard the health of patients and operators. In fact, no new case of COVID-19 infection related to the presence or to the diagnostic activity of the unit was reported in patients or even in the staff. **References:** None

TEPS-22

Covid19 emergency: how the Nuclear Medicine dept of Verona reacted

L. Pavanello, F. Sciume, D. Grigolato, M. Cucca, L. Locantore, E. Biggi, M. Naseri, M. Zuffante;
AOUI di Verona, Verona, ITALY.

Aim/Introduction: We describe our experience to contain and reduce the ongoing transmission of the virus while ensuring scintigraphy or PET/CT in patients who need it for diagnostic purpose and monitoring response to therapy. Our operating unit has implemented all the legal provisions given by the Ministry of Health involving the Nuclear Medicine staff to contain the infection. **Materials and Methods:** Our actions have been: hang signboards with the instructions for hand washing, use of mask and social distancing at the hall of our department. Give new surgical masks to all our patients. Ensure that all patients do the hand washing with the available gel as soon as they enter in the hall. Reduce the number of people entering the dept. Modify the Appointment Agenda, in order to avoid gathering in the waiting room. The diagnostic activity was reviewed on the basis of urgency and priority. The day before the exam our nurses call patients and do a triage, asking information on their health. The day of the exam their temperature is checked, in diagnostic, the patients remove their gloves and wash again their hands, the staff ensures that patient mask is well kept during the examination. When

the scan is completed, the patient waits for the doctor's approval in the same diagnostic room, this to prevent the patient to stay in different waiting rooms. If patients have a temperature on the day of the scanning they are invited to go home and contact their GP. In case the scans are needful and still the test, the patients are considered suspected for coronavirus and they are asked to come at the end of the day. **Results:** Our operativity has changed by raising the level of attention to the highest risk, this to limit or contain the coronavirus contagion between operators and patients as low as possible. We work with even more attention to the behavior and management of the patient, who is always seen as potentially infected. **Conclusion:** To date, after 2 months of emergency, being in a location where the infection is at a high level and having had few patients in our dept where viral pneumonia was discovered at PET/CT and subsequently tested positive with the swab, nobody of the staff had the coronavirus disease. Our personnel was tested once or twice for the virus. This validate the management policy in our service as a good one. **References:** None

A Novel Clickable MSAP Agent for Dual Fluorescence/ Nuclear Labeling of a GRPR-Targeted Peptide

K. Chen, J. Nieuwenhuizen, M. Handula, Y. Seimbille;
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Dual-modality optical/radio-imaging has received great attention in preoperative surgical planning and intraoperative optical guidance for tumor therapy.¹ Gastrin-releasing peptide receptor (GRPR) is an established target for many cancers, such as prostate and breast cancers.² We herein describe the development of a novel dual-modality agent for site-specific labeling of a GRPR-targeted peptide through a 2-cyanobenzothiazole (CBT)/1,2-aminothiol click reaction. Notably, the CBT-based multifunctional single-attachment-point (MSAP) agent enables a general and single-step synthesis of the dual-modality probe. In this study, the radiolabeling protocol was optimized by using CBT-scavenger to improve the reaction rate and molar activity of the imaging probe. **Materials and Methods:** DOTA-Cy5.5-CBT (1) and the GRPR-targeted

peptide (Cys-d-Phe-Gln-Trp-Ala-Val-Gly-His-NHCH[CH₂-CH(CH₃)₂]₂, 2) were prepared by solid phase synthesis. The DOTA chelator was labeled with ⁶⁸Ga (or ¹¹¹In) in a NaOAc buffer (pH 5.5) at 100 °C for 15 min. The CBT/1,2-aminothiol click reaction was performed by mixing [⁶⁸Ga]-1 (or [¹¹¹In]-1) with the peptide 2 in a molar ratio of 1:20 at 37 °C in PBS buffer (pH 7.4) and in the presence of TCEP. After 20 min, the mixture was incubated with CBT-magnetic beads for another 5 min. The radiolabeling and scavenger reaction was monitored by RP-C18 HPLC. **Results:** CBT-bearing chelator 1 and peptide 2 were obtained in a yield of 45% and 23% after purification by RP-C18 HPLC, respectively. Labeling of 1 with ⁶⁸Ga and ¹¹¹In was successfully achieved in slightly acidic aqueous conditions to give [⁶⁸Ga]-1 and [¹¹¹In]-1 with high RCYs (> 99%). Two-step radiolabeling of 2 with [⁶⁸Ga]-1 or [¹¹¹In]-1, provided the corresponding radiolabeled GRPR-targeted peptides with high RCYs (> 99%) and molar activities (~10 MBq/nmol). Completely removal of non-reacted 2 from the solution was successful with using CBT-scavenger. **Conclusion:** The novel dual-modality GRPR-targeted probe was successfully synthesized and labeled with ¹¹¹In and ⁶⁸Ga for respective SPECT/fluorescence and PET/fluorescence imaging studies. The MSAP radiolabeling approach based on the orthogonal CBT/1,2-aminothiol click reaction is very practical for regioselective labeling of N-terminal cysteine-containing sensitive biomolecules. Further in vitro stability, biodistribution and imaging studies of the GRPR ligand are currently underway in our laboratory. **References:** (1) Kuil, J.; Velders, A. H.; van Leeuwen, F. Fluorescence-based video tracking of the DROP-IN gamma probe during robotic surgery - technological evaluation in porcine models

M. van Oosterom^{1,2}, K. M. Houwing¹, P. R. Roos¹, T. Buckle^{1,2}, D. M. van Willigen¹, E. Mazzone^{3,4}, K. Bauwens⁴, P. Dell'Oglio^{1,4}, F. W. B. van Leeuwen^{1,2,4};

¹IMI-Lab, Dept. of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS, ²Department of Urology, Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, ³Division of Oncology/Unit of Urology, URI, IRCCS Ospedale San Raffaele; Vita-Salute San Raffaele University, Milan, ITALY, ⁴ORSI Academy, Melle, BELGIUM.

Aim/Introduction: Minimally invasive interventions in the form of robot-assisted laparoscopic surgery, are claiming an increasing share of the surgeries performed. Through the clinical introduction of the DROP-IN gamma probe, surgical robotic systems have become compatible with radioguided surgery (e.g. sentinel node or PSMA-targeted dissection) [1,2,3]. 'GPS-like' surgical navigation of laparoscopic

detection modalities based on preoperative roadmaps has been suggested to further advance the realization of precision surgery [4]. The tool-tracking needed for navigation, however, is complex in a laparoscopic setting. In an effort to integrate the DROP-IN modality in a robotic navigated workflow, a fluorescence-based video-tracking method was developed and validated in a surgical setting. **Materials and Methods:** A clinical grade multispectral fluorescence laparoscope, capable of detecting fluorescein (λ_{ex} =488 nm, λ_{em} =515 nm) and indocyanine green (ICG; λ_{ex} =800 nm, λ_{em} =820 nm), was used [5]. Dedicated video-processing algorithms were developed to detect and segment fluorescent markers on the DROP-IN gamma probe. Based on this information the relative position and orientation (pose) of the DROP-IN could be calculated, in real time, with respect to the fluorescence laparoscope. Tracking algorithms were integrated with a surgical navigation system able to optically track the pose of the laparoscope and the patient. In a robotic torso phantom this allowed DROP-IN probe navigation towards radioactive lesions (^{99m}Tc) identified on SPECT/CT. The functionality of the DROP-IN probe navigation was further validated during robotic surgery in porcine models (n=4). **Results:** Using multispectral fluorescence imaging, the DROP-IN markers could be differentiated from ICG-positive lesions based on emission wavelength. Maintaining a direct line-of-sight with respect to the fluorescent markers enabled intraoperative tracking of the DROP-IN probe with respect to lesions even under surgical conditions. Augmented reality overlays, indicating the real-time distance between the DROP-IN and the lesion targets, were visualized in the surgical robotic console. Integration with the SPECT navigation workflow, allowed accurate positioning of the DROP-IN probe relative to radioactive lesions as defined in preoperative SPECT/CT scans. Real-time audible and numerical feedback provided by the DROP-IN gamma probe verified that the localization was correct. **Conclusion:** We have shown that the implementation of the DROP-IN probe technology can in the future be expanded with (multispectral) fluorescence imaging-based surgical navigation towards lesions identified in preoperative images. With that a next step has been taken towards creating impact on clinical care using radioguided surgery in the robotic setting. **References:** [1] M.N.van_Oosterom_et_al.,AJNMMI,2016; [2]P.Meershoek_et_al.,EJNMMI,2019; [3]F.W.B.van_Leeuwen_et_al.,Clin_Nucl_Med,2019; [4]M.N.van_Oosterom_et_al.,J_Urol,2018; [5]P.Meershoek_et_al.,J_Nucl_Med,2018.

²Radboud University, Nijmegen, NETHERLANDS, ³Canisius
 Wilhelmina Hospital, Nijmegen, NETHERLANDS,
⁴University hospital Bonn, Nijmegen, NETHERLANDS.

Aim/Introduction: Incomplete resection of prostate cancer (PCa) leads to disease recurrence and consequently poor oncological outcome. To achieve complete resection, prostate specific membrane antigen (PSMA) targeting multimodal ligands may be used for intraoperative tumor detection, delineation, and targeted photodynamic therapy (tPDT). Previously, we demonstrated that PSMA-N064, a PSMA ligand conjugated with IRDye700DX and labeled with ¹¹¹In via DOTAGA, shows promising tumor-targeting properties and tPDT efficacy in preclinical tumor models. Here, we aimed to evaluate its potential for intraoperative multimodal imaging and tPDT using human PCa samples in an ex vivo incubation study. **Materials and Methods:** Eleven patients scheduled for radical prostatectomy were included. Biopsy samples were obtained from the surgically removed prostate, both from the tumor and from contralateral (healthy) prostate tissue. To study the tumor-binding potential of PSMA-N064 ex vivo, tissue samples (n=10) were incubated with ¹¹¹In-labeled PSMA-N064 (0.025 nmol, 26.3 MBq/nmol, 4 hrs). To study the efficacy of tPDT (n=1, patient inclusion is ongoing), tissue samples were incubated with PSMA-N064 (0.05 nmol, 4 hrs), washed and exposed to near infrared (NIR) light (100 J/cm²). Cellular distribution of the ligands within the tissue sample was evaluated macroscopically using fluorescence flatbed scanning and autoradiography. Subsequently, tissue samples were sectioned and analyzed immunohistochemically (H&E, PSMA, Caspase-3 and γH2AX). Discrimination between tumor and normal tissue regions within the tumor sample was performed by a pathologist based on H&E staining. Localization of the marked tumor regions was compared with autoradiography, fluorescence imaging, and PSMA immunohistochemistry. **Results:** Macroscopic fluorescence imaging and autoradiography of ¹¹¹In-PSMA-N064 showed preferential accumulation in tumor tissue. A significant difference in fluorescence intensity was observed when comparing tumor regions of ¹¹¹In-PSMA-N064-incubated tissue samples (mean fluorescence intensity 58,143 ± 17,267) to either adjacent normal tissue regions within the same tissue sample (23,712 ± 10,364, p < 0.01) or the contralateral control sample from healthy tissue (20,220 ± 10,871, p < 0.001). Moreover, co-localization of the radiosignal, fluorescence signal and PSMA expression in the marked tumor regions was observed. tPDT treatment with NIR light increased Caspase-3 and γH2AX staining in tumor samples compared with healthy prostate tissue. **Conclusion:** The current results strongly suggest a PSMA-specific accumulation of ¹¹¹In-PSMA-N064 in human PCa

samples, that can be visualized by both radionuclide and fluorescence imaging. Although patient inclusion has to be completed, preliminary results point towards increased cell death, as proven by Caspase-3 and γH2AX staining, upon PSMA-N064 mediated tPDT on human PCa samples.

OP-415

C-Met receptor-specific fluorescence-guided surgery in penile cancer patients

H. M. de Vries¹, M. N. van Oosterom², D. M. van Willigen², H. G. van der Poel¹, F. W. B. van Leeuwen², O. R. Brouwer¹, T. Buckle²;
¹Netherlands Cancer Institute - Antoni van Leeuwenhoek hospital, Amsterdam, NETHERLANDS, ²Leiden University Medical Center, Leiden, NETHERLANDS.

Aim/Introduction: Surgery is still mainstay of treatment in penile squamous cell carcinoma (pSCC). During surgery, the goal is to find the optimal balance between an oncologically safe surgical margin, while minimizing unnecessary mutilation. Unfortunately, positive margins currently occur in 7-36% of patients. As c-Met receptor over-expression is reported for 87% pSCC, the feasibility of targeting this receptor to support image-guided surgery applications was clinically investigated. **Materials and Methods:** A total of fifteen patients (≥ 18 years of age with ≥T1 pSCC undergoing primary tumour surgery) were included in a prospective pilot study. For initial ex vivo assessment of tracer performance (N=10) surgically excised penile tumour samples were incubated in a solution containing the Cy5 labelled C-Met targeting tracer EMI137 [1]. In vivo assessment of EMI137 was performed in five patients (0.13mg/kg; imaging at 3h p.i.). White light and fluorescence imaging were conducted using a prototype STORZ fluorescence laparoscope complemented with in-house developed image-processing software. The location and intensity of signal enhancement in the fluorescence images were correlated to standard pathological assessment including c-Met immunohistochemistry (% positive cells and combined c-Met score (mean multiple regions per tumour)) and H&E staining. **Results:** C-Met mediated fluorescence imaging combined with image-processing allowed tumour identification in all tumour specimens (diameter 5-55mm and infiltration depth 2-24mm). Tumour-to-background ratios did not significantly differ between ex vivo (range: 2.0 ± 0.6 - 3.4 ± 0.3) and in vivo (range: 2.0 ± 0.4 - 4.2 ± 0.9) sample analyses. In line with previous in vivo studies in colon cancer [1], no tracer-related adverse effects occurred. Microscopic immunohistochemistry showed a possible correlation of macroscopic tumour-to-background ratios with the percentage of c-Met expressing cells in the surgical specimens, suggesting that this application could potentially be used for tumour margin visualization. Inter-patient differences were observed in

the percentage of c-Met positive cells (30-100%) and the combined c-Met score (0.3-2.3). **Conclusion:** C-Met receptor-specific fluorescence imaging of primary pSCC tumours using EMI137 appears to be feasible. This pilot study is the first to report in vivo application of a targeted fluorescent tracer in pSCC and paves the way for further development of this surgical guidance approach in order to visualize surgical margins and (potentially) assess tumour spread using c-MET specific (PET) tracers. **References:** 1. Burggraaf et al. Detection of colorectal polyps in humans using an intravenously administered fluorescent peptide targeted against c-Met. *Nat Med.* 2015; 21: 955-61.

OP-416

Accuracy of 68Ga-PSMA-11 for pelvic nodal metastasis detection prior to radical prostatectomy and pelvic lymph node dissection: A multicenter prospective phase III imaging study

J. Calais¹, W. R. Armstrong¹, V. Murthy², C. L. Heath², S. Behr², F. Barbato³, F. Ceci⁴, A. Farolfi⁵, S. Schwarzenboeck⁶, M. Unterrainer⁷, H. Zacho⁸, M. R. Cooperberg², H. G. Nguyen², R. E. Reiter¹, S. Holden¹, K. Herrmann¹, W. P. Fendler³, M. Eiber⁹, J. Czernin¹, T. A. Hope²;

¹University of California, Los Angeles, CA, UNITED STATES OF AMERICA, ²University of California, San Francisco, CA, UNITED STATES OF AMERICA, ³University Hospital Essen, Essen, GERMANY, ⁴University of Turin, Turin, ITALY, ⁵S.Orsola University Hospital, Bologna, ITALY, ⁶Rostock University Medical Centre, Rostock, GERMANY, ⁷Ludwig-Maximilians-University Munich, Munich, GERMANY, ⁸Aalborg University Hospital, Aalborg, DENMARK, ⁹Technical University Munich, Munich, GERMANY.

Aim/Introduction: To determine the accuracy of 68Ga-PSMA-11 PET for the detection of pelvic nodal metastases (N1) compared to histopathology at time of radical prostatectomy (RP). **Materials and Methods:** This is a prospective multicenter single-arm open-label phase 3 imaging trial. Patients with intermediate to high risk prostate cancer (PCa) considered for RP with lymph node dissection (PLND) were enrolled at the University of California, Los Angeles (UCLA) and at the San Francisco (UCSF) (NCT03368547, NCT02611882, NCT02919111), and underwent one 68Ga-PSMA-11 PET. The primary endpoint was the sensitivity (Se) and specificity (Sp) of 68Ga-PSMA-11 PET for the N1 detection compared to PLND histopathology (reference-standard) on a per patient basis using nodal region-based correlation. Each scan was read by three blinded independent central readers (BICR). Consensus was based on majority rule. **Results:** From December 2015 to August 2019, 633 patients underwent one 68Ga-PSMA-11 PET for primary staging, and 277/633 (44%) subsequently underwent RP and PLND. The median initial PSA was 11.1 [0.04-147]. 75/277 patients (27%) had N1 disease per histopathology. Using a regional based analysis, Se, Sp,

positive predictive value (PPV) and negative predictive value (NPV) for N1 detection was 0.40 [0.34, 0.46], 0.95 [0.92, 0.97], 0.75 [0.70, 0.80], 0.81 [0.76, 0.85], respectively. Se was higher for patients with higher PSA: 0.29 [0.24, 0.35] for PSA < 11 ng/ml versus 0.48 [0.42, 0.54] for PSA > 11. Se was higher when the nodes were larger: 0.30 [0.25, 0.36] for nodes < 10 mm versus 0.68 [0.63, 0.74] for nodes > 10. The average node size in true positive patients was 10 mm versus 4 mm in false negative patients. **Conclusion:** In intermediate to high risk PCa patients who underwent RP and PLND, 68Ga-PSMA-11 PET detected pelvic nodal metastases with a sensitivity of 0.40 and a specificity of 0.95. Higher PSAs and larger node size correlated with increased sensitivity. **References:** None

OP-417

Local recurrence after radical prostatectomy and additive radiation - can PSMA-radioguided surgery prolong therapy-free survival?

S. Knipper¹, L. Ascalone¹, B. Ziegler¹, R. Simon², C. Berliner³, M. Graefen¹, M. Eiber⁴, M. Heck², T. Horn², T. Maurer¹;

¹Martini-Klinik Prostate Cancer Center, University Hospital Hamburg-Eppendorf, Hamburg, GERMANY, ²Department of Urology, Technical University of Munich, Munich, GERMANY, ³Department of Radiology and Nuclear Medicine, University Hospital Hamburg-Eppendorf, Hamburg, GERMANY, ⁴Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY.

Aim/Introduction: Since the introduction of prostate specific membrane antigen (PSMA)-positron emission tomography (PET) imaging, isolated local recurrence may be precisely detected after radical prostatectomy (RP). We aimed at evaluating the biochemical response and therapy-free survival after salvage surgery in patients with local recurrence in the area of the former seminal vesicles. **Materials and Methods:** We assessed 32 patients treated with PSMA-radioguided surgery (PSMA-RGS) between 04/2014 and 02/2020 in two centers. All patients presented with biochemical recurrence after RP with a singular local recurrence at PSMA PET imaging. Previous radiation therapy was administered in 18 patients. PSA nadir without further treatment, as well as percentage of patients with complete biochemical response (cBR, PSA <0.2 ng/ml) after 6-16 weeks were assessed. BCR-free survival and therapy-free survival (TFS) were calculated using Kaplan-Meier. Moreover, Clavien-Dindo complications were evaluated. **Results:** Prior to PSMA-RGS, overall median PSA was 1.1 ng/ml (interquartile range [IQR]: 0.7-1.8 ng/ml). Post PSMA-RGS, overall median PSA Nadir was 0.1 (IQR: 0-0.4 ng/ml). In 26 patients (81.3 %), cBR was observed. During the median follow-up of 27.0 months (IQR: 17.1-44.7 months), 16 patients experienced BCR and 11 patients received further therapy. At 2 years of follow-up, BCR-free survival rate was

58.7% and TFS rate was 81.3%. Three Clavien–Dindo Grade III complication were observed (ureter injury, rectal injury, suprapubic catheterization). **Conclusion:** Salvage surgery of local recurrence within the seminal vesicle bed with PSMA-RGS is feasible and may present an opportunity in highly selected patients with local recurrence to prolong BCR-free survival and therefore possibly increase therapy-free survival. Further studies are needed to confirm our findings. **References:** None

OP-418

Between pathological prostate cancer lymph node and sentinel lymph node status : which one is the most informative ?

A. Morel¹, V. Fleury¹, M. Le Thiec¹, B. Maucherat¹, M. Colombié¹, D. Rusu¹, G. Aillet², F. Kraeber-Bodéré^{1,3}, T. Rousseau⁴, L. Campion^{1,3}, C. Rousseau^{1,3};

¹ICO René Gauducheau, Saint-Herblain, FRANCE,

²Histopathology Institute, Nantes, FRANCE, ³Nantes

University, CNRS, Inserm, CRCINA, Nantes, FRANCE, ⁴Urologic Clinic Nantes-Atlantis, Saint-Herblain, FRANCE.

Aim/Introduction: Due to the concept of sentinel lymph node (SLN) where the pathologic status of SLN reflects the other pathologic lymph nodes status, SLN should contain decisive information for clinical outcome. This study assessed the clinical outcome after laparoscopic prostatectomy associated with isotopic SLN detection and extensive pelvic resection (ePLND) in localized prostate cancer (PCa) patients. **Materials and Methods:** From February 2009 until October 2015, a total of 231 consecutive patients were analyzed. Biochemical Progression-Free Survival (PFS) was assessed with Kaplan-Meier curves. Various histopathological parameters were analyzed by univariate and multivariate analysis by Cox regression analysis. **Results:** The study median follow-up was 7.1 years (95% CI: [6.6–7.5]). Lymph node (LN) metastases occurred in 38 patients. We removed an average of 20.2 ± 9.2 LNs via ePLND and 6.05 ± 3.99 SLN. At the time of final follow-up, 36.4% (84/231) patients had recurrence and we noticed 11 specific mortalities. In univariate analysis, characteristics of primary tumour, as pT stage, ISUP Grade Group, percentage of positive biopsy cores, intersection margin, vesicles and prostate capsule involved, significantly affected the PFS from $p < 10^{-4}$ to 10^{-6} . Concerning LN metastases, the most relevant data were the number of metastases both in LN and in SLN and particularly the presence of SLN and LN macro-metastases ($p < 10^{-12}$ to 10^{-15}). In the multivariate analysis evaluating PFS, the most significant prognostic factor was evidence of macro- or micro-metastases in SLN (adjusted hazard ratio of 3.88 [95%CI: 2.24–6.71], $p < 2.10 \times 10^{-6}$) but very interestingly not in extra SLN (adjusted hazard ratio of 0.85 [95%CI: 0.37–1.97], $p = 0.71$). **Conclusion:** SLN detection seems to contain decisive information for the

clinical outcome of patients with localized PCa because metastatic or non-metastatic status of SLN had a strong impact on the PFS. The question arises as to propose immediate postoperative additional treatment to patients with metastatic SLN as temporarily received adjuvant androgen deprivation therapy? **References:** ¹Muck A et al. Extremity dose in nuclear medicine: EURADOS initiative to update the ORAMED results

R. Kollaard¹, A. Zorz², N. Cherbuin³, J. Cooke⁴, P. Covens⁵, M. Crabbé⁶, L. Cunha⁷, J. Dabin⁶, A. Dowling⁸, M. Ginjaume⁹, S. Haruz-Waschitz¹⁰, A. Kyriakidou¹¹, A. McCann⁸, L. McNamara¹²;

¹Nuclear Research and Consultancy Group (NRG), Arnhem, NETHERLANDS, ²Istituto Oncologico Veneto IOV - IRCCS, Padua, ITALY, ³HUG-CHUV, Lausanne, SWITZERLAND, ⁴St. James Hospital, Dublin, IRELAND, ⁵VUB, Bruxelles, BELGIUM, ⁶SCK.CEN, Mol, BELGIUM, ⁷IsoPor-Azores, Angra do Heroísmo, PORTUGAL, ⁸St. Vincent's University Hospital, Dublin, IRELAND, ⁹UPC, Barcelona, SPAIN, ¹⁰Shamir Medical Center, Shamir, ISRAEL, ¹¹EEAE, Athens, GREECE, ¹²University Hospital Limerick, Limerick, IRELAND.

Aim/Introduction: Extremity dose is a radioprotection concern for Nuclear Medicine (NM) departments. According to the ORAMED study, nearly one of five workers could receive an equivalent skin dose over the annual limit. Since the publication of the ORAMED project results in 2011, NM departments have undergone several novelties. New isotopes have been introduced, like ⁶⁸Ga or ¹⁷⁷Lu, and radiation protection devices, such as (semi-)automatic dose dispensers, are now widely used. A subgroup of the EURADOS working group 12 has been established in order to update the results of ORAMED project according to the actual state of the NM departments in Europe. **Materials and Methods:** A detailed literature review regarding the extremity exposures of NM workers has been performed. A questionnaire has been distributed to the European regulators, to investigate the extremity doses collected in national dose registries as well as some issues related to the use of dosimeters for extremities. A second questionnaire is in preparation to be submitted to single European NM departments. **Results:** Regarding the literature review, more than 150 papers published between 1985 and 2019 have been analyzed. Articles were stratified according to the type of isotopes and procedures. 44% of the articles

cover diagnostic PET acquisition (92%, 5% and 3% related respectively to ^{18}F , ^{68}Ga and ^{124}I), 38% of articles cover therapeutic procedures with beta isotopes, while only 18% cover $^{99\text{m}}\text{Tc}$ diagnostic scintigraphy. Several articles evaluate the use of automatic dispensers, especially for ^{18}F . Regarding therapeutic procedures, the majority of the articles consider consolidated therapies with ^{90}Y (60%), ^{131}I (15%), ^{153}Sm (6%), ^{188}Re (6%), ^{186}Re (3%) and ^{169}Er (2%). Very few works consider innovative therapies such as ^{166}Ho (3%) or ^{177}Lu (5%). The questionnaire was sent to 25 countries in October 2019. The average doses in NM, as reported by 15 European regulators are between 4–14 mSv, with a very low number of doses over the limit of 50 mSv (< 5%). A questionnaire focused on the use of radiation protection devices in Europe is under evaluation in a pilot court of NM departments. **Conclusion:** The literature review shows that there is a lack of data for radioisotopes introduced in the last 10 years. The task group is preparing pilots to investigate extremity exposure for ^{68}Ga and ^{177}Lu . The questionnaire that will be distributed to single hospitals will help to validate data from regulators, as well as to investigate the radiation protection measures in use. **References:** None

Optimization of the exposure to workers handling of radiopharmaceuticals

M. Fulop¹, **J. Hudzietzová²**, **J. Sabol³**, **P. Povinec⁴**, **A. Vondrák⁵**, **D. Baček⁴**, **P. Ragan¹**, **L. Foltínová⁶**, **I. Benkovský⁷**;
¹ABRS, s.r.o., Samorin, SLOVAKIA, ²Faculty of Biomedical Engineering, Czech Technical University in Prague, Prague, CZECH REPUBLIC, ³Faculty of Security Management PACR in Prague, Prague, CZECH REPUBLIC, ⁴PET center BIONT, a.s., Bratislava, SLOVAKIA, ⁵IZOTOPCENTRUM, s.r.o., Nitra, SLOVAKIA, ⁶University of Economics in Bratislava, Bratislava, SLOVAKIA, ⁷Faculty of Pharmacy, Comenius University in Bratislava, Bratislava, SLOVAKIA.

Aim/Introduction: Contacts of workers with radiopharmaceuticals during their preparation and application include a number of operations, which, depending on the geometry and duration of irradiation, cause different exposure of the skin on the hands. The results of personal monitoring show that approximately 10% of workers at nuclear medicine departments in Slovakia and in the Czech Republic regularly receive an increased skin exposure reaching the investigation level set by the respective regulatory authorities. The reasons for such elevated exposure are not always understood and identified. The paper proposes a new approach in identifying a probable cause of elevated exposure associated with the specific working procedures. **Materials and Methods:** The contact of workers with radioactive sources include preparation and application of radiopharmaceuticals. The ORAMED studies found a direct relationship between

the total distribution of the personal dose equivalent $H_p(0.07)$ characterizing skin exposure when preparing or administering radiopharmaceuticals to patients and various individual working approach or techniques used. In case of overexposure the dose distribution of workers is visibly distorted. By comparing the analysis of this distribution using the multiple linear regression (taken into account spatial distributions from individual operations) with a similar analysis of a worker normally exposed under the same radiopharmaceutical manipulation procedures, it is possible to identify possible reasons causing excessive exposure. The dose distribution matrix have been determined by the measurement on a physical phantom in combination with Monte Carlo calculations using MCNP5 code and a voxel hand phantom. Ten TLDs positioned on gloves were used to map the overall dose distribution during the administration. **Results:** The method of identifying the operations or procedures causing excessive exposure was used for the investigation of two overexposed workers. The matrix of the mean hand dose distribution was determined by measuring on the physical hand phantom in combination with Monte Carlo code calculations (MCNP5) using a hand voxel phantom. As to the first investigated worker, the most serious procedures behind the excessive skin exposure was attributed to the non-reported administration of FDG to patients by unshielded syringe while in the second case, the overexposure was caused by the undetected surface contamination of the hands. **Conclusion:** The proposed new method of the optimization of handling of radiopharmaceuticals allows for effective disclosures of the cases of reducing hand exposure in individual steps of handling radiopharmaceuticals related to their preparation or application to patients. **Acknowledgments:** The paper was partially supported by project SGS18/100/OHK4/1T/17. **References:** None

OP-421

Femur surgery and clinical management of a patient hospitalized after 131 Iodine cancer radiometabolic therapy: dosimetry evaluations for healthcare personnel

F. Zito¹, **M. Schiavini¹**, **E. Cristini¹**, **S. Mazzola¹**, **M. Tolentini¹**, **F. La Fauci²**, **A. Gebbia²**, **L. Solimeno¹**;
¹Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, ITALY, ²University of Milan Specialization in Medical Physics, Milan, ITALY.

Aim/Introduction: To report our experience in managing femur surgery and ten day hospitalization for a 84 old patient admitted the 4th day after administration of 5.55 GBq of ^{131}I for thyroid carcinoma metastases. **Materials and Methods:** The patient had a femur fracture at home and was admitted in emergency. He had surgery 8 days after ^{131}I administration. The ^{131}I radioactivity was mainly distributed in lung and thorax metastases. Radioactive

patient was isolated in a room in the peripheral zone of emergency unit. For involved operators (nurses, physicians, surgeons) a radiation protection program was planned. All healthcare personnel involved was alerted about entity of exposure for irradiations and risk for contaminations. To all staff was recommended to wear protective disposable clothes, to increase distance, whenever possible speed up procedures, to collect and differentiate as radioactive all produced wastes (disposable clothes, objects touched by the patient or cloths used for cleaning surfaces and room floor) and to control laundry radioactivity. Personal dosimeters were worn by 2 of eight nurses, considered the most exposed persons. For femur surgery only 3 orthopaedists, 1 anaesthetist and 2 nurses were asked to participate; all operators wore dosimeters during surgery. At the end of surgery, contaminations of staff, object surfaces, floor, surgery instruments and waste were checked. Contaminations of hospitalization room were also controlled after patient discharge. **Results:** At admission ^{131}I retained activity in patient body was about 600 MBq. For the 10 days hospitalization, exposure doses for nurses was maximum 0.16 mSv and none reported individual contaminations. For surgery treatment, exposure rate at 1 m from the patient thorax was 20 $\mu\text{Sv/h}$ (about 220 $\mu\text{Sv/h}$ at contact) and blood activity concentration 22.6 kBq/ml. Surgery lasted 2 hours, an operator had 0.6 mSv/cm² contamination on forearm skin. Irradiation doses for surgery staff were between 0.035 - 0.240 mSv (maximum value reported by the surgeon attending closer to the patient trunk). Contaminated surgery instruments were completely cleaned after washings in chloride solutions. No surface contaminations were detected in surgery room and floor. After patient discharge, contaminations were detected on porous-plastic surfaces of bed handles (30 Bq/cm²) and on floor near the bed (15 Bq/cm²). Produced wastes, 1 m³ (17 boxes of 60 L), contained almost 70 MBq of ^{131}I . **Conclusion:** Specific recommendations to prevent exposures and contaminations as well as to collect radioactive wastes correctly are mandatory. Safety precaution observation and collaboration among professionals are crucial. **References:** None

OP-422

Preliminary Investigations on Radiation Exposure in [^{68}Ga]Ga-PSMA-11 based Cerenkov Luminescence Imaging Procedures

P. Fragoso Costa¹, W. Sonnenschein¹, I. Binse¹, W. P. Fendler¹, K. Herrmann¹, M. R. Grootendorst², U. Krafft³, J. P. Radtke³, B. Hadaschik³, C. Darr³;

¹University Hospital Essen, University of Duisburg-Essen, Department of Nuclear Medicine, Essen, GERMANY,

²Lightpoint Medical Ltd., Clinical Research, Chesham, UNITED KINGDOM, ³University Hospital Essen, University of Duisburg-Essen, Department of Urology, Essen, GERMANY.

Aim/Introduction: The current study was designed to provide a quantitative description on the occupational exposure to surgery and histopathology personnel from image-guided robotic surgery using a [^{68}Ga]Ga-PSMA-11 one day PET/CT / Cherenkov Luminescence Imaging (CLI) protocol. **Materials and Methods:** In this ongoing study (DRKS00020942), the dose rate in the patient's environment was assessed in four patients in supine position following [^{68}Ga]Ga-PSMA-11 PET/CT imaging. Four positions were measured (head, feet, left/right abdomen) at one meter distance. Exposure to the medical personnel was assessed in ten procedures using electronic personal dosimeters (EPD). Measurements included the first assistant, scrub nurse and the surgeon (representing CLI operator), encompassing the duration of surgery. A simple point source model was used to compare the calculated dose rate with the EPD readouts. Finally, to measure pathologist's skin exposure, eight prostate specimens were placed in a semiconductor radiation detector after CLI to quantify the tracer activity decay-corrected to the time of excision. As a threshold, we use the nuclide-specific exemption limit in Germany (Ga-68 < 100 kBq). **Results:** All presented results refer to median (range). The patients included in this study were injected with a median of 122 MBq (79-203 MBq) [^{68}Ga]Ga-PSMA-11. Measurements of the ambient dose rate were performed at median 101 min (88-151 min) post tracer administration. The median dose rate measurements were 0.38, 1.13, 0.99 and 0.27 $\mu\text{Sv/hour}$ corresponding to head, abdomen right, abdomen left and feet, respectively. After correcting for physical decay and normalizing for activity, a specific dose rate (SDR) of 0.011, 0.026, 0.021 and 0.006 $\mu\text{Sv MBq}^{-1} \text{m}^{-2}$ were obtained for the same positions. Surgery started at median 192 min (141-330 min) after [^{68}Ga]Ga-PSMA-11 administration and lasted for 240 min (209-264 min). The median personal dose equivalent was 6.5 (1-10), 2 (1-5), and 0.5 (0-1) μSv for first assistant, scrub nurse and surgeon, respectively. The time-integrated point source SDR model provided 7.9 (1-13), 2 (1-3), 0.7 (0-1) μSv . Semiconductor measurements revealed a median tracer activity of 3.0 (0.9-38.6) kBq on the excised prostate specimen, decay-corrected to the time of excision. **Conclusion:** Our results suggest that the current CLI protocol is very low in occupational exposure, and that there is no need for monitoring in the operating room or histopathology department (up to 153 procedures/year for the first assistant). A SDR point source model should be used to predict occupational exposure if other radionuclides are to be used on CLI. **References:** None

Institute of Radiological Sciences, Chiba, JAPAN, ⁵Kindai University Atomic Energy Research Institute, Higashi-Osaka,

JAPAN, ⁶Juntendo University Faculty of Health Science,

Tokyo, JAPAN, ⁷Tokai University Hospital, Isehara, JAPAN.

Aim/Introduction: This study was conducted as a research project that was supported by Ministry of Health, Labour and Welfare, Japan. We surveyed the occupational radiation exposure of staff members in nuclear medicine and other radiological procedures. We also investigated how radiation exposure of staff was managed in hospitals by correlating it with exposure doses of staff. And the goal was to propose countermeasures of reducing occupational exposure by improving management and implementing PDCA (plan-do-check-act) cycle on the basis of data. **Materials and Methods:** We investigated the radiation exposures of radiological staff members including radiological practitioners, technologists, and nurses who were serving in nuclear medicine, X-ray fluoroscopy procedures, and brachytherapy in hospitals across Japan. The exposure doses included the effective dose and equivalent doses to the lens and the skin. Also we investigated the management status in 49 hospitals by sending a questionnaire including individual dose measurements, protection countermeasures, work environment, occupational health education, and how PDCA cycle worked in hospitals. We also focused on exposure of the lens by measuring 3-mm-depth dose equivalent using a dedicated dosimeter DOSIRIS™ and by comparing the values with those measured as 10-mm- or 70- μ m-depth dose equivalent. **Results:** Nuclear medicine physicians received lower exposure than cardiologists and other physicians who used X-ray fluoroscopy, however, nuclear medicine technologists received higher effective dose (mean 0.13 mSv/month) among technologists in all radiological practices. Among all, cardiologists received a higher effective dose (mean 0.19 and maximum 0.7 mSv/month), and cardiologists and IVR radiologists received a higher equivalent dose to the lens (mean 1.03 and 0.55 mSv/month). Among nurses, those who worked at endoscopy facilities received higher equivalent doses to the skin and the lens (mean 0.13 and 0.13 mSv/month). To the questionnaire on the management of occupational exposure, 31 hospitals of 49 replied, resulting in a response rate of 63%. The implementation rate of training for workers on radiation protection was 60%. There was a shortage in the deployment of protective equipment in the X-ray facilities, which might increase the equivalent dose of the lens. **Conclusion:** This study can provide fundamental materials and suggestions for advancing radiation protection of

staff through clarifying exposure dose and management status in hospitals. **References:** ICRP, 2018. Occupational radiological protection in interventional procedures. ICRP Publication 139. Ann. The current situation and problems in quantifying radiation exposure of workers and patients in nuclear medicine

J. Sabol;

Department of Crisis Management PACR,
Prague, CZECH REPUBLIC.

Aim/Introduction: The purpose of this paper is to summarize the present situation regarding quantities used for the quantification of radiation exposure of persons and, based on the analysis performed, some relevant suggestions aimed at the simplification of the current system are proposed. **Materials and Methods:** The overview and assessment of the present system of radiation protection quantities, with special emphasis on their use in nuclear medicine, took into account the latest recommendations by the ICRP, ICRU, EANM and other professional expert bodies. A new modified and simplified approach in the quantification of the radiation exposure of persons has been proposed in order to reduce confusion associated with the excessive number of quantities and units used at present and defined in a rather complicated manner. **Results:** Analysis of the present situation has shown that it would be most appropriate to clearly distinguish between the quantification of stochastic and deterministic health effects, where quite often in both cases the unit Sv is generally used without mentioning the relevant quantity. Moreover, the same unit is also applied for the assessment of deterministic effects where the most appropriate unit should be Gy-Eq. It is proposed to rely only on the following five quantities for the assessment of personal exposures: the organ dose in Gy, equivalent organ dose in Sv, RBE-weighted organ dose in Gy-Eq, effective whole-body dose in Sv, and RBE-weighted whole-body dose in Gy-Eq, these quantities reflecting the detriment of individual organs and the whole body in terms of stochastic and deterministic effects, respectively. The monitoring of these quantities should rely on measurements of particle fluence and fluence rate at the point of interest weighted by the conversion factors that relate to the measured quantities to appropriate radiation protection quantities. **Conclusion:** The proposed system of quantities would significantly simplify the present system, which is based on too many quantities, some of which are defined in a somewhat complicated way so that even those responsible for radiation protection at nuclear medicine workplaces are

confused and are not in a position to correctly interpret the results of their radiation monitoring. Even in some scientific literature, everything related to the exposure is a dose and unit Sv, which are often used for deterministic assessment. Sometimes, many commercially available monitors are “calibrated” in the range of the “dose” up to 10 Sv. For such high exposure, this unit obviously cannot be used under any circumstances. **References:** None

OP-425

The current use of multi-modality imaging in nuclear medicine in Europe: results from the MEDIRAD project

G. Verfaillie¹, Y. D'Asseler², K. Bacher¹;

¹Ghent University, Ghent, BELGIUM, ²Ghent University Hospital, Ghent, BELGIUM.

Aim/Introduction: The use of CT in multimodality SPECT/CT and PET/CT systems is increasing. This study presents the status of the use of these multi-modality imaging systems in nuclear medicine in Europe. **Materials and Methods:** As a part of the Horizon 2020 MEDIRAD project, a European-wide online survey was set up to gather information on the current implementation and use of hybrid imaging in nuclear medicine. Special attention was paid to the clinical use of CT, CT technology and dosimetry in PET/CT and SPECT/CT. **Results:** 109 responses from 38 countries, of which 58.3% came from university hospitals, were received until October 2019. Overall, 85% of the reported PET systems are equipped with CT, whereas for SPECT systems, CT is integrated in only 40% of the cases. More than half of the responders indicated that they will invest into a new PET/CT or SPECT/CT in the near future. In PET/CT, CT is performed routinely (about 90%) in clinical practice, while for SPECT/CT this seems less systematic and standardized. For both SPECT/CT and PET/CT, the majority of the CTs are linked to attenuation correction and anatomical localisation. Full diagnostic CT scans are used more often in PET/CT than in SPECT/CT. Modern dose reduction techniques (such as iterative reconstruction and tube current modulation) are widely available in hybrid imaging systems. Automatic tube current modulation is used in about 80% and 45% of the PET/CT and SPECT/CT systems, respectively. Iterative reconstruction is available in about 51% and 62% of the SPECT/CT and PET/CT systems, respectively, and is routinely used. In the large majority (70%) of nuclear medicine departments, CT doses are centrally stored in a database or dose management system. The survey revealed that there are no specific paediatric CT protocols available in about 30% and 65% of the PET/CT and SPECT/CT systems, respectively. About 70% of nuclear medicine physicians and nuclear medicine technologists indicate a need for additional education in CT technology and CT dosimetry. **Conclusion:** The survey indicated the wide spread use of CT in nuclear medicine departments.

Especially in PET/CT, modern CT dose reduction techniques are widely available. While the use of CT in SPECT examinations seems less systematic and standardized, CT acquisitions in PET examinations are performed in about 90% of the cases. **References:** None

Comparative Study of PET injectors in the routine practice of Nuclear Medicine

M. Costa¹, M. Silva¹, R. Parafita², A. Canudo¹, B. Freitas¹, H.

Delgado¹, J. M. Correia¹, M. Andrade¹, M. Machado¹, R. Oliveira¹, S. Teixeira¹, F. Oliveira¹, P. Ferreira¹, D. Costa¹;

¹Champalimaud Foundation, Lisbon, PORTUGAL,

²Mercurius Health, Lisbon, PORTUGAL.

Aim/Introduction: Staff radiation protection is more and more a concern in the practice of clinical Nuclear Medicine. There are, nowadays, several PET automatic injectors for use in the daily routine practice to help and reduce staff radiation daily exposures. Our work's purpose was to try and find the most suitable equipment to fulfil our nuclear medicine service needs. The following properties were chosen to be tested: radiation safety, costs and user-friendliness of the equipment. **Materials and Methods:** The selected injectors were MedRad's Intego, Comecer's IRIS and Tema Sinergie's Karl100. In order to monitor the equivalent dose rate (using Thermo-Scientific RadEye B20-ER) being received by the injector's operator, a set of regions of interest were established on the surface and all sides of the equipment, during the injection procedure. The measurements were done on the surface (worst case scenario) making sure that at a reasonable operating usage (40-50 cm) all staff will be significantly less exposed to the radiation. Considering the “worst case scenario” we decided to calculate the equivalent dose assuming that all measures were obtained for a single operator, for an entire working year. It was taken into consideration the mean exposure time throughout the procedure, at the different regions of interest and for a single injection. The received equivalent dose rate was always assumed on contact with the equipment. In average, six measurement sets were obtained with an average initial vial activity of 2.8 ± 0.9 GBq of ^{18}F -FDG, performing a total of more than 30 measurement sets for each injector. **Results:** The determined equivalent dose per year for single user, showed the following values: Intego 0.9 ± 0.4 mSv/year, IRIS 1.7 ± 0.6 mSv/year and Karl100 4.2 ± 1.3 mSv/year. However, Karl100 in our practice conditions, obliges to handle the injection procedure by hand, increasing the dose rate to 38 ± 14 mSv/year. Regarding equipment's interface and costs, Karl100 offered a more user-friendly interface and IRIS (plus accessories) by the end of one full year, was the less expensive and in addition it is registered for the use of other radiopharmaceuticals, in particular Gallium-68 and Luthetium-177. **Conclusion:** Taking into account the chosen

properties to be tested, the most adequate injector for our routine practice is IRIS, which excels by being registered for the usage of Gallium-68 and Luthetium-177. Intego does not have this feature and Karl100 delivers higher equivalent dose rates and therefore fails in reducing significantly, as we wish, radiation exposure to staff. **References:** None

Amyloid hybrid membranes for the treatment of radioactive wastewater from nuclear medicine and nuclear industry

G. Prenosil¹, S. Bolisetty², N. M. Coray², A. Palika², R. Mezzenga²;

¹Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, ²Department of Health Science and Technology, ETH Zürich, Zürich, SWITZERLAND.

Aim/Introduction: Before being discharged to the municipal sewage system, medium lived radioactive waste from nuclear medicine must be stored until sufficiently decayed. To this end, costly storage facilities for monitoring and holding large volumes of liquid nuclear waste are employed. The nuclear power industry produces even larger amounts of long-lived nuclear waste, which needs to be conditioned before final storage. Previously, we reported hybrid membranes composed of amyloid fibrils produced from cheap and readily available proteins and activated carbon, which efficiently removed heavy metal ions and radioactive compounds from water. Here, we show that these membranes are highly efficient in the removal of diverse, clinically relevant radioactive compounds from hospital wastewater by single-step filtration. Our aim was to initiate the development of a cost-efficient method for volume reduction of liquid radioactive waste. **Materials and Methods:** Aqueous solutions containing Technetium (Tc-99m), Iodine (I-123) and Gallium (Ga-68) at clinically relevant concentrations were passed in a single step through amyloid membranes. Additionally, real clinical wastewater from a Swiss hospital containing Iodine (I-131) and Lutetium (Lu-177) was purified by tangential filtration using our membranes. Radioactivity was measured with a gamma counter in the feed and the filtrate, and accumulation of radioactive compounds in the membranes was visualized by PET/CT and SPECT imaging. Filtration of clinical wastewater with amyloid membranes was compared against filtration with cellulose and activated carbon. Saturation experiments with increasing nuclide concentrations and with multiple filtration rounds per membrane were performed. **Results:** The single filtration removed Tc-99m, I-123, and Ga-68 from the water with efficiencies above 99.8%. Similar efficiencies were found for the removal of I-131 Lu-177 from wastewater, whereas cellulose and pure carbon removed nothing. Nuclear imaging confirmed the buildup of radioactive isotopes

in the membranes and revealed the flow in the filtration systems. The removal efficiency still did not decrease with multiple cycles of wastewater filtration. **Conclusion:** The radioactivity of the water after filtration was below the level of detection and thus could be considered as non-radioactive. By converting large volumes of radioactive wastewater into low volumes of solid radioactive waste, the present technology emerges as a possible game changer in the treatment and conditioning of nuclear wastewater. Additionally, our approach shows that the tracer principle and nuclear imaging can help in engineering better filtration systems. **References:** [1] S. Bolisetty, R. Mezzenga, Nat Nanotechnol 2016, 11, 365-371

OP-428

Calibration, radioprotection and dosimetry in Lu-177 treatment of Neuro Endocrine tumours

P. Saletti¹, S. Raspanti², A. D'Agata¹, F. Rossi¹, M. Papi¹, G. Belli¹;

¹Azienda Ospedaliero-Universitaria Careggi, Florence, ITALY, ²University of Florence, Florence, ITALY.

Aim/Introduction: A ¹⁷⁷Lu based radiopharmaceutical was recently employed for the first time at Careggi hospital for radiometabolic neuroendocrine tumors treatment. First of all, dose calibrator adjustment was necessary because ¹⁷⁷Lu was not included in control unit. Dose rate measurements and estimate were then carried out in vial and in phantom to evaluate dosimetric impact on operators. **Materials and Methods:** A calibrated vial of ¹⁷⁷Lu was used to adjust two Biodex Atomlab100 dose calibrators. This was achieved by inserting the vial in the housing and tuning the calibration factor to match the exact activity reported in calibration certificate. The same vial was then inserted in a home-made phantom (consisting of two 5 liters water bags arranged in sandwich around the vial) and dose rate measurements were made at various distances with a Victoreen 450P ionization chamber. Approximately 40 days later, the same vial was used for irradiating for 88 hours a set of 10 TLD LiF100 which were then read in a Harshaw 6600 reader. Finally, a therapeutic dose of 7400MBq of ¹⁷⁷Lu was injected by infusion pump in approximately 40 minutes to the first patient. Radiopharmaceutical manipulation, administration and patient assistance timing were measured together with dose rate and distances between operators and radioactive sources (vial, patient) for an accurate radioprotection evaluation. **Results:** A calibration factor of 116 was found for both Atomlab 100 dose calibrators, in perfect agreement with manufacturer suggested value of 115 for ¹⁷⁷Lu. Dose rate measurements with ionization chamber were normalized per activity and plotted as a function of distance for vial and phantom to obtain exposition at any distance. A dose rate of 6.57µSv/(h*GBq) at 1 meter was found for vial source while 3.16µSv/(h*GBq) is the dose rate from phantom at the same distance. From manipulation, administration and assistance

measured timing an effective dose of respectively 0.13 μ Sv, 6.2 μ Sv and 14.4 μ Sv resulted for involved operators. A very good agreement was found with 10 exposed TLD reading proving that routine dosimetry with LiF100 is reliable even for β emitters such as ^{177}Lu . **Conclusion:** Dose calibrator adjustment, dose rate measurements and timing to carry out specific tasks (radiopharmaceutical manipulation and administration, patient assistance) have made it possible a first assessment of radiological impact on operators involved in treatment with ^{177}Lu for neuroendocrine tumours. This is the starting point for subsequent and more detailed evaluations that will also be compared with operators TLD dosimetry evidences. **References:** None

Aim/Introduction: The aim of this study was to evaluate the role of visual assessment and quantitative metabolic parameters for predicting axillary lymph node (AxLN) metastasis on F-18 FDG PET/MRI in newly diagnosed patients with invasive ductal carcinoma (IDC) of breast. **Materials and Methods:** Histopathological and imaging data of 265 female patients who underwent PET/MRI for primary staging between 2016-2019 in our department were analyzed retrospectively. In visual assessment, AxLNs were scored as 0 (negative) and 1 (positive) according to the presence of FDG uptake above background. In quantitative evaluation of PET positive group, maximum standardized uptake values (SUVmax) of AxLNs (SUV-LN) and AxLN/Primary tumor SUVmax ratios (Ax/T) were obtained from PET/MR images. The presence of AxLN metastasis was accepted as positive according to the i) histopathological verification or ii) AxLN FDG uptake intensities on baseline and follow-up imaging in patients who received neoadjuvant treatment. Statistical analyses were performed on SPSS version 23.0. **Results:** The characteristics of patients were shown in Table 1. The sensitivity, specificity, positive predictive value, negative predictive value and accuracy of visual evaluation were 89.8 %, 78.2 %, 89.4 %, 79.0 % and 86.0 %, respectively. 8 of 18 patients with false negative PET had micrometastasis. In ROC curve analysis, SUV-LN and Ax/T had the AUCs of 0.88 and 0.89, respectively. The optimal cut-offs were 2.95 for SUV-LN and 0.31 for Ax/T. Using the set cut-off values, the sensitivities of SUV-LN and Ax/T were 77.5% and 90.6% ($p < 0.001$), their specificities were 94.7% and 84.2% ($p = 0.625$), and their diagnostic accuracies were 79.2 % and 89.9%, respectively. In patients with micrometastasis ($n = 9$), only 1 patient had PET positive AxLN, with an SUV-LN of 1.2 but an Ax/T of 0.43. In patients with SUV-LN ≤ 2.95 and Ax/T > 0.31 the rate of AxLN metastasis was 89 % (24/27). In patients with SUV-LN > 2.95 and Ax/T ≤ 0.31 this rate was 75% (3/4). **Conclusion:** Visual evaluation of AxLN on FDG PET/MRI had high diagnostic performance, and nearly half of patients with false negative PET had micrometastasis. With respect to the quantitative parameters, Ax/T values demonstrated better diagnostic performance for predicting AxLN metastasis than SUV-LN in patients with IDC. Ax/T had added diagnostic value especially in patients with lower SUV-LN. For the evaluation of AxLN status, visual assessment and quantitative parameters seem to be complementary to each other. **References:** None

Identification of aggressive breast cancer lesions with [18F]-FDG-PET/CT in combination with machine learning and data pre-processing

D. Krajnc, L. Papp, T. S. Nakuz, H. F. Magometschnigg, M.

Grahovac, C. P. Spielvogel, Z. Bago-Horvath, A. Haug, G. Karanikas, T. Beyer, M. Hacker, T. H. Helbich, K. Pinker; Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Breast cancer is the common cancer in women and the 2nd most common cause of female cancer deaths. [18F]-FDG-PET/CT has been established as a sensitive diagnostic test for detecting distant metastases and lymph node infiltration in high-risk breast cancer patients as well as for assessing treatment response. The aim of this study was to investigate the performance of breast cancer detection and the identification of aggressive breast cancer from [18F]-FDG-PET/CT incorporating data pre-processing algorithms in machine learning predictive models. **Materials and Methods:** A cohort of 170 patients with suspicious imaging finding (BI-RADS 4/5) was examined with [18F]-FDG-PET/CT imaging as part of a prospective study. Histopathology was used as the standard of reference. Breast tumours were classified as benign or malignant. Lesions were classified as (a) less aggressive to targeted treatment (luminal A/B, Her2-positive) and (b) more aggressive (ER, PR, Her2-negative, triple negative (TN) breast cancer) based on immunohistochemical (IHC) receptor status (estrogen (ER), progesterone (PR), Her2) and proliferation rate (ki-67). 173 lesions from 170 patients were delineated in the Hermes Hybrid 3D software. Radiomic features were extracted from all 173 delineated 18F-FDG-PET/CT lesions. Ensemble learning approaches were applied to predict tumour malignancy as well as IHC triple negative subgroup in a 100-fold Monte Carlo cross-validation scheme. This step was performed twice for both reference labels: (a) with training the predictive models on the original training datasets, and (b) with processing the training datasets by data pre-processing approaches for class imbalance and feature redundancy correction, noisy data samples cleansing as well as outlier detection. Predictive performance was estimated over the ML fold validation cases with confusion matrix calculations (sensitivity (SENS), specificity (SPEC) and overall accuracy (ACC)). **Results:** The validation performance of [18F]-FDG-PET/CT ML models built over the original training data was 83% (SENS), 68% (SPEC) and 76% (ACC) for breast cancer detection, and 58% (SENS), 90% (SPEC) and 74% (ACC) for identification of aggressive breast cancer. The validation performance of [18F]-FDG-PET/CT ML models built over the pre-processed training data was improved to 82% (SENS), 78% (SPEC) and 80% (ACC) for breast cancer detection and 67% (SENS), 92% (SPEC) and 80% (ACC) for identification of aggressive breast cancer. **Conclusion:** We demonstrated that ML models based on radiomic tumour features extracted from [18F]-FDG-PET/CT in conjunction with the utilization of data preparation approaches provide breast cancer detection and identification of aggressive breast cancers with high accuracy. **References:** None

Incidental Focal Breast Uptake On ¹⁸F-FDG PET-TC. Our Center Experience

C. Wakfie Corie^h1, C. Rodríguez Rey¹, A. Ortega Candil^h, R. Valhondo-Rama¹, A. Blanes García¹, L. García Beláustegui¹, M. Ruiz Tolón¹, B. Lannegrand¹, A. Pascual Martín¹, F. Ferrando-Castagnetto², J. Carreras Delgado¹;

¹Hospital Clínico San Carlos, Madrid, SPAIN, ²Hospital de Clínicas Dr. Manuel Quintela, Facultad de Medicina, Universidad de la República, Montevideo, URUGUAY.

Aim/Introduction: Breast incidental ¹⁸F-FDG uptake (BIU) in patients undergoing PET-CT for reasons unrelated to breast pathology represent a diagnostic challenge. In this study we aim to determine the frequency and clinical significance of focal breast incidental ¹⁸F-FDG uptake detected with this technique. **Materials and Methods:** From January 2017 to January 2020, a total of 10,615 whole-body (WB) ¹⁸F-FDG PET-CT studies were performed in our center. We retrospectively identified 26 patients showing incidental focal hypermetabolic activity in breast, we measured SUVmax and the maximum diameter of the lesion. We also analyzed the clinical management, images (ultrasound/mammography) and pathology reports (with or without histopathological confirmation). **Results:** We found BIU in 0.3% (27 scans of 26 patients) of the studies. The mean age was 62.2 years. 88.5% (23/26) of the patients were women. Among the reasons for the request, 84.6% (22/26) were oncological and 15.4% (4/26) non-oncological. On 23 patients (88.5%) ultrasound/mammography was performed consequently PET-CT findings, showing BIRADS-5 in 30.4% (7/23), BIRADS-4C in 13% (3/23), BIRADS-4A in 8.7% (2/23), BIRADS-3 in 13% (3/23) and BIRADS-2 in 34.8% (8/23). The remaining 11.5% (3/26) of the patients had no ultrasound/mammography reports, one patient died shortly after PET-CT was performed, another patient progressed into palliative care and the last one carries out gynecological controls in a private center (we have no access to this information). Of the 23 patients studied with ultrasound/mammography and histological correlation (BIRADS-4 and 5), the findings were benign in 60.9% (14/23) of which 8.7% (2/23) have risk of malignancy, and malignant in 39.1% (9/23). The mean SUVmax of the 14 benign lesions and 9 malignant lesions were 2.6±1.4 and 5.8±3.7, respectively (p=0.0019). At a cut-off value of 4.0, the rate of malignancy and specificity of the mean SUVmax for differentiating benign and malignant breast lesions were 67% and 93%, respectively. The CT data from PET-CT revealed that the mean diameters of benign and malignant lesions were 1.3±0.5 cm and 2.0±0.5 cm, respectively (p=0.019). **Conclusion:** Although BIU detected by WB ¹⁸F-FDG PET-CT is very rare (0.3% of our studies), it was indicative of malignancy and benign with risk of malignancy lesions in 39.18% (11/23) and 8.7% (2/23) of our patients, respectively. Both mean SUVmax and diameter

of the lesion were greater for malignant than benign lesions. According to our experience, we consider essential exhaustive study (ultrasound/mammography and even histopathological study) in case of BIU findings in ^{18}F -FDG PET-CT studies. **References:** None

OP-436

Dual Tracers of ^{18}F -FES and ^{18}F -FDG for Prediction of Progression-Free Survival After Fulvestrant Therapy in Patients with HR+/HER2- Metastatic Breast Cancer

Z. Yang;

Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: The purpose of this study was to use dual tracers ^{18}F -fluoroestradiol (^{18}F -FES) and ^{18}F -fluorodeoxyglucose (^{18}F -FDG) as imaging biomarkers in predicting progression-free survival (PFS) in ER-positive MBC patients receiving fulvestrant therapy. **Materials and Methods:** We retrospectively analyzed thirty-five HR+/HER2- metastatic breast cancer patients who underwent ^{18}F -FES and ^{18}F -FDG PET/CT scans prior to fulvestrant therapy in our centre. The SUVmax across all metastatic lesions on the baseline PET/CT were assessed. The heterogeneity of ER expression was assigned by presence of ^{18}F -FES negative lesions, for patients with 100% ^{18}F -FES positive lesions were categorized into two groups by the median ratio of FES/FDG SUVmax, low FES/FDG and high FES/FDG. PFS were estimated by the Kaplan-Meier method and compared by the log-rank test. Univariate and multivariate analyses were performed using the Cox proportional hazard model. **Results:** In total, 12 of 35 patients' presence of ^{18}F -FES negative lesion(s), suggesting that heterogeneity of ER expression in metastatic lesions. These patients had a low median PFS of 5.5 months (95%CI 2.3-8.7). Of patients with 100% ^{18}F -FES positive lesions, 11 had a low FES/FDG and 12 had a high FES/FDG. These groups had a median PFS of 29.4 months (95%CI 2.3-56.5) and 14.7 months (95%CI 10.9-18.5), respectively. The patients were stratified in three categories based on incorporating both ^{18}F -FES and ^{18}F -FDG imaging results that were significantly correlated with PFS by univariate analysis ($P < 0.001$) and multivariate analysis ($P = 0.006$). **Conclusion:** Our data suggest that dual ^{18}F -FDG and ^{18}F -FES PET imaging could be a potential predictor of efficacy to fulvestrant therapy among HR+/HER2- MBC patients. These findings indicate that endocrine therapy should be individualized for patients with ER-positive MBC, particularly that presence of ^{18}F -FES negative lesions. **References:** None

Standardisation Of Normalized Workflow For ^{18}F -FDG PET/MRI Studies In Staging Of Patients With Breast Cancer

J. Garcia, A. Compte, E. Valls, S. Mourelo, M. Buxeda, T. Blanch, P. Bassa, M. Soler, E. Riera;

CETIR ASCIRES Grupo biomédico, Barcelona, SPAIN.

Aim/Introduction: We aimed to apply a Standard Operating Procedure (SOP) on ^{18}F -FDG PET/MRI studies for local-regional and distant staging in patients with ductal breast carcinoma. **Materials and Methods:** A theoretical SOP on ^{18}F -FDG PET/MRI in breast study was developed and optimized, and which included the following acquisition parameters: Whole-body synchronic PET+MRI acquisition, 1 h after ^{18}F -FDG injection (dose 2.5 MBq/Kg). Body PET acquisition (5 beds; 4 min/bed). Body MRI acquisition (Axial LAVA Flex, Axial MRAC, Axial DWE, Axial T2 SSFSE sequences). Selective breast synchronic PET+MRI acquisition, with patient lying in prone position, 2 h after tracer injection. Breast PET acquisition (1 bed; 10 min). Breast MRI acquisition: 3D Axial T2, 3D T2 Fat, 3DT1, Axial DWE, Gradient Coronal, 3D Axial VIBRANT dynamic sequences (Gadolinium dose 0.2 ml/Kg). In order to assess its clinical role, the above SOP was applied over the first 15 patients who were referred to our clinic for primary staging of a ductal breast carcinoma (cT2-4N0 or cT1-4N+). Selective and whole-body PET, MRI and PET/MRI studies were all jointly reviewed by a specialist in Nuclear Medicine and a Radiologist, both with extensive expertise in breast oncology studies. A consensus was reached over the T-staging, as well as for nodal disease and distant metastases detection. Results were compared with histopathological study and/or other diagnostic procedures available. **Results:** PET/MRI procedures performed in our first 15 patients did not show artifacts due to synchronous acquisition, or incidences due to technical reasons, or claustrophobia events. Not performing the whole-body CT on a standard ^{18}F -FDG PET/CT study meant a radiation dose reduction of 50% for every patient. Mean time of our studies was 60 min, divided into 35 min for the breast PET/MRI acquisition, and 25 min for the whole-body PET/MRI acquisition. Preliminary assessment of the simultaneous/synchronous PET/MRI studies in our first 15 patients was as follows: T-staging: Agreement (n:8), better boundary detection (n:5), hypermetabolic uptake not depicted on MRI (n:2). N-staging: Axilla (n:9): infracentimetric in 5 (PET and Diffusion agreement). Internal mammary chain (n:3). M-staging: Bone metastases (n:2): Lung metastases (n:2): Liver metastases (n:1). **Conclusion:** Our SOP on ^{18}F -FDG PET/MRI studies provided us with global information on the local-regional and distant staging of patients with breast cancer, with an optimized procedure time due to synchronous acquisition, as well as a significant reduction in radiation dose in comparison to performing a breast MRI and a whole-body ^{18}F -FDG PET/CT procedures consecutively. **References:** doi:10.1007/s00259-017-3823-0doi:10.3892/ijo.2017.4012

OP-438**Radionuclide bone scans can be removed from the pathway for staging breast cancer patients prior to neoadjuvant chemotherapy after introduction of FDG PET-CT**

P. Holdgaard¹, S. T. Nygaard², E. H. Jakobsen², S. Hess^{3,4};

¹Department of Nuclear Medicine, Lillebælt Hospital, Vejle, DENMARK, ²Department of Oncology, Lillebælt Hospital, Vejle, DENMARK, ³Department of Radiology and Nuclear Medicine, Hospital Southwest Jutland, Esbjerg, DENMARK, ⁴Department of Regional Health Research, Faculty of Health Sciences, University of Southern Denmark, Odense, DENMARK.

Aim/Introduction: Breast cancer patients were originally staged with CT and Tc99m bone imaging. Recently FDG PET-CT was added prior to neoadjuvant treatment. Some departments have replaced Tc99m scanning with NaF PET-CT. The aim was to evaluate the added clinical benefit of NaF PET-CT in addition to FDG PET-CT. **Materials and Methods:** Retrospective evaluations were made for 200 consecutive breast cancer patients prior to neoadjuvant chemotherapy from Lillebælt Hospital (2017-2019) with <14 days between FDG and NaF, and agreement in presence or absence of bone metastases assessed. True bone disease status was determined using all image and biopsy data available up to April 2020. FDG and NaF images for all examinations with bone findings were reviewed and any disagreement in diagnoses recorded. **Results:** 187/200 patients demonstrated agreement in reported presence or absence of bone metastases between FDG and NaF examinations (reported metastases were present in 16 patients (all true positive) and absent in 171). 13 patients demonstrated disagreement, with presence of metastases reported on FDG with absence on NaF in 4 patients (1 false-negative NaF, 3 false-positive FDG) and 9 patients with absence of metastases reported on FDG with presence on NaF (8 false-positive NaF, 1 false-negative FDG). All patients with confirmed metastases showed bone lesions with both tracers. 6 patients showed more lesions on FDG, 6 showed more on NaF, and 6 demonstrated the same lesions. The patient reported false negative with NaF had bone lesions misinterpreted as benign but was correctly identified as metastases by FDG. The false negative FDG patient also had misinterpreted FDG uptake in bone correctly identified as metastases by NaF. The 3 false-positive FDG scan results were owing to a solitary lesion being interpreted as malignant which NaF confirmed to be benign, demonstrating importance of dual FDG/NaF scanning in the case of solitary lesions. In the remaining 196 patients (98%), NaF scanning did not add clinical value to the FDG scan. **Conclusion:** FDG and NaF scans provide comparable outcomes in evaluating presence or absence of bone metastases in staging breast cancer prior to neoadjuvant therapy. This obviates the need for the bone scan in the vast majority of patients. However,

the small proportion of patients demonstrating FDG uptake in solitary lesions may still benefit from a NaF scan in addition to confirm diagnosis. FDG is preferred to NaF scanning due to additional detection of soft tissue metastases and a lower number of false-positives. **References:** None

OP-439**Pretreatment 18F-FDG-PET/CT Parameters Predict Treatment Outcome of First-Line Therapy in Patients with Metastatic Breast Cancer**

Z. Yang;

Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: 18F- fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG-PET/CT) imaging could provide prognostic information, especially the 18F-FDG uptake has proven to be a predicting marker for treatment outcome in various tumors. However, the prognosis of other PET parameters in metastatic diseases is still unclear. The aim of this study was to evaluate pretreatment 18F-FDG-PET/CT based parameters for the prediction of the progression free survival (PFS) of first-line treatment in metastatic breast cancer (MBC). **Materials and Methods:** MBC patients with whole-body 18F-FDG PET/CT scans before first-line treatment were included. In PET/CT scans, conventional parameters (maximum and mean standardized uptake value, metabolic tumor volume [MTV], total lesion glycolysis [TLG]) and heterogeneity parameters: intra-tumor heterogeneity index [HI] were analyzed. PFS was mainly assessed for efficacy. The survival analyses were performed using the Kaplan-Meier method and compared by the log-rank test. **Results:** A total of 177 patients with MBC were enrolled in this study, of which 68 were De novo stage IV. Among 177 MBC patients, 87 patients with hormone receptor (HR) positive and human epidermal growth factor receptor 2 (HER2) negative, 30 patients with HER2 positive and 60 patients with triple-negative. In the overall population, patients with high SUV_{max}, high SUV_{mean}, high MTV, high TLG and high tumor HI at baseline were associated with lower PFS ((P=0.028, P=0.005, P=0.017, P=0.026, P=0.035, respectively). In Patients with De novo stage IV, patients with high HI had significantly shorter PFS (P=0.001). In HR+/HER2- and HER2+ subgroups, only baseline HI showed the predictive value of PFS (P=0.023, P=0.049, respectively). In the triple-negative subgroup, high SUV_{max}, MTV and TLG showed predictive value of worse PFS (P=0.030, P = 0.011 and P=0.023, respectively). **Conclusion:** Pretreatment 18F-FDG-PET/CT Parameters showed the prediction value of PFS of first-line therapy in MBC patients. However, in patients with De novo stage IV and different molecular subtypes, the predictive PET-CT parameters may be different. **References:** None

OP-440**Role of ¹⁸F-FDG PET/CT metabolic/volumetric parameters to predict response to neoadjuvant chemotherapy/chemo-immunotherapy and risk stratification in patients with Triple-Negative (TNBC) and HER2+ breast cancer (HER2+)**

G. Paone¹, S. Di Lascio², L. Knappe¹, T. Ruberto¹, G. Treglia¹, L. Ceriani¹, L. Giovanella¹;

¹IIMS, Bellinzona, SWITZERLAND, ²IOSI, Bellinzona, SWITZERLAND.

Aim/Introduction: The aim of this study was to assess response to NAC and prognostic value considering dynamic evolution of metabolic/volumetric parameters measured on 18F-FDG PET/CT in TNBC and HER2+. **Materials and Methods:** We retrospectively analyzed 50 patients with TNBC and HER2+, who performed a staging PET/CT before and after neo-adjuvant chemotherapy (for TNBC) and chemo-immunotherapy (for HER2+). Treatment-related changes in SUVmax, MTV and TLG were evaluated (Δ SUVmax, Δ MTV and Δ TLG) in the primary tumor and nodal lesions. To identify the optimal cut-off value of these parameters a receiver-operating curve analysis was performed. Kaplan-Meier method was used to evaluate prognostic value. The associations between early metabolic/volumetric changes, pathological complete response (pCR), and event-free survival (EFS) were examined. **Results:** Of the 50 patients, 16 (32%) achieved pCR, 13 (26%) relapsed and 8 of them died (median FU, 48 mo). 1 relapse and no deaths were observed in patients with pCR. A multivariate analysis underlined that Δ SUVmax was significantly associated with pCR (p 0.028) with an optimal percent of decrease (cutoff value Δ SUVmax 81%, p 0.010). Kaplan-Meier analysis underlined that pCR showed a significant difference for predicting EFS (p 0.036) and OS (p 0.045). A subgroup analysis in no-pCR patients showed a close correlation positive between high reduction gradients of metabolic/volumetric parameters and less postoperative morbidity. Nevertheless, a multivariate analysis underlined that only pretreatment SUVmax absolute value was significantly associated with disease recurrence (with a cutoff value of SUV 7.28 p 0.0069). No significant correlation was found with MTV and TLG absolute value, age, Ki-67, NLR ratio and adjuvant regimen. **Conclusion:** Our data suggest that the dynamic variation of metabolic/volumetric parameters could be a useful predictive marker for pCR and EFS in TNBC and HER2+. The Pretreatment SUVmax absolute value is the only parameter in no-pCR subgroup to predict higher risk of relapse. Prospective studies are needed to validate these tools to evaluate the response to neoadjuvant treatment and the risk stratification in these patients. **References:** None

OP-441**Diagnostic performance and impact on management of 18F-FDG PET/CT for suspected recurrence in Invasive Lobular Breast Carcinoma**

J. Alberini¹, D. Bonnin¹, S. Ladoire¹, A. Bertaut¹, N. Briot¹, C. Drouet¹, Y. E Silva¹, G. Nodari¹, C. Tabouret-Viaud¹, A. Berriolo-Riedinger¹, I. Dygai-Cochet¹, H. Boulahdour², A. Cochet¹;

¹Centre Leclerc - University Hospital, Dijon, FRANCE,

²University Hospital, Besancon, FRANCE.

Aim/Introduction: Invasive Lobular Carcinoma (ILC), which accounts for 10-15% of all breast cancers, is usually characterized by a low FDG uptake of primary tumor and metastases, when compared with invasive ductal carcinoma (IDC), during initial staging. The aim of this retrospective monocentric study was to examine the diagnostic performance of 18F-FDG PET/CT to detect sites of recurrence when first recurrence was suspected in women previously treated for ILC, and the impact on management. The final diagnosis of recurrence made by the oncologist was used for reference. Results were correlated with the pathological and biological prognostic factors of the primary tumor. **Materials and Methods:** 64 patients (mean age: 60.3±12.4 years [32-86]), for whom a PET/CT scan (Gemini TF, Philips and Discovery MI, GEHC) was performed between January 2011 and May 2019, were included. The association with IDC was an exclusion criterion. Recurrence was suspected based on clinical symptoms (48%), conventional imaging findings (42%) and/or an increase in tumor markers (30%). The mean time between initial diagnosis and suspicion of recurrence was 5.2 years. **Results:** ILC primary tumors were mainly grade II (75%), expressing estrogen receptors (95%) or Her2 negative (95%). 40 patients out of 64 (62.5%) underwent a biopsy, of which 32 were in favor of a local or metastatic ILC recurrence. In the 8 remaining patients, pathological findings corresponded to the IDC subtype, primary pulmonary or gastric tumors, lymphoma or benign material. Among the 64 patients, 48 were judged to be recurrent by the oncologist: 16 local recurrences and/or 41 metastatic with mainly bone (n=24), lymph node (n=14) and liver (n=10) metastases. Bone metastases were mainly sclerotic or mixed (14/24) on CT. PET sensitivity, specificity, PPV and NPV were 87%, 87%, 95% and 70%, respectively. SUVmax at recurrence sites was generally high (mean: 6.4±2.7; 1.9-17.3). The 6 false negative PET results corresponded to local (n=2), bone (n=1), meningeal (n=1), peritoneal (n=1) or bladder (n=1) recurrences, sites for which 18F-FDG PET may lack sensitivity. The detection of a recurrence resulted in a change in treatment in 44 patients (92%). No correlation with the pathological prognostic factors of the primary tumors was demonstrated. **Conclusion:** While highlighting its limits in relation to certain recurrence sites specific to ILC, the present study demonstrates that 18F-FDG PET/CT remains an effective and reliable tool for the detection of

ILC recurrence. **References:** None

OP-442

18F-FES PET/CT influences the diagnosis and management of stage IV patients with dual primary malignancies: ER-positive breast cancer combined with another primary tumour

Z. Yang;

Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: We aimed to investigate the clinical value of 18F-fluoroestradiol (18F-FES) positron emission tomography (PET)/computed tomography (CT) in stage IV patients previously diagnosed with oestrogen receptor (ER)-positive breast cancer and another primary malignancy.

Materials and Methods: We retrospectively analysed 20 female patients who had been diagnosed with ER-positive breast cancer and another primary tumour and underwent 18F-FES PET/CT scans in our centre. To investigate the definite clinical impact of 18F-FES on managing such patients, we designed questionnaires. Physicians completed the questionnaires, including diagnosis and treatment decisions, before and after the imaging reports of 18F-FES.

Results: In total, eleven physicians were given questionnaires referring to the treatment strategy of the 20 patients. The application of 18F-FES had reference significance for management decisions in 80% (n = 16) of the patients. Out of the 16 patients with consideration of profit from 18F-FES PET/CT reports, 8 patients were considered to have definite changes in the treatment strategies. And the scan was considered to be instructive to develop management plans in 8 patients. Most physicians (86.7%, 52/60) considered that 18F-FES PET/CT scans played definitely instructive roles in the decision-making of the treatment strategy in these patients (0.032, 95% CI 0.024–0.042). The intended diagnosis was changed by 71.7% of physicians (0.033, 95% CI 0.023–0.056) and the treatment strategy was changed by 68.3% of physicians (0.032, 95% CI 0.023–0.045), respectively.

Conclusion: 18F-FES PET/CT scans in stage IV patients diagnosed with ER-positive breast cancer combined with another primary tumour have significantly clinical value for diagnosis and treatment management. **References:** None

²University of Health and Sciences, Istanbul Training and Research Hospital, Clinic of Surgery, Istanbul, TURKEY;

³University of Health and Sciences, Istanbul Training and Research Hospital, Department of Radiation Oncology, Istanbul,

TURKEY, ⁴University of Health and Sciences, Istanbul Training and Research Hospital, Department of Medical Oncology, Istanbul, TURKEY, ⁵University of Health and Sciences, Istanbul Training and Research Hospital, Department of Pathology, Istanbul, TURKEY.

Aim/Introduction: Limited studies about using 68-Ga prostate specific membrane antigen (PSMA) PET/CT imaging have been published on breast-cancers, especially in triple negative subtype (TN) and Her2 positive NST subtypes. High endothelial PSMA expression has been demonstrated in 60% of breast cancer patients. In this study, we aimed to determine the possible contributions of 68-Ga PSMA PET/CT to 18-F FDG PET/CT imaging for TN breast cancer staging and restaging.

Materials and Methods: Fifteen women patients with 18 primary lesions (Age range: 26-67 years; mean: 50,3 years) underwent prospective assessment with 18-F FDG and 68-Ga PSMA PET/CT imaging. PSMA expression and FDG uptake were semiquantitatively (SUVmax) compared in primary tumor, metastatic axillary lymph nodes, as well as distant metastases such as bone and liver.

Results: Primary lesions were detected in all 15 patients with 68-Ga PSMA PET/CT (median SUVmax: 4.5, range: 1.6-10.7), and also high FDG uptake was observed in primary tumors and metastatic lesions of the entire patient group. Fourteen patients with FDG avid lesions showed substantial PSMA expression but one patient with multiple bone and distant metastatic lesions has very low PSMA expression.

Conclusion: 68-Ga PSMA PET/CT showed similar results to 18-F FDG PET/CT staging in patients with TN breast cancer. For this reason, it also may play a guiding role in targeted radionuclide therapies in this breast cancer subtype with a high risk of recurrence. **References:** None

Is there a role for ^{99m}Tc-PSMA in times of ¹⁸F-PSMA?

T. Oliveira, B. Beier, J. Sailer, P. Peloscheck, M. Hoffmann;
Radiology Center, Vienna, AUSTRIA.

Aim/Introduction: Prostate cancer is the second most common cause of death in developed countries and is the most common type of cancer in men. PSMA provides a promising target for prostate cancer specific imaging. ^{99m}Tc-labelled PSMA for planar and SPECT/CT imaging appears a promising alternative to PET tracers for diagnostic work-up of prostate cancer patients. We present a retrospective single-center experience with ^{99m}Tc-PSMA and ¹⁸F-PSMA.

Materials and Methods: From December 2018 to March 2020,

22 patients were examined for staging of prostate cancer. In 16/22 patients ^{99m}Tc -PSMA whole-body scintigraphy followed by SPECT/CT was performed. In 8/22 patients ^{18}F -PSMA PET/CT was performed. In 2 patients, both scans were used during follow up. The inclusion criteria for the performance of any of these studies was a bioptic diagnosis of prostate cancer, an elevated PSA or clinical suspicion of recurrence with detectable PSA level during or following therapy. A whole-body scan and SPECT/CT of the thorax and abdomen were performed earliest 6 hours after administration of 720 MBq (mean activity) ^{99m}Tc -PSMA. ^{18}F -PSMA-PET/CT was performed 2 hours after injection of 453 MBq (mean activity) with IV contrast enhancement. **Results:** Local prostatic uptake of ^{99m}Tc -PSMA was found in 5/16 patients. Another 5 patients showed lymph node metastases, predominantly local and iliacal but also in paraortal regions. In 1 of these patients also distant spread was detected, namely bone metastases. A total of 8 patients were examined prior to surgery. In 3 patients with ^{99m}Tc -PSMA positive lymph nodes, a gamma probe was used for surgical resection, which was carried out on the same day or the morning of the following day. In 8 patients who have undergone the study with ^{18}F -PSMA, local uptake was found in 1/8 patient. In 6/8 patients, the study showed lymph node metastases and distant osseous spread was detected in 4 patients. **Conclusion:** For staging and follow up in prostate cancer ^{68}Ga PSMA or ^{18}F PSMA will stay to be the tracers of first choice. Yet, PSMA scintigraphy including SPECT/CT is an acceptable alternative when no PET/CT machine or tracer for prostate cancer are available. Especially, when applied preoperatively it allows the specific localization of involved lymph nodes metastases during surgery with the use of a gamma probe. **References:** None

TEPS-24

Cardiac Inhibition Protocol For The Diagnosis Of Infective Endocarditis With ^{18}F -FDG PET/CT

M. Cabanillas Perez, S. Ruiz Solis, P. Pilkington Wol, J. Sánchez Redondo, J. Estenoz Alfaro;
Hospital Universitario 12 Octubre, Madrid, SPAIN.

Aim/Introduction: Inhibition of the physiological cardiac activity on ^{18}F -FDG PET/CT is essential for the diagnosis of infective valve endocarditis. The objective of this work is to determine the effectiveness of the cardiac inhibition protocol used in our department. **Materials and Methods:** We retrospectively analyzed all the PET/CT studies done to patients with suspected infective endocarditis from April 2019 to January 2020. Previous to the scan, these patients are contacted to explain the cardiac inhibition protocol used in our department and which they have to follow. This protocol consists in a low-carbohydrate and high-fat diet for at least 24 hours, and an 8 hour period of fasting previous to the scan. Good hydration is also recommended. The PET/CT used was a Siemens Biograph

6. Following glycemic control, a standard dose of 5 MBq/kg of ^{18}F -FDG was injected intravenously. After 50 - 60min a standard acquisition protocol was followed, which consists in performing images from the base of the skull to the mid-thighs, with a 3min per bed position acquisition in a cranial to caudal direction and using a low dose CT (mAs modulated with CARE Dose4D, 130 kV, 4mm slices). Following the scan acquisition, images were evaluated for total, partial or no cardiac inhibition by a nuclear medicine physician. **Results:** Twenty studies performed with the cardiac inhibition protocol were evaluated. After analysis, we found that 11 patients (55%) had total cardiac inhibition, 8 patients (40%) had partial cardiac inhibition (never the less only in 1 case this partial inhibition affected image interpretation) and only 1 patient (5%) had no cardiac inhibition (we suspect that this result is because the patient did not follow the protocol). Therefore, taking into account our results, we can say that a satisfactory cardiac inhibition was achieved in 90% of patients (18 patients). **Conclusion:** The cardiac inhibition protocol used in our department allowed for a correct cardiac evaluation in 90% patients with suspected infective endocarditis following ^{18}F -FDG PET/CT scan. **References:** None

TEPS-25

The Use Of Fatty Acids Labeled With Technetium-99m For Visualization Of The Cardiac Muscle

A. Rogov, E. Stasyuk, E. Nesterov;
National Research Tomsk Polytechnic University,
Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: The results of studies on the development of methods for the synthesis of new X-ray diagnostic tools based on a modified fatty acid are presented. Labeled technetium-99m fatty acid is necessary for a detailed scintigraphic evaluation of myocardial metabolism. In the process of synthesis of the radiopharmaceutical, the interaction of the substance with technetium-99m in an alcohol medium was studied using ethanol as a solvent. **Aim:** Developing methods for the synthesis of a new radiopharmaceutical based on modified fatty acid labelled with technetium-99m. **Materials and Methods:** This agent is intended for studying the metabolism of cardiac muscle and this will allow differentiating viable heart and scar tissue. An important task of cardiology is the diagnosis of viable myocardium, since its presence in an ischemic area is a direct indication for invasive correction of coronary insufficiency. As a substance for radiolabelling fatty acid was synthesized derivative (PDA-DTPA). PDA-DTPA molecule includes two structural fragments ensuring successful functioning of the radiopharmaceutical. The first is that provided bioavailability acid fragment of the radiopharmaceutical to myocardium. The second fragment which serves for chelate binding of ^{99m}Tc . Ethanol was used as solvent for PDA-DTPA but it acts as a reducing agent for $\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$. To perform labelling

1mg PDA-DTPA dissolved by heating in 1.0 ml 96% ethanol. Then 1.0ml ^{99m}Tc , 50 mcl Sn(II) solution and 50mcl ascorbic acid as a stabilizing additive were successively placed in a test tube. Determine radiochemical purity was carried out by thin layer chromatography. Determine radiochemical purity was carried out by thin layer chromatography. As mobile phases have been identified Chloroform and Acetone. Acetone was selected for comparing mobility ^{99m}Tc (VII). **Results:** Determine radiochemical purity was carried out by thin layer chromatography. As mobile phases have been identified Chloroform and Acetone. Acetone was selected for comparing mobility ^{99m}Tc (VII). Radiometer «RIS-A1» was used to measure the total activity of the vial. After incubating the mixture for 15min and it is heated on a steam bath for 30min at temperature to 98°C. Then was carried out repeated sampling for chromatography in the same media. **Conclusion:** The experiments carried out show that receiving PDA-DTPA- ^{99m}Tc , having a pH of ~6, the desired product yield is insufficient. The next stage of our research will be the study of PDA-DTPA behavior in aqueous media and effect on solubility of the pH medium. **References:** None

TEPS-26

Comparison of quantitative assessment for cardiac sarcoidosis inflammation site using ^{18}F -FDG PET / CT images

R. Murayama¹, R. Morimoto², N. Fujita^{1,3}, Y. Ito¹, R. Ono¹, T. Tada¹, H. Ikeda⁴, Y. Ochi⁴, M. Nishio⁴, Y. Tsutsumi³, M. Tamura¹, T. Odagawa¹, S. Abe³, K. Kato⁴;

¹Department of Radiological and Medical Laboratory Sciences, Nagoya University Graduate School of Medicine, Nagoya, JAPAN, ²Department of Cardiology, Nagoya University Graduate School of Medicine, Nagoya, JAPAN, ³Department of Radiological Technology, Nagoya University Hospital, Nagoya, JAPAN, ⁴Department of Integrated Health Sciences, Nagoya University Graduate School of Medicine, Nagoya, JAPAN.

Aim/Introduction: Cardiac involvement in sarcoidosis is associated with a worse prognosis and accounts for 25% of deaths from sarcoidosis, so early diagnosis and treatment of cardiac sarcoidosis (CS) are very important. ^{18}F -FDG PET/CT detects CS inflammation site as focal areas of FDG uptake with high sensitivity, so that cardiac imaging is a useful method for diagnosis of CS. For CS ^{18}F -FDG PET/CT, indices such as standardized uptake value (SUV), cardiac metabolic volume (CMV), and cardiac metabolic activity (CMA) are used to evaluate CS inflammation site. These indices are calculated by volume of interest (VOI) setting at CS inflammation site using a threshold value. However, the thresholds for calculating these indices have not been clarified. The aim of this study was to verify whether VOI set using the threshold from the liver SUV normalized by lean body mass (SUL) or the left ventricular blood pool (LVBP) SUL was consistent with CS inflammation site confirmed

by clinical diagnosis. **Materials and Methods:** Study subjects were 50 patients (62 examinations in total) who underwent CS ^{18}F -FDG PET/CT studies and diagnosed with CS at Nagoya University Hospital. Analyzing software programs PMOD (PMOD Technologies) was used for measurement of the liver SUL and the LVBP SUL, and calculation of the threshold value. VOI was set at the heart using the threshold from the liver SUL or the LVBP SUL and was compared with CS inflammation sites confirmed by clinical diagnosis. CMA inside VOI set at the heart was measured. To select the best threshold for CMA, receiver-operator curves (ROC) analysis was used, and the sensitivity, specificity and area under the curve (AUC) were calculated. **Results:** CS inflammation sites set using threshold from the LVBP SUL were better consistent with CS inflammation sites confirmed by clinical diagnosis than those set using threshold from the liver SUL. CS inflammation sites set using the threshold from the liver SUL were mostly not consistent with CS inflammation sites confirmed by clinical diagnosis in the cases on the way of treatment. Since the visual assessment of CS evaluated the difference of uptake between CS inflammation sites and LVBP, VOI using threshold from the LVBP SUL could be set exactly. **Conclusion:** CS inflammation sites set using threshold from the LVBP SUL were comparatively well consistent with CS inflammation sites confirmed by clinical diagnosis. **References:** None

Patient Non-Compliance Rates in Following Dietary Instructions for Cardiac Inflammation/Infection Imaging with FDG PET/CT

N. Martins, F. Alves, K. Wechalekar;
Royal Brompton & Harefield NHS Foundation
Trust, London, UNITED KINGDOM.

Aim/Introduction: ^{18}F - Fluorodeoxyglucose (FDG) has a high physiological uptake in the heart. Hence, it is difficult to evaluate pathologies such as cardiac involvement of sarcoidosis and heart infections. Our protocol of no-carbohydrate diet on day prior followed by fasting (18 hours) before scan deprives the heart from using glucose as a substrate for metabolism allowing us to secure diagnosis of cardiac inflammation/infection. Despite providing patients with elaborate instructions on how to follow this diet, some patients fail to adhere to these dietary restrictions leading to cancellations and ultimately delaying their diagnosis and subsequent management. We have been working to improve on protocol compliance. This follow up study was performed after introducing new dietary menus and multi-lingual text. Our aim was to identify potential reasons for cancellations. **Materials and Methods:** All planned cases from October 2019 to February 2020 were checked for cancellations. The percentage of failing dietary restrictions in comparison to total FDG doses was calculated. The

reasons for failing the dietary restrictions were gathered from the patients. **Results:** In the 5 months, 26 FDG doses out of 599 were cancelled due to patients failing the dietary restrictions (4.34%). The reasons for this can be divided into patient related and voluntary (misunderstanding/not reading the instructions and ingesting carbohydrates), patient related and involuntary (hypoglycaemia due to change in diet) and non-patient related (interpreters providing incorrect information to the patients). The first category accounts for most of the cancellations. Hence to tackle this problem, changes such as the inclusion of new menu choices and translation of menus were made. In a similar study concerning the five months prior, the percentage of cancellations due to failing the diet was of 3.57%. One of the main reasons of cancellation in that study was the disregard for the diet and after changes to the patient's letter, this is rarely the reason for cancellation. **Conclusion:** Cancellations due to failing the diet restrictions are mostly due to human error which can never be brought to 'zero'. However, studies such as these help technologists understand the reasons behind compliance, so measures can be implemented to keep them to minimum. By doing so, delays in clinical pathways can be avoided and save the cost of cancelled FDG exams. The study aims to share our experience to raise awareness for the potential problems that arise and what measures can be implemented to tackle them. **References:** None

TEPS-28

Sweet child of mine: the use of music in dynamic renal scintigraphy in pediatric patients

M. Maccagnani, A. Farina, R. Bonfiglioli, M. Levorato, S. Fanti; Nuclear Medicine Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY.

Aim/Introduction: Dynamic renal scintigraphy in pediatric patients is one of the most demanding examinations depending on the way children relate to their surroundings. The aim of this work is to describe our center experience and a new strategy to increase the quality of the examination and reduce the stress in little patients and their parents. **Materials and Methods:** The dynamic renal scintigraphy is one of the stressful examinations for paediatrics patients due to the injection of the radiopharmaceutical and the need to remain as still as possible for a long time. The help of the parents is not always sufficient to guarantee a successful exam. Over the years we have applied different strategies to calm down young patients: the use of sucrose drops for infants from 1 to 6 months and the use of a tablet with cartoons for children from 2 to 6 years obtaining excellent results. We still miss a strategy for children from 6 months to 2 years. In summer 2019 during the injection of the radiotracer for dynamic renal scintigraphy to a 7-month-old infant, doctors began to sing the popular Korean song

"Baby Shark" for fun. The baby calmed down quickly making the injection easier. It was decided to keep listening to the song, via-Youtube, for the duration of the exam. As a result, the child remained serene throughout the procedure and the examination required a reduced intervention of realignment of the images, increasing their general quality. In light of this incidental experience, in the following weeks, the same attempt has been repeated on every possible occasion always leading to remarkable results. **Results:** Since September 2019 the use of music while performing dynamic renal scintigraphy in pediatric patients has been adopted as a standard procedure. From July 2019 to April 2020, dynamic renal scintigraphy was acquired for 35 children in the age group from 6 months to 2 years, every time background music was used throughout the exam. This strategy seems to decrease stress in children and consequently the same effect on parents, thus eliminating emotional feedback. **Conclusion:** In all cases examined, the benefits of music have been significant: the increased complement of the child during the injection and acquisition phase of the examination resulted in a reduced need for post-image processing. A playlist containing several children's songs has been uploaded on a tablet but "Baby Shark" seems to remain the favourite song of younger children and doctors. **References:** None

Psychosocial characteristics of patients with coronary artery disease during imaging examinations in the Nuclear Medicine Department

M. Stolidou¹, F. Rondoyanni¹, I. Datselis¹, G. Alexias²; ¹Evangelismos Hospital, Athens, GREECE, ²Panteion University, Athens, GREECE.

Aim/Introduction: To explore the effect of anxiety and depression, as well as social support, on patients with coronary artery disease. **Materials and Methods:** 155 patients with known coronary artery disease were subjected to myocardial perfusion imaging at the Nuclear Medicine Department of "Evangelismos" Hospital. Data were collected by the completion of questionnaires, which apart from the socio-demographic and clinical variables, included the Hospital Anxiety and Depression Scale (HADS) and the short form of the Social Support Questionnaire (SSQ-6). The statistical analysis was conducted by using the statistical software SPSS 19.0. **Results:** From the participants 85.2% were 51-80 years old, 80.6% were men, 71.6% married and 55.5% retired. As to their educational level, 42.6% were high school/college graduates and 31.0% were graduates of elementary school. Regarding the clinical characteristics of the sample-studied, 71.6% had myocardial infarction and 71.0% angioplasty. 34.2% of patients had cardiovascular disease of 2-5 years' duration, 23.2% were diagnosed within the last year, while 94.8% of patients had been hospitalized

for the same reason. Also, 74.2% of the participants had hypertension, 51.0% had family history of cardiovascular disease, 43.9% obesity, 34.8% diabetes, and 36.8% were smokers. 44.5% of patients experienced a myocardial perfusion imaging for the first time. Regarding social support, higher levels were found for the most educated and those who had children. In addition, angina pectoris patients had significantly less social support than non-angina patients. In addition, in terms of satisfaction with their social support, multivariate linear regression showed that women were significantly more satisfied with their social support than men. Higher levels of depression based on the HADS questionnaire were found according to multifactorial analysis in women and patients with arrhythmias. In addition, it was found that the more social support the patients had, the less depressive symptoms they experienced. In terms of anxiety levels as measured by the HADS questionnaire, it was found to be higher in women, in patients suffering from angina pectoris, while the more social support the patients had, the fewer the symptoms of anxiety were. **Conclusion:** For the holistic treatment of coronary artery disease the systematic approach of anxiety and depression, as well as social support, should be an integral part of the patients' treatment. **References:** None

TEPS-30

Flow motion modality reduce the patient radiation exposure of whole-body PET-CT

G. Pecchia¹, E. Palladino², S. Amabile¹, G. Borselleca¹, C. Del Vasto¹, C. Lanotte¹, U. Marra¹, V. Milone¹, D. Palma¹, S. Piccolo¹, A. D'Acunzo¹, M. Spadafora¹;

¹Nuclear Medicine Unit, Ospedale del Mare, Naples, ITALY, ²Ospedale Civile Lipari, Messina, ITALY.

Aim/Introduction: The first priority of actual ICRP Strategic Plan, as well as the basic principle of radioprotection, is to reduce radiation exposure maintaining diagnostic information. Continuous motion in flow modality (FM) of the patient table has recently been introduced in modern PET/CT tomograph. This individualized acquisition, without the limitations of multi-bed position-based planning (MB), increased patient comfort with image quality at least comparable to that step-and-shoot acquisition. FM, avoiding additional CT range scanning, can be conceptually advantageous from a dosimetric point of view. However, to our knowledge no studies explored the effect of two modalities in reducing CT patient dose. Aim of this study was to compare the patient radiation exposure of FM and MB acquisition modality, related to whole-body (wb) PET/CT scan. **Materials and Methods:** We have collected our first 80 patients referred for whole-body FDG-PET/CT for different malignancies. PET/CT images were acquired using an integrated 3-D mode PET/CT systems, from the base or top of the skull to mid-thigh (wb-PET/CT), starting 60 min after

tracer administration. In each patient, after the topogram, two acquisition mode, FM and MB, were set in order to preliminarily obtain an estimate of both dose-length product (DLP) and scan length (in mm) for FM and MB modality. At the end of the PET/CT study, the effective values of both DLP and ED were recorded. DLP was calculated as CTDI vol*length of scan in mGy*cm. The transformation of DLP in Effective Dose (ED in mSv) was made accordingly ICRP 103. The relative risk of cancer was evaluated by the software X-ray risk, based on the BEIR VII report. Differences between continuous data were assessed using paired Student's t test. **Results:** In study population estimate mean values of both DLP and scan length was significantly higher by MB than FM modality of whole-body PET/CT (762.8+381.8 vs 744.3+376.0 mGy*cm, $p < 0.0001$; 963.5+78.0 vs 928.2+75.2 mm, $p < 0.0001$, respectively). Similarly, estimate ED was significantly higher by MB than FM modality (13.7+6.9 vs 13.4+6.8 mSv, $p < 0.0001$). The effective values of both DLP and ED were slightly lower than the same parameters estimate before the study (662.0+342.8 mGy*cm and 12.0+6.2 mSv, respectively). The lower DLP in FM than in MB modality produces a lower relative risk of cancer due to whole-body PET/CT procedure (0.059+0.05 vs 0.058+0.05, $p < 0.0001$). **Conclusion:** Compared to standard MB modality, the flexibility of FM significantly reduces the radiation exposure and relative cancer-risk of wb-PET/CT, according to ICRP provisions. **References:** None

TEPS-31

Occupational Radiation Exposure in the Department of Nuclear Medicine - the Effect of Distance and Shielding Material on the Dose Rate

T. Salla¹, S. Hakkarainen¹, K. Hirsimäki¹, T. Taatila², H. Vilpas²;

¹Tampere University of Applied Sciences, Tampere, FINLAND,

²Tampere University Hospital, Tampere, FINLAND.

Aim/Introduction: To increase knowledge related to the importance of radiation safety procedures which permit safe working in the Department of Nuclear Medicine. An answer was sought to the question of how distance and shielding material affect dose rate when dealing with Tc99m-labeled radiopharmaceuticals. **Materials and Methods:** The entire data comprises two parts: the first data were collected during Myocardial perfusion SPECT and Bone scan and the second data were related to syringe measurements. In the case of imaging situations, the dose rate was measured at different distances (2 m, 1 m, 50 cm, 25 cm) from the patient who had received the radiopharmaceutical. Myocardial perfusion SPECT and bone scan were chosen because both examinations are common, and the activity used in these examinations is relatively high. The effect of distance (1 cm, 20 cm) and syringe shield (2 mm tungsten) on the dose rate was investigated with syringe measurements. The radioactive component to be measured was

technetium-99m eluate. The measurements were made with several activities (805.1 MBq, 600.4 MBq, 502.6 MBq, 402.6 MBq, 311.8 MBq). Instructions and data collection forms were prepared in advance for the measurements. Their purpose was to ensure that no errors occur during the measurements. The dose rates were measured with a radiation meter calibrated by the Radiation and Nuclear Safety Authority. **Results:** The study is currently in process, so the results are still underway. The results related to the patient examinations determine how extensive the change (%) in dose rate is when the distance increases. The dose rates will be described using tables and graphs, separately from skeletal and myocardial perfusion examinations. The results of the syringe measurements determine how much (%) the syringe shield affects the dose rate. In addition, average dose rates in the immediate vicinity of the syringe (0–1 cm) and at 20 cm from the syringe will be compared. **Conclusion:** The dose rates will be presented in a concrete way. The radiographers and nuclear medicine technologists working in the department of NM ought to understand the importance of distance and shielding material in their daily routine. Dose rates are illustrated by describing how long it takes for the worker's effective dose limit of 20 mSv or the finger dose limit of 500 mSv to be reached, at different distances, or without and with a syringe shield. Dose rates will be also compared to air travelling and natural background radiation. **References:** None

TEPS-32

Hand exposure in nuclear medicine technologists working in the radiopharmaceutical laboratory in diagnostic nuclear medicine

C. Sobral, J. O. Prior, E. Perez;

Centre hospitalier universitaire vaudois (CHUV), Lausanne, SWITZERLAND.

Aim/Introduction: We aimed to assess dose-extremity, its distribution and to define a personal correction factor from measurements on the hands of technologists working in a radiopharmaceutical laboratory. **Materials and Methods:** From October–November 2019, five technologists were equipped with 22 thermoluminescent dosimeters (TLDs) (11 positions by hand) to measure their personal dose equivalent Hp (0.07). We used TLD-100 LiF 3.2x3.2x0.9mm, GIM1, calibrated on 23/05/2019, and measured with a reader Harshaw 5500 with a Co-60 beam. Measurements were repeated twice over 1 week for 2 out of the 5 participants. A TLD was used to measure the background activity in the laboratory. **Results:** For all 5 technologists, the index tip of the non-dominant hand demonstrated the maximum received dose, followed by the ipsilateral thumb. A comparison of dose measurements between the maximum dose position and the base of the index finger of the non-dominant hand where it is routinely measured

showed values for the correction factors ranging from 2 to 2.7 (2.3±0.3). On average, the non-dominant hand received 1.7±6.2mGy (or 59%) more dose than the dominant hand (laboratory background activity was 0.159mGy). **Conclusion:** According to our results, we recommended wearing of the extremity dosimeter at the base of the index finger of the non-dominant hand facing its palm. In addition, an average correction factor of 3 can be applied to estimate the absorbed dose on the position with the most exposure, the tip of the index finger of the non-dominant hand; this compares to the factor of 5 taken by default in the Swiss Radioprotection Ordinance. **References:** Carnicer, A., Sans-Merce, M., Baechler, S., Barth, I., Donadille, L., Ferrari, P., - Vanhavere, F. TEPS-33

Using common tungsten vs. special plastic syringe shield with yttrium-90: more radiation exposure to staff or not?

E. Tyyskä, N. Takalo, M. Ladev, M. Eskola, J. Hyypiä, M. Tenhunen, V. Reijonen;

Helsinki University Hospital Cancer Center, Helsinki, FINLAND.

Aim/Introduction: Yttrium-90 is a high-energy beta emitter used in radionuclide therapy such as radioembolization. Handling an unshielded syringe containing yttrium-90 can quickly lead to significant skin exposure. Syringe shielding is thus very important. Beta radiation produces Bremsstrahlung X-rays as it travels through medium, and using right shielding materials is essential. Lead/tungsten shields are commonly used when handling radiopharmaceuticals; however, for yttrium-90, plastic or aluminium-based low-Z special syringe shields are recommended as they produce a softer Bremsstrahlung spectrum. On the other hand, there are results suggesting that tungsten is the shield material of choice for yttrium-90. **Materials and Methods:** We drew 0.54 GBq of yttrium-90 resin microspheres into a 5 ml plastic syringe (polypropylene, wall thickness 1 mm) and placed it into three different syringe shields at a time: a plastic (PMMA) 12 mm thick syringe shield used in radioembolization, a "high energy" tungsten syringe shield (5 mm tungsten, 9 mm lead glass window) and a "low/medium energy" tungsten syringe shield (2 mm tungsten, 6 mm lead glass window). All beta radiation is absorbed in the three syringe shields and the exposure is due to Bremsstrahlung only. We measured dose rates with a multi-purpose survey meter (gamma/X-ray detection range: 48 keV–3 MeV, energy response according to ambient dose equivalent H*(10)) at the distances of 1.0 m and 10 cm from the shielded syringe, and in close contact to the shield. **Results:** For the plastic syringe shield, the measured dose rates were 1 µSv/h at 1.0 m, 75 µSv/h at 10 cm and 500 µSv/h in close contact

to the shield. For the “HE” tungsten syringe shield the dose rates were 0.4 $\mu\text{Sv/h}$, 17 $\mu\text{Sv/h}$ and 165 $\mu\text{Sv/h}$, respectively. For the “ME/LE” tungsten syringe shield the dose rates were 0.6 $\mu\text{Sv/h}$, 30 $\mu\text{Sv/h}$ and 265 $\mu\text{Sv/h}$, respectively. Earlier, our technologist used by error the “HE” tungsten syringe shield instead of the plastic special syringe shield while handling yttrium-90 microspheres. The personal dosimeter (TLD based, worn three weeks before read-out) readings were $H^*(10)=0.13$ mSv and $H_p(0.07)=1.85$ mSv (finger). These values do not differ from the average doses recorded in normal working conditions at our radionuclide therapy unit. **Conclusion:** Common tungsten syringe shields appear to provide adequate shielding with yttrium-90. It is important to use shielding meticulously when handling yttrium-90 radiopharmaceuticals, and finding a consensus on the optimal shielding solutions is encouraged. **References:** None

TEPS-34

Image quality improvement method for nuclear medicine images based on deep learning

R. Yamada¹, M. Momiuchi¹, T. Hara¹, T. Katafuchi², X. Zhou¹, H. Fujita¹;

¹Gifu University, Gifu, JAPAN, ²Gifu University of Medical Science, Seki, JAPAN.

Aim/Introduction: Nuclear medicine images can acquire functional information of organs that cannot be imaged by other radiological modalities, but it is difficult to extract detailed structures of organs. In this study, we examined an image quality improvement method of nuclear medicine images with low spatial resolution by using a super-resolution technique with deep learning and an original dataset. **Materials and Methods:** In this study, low resolution (LR) images were created from high resolution (HR) data using a food printer containing RI materials in the ink. 108 pairs of the LR and HR images were employed as image database for the deep learning. The image database contains a medical image set using CT and MRI, and a natural image set as the HR images. These HR images were printed on paper by a food printer using specialized ink mixed with a radiopharmaceutical, and the printed images on the paper were captured by using a gamma camera. The captured images were defined as the LR images. Four-fold cross-validation was performed using a network created based on SRResNet. The input image size was 64×64 [pixels] and the output image size was 256×256 [pixels]. We compared the proposed method with the Bi-cubic method by numerical evaluation using PSNR and SSIM and subjective evaluation. **Results:** In the numerical evaluation, PSNR and SSIM were 33.71 and 0.861 in the proposed method and 32.53 and 0.808 in Bi-cubic method, respectively. **Conclusion:** We have suggested a super-resolution method using deep learning and a creation method for the image database using a food printer. These approaches can contribute to

improve the visibility of nuclear medicine images with low spatial resolution. **References:** None

TEPS-35

Striatum extraction using deep learning in ioflupane brain scintigraphy - Learning using Monte Carlo simulation images -

H. Tsushima¹, R. Murakawa¹, S. Kurata^{2,1}, R. Ishitsuka³, H. Nosaka⁴, A. Onoma⁵, S. Koike^{6,1};

¹Ibaraki Prefectural University of Health Sciences, Amimachi, Ibaraki, JAPAN, ²Ibaraki Prefectural Central Hospital, Kasama, Ibaraki, JAPAN, ³Chiba University Hospital, Chiba, JAPAN, ⁴Clinical Imaging Center for Healthcare, Nippon Medical School, Bunkyo-ku, Tokyo, JAPAN, ⁵Yokohama City University Hospital, Yokohama, Japan, JAPAN, ⁶University of Tsukuba Hospital, Tsukuba, Ibaraki, JAPAN.

Aim/Introduction: Ioflupane brain scintigraphy is evaluated by the accumulated amount and shape of the radiopharmaceutical accumulation in the striatum. The Specific Binding Ratio proposed by Bolt et al. (SBR_{Bolt}) is widely used for quantitative evaluation of the accumulated amount; however, this method underestimates because the region of interest (ROI) is set larger than the striatum and includes the ventricle. In order to improve the accuracy of these evaluations, attempts have been made to extract only the striatum. In this study, we examined whether deep learning with Monte Carlo simulation images can be applied to the extraction of the striatum. **Materials and Methods:** First, single-photon emission computerized tomography (SPECT) images, with an accumulation ratio of 1:2 to 1:8 between the brain parenchyma and the striatum, were created by Monte Carlo simulation (SIMIND ver.6.1.0 Lund university) based on the striatum phantom as training data. Furthermore, SPECT images, with no accumulation in the brain parenchyma but only in the striatum, were similarly created as reference images. The network then trained on these SPECT images. Using the U-net and Convolutional Neural Network (CNN) for the network, the results of the extraction of the striatum were compared by Dice coefficient to evaluate the extraction accuracy. Furthermore, the same comparison was performed for the extraction results using 2D data and 3D data as learning data. **Results:** The Dice coefficients of U-net and CNN were 0.9 and 0.5 in normal striatum models, respectively. The Dice coefficients of 2D data and 3D data were 0.93 and 0.99 in normal striatum models, respectively. When 3D data was used as learning data, it was possible to extract from the top to the bottom of the striatum. However, some images with low accumulation were not extracted by the 3D algorithm. **Conclusion:** On the basis of the findings of this study, U-net is more suitable than CNN and 3D data is more suitable for learning data than 2D data in striatal scintigraphy. It was suggested that the underestimation of SBR_{Bolt} would

be improved by the accurate extraction because the ROI of the striatum does not include the ventricle. It was also suggested that it can be applied to quantitative evaluation methods for accumulated shape. In the future, it will be necessary to improve the extraction accuracy by learning more low accumulation images on a 3D U-net algorithm. **References:** None

TEPS-36

Development of the pulmonary artery region of interest setting program using deep neural networks for the ¹²³I-MIBG myocardial quantification

S. Itoyama¹, Y. Uchiyama², K. Yamashita¹, A. Takaki³, S. Ito²; ¹Graduate school of health sciences, Kumamoto University, Kumamoto, JAPAN, ²Faculty of Life Sciences, Kumamoto University, Kumamoto, JAPAN, ³Faculty of Fukuoka Medical Technology, Teikyo University, Fukuoka, JAPAN.

Aim/Introduction: In this study, we developed a fully automatic myocardial uptake quantification analytical program for the Iodine-123 metaiod-obenzylguanidine (¹²³I-MIBG) myocardial uptake quantification method. The input function of this method was determined using the administered dose, which was obtained by analysing the count-time activity curve of the pulmonary artery (PA) in dynamic chest images. The automatic region of interest (ROI) setting program for the PA was developed by mathematically and statistically analysing a chest RI angiogram (mathematical method). The coincidence ratio between the location of the PA-ROI obtained using the mathematical method and that obtained using manual methods was approximately 90%. However, to practically use this program, further improvements of 10% are required. If the PA region can be determined by using deep neural networks for segmentation, the accuracy of the PA-ROI setting program can be improved in terms of simple analytical operations, repeatability, and reproducibility. The purpose of this study is to develop a new PA-ROI setting program by using deep neural networks. **Materials and Methods:** A U-Net architecture based on convolutional neural networks was used to determine the PA candidate region. Images of 364 patients who underwent the chest RI angiography were used as training images. An ROI with a radius of 4 pixels (8.76 mm) was set on the candidate PA region, and the highest mean pixel value on the ROI was identified. To confirm the usefulness of this program, 44 patients were examined using the PA-ROI setting program, and the results were compared with those obtained through the manual method. **Results:** The dice coefficient between the training PA regions and the segmented PA regions was 76.5%. The coincidence ratio between the location of the PA-ROI obtained using this program and that obtained using manual methods was 98%. A strong correlation was observed between the PA-ROI setting method and

the manual setting methods. **Conclusion:** We developed a fully automated PA-ROI setting program using deep neural networks for ¹²³I-MIBG myocardial quantification. This program improves the reproducibility, repeatability, and accuracy of the ROI setting. **References:** None

Computer-aided detection of cancer on PET/CT images based on anomaly detection using GAN-based deep learning

T. Maeda¹, M. Haga¹, T. Hara¹, T. Katafuchi², X. Zhou¹, M. Matsusako³, S. Ito⁴, M. Kato⁴, A. Yamada⁵, H. Fujita¹; ¹Gifu University, Gifu, JAPAN, ²Gifu University of Medical Science, Seki, JAPAN, ³St. Luke's International Hospital, Tokyo, JAPAN, ⁴Daiyukai General Hospital, Ichinomiya, JAPAN, ⁵Shinshu University, Matsumoto, JAPAN.

Aim/Introduction: Reducing false positives (FPs) is also an important issue in computer-aided diagnostic system as an interpretation help for radiologists. We propose an automated detection method for cancer-screening on PET/CT images based on anomaly detection using Generative adversarial networks (GANs). **Materials and Methods:** In this study, both of PET and CT images are used to detect cancer regions. OCGAN[1] is a deep learning model proposed for anomaly detection in two-dimensional images. We apply the GAN's model to PET images. The model trained axial, coronal and sagittal slices of many normal PET images. After that, the model would then produce a normal image even if the input image contains cancer regions as abnormal region. Subsequently, cancer regions were identified by a dynamic threshold processing on the differential image between the input and output of the model. Since the same process was performed for each cross-section. Areas where the results of the three cross-sections did not match were removed as FPs. The FPs were eliminated by using a gradient of voxel values within an organ on the CT images. **Results:** The detection performance was evaluated using 71 PET/CT images included 38 normal cases for a training dataset and 33 anomaly cases for a test dataset. The sensitivity was 87.6% with 84.4 FPs per case. The area of FPs was 904.7 voxels per case, which showed that FPs of small size were seen interspersed. **Conclusion:** We have developed a detection method based on anomaly detection using GANs for screening of cancer in PET/CT images. GANs trained only normal cases were contributed to correctly detection of cancer. **References:** [1] P. Perera et al., "OCGAN: One Class Novelty Detection Using GANs With Constrained Latent Representations", The IEEE Conference on Computer Vision and Pattern Recognition (CVPR), pp. 2898-2906, 2019

TEPS-38**Use of artificial neural network for the diagnosis of myocardial ischemia :Comparison of imaging diagnosis between two devices in the clinical conditions**

M. Kano¹, D. Ogura¹, T. Ino², T. Toyama³, K. Koyama¹;

¹Gunma Prefectural Cardiovascular Center, Maebashi-shi, Gumma-ken, JAPAN, ²Gunma Prefectural Phychiatric Medical Center, Isesaki-shi, Gumma-ken, JAPAN, ³Toyama cardiovascular Clinic, Maebashi-shi, Gumma-ken, JAPAN.

Aim/Introduction: The advances in the myocardial perfusion analysis software have enabled the diagnosis of myocardial ischemia using artificial neural network (ANN). ANN supports radiological technologists and less-experienced physicians in interpreting images. Two different devices using for nuclear medicine examination are used in our hospital, both requiring the same diagnostic results. Here, we compared ANN values and summed stress scores (SSS) for a cardiac phantom and patients between the two devices. Although there are a few diagnostic studies using ANN, no studies have compared two different devices. **Materials and Methods:** The used devices were PRISM-IRIX: LEGAP and Infinia 8 Hawkeye 4: LEHR. The phantom study was performed using a heart/liver phantom without defects or with 2-cm defects in the anterior and inferior walls of the left myocardium. Imaging was performed under various conditions with two different devices. Thirty patients with proven or suspected ischemic heart disease underwent stress myocardial perfusion imaging with the two devices. ANN values and SSS were calculated from the images using myocardial perfusion analysis software. The results were compared between the two devices, and also compared with those by expert image interpreters. **Results:** In the phantom study, the ANN values of both devices showed normal in phantom without defect and abnormal in phantom with defects. In the clinical conditions, ANN values and SSS did not differ significantly between the two devices (P=0.131 and P=0.118, respectively). Using ANN normal and abnormal values obtained by expert interpreters as standard, the sensitivity and specificity were 78% and 95% for PRISM, and 78% and 95% for Infinia, respectively. When SSS were categorized into normal, mild, moderate, and severe abnormalities, the concordance rate between the SSS categories and expert interpretations was 70% (21/30) for both devices. The discrimination of normal from abnormal ANN values was possible even with different devices in both phantom and clinical studies. However, it is important to use not only ANN values but also other parameters such as SSS with an understanding of the device characteristics and imaging findings. Different results from those based on expert interpretations were influenced by extracardiac accumulation, inferior wall artifact, and cardiac enlargement. **Conclusion:** By using ANN in myocardial perfusion analysis software even with different devices

may allow imaging diagnosis. Japan has a shortage of diagnostic radiologists, given that certain skills are required for diagnosis, a diagnostic support system using ANN is anticipated. **References:** None

⁵Alrijne ziekenhuis leiderdorp, Leiderdorp, NETHERLANDS.

Aim/Introduction: To evaluate the value of Molecular Breast Imaging (MBI) in patients with indeterminate breast abnormalities and unresolved diagnostic concerns, especially in terms of its ability to rule out malignancy.

Materials and Methods: Data of patients who underwent MBI because of equivocal findings or diagnostic concerns on conventional diagnostic (CD) work up in the period from March 2012 until February 2015 were analysed retrospectively. All patients underwent digital mammography, ultrasound and MBI. MBI was performed using a Dilon 6800 gamma camera 5 min after administration of 600 MBq ^{99m}Tc-sestamibi intravenously. Pathological findings or follow-up imaging for at least 6 months were used as the reference standard. Sensitivity and specificity rates for CD alone and MBI adjunct to CD were statistically compared using McNemar's test **Results:** Out of 226 women, 25 (11%) patients were diagnosed with breast malignancies. Histopathological data were available for 106 (47%) patients and mean follow-up time was 5.4 years (IQR 3.9-7.1). In 68 out of 226 (30%) patients, MBI showed discordant findings with CD. MBI correctly adjusted treatment strategy in 46/226 (20%) patients and detected 21 out of 25 malignancies, including 15 (7%) patients categorised BI-RADS ≤ 3 on CD imaging. MBI correctly downstaged 31 of 33 patients categorised BI-RADS 4 or 5 on CD. In this highly selected study population with complex cases sensitivity of CD combined with MBI was, as expected, higher compared to CD alone (84% vs. 32%) but specificity did not differ significantly (86% vs. 81%). PPV and NPV for CD plus MBI were 43% and 98%, respectively, compared to 17% and 91% for CD alone. In the subgroup of 42 patients with nipple discharge, sensitivity of MBI was 88%; all malignancies were occult on CD. In the subgroup of 113 patients with BI-RADS 3 lesions on CD, MBI detected 7/8 malignancies and correctly categorized 99/113 (88%)

patients in the 'benign' or 'malignant' category. **Conclusion:** MBI as problem solving modality in patients with equivocal breast abnormalities or unresolved diagnostic concerns changed clinical treatment strategy in 20% of patients and could safely rule out malignancy with a high NPV of 98%.

Selective sentinel node biopsy in ductal carcinoma in situ of the breast. Is it justified?

P. Fernández-Rodríguez, Á. De Bonilla Damia, J. De León Carrillo, R. Álvarez Pérez, J. Jiménez-Hoyuela García; Virgen del Rocio University Hospital, Seville, SPAIN.

Aim/Introduction: Ductal carcinoma in situ (DCIS) of the breast is a pre-invasive malignancy without periductal stromal invasion, theoretically unable to metastasize. The incidence has experienced an important increase with the introduction of mammography screening. Currently, sentinel lymph node biopsy (SLNB) procedure for DCIS is controversial and is not standard of care. Aim of the study was to identify the existence of lymphatic involvement through SLNB and preoperative features predictive of nodal involvement in DCIS patients. **Materials and Methods:** We have retrospectively reviewed 212 patients with a preoperative diagnosis of DCIS in vacuum-assisted breast biopsy (VABB) undergoing surgery with sentinel node biopsy from January 2015 to December 2018 with an average follow-up of 32 months [range, 7-53 months]. From this group, 129 patients with preoperative histopathology of pure DCIS and criteria for SLNB with not microinvasive disease and ultrasound or MRI evidence of lymph node involvement (pTis cN0) were included in the analysis. The variables distribution were compared between patients with positive vs. negative sentinel node as well as invasion criteria in the final histopathology. The Van Nuys index was calculated for each patient. **Results:** The final histopathology result of breast exeresis determined the presence of infiltrating carcinoma (upstaging disease) in 35/129 patients (27.1%). The SLNB was positive for DCIS in 20/129 (15.5%) of the patients; 11 presented macrometastasis (55%) and 9 micrometastasis (45%). In this subgroup, 13/20 patients presented infiltration in the final breast exeresis. Nevertheless, pure DCIS was confirmed in 7/20 patients (35%). Several predictive factors of nodal involvement were observed such as a BI-RADS \geq 4, size $>$ 20mm, multicentricity/multifocality, nuclear grade 2-3, presence of necrosis and a cribriform and solid pattern. Upstaging disease was directly related to lymph node involvement, however, it was not a predictive preoperative factor. **Conclusion:** The role of SLNB in DCIS is controversial. However, the non-implementation of this technique could increase the risk of underestimation and therefore undertreatment of these patients. The presence of axillary lymph nodes involvement could

change the subsequent adjuvant treatment. A particular subgroup of DCIS patients with the factors described would have an increased risk of developing SLNB+, requiring axillary evaluation to define the most appropriate clinical treatment. **References:** None

OP-459

Utility Whole Body PET/CT Scan In Malignant Melanoma. Can The Location Of The Primary Tumor Guide Image Planning?

V. Godigna Guilloteau, J. P. Pilkington Woll, E. Martínez Albero, A. Galiana Morón, D. Vega Pérez, S. Ruiz Solis, A. Gomez Grande, M. Tabuenca Mateo, M. Sarandeses Fernandez, M. Marin Ferrer, J. Estenoz Alfaro; Hospital Universitario 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: To determine the value of systematically performing whole-body (head-to-toe) PET/CT images (WB-PET) in the evaluation of patients with malignant melanoma and propose a criteria of when standard imaging can be performed. **Materials and Methods:** Retrospective study of all WB-PET scans performed in patients with malignant melanoma in our hospital, either for staging, restaging, recurrence or post-treatment follow-up, between January 2011 and January 2020. We looked for any FDG avid foci in the lower extremities. The findings were considered as true positives if histopathological findings were confirmed, if the lesion was treated as melanoma because of other complementary findings (physical exploration, ultrasound, etc) or if during follow-up it was determined as malignant in nature. We also analyzed if the true positive findings had any change in patients management. **Results:** We analyzed 367 WB-PET studies belonging to 169 patients, 93 male (55%) and 76 female (45%), with a mean age of 56.4 years (range 19- 90 years). Of the 367 studies performed 170 (46,3%) where for staging (all at least stage IIIB), and 197 (53,7%) for suspected recurrence or post treatment follow-up. From all the WB-PET scans we observed that 19 (5 %) had positive findings in the lower extremities, 11 (3%) of which were true-positive findings (all with histopathological confirmation), 8 (2%) scans were false positive (5 inflammatory foci demonstrated by clinical follow-up and 3 benign lesions (dermatophibroma, nevus and encondroma). From the 11 true-positive findings, 8 (2%) had the primary lesion in an infra-umbilical location; 1 (0,2%) was an extracutaneous melanoma (paranasal) but the finding could be included on a standard study, and the other 2(0,4%), had disseminated disease so the findings did not change clinical management. Also, none of these findings generated a change in management. **Conclusion:** In our cohort, we found that WB-PET in patients with melanoma had no additional value to standard (head-to-mid-thigh) PET/CT images. We propose to perform WB-PET only in patients with the primary melanoma lesion located

below the umbilical line. PET/CT acquisition of the lower extremities results in increased scan time and unnecessary radiation dose without generated therapeutic impact. **References:** Clinical and therapeutic impact of 18F-FDG PET/CT whole-body acquisition including lower limbs in patients with malignant melanoma Solene Querellou. OP-460

The value of lymph node ultrasound and [18F]FDG PET/CT in stage IIB/C melanoma patients prior to sentinel lymph node biopsy

B. van der Hiel, E. Stahlie, A. Bruining, B. van de Wiel, Y. Schrage, M. Wouters, W. van Houdt, A. van Akkooi;
the Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.

Aim/Introduction: Stage IIB/IIC (pT3b-T4N0) patients are known to have high-risk primary tumors, even higher risk than some stage IIIA/B melanomas (AJCC Staging System 8th edition), however they follow the same routine to sentinel lymph node biopsy (SLNB) as more low risk tumors. A priori the risk of finding positive SLN or other metastases is much higher for these thick and/or ulcerated primary melanomas compared to the thinner ones. Guidelines are not conclusive regarding the use of preoperative imaging in these cases. Recently, a trend to more frequently use cross-sectional imaging has been noticed. However, others have previously shown that preoperative ultrasound (US) was the most sensitive. The aim of this pilot study was to assess the value of US and whole body [18F]FDG PET/CT prior to lymphoscintigraphy (LSG) and SLNB for stage IIB/C (pT3b-T4N0) melanoma patients. **Materials and Methods:** Starting 2019-04, all patients with a pT3b melanoma or higher (8th AJCC) were included. All patients underwent US and [18F]FDG PET/CT before their planned LSG and routine SLNB. Suspected metastases were confirmed with fine needle aspiration (FNA). **Results:** A total of 23 patients were screened. Six patients (26%) had metastases detected by imaging: five by ultrasound and four by PET/CT. Three of these metastases were detected by US as well as PET/CT. All metastases were nodal. For all patients, treatment was altered to lymph node dissection, all but one also received adjuvant therapy. Of the 17 patients in whom no metastases were identified by imaging, 8 (47%) still had a positive sentinel node. **Conclusion:** This study suggests that nodal staging with US is sufficient in the work-up of stage IIB and IIC melanoma. Staging with whole body [18F]FDG PET/CT is not of added value prior to LSG and SLNB and should therefore not be used. Despite normal imaging result, SLNB cannot be foregone for pT3b-pT4N0 melanoma,

as many patients still have an involved SN. Cross-sectional imaging should be reserved for patients after positive FNA or SN to confirm the absence of distant visceral metastases.

Sentinel node lymphoscintigraphy reproducibility in melanoma

P. Soeiro, R. Silva, F. Morgado, A. Albuquerque, G. Costa, J. Pedroso de Lima;
Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Sentinel lymph node biopsy (SNB) is based on the identification of the node(s) that directly drain the lymph vessel(s) originating in the tumour. Several techniques are available to identify these nodes, lymphoscintigraphy being one of the most commonly used. Despite its popularity, reproducibility remains mostly untested. The aim of this study was to assess the reproducibility of lymphoscintigraphy in melanoma patients. **Materials and Methods:** Melanoma patients proposed for SNB in a tertiary hospital center from January 2005 to December 2019, and who underwent two separate lymphoscintigraphy exams in a very short time period, were retrospectively included. These paired lymphoscintigraphies were compared regarding the number and location of sentinel nodes (SN) and drainage pathways and classified accordingly into 2 different groups: group: 1 - perfect overlap (same number of SN and in the same clusters); 2 - partial or no overlap (different number of SN and/or in different clusters). **Results:** 17 patients were included (mean age 66 ± 10.8 years). The average time between paired exams was 15 ± 8 days. Perfect overlap was found in 82% (14) of the patients (same number of SN and in the same clusters). Two patients did not show the same number of SN, in the same clusters, and one patient that did not show a perfect overlap, with one additional SN in a different cluster. In the latter case, this SN had very few radioactive counts per minute and was not surgically removed in the operating theatre the following day due to the absence of measurable radioactivity. **Conclusion:** Sentinel node lymphoscintigraphy is an extremely reproducible technique. **References:** None

¹Vita-Salute San Raffaele University, Milan, ITALY, ²Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute,

Milan, ITALY, ³Radiology Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, ⁴Unit of Obstetrics and Gynaecology, IRCCS San Raffaele Scientific Institute, Milan, ITALY, ⁵University Centre of Statistics in the Biomedical Sciences, Vita-Salute San Raffaele University, Milan, ITALY, ⁶Unit of Pathology, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim/Introduction: The aim of the present study is to explore the diagnostic performance and predictive value of fully hybrid 18F-FDG PET/MRI in the preoperative staging of endometrial cancer. **Materials and Methods:** 16 pts with biopsy-proven endometrial cancer were prospectively enrolled. All pts underwent preoperative fully hybrid 18F-FDG-PET/MRI for initial staging, between December 2018 and May 2019. All patients underwent surgery, with availability of histological examination as reference standard to assess the diagnostic performances. PET/MRI findings were compared to FIGO staging score. In addition to qualitatively evaluation, semi-quantitative PET (SUVmax, SUVmean, MTV, TLG) and MRI (Volume index, ADCmean, ADCmin, Ktrans and Kep) parameters were evaluated on the primary tumour and their role in predicting myometrial invasion (MI) or lymphovascular invasion (LVSI) was assessed. **Results:** Patients' median age was 65 yrs (range: 52–86). 18F-FDG PET/MRI identified the primary tumour in all pts. Thirteen/16 patients had endometrioid tumor, 1/6 had mixed-serous carcinoma, 1/6 had a malignant mixed-mullerian tumour and 1/16 serous histotype. 18F-FDG PET/MRI detected lymphnodal involvement in 5/16 pts, confirmed by histology in 4/5 while in 1/4 chronic reactive lymphadenitis was diagnosed. Accuracy, sensitivity, specificity and PPV in the assessment of lymph node metastases were 93%, 100%, 91%, 80% and 100%, respectively. 18F-FDG PET/MRI was in agreement with FIGO score in 10/16 pts (62.5%). Discordant results were: histologically proven micrometastatic peritoneal (2/6) or lymphnodal (1/6) involvement not detected by PET/MRI; lymphnodal chronic inflammation (1/6) reported as metastatic on PET/MRI; myometrial invasion higher than 50% (1/6) at HE, compared to MRI finding of myometrial invasion <50%; presence of lung metastases assessed only by PET/MRI. MTV predicted LVI with a cut-off value of 18.9 and correspondent sensitivity and specificity of 80% and 90%, respectively (p=0.0495). MRI volume index was able to predict LVI (p=0.0207). Neither PET nor MRI parameters were able to predict myometrial invasion. **Conclusion:** 18F-FDG PET/MRI has good diagnostic performance in preoperative staging of endometrial cancer; despite the possibility of false positive and negative results, it provides a whole body staging with detection of distant metastases beyond the surgical FIGO staging. PET and MRI parameters has synergic role in preoperatively predicting myometrial and lymphovascular invasion. **References:** None

OP-463

Validation Study Of Sentinel Lymph Node Biopsy In The Staging And Treatment Of Endometrial Cancer

D. Patrut, J. Alors Ruiz, I. Sanchez Urbaneja, O. Rahmouni, J. Oliva Pastor, S. Sanz Viedma;
University Hospital Virgen de la Victoria, Málaga, SPAIN.

Aim/Introduction: Sentinel Lymph Node Biopsy (SLNB) emerged as an alternative to complete lymphadenectomy in patients with endometrial cancer. The aim of this study is to evaluate the utility of SLNB in the staging and treatment of women diagnosed with endometrial cancer. **Materials and Methods:** 64 patients with endometrial cancer were prospectively included between January 2014 and December 2019. A lymphoscintigraphy was performed the day prior to the intervention by injecting the patients with 4mCi of ^{99m}Tc-nanocolloid. Static planar images at 30 minutes and 3 hours post-injection, and a SPECT/CT were acquired. After the induction of general anesthesia, methylene blue dye was injected in the cervix, prior to the surgical procedure. The SLN was identified with the laparoscopic or conventional gamma-detection probe. Completion pelvic/para-aortic lymphadenectomy was performed, regardless of the SLNB result. The SLN was analyzed by hematoxylin-eosin staining and immunohistochemistry. **Results:** SLN detection rate was 81.25%, with 41.67% bilateral detection. SLN was negative in 45 cases (25 being low-risk, 13 intermediate-risk and 7 high-risk) with posterior negative lymphadenectomy. There were no false negatives (NPV: 100%, Sensitivity: 100%). The incidence of metastases was 10.7% (7 patients): 5 macrometastases and 2 micrometastases. Intraoperative analysis of SLN showed a false negative rate of 57.1%. Ultrastaging in SLN detected 28% more metastases. 3 out of 60 performed lymphadenectomies showed positive lymph nodes. In the pre-operative staging, 40 cases were classified as low-risk, 14 as intermediate-risk and 4 as high-risk, while post-operative staging modified the stage in 39.7% of the cases. **Conclusion:** SLNB can be considered an adequate technique for standardizing the surgical management of the lymphatic system (mainly in low and intermediate risk cases), allowing the selection of patients who would truly benefit from a lymphadenectomy, and those in whom this procedure could be avoided. **References:** None

18F-FDG PET/CT Radiomics Of Cervical Cancer In Predicting Lymph Node Metastasis

L. Monaco¹, G. Mathoux¹, C. Crivellaro², F. Elisei², A. Buda³, R. Fruscio^{4,3}, C. Landoni^{4,2}, L. Guerra^{4,2}, C. Messa⁵, E. De Bernardi⁴;
¹University of Milan–Bicocca, Milan, Lombardia, ITALY, ²Nuclear Medicine Department, ASST Monza San Gerardo Hospital, Monza, ITALY, ³Gynaecologic Oncology Surgical Unit, Obstetrics and Gynaecology Department, ASST Monza San Gerardo Hospital, Monza, ITALY, ⁴School of Medicine and Surgery,

University of Milan–Bicocca, Milan, Lombardia, ITALY, ⁵Tecnomed Foundation, University of Milan–Bicocca, Milan, Lombardia, ITALY.

Aim/Introduction: Cervical cancer is the second most frequent diagnosed gynecological tumor and the third leading cause of cancer death among females in less developed countries. The aim of the study was to evaluate the role of 18F-FDG PET/CT in preoperative assessment of N-staging in early stage cervical cancer patients. In addition, radiomics features extracted from primary lesion FDG uptake were correlated to the presence of lymph node metastases. **Materials and Methods:** From March 2006 to April 2019, 74 cervical cancer patients in early stages were retrospectively considered. All women underwent 18F-FDG PET/CT before surgical staging with pelvic lymphadenectomy. Histology was used as standard reference. PET cervical lesions were contoured with PETVCAR (GE Healthcare) by using iterative threshold. SUVmax, SUVmean, MTV, TLG and radiomics features were computed inside tumor contours using standard Image Biomarker Standardization Initiative (IBSI) methods. Radiomics features associated with lymph-node metastases were identified by Mann-Whitney test. Receiver operating characteristic (ROC) curves and area under the curve (AUC) values were computed and optimal cut-off (Youden index) was assessed. **Results:** In our study 14/74 patients had nodal metastases at histology (18.9%): 5/14 correctly identified by PET/CT with 9 false negative cases. Sensitivity, specificity, accuracy, positive predictive value and negative predictive value of PET/CT for pelvic nodal metastases were 36%, 93%, 82%, 55%, 86%, respectively. A significant correlation was observed between MTV (p value= 0,013; AUC= 0,72 ; cut-off= 17ml) and the presence of nodal metastasis. Among radiomics features, a significant correlation was found between the presence of nodal metastases and Inverse Difference- Grey Level Co-occurrence Matrix (p value=0,03, AUC=0,76, cut-off =0,17), that is an homogeneity index. No significant correlation was found for SUV parameters. **Conclusion:** PET/CT demonstrated low sensitivity, high specificity and high NPV in detecting pelvic nodal metastases in preoperative staging of cervical cancer. These preliminary data suggest a promising application of radiomics PET for predicting the presence of nodal metastases in cervical cancer; further studies on larger populations are needed. **References:** None

Sentinel lymph node detection in oral cancer: a head to head comparison between [^{99m}Tc]Tc-Tilmanocept and [^{99m}Tc]Tc-Nanocoll

R. Mahieu, I. J. den Toom, R. van Rooij, R. J. J. van Es, M. G. Hobbelink, G. C. Krijger, B. M. Tijink, B. de Keizer, R. de Bree; University Medical Center Utrecht, Utrecht, NETHERLANDS.

Aim/Introduction: Sentinel lymph node (SLN) biopsy has

proven to reliably stage the clinically negative neck in early-stage oral cavity squamous cell carcinoma (OSCC). [^{99m}Tc]Tc-Tilmanocept has been specifically designed for SLN detection. Due to its proposed rapid clearance from the injection site, rapid uptake and high retention within SLNs, and low uptake in higher echelon nodes, [^{99m}Tc]Tc-Tilmanocept may be of benefit in OSCC with complex drainage patterns and close spatial relation to SLNs. **Materials and Methods:** A monocenter prospective within-patient evaluation study was designed to compare [^{99m}Tc]Tc-Tilmanocept (74MBq) with [^{99m}Tc]Tc-Nanocoll (120MBq; 74MBq) for SLN detection. A total of 20 patients with early-stage OSCC were included, who underwent lymphoscintigraphy for both [^{99m}Tc]Tc-Tilmanocept and [^{99m}Tc]Tc-Nanocoll. Both lymphoscintigraphic images of each patient were evaluated for SLN detection and radiotracer distribution at 2-4 hours postinjection (i.e. injection site retention, uptake in SLNs). **Results:** A median of 3.0 and 2.5 SLNs were identified with [^{99m}Tc]Tc-Tilmanocept and [^{99m}Tc]Tc-Nanocoll, respectively (p=0.271). A median of 2.0 and 2.5 higher echelon nodes were identified with [^{99m}Tc]Tc-Tilmanocept and [^{99m}Tc]Tc-Nanocoll, respectively (p=0.103). Radioactive uptake in SLNs was significantly higher for [^{99m}Tc]Tc-Nanocoll (3.16%) compared to [^{99m}Tc]Tc-Tilmanocept (1.95%) (p=0.010). Radioactive uptake in higher echelon nodes was not significantly different between [^{99m}Tc]Tc-Nanocoll (0.86%) and [^{99m}Tc]Tc-Tilmanocept (0.57%) (p=0.052). The injection site's remaining radioactivity was significantly lower for [^{99m}Tc]Tc-Tilmanocept (29.9%; SD±7.6), compared to [^{99m}Tc]Tc-Nanocoll (60.9%; SD±16.1) (p<0.001). No significant difference was seen in SLN to injection site ratio in radioactivity between [^{99m}Tc]Tc-Nanocoll (0.054) and [^{99m}Tc]Tc-Tilmanocept (0.067) (p=0.232). **Conclusion:** The significantly higher injection site clearance and slightly, although not statistically significant, improved SLN to injection site ratio of [^{99m}Tc]Tc-Tilmanocept may benefit SLN detection, particularly in situations with close spatial relation between injection site and SLNs. However, the relatively low radioactive uptake in SLNs of [^{99m}Tc]Tc-Tilmanocept may limit intraoperative detection of SLNs, but can probably be overcome by higher injection dose **References:** None

Use of ^{99m}Tc-Tilmanocept for selective sentinel lymph node biopsy in oral cavity tumours. Our experience at Hospital Clínic in Barcelona, Spain

R. Valhondo-Rama^{1,2}, C. Martí Pagés¹, A. Perissinotti¹, A. Tapias Mesa¹, N. Sánchez Izquierdo¹, A. Ferrer Fuertes¹, R. Sieira Gil¹, M. Cámara Vallejo¹, E. García Díez¹, S. Vidal-Sicart¹; ¹Hospital Clínic, Barcelona, SPAIN, ²Hospital Clínic San Carlos, Madrid, SPAIN.

Aim/Introduction: To assess our initial experience with ^{99m}Tc-Tilmanocept for selective sentinel lymph node biopsy (SLNB)

in oral cavity tumours. **Materials and Methods:** Retrospective analysis of 16 patients with oral cavity cancer who underwent a SLNB procedure by means of perilesional injection of ^{99m}Tc -Tilmanocept. The variables collected were the following: age, sex, type of tumour, laterality, initial stage, number of sentinel nodes (SN) visualized by lymphoscintigraphy, if there was secondary drainage, number of SN biopsied, anatomical territories, anatomopathological result and if there were relapses. **Results:** The mean age was 68.9 years (range 57–90). 50% males and 50% females. One of the 16 cases (6.25%) presented melanoma on the palate. The rest (93.75%) were diagnosed of squamous cell carcinoma: 8 on the tongue (53.33%), 3 on the gingiva (maxillary-mandibular) (20%), 2 on the floor of the mouth (13.33%), 1 on the palate (6.67%) and 1 in the jugal mucosa (6.67%). Six cases had the primary tumour involvement in their left side (37.5%), 6 right (37.5%) and 4 bilateral or midline (25%). Ten had initial T1N0 stage (62.5%). Lymphoscintigraphy showed 52 SN in total (11 at cervical level I, 20 at level II, 13 at level III, 4 at level IV and 4 at level V), obtaining a mean of 3.25 SN per patient. Secondary drainage was evident in 10 cases (62.5%). Intraoperatively, 51 SN (10 at level I, 20 at II, 13 at III, 4 at IV and 4 at V) were biopsied, resulting in 3.19 SN/patient. Two out of 16 patients (12.5%) had metastatic SN. Regional lymphadenectomy was performed in one of them (6+/8), who subsequently suffered a relapse. The other patient with positive SN is awaiting lymphadenectomy. Another patient (12.5%) - whose SN had been negative - developed a second primary tumour of the oral cavity with lymph node involvement 10 months later. **Conclusion:** ^{99m}Tc -Tilmanocept is a valid radiotracer for SLNB in tumours of the oral cavity, with good results in locating SN at cervical lymphatic level I. Secondary drainage is also observed with ^{99m}Tc -Tilmanocept. **References:** None

Improved radiooncological management by FAPI-PET/CT as primary staging for patients with esophageal cancer

S. Koerber^{1,2,3}, J. Ristau^{1,2,3}, F. Staudinger⁴, J. Schlittenhardt⁴, M. F. Haefner^{1,2,3}, C. Kratochwil^{4,5}, T. Lindner⁴, J. Debus^{1,2,6}, U. Haberkorn^{4,5,6}, F. L. Giesel^{4,5,6}

¹Department of Radiation Oncology, Heidelberg University Hospital, Heidelberg, GERMANY, ²Heidelberg Institute of Radiation Oncology (HIRO), Heidelberg, GERMANY, ³National Center for Tumor diseases (NCT), Heidelberg, GERMANY,

⁴Department of Nuclear Medicine, Heidelberg University Hospital, Heidelberg, GERMANY, ⁵Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, ⁶German Cancer Consortium (DKTK), partner site Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: FAP-ligands in oncology has recently shown as very promising PET tracers with also equal or even superiority to FDG. Therefore, the current study

aimed to evaluate the potential of FAPI-PET/CT for the primary assessment of patients with esophageal cancer and its usefulness in radiotherapy planning as a first clinical analysis. **Materials and Methods:** FAPI-PET/CT imaging was performed for a cohort of seven patients (median age: 63.5 years) with treatment-naïve esophageal carcinoma undergoing irradiation. Six patients obtained definitive radio(chemo)therapy, one patient had an indication for neoadjuvant chemoradiation. All patients were referred to the experimental diagnostics by their caring oncologist/therapist. Tumor uptake was quantified by standardized uptake value (SUV)_{max} and SUV_{mean} (60% isocontour). Consequences for radiooncological management were documented after image evaluation and comparison with conventional imaging and/or clipping. **Results:** For almost all patients, uptake of FAPI tracer was high in primary tumor tissue with a median SUV_{max} of 17.23. Excellent tumor-to-background ratios resulted in improved target volume delineation. FAPI imaging led to dose escalation (simultaneous integrated boost) for nodal metastases in two patients. For three patients (42.9%) with multiple small nodes, boost irradiation was omitted due to absence of significant FAPI tracer uptake. In all patients who underwent pretherapeutic endoscopic clipping of the tumor margins, conformity of tracer uptake and clipping distance was considerably well-matching. **Conclusion:** FAPI-PET/CT was able to demonstrate very promising results in esophageal cancer for tumor delineation and tumor-to-background contrast in radiooncological management. With these very promising results, FAPI should be more explored in other cancer entities for improved radiooncological treatment purposes. **References:** None

Cutting Edge Science Track - TROP Session: Dosimetry Methods and Models - Part 1

Saturday, October 24, 2020, 09:00 - 10:30

Channel 6

OP-468

Is a single late SPECT/CT-based kidney ^{177}Lu -dosimetry superior to dosimetry with sequential whole-body scans in combination with an early SPECT/CT?

S. Beykan¹, J. Tran-Gia¹, S. B. Jensen^{2,3}, M. Lassmann¹;

¹Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY, ²Department of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, ³Department of Chemistry and Bioscience, Aalborg University, Aalborg, DENMARK.

Aim/Introduction: The aim is to find a more practical and equally accurate alternative for the time-consuming multiple SPECT/CT based dosimetry. For that reason, dosimetry was performed based on data from an in-vivo

pig study (1) as well as data from a 3D-printed kidney phantom using three different dosimetry approaches (multiple SPECT/CT [MS, gold standard], multiple planar + 1 SPECT/CT [MP1S], single time-point SPECT/CT (2)[STS]). **Materials and Methods:** Planar and SPECT/CT scans were performed for five ^{177}Lu -OPS201 injected pigs at 4h-298h (injected activity: 102-113 MBq) and a phantom (injected activity: 4 MBq, time-points simulated by adjusting acquisition duration based on pig 1 data). The kidney time-integrated activity coefficients (TIACs) and absorbed doses (kidneyADs) of the pigs and phantom were calculated applying three methods MS, MS1P, STS at 54h, 101h, 148h, 293h. In addition, to show the effect of late scans on AD calculation, MS- and MS1P-based TIACs difference of pig 1 and phantom were calculated by eliminating the late two time-points. **Results:** In comparison to MS, the mean difference in kidneyADs of pigs was $-31\pm 19\%$ for MP1S (pig 2 excluded: +40%) and it was in the range of $-23\pm 12\%$ to $-13\pm 9\%$ for STS. The STS-based kidneyADs of pigs at all time-points resulted in lower kidneyADs in comparison to MS. STS at 101h showed the best agreement with MS-based kidneyADs (mean deviation: $-12.5\pm 9\%$). Higher differences were observed between MP1S- and MS-based kidneyADs associated with organ activity overlay on planar scans. Based on phantom and pig 1 experiments, MP1S-based kidney TIAC was lower than MS results respectively 42% for pig 1 and 3% for the phantom. Eliminating late time-points resulted in up to 56% higher TIACs for pig 1 (MS) and the phantom (MS and MP1S), whereas the MP1S-based TIACs for pig 1 decreased by 10%. **Conclusion:** MS gives the most accurate results, but it is time-consuming and, therefore, difficult to integrate in clinical routine. For MS, scans acquired after 120h are essential for accurate absorbed dose calculations since lack of late follow-up scan time points results in over- or underestimations of the ADs. MP1S, considered as a potential alternative, showed, however, high differences associated with organ overlay. STS-based dosimetry, with a single SPECT/CT acquired after ~4 days, is less time-consuming and results in ADs, which are systematically lower with a small deviation ($12.5\pm 9\%$) compared to MS. **References:** 1. OP-469

In pursuit of fully automated dosimetry: evaluation of an automatic VOI propagation algorithm using contour intensity-based SPECT alignments

D. Mirando¹, Y. K. Dewaraja², N. M. Cole¹, A. S. Nelson¹;

¹MIM Software, Cleveland, OH, UNITED STATES

²University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: Personalised dosimetry has emerged as a promising tool for treatment planning and prediction

of patient outcomes in molecular radiotherapies. Time requirements of image segmentation contribute to high burdens associated with dosimetry, especially dosimetry with multiple SPECT/CTs for which 3D segmentation is required on all timepoints. Here, a fully automated method of propagating kidney and tumour volumes of interest (VOIs) to subsequent timepoints is compared to manual transfer and adjustment. **Materials and Methods:** After the first cycle of ^{177}Lu -DOTATATE in 10 patients, SPECT/CT images were acquired. Kidney VOIs were manually segmented on the first post-injection CT image, while a radiologist defined tumour VOIs on the diagnostic CT and rigidly transferred these to the first CT. In the manual method of propagation, VOIs were rigidly transferred to each subsequent SPECT/CT timepoint before visual fine-tuning by the radiologist. In the automatic approach, subsequent SPECT images were first rigidly registered to the first SPECT. The SPECT intensity information within a 1cm expansion zone around each VOI was then used to perform local rigid registrations between the images, which were spliced together to generate a composite image aligned to the first SPECT. VOIs were then directly propagated to each timepoint. For both VOI propagation methods, total activity in each VOI was recorded at each timepoint and organ-level biexponential fitting was applied and integrated [1]. **Results:** Fully automatic VOI propagation resulted in average activity measurements on subsequent SPECT scans that deviated from the manual method by 3.6% (95% CI: [-8.4%, 10.5%]) in kidneys and 2.3% (95% CI: [-8.0%, 12.5%]) in tumours, excluding 1 outlier with minimal uptake where the difference was 30.4%. The time-integrated activity deviated by 0.3% (95% CI: [-8.0%, 8.7%]) for kidneys and 1.9% (95% CI: [-17.8%, 21.7%]) for tumours (12.8% for the outlier). **Conclusion:** Automatic VOI propagation using contour intensity-based SPECT alignments showed good agreement with the activity from manual propagation/adjustment. It is worth emphasizing that the manual reference method is not a gold standard. Indeed, visual inspection reveals cases where the automatic propagation worked excellently despite moderate deviations from the manual method, suggesting that it can sometimes outperform the manual method. Notably, the generation of composite aligned SPECTs in this automatic method permits voxel-based activity integration and dose calculation. Combined with recent advances in neural network-based segmentation [2], such a technique can allow for completely automated dosimetry. **References:** [1] Sarrut et al, MedPhys, 2017. OP-470

^{177}Lu dosimetry may be obtained on a whole-body scale through serial high-speed CZT-SPECT recordings

L. Imbert, E. Chevalier, C. Boursier, V. Roch, G. Karcher, P. Marie;

CHU Nancy Hopital Brabois Adultes, Vandœuvre-lès-Nancy, FRANCE.

Aim/Introduction: Although ^{177}Lu radionuclide therapy is increasingly used in clinical routine, its dosimetry remains difficult to assess, requiring long recording times on standard gamma-camera systems. However, this issue could be overcome with new CZT-SPECT imaging systems. The whole-body Veriton[®] 360[°] CZT-camera (Spectrum Dynamics Medical) is equipped with 12 swiveling detectors, which can be positioned in very close proximity to each part of the body during acquisitions, thereby providing a high count-sensitivity that is particularly advantageous for the current low-count rate conditions of ^{177}Lu imaging. The aim of this study was to evaluate the feasibility of monitoring Lutathera[®] dosimetry on a whole-body scale through serial high-speed recordings provided by this CZT camera. **Materials and Methods:** SPECT and low-dose CT whole-body recordings lasting 20 minutes or less were obtained with the Veriton[®] camera at 4, 24 and 48 hours, and at 7 days after a full-dose Lutathera[®] injection in 3 patients with neuroendocrine tumors. SPECT images were recorded on the 113 keV ($\pm 10\%$) energy peak and reconstructed with CT-based attenuation correction, scatter correction and resolution recovery, a method already validated for absolute quantification on an IEC body phantom. The total-body dose, as well as individual doses received by kidneys, liver, spleen, bone marrow and tumors, were calculated using MIM SurePlan[™] MRT software. **Results:** The whole-body SPECT images exhibited a high signal-to-noise ratio, even at 7 days after injection. For the three patients, mean absorbed doses expressed per MBq of injected Lutathera[®] were variable and ranged from 0.07 to 0.09 mGy/MBq for bone marrow, 0.21 to 0.30 mGy/MBq for kidneys, 0.16 to 0.78 mGy/MBq for liver, and 0.17 to 0.48 mGy/MBq for spleen. These values are in the range of those documented within the literature for ^{177}Lu dosimetry measured on thoracic and abdominal recordings provided by conventional gamma-camera systems. Mean tumor doses ranged from 1.15 to 2.55 mGy/MBq and finally, the mean total-body dose ranged from 0.028 to 0.037 mGy/MBq, a variability due to differences in body size and in the elimination rate of Lutathera[®]. **Conclusion:** from the Veriton[®] camera. This original tool could help enhance the medical monitoring of ^{177}Lu -based therapy in clinical routine. **References:** 1. Cremonesi M, Ferrari M, Bodei L, Tosi G, Paganelli G. OP-471

Voxel-wise Prediction of Post-therapy Dosimetry for ^{177}Lu -PSMA I&T Therapy using Deep Learning

S. Xue¹, A. Gafita², Y. Zhao², A. Afshar-Oromieh¹, M. Eiber², A. Rominger¹, K. Shi^{1,2};

¹University of Bern, Bern, SWITZERLAND, ²Technical University of Munich, Munich, GERMANY.

Aim/Introduction: PSMA-directed radioligand therapy (RLT) has become one of the effective treatment options for metastatic castration-resistant prostate cancer (mCRPC). However, individual treatment planning is still not feasible as it is for the external beam radiotherapy. Our group has presented an organ-based research in the prediction of post-therapy dosimetry in EANM 2019. However, an organ-based approach is unable to reveal the heterogeneity of dose distribution and therefore is not sufficient for the realization of treatment planning. In this study, we propose an approach for voxel-wise prediction of post-therapy dosimetry from pre-therapy positron emission tomography (PET) using deep learning. **Materials and Methods:** 30 patients with mCRPC treated with ^{177}Lu -PSMA I&T RLT were retrospectively included in this study. Totally 48 treatment cycles with ^{68}Ga -PSMA-11 PET/CT directly before the treatment and at least 3 post-therapeutic SPECT/CT dosimetry imaging were considered for this proof-of-concept study. Post-therapy voxel-wise dosimetry was calculated using Hermes Voxel Dosimetry. 3D RLT Dose generative adversarial networks (GANs) were developed with a 3D U-net generator and a convolutional neural network (CNN) based discriminator. A dual-input-model was designed to incorporate both information from PET and CT, for the purpose of anatomical coregistration. Both voxel-wise content loss alongside image-wise loss were taken into account for better synthesis performance. 5-fold cross validation was applied to verify the trained network. **Results:** The proposed 3D RLT Dose GANs achieved the voxel-wise mean absolute percentage error (MAPE) of $17.56\% \pm 5.42\%$. The dual-input-model was able to synthesize dose maps with comparable accuracy while preserving anatomical consistency, which achieved a MAPE of $18.94\% \pm 5.65\%$. **Conclusion:** Our preliminary results demonstrate the potential of artificial intelligence to estimate voxel-wise post-therapy dosimetry both qualitatively and quantitatively. This may provide a practical solution to improve the dosimetry-guided treatment planning for RLT. **References:** 1. Sumanasuriya, S. and J. Combined planar and SPECT image method for bone marrow dosimetry during ¹⁷⁷Lu-DOTATATE treatments using deep learning generated synthesized projections

L. Hagmarker¹, J. Svensson², T. Ryden¹, M. van Essen³, A. Sundlöf⁴, K. Sjögreen Gleisner⁵, P. Gjerdtsson³, P. Bernhardt¹;

¹Department of Radiation Physics, Sahlgrenska Academy, University of Gothenburg, Gothenburg, SWEDEN, ²Department of Oncology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, SWEDEN, ³Department of Clinical Physiology, Sahlgrenska academy, University of Gothenburg, Gothenburg, SWEDEN, ⁴Department of Oncology and Pathology, Clinical Sciences, Lund University, Lund, SWEDEN, ⁵Department of Radiation Physics, University of Lund, Lund, SWEDEN.

Aim/Introduction: Post-therapy imaging during treatment with ¹⁷⁷Lu-DOTATATE is time-consuming and at many centres the camera availability is limited. A recent study by Ryden et al showed that it is possible to reduce the number of sampled projections by adding deep learning generated synthesized projections (SIPs), thereby decreasing the acquisition time, without impairing image quality. This study aims to investigate how this approach affects the bone marrow absorbed doses (ADs) determined using a hybrid planar and SPECT-image method, and if it allows for a less demanding strategy for volume-of-interest (VOI) delineation. Evaluation was performed by comparing the ADs when using the full and reduced projection sets, and by analyses of predictive ability of haematological response.

Materials and Methods: This study included 44 patients with advanced neuroendocrine tumours treated with ¹⁷⁷Lu-DOTATATE at Sahlgrenska University Hospital (ILUMINET-study, EUDRACT nr 2011-etc). ADs were calculated using a hybrid planar and SPECT-image method. Cross-doses from high-uptake organs and the remainder of the body were determined by time-activity curves created using planar images. The self-dose was determined using the time-activity concentration curve for the remainder of the body adjusted by the activity concentration determined in VOIs placed in the lumbar vertebral bodies in SPECT-images collected at 24 h.p.i. Three VOIs were studied; spheres with radius of 5.5 mm (r5.5) and 10 mm (r10) and the complete lumbar vertebral body (LV). Three reconstructions were performed; using all 120 projections (120), using 30 of the 120 projections (30) and using 30 projections together with 90 synthetic intermediate projections created by a deep Convolutional U-net shaped neural network (30-120SIP). The SPECT-images were reconstructed using the

Monte-Carlo based reconstruction code SARec in the image-platform phONSAi, developed in-house. **Results:** The hybrid method 120 using r5.5, r10 and LV yielded ADs after treatment cycle one of 0.44 (0.22-1.73), 0.45 (0.20-1.64), and 0.45 (0.19-1.51) Gy/7.4 GBq, respectively. There were no significant differences between ADs determined using the 120 and 30-120SIP or using r5.5 and r10. Small differences were found when using only 30 projections and the VOI LV. Significant dose-response relationships were observed between decreased platelet counts and ADs using all reconstruction methods and all VOIs with r-values between -0.53 and -0.57. **Conclusion:** Reducing the number of sampled projections to decrease the acquisition time without significantly affecting the ADs and the dose-response relationships is possible. Smaller spheres might be used instead of a more time-consuming VOI containing the complete vertebral body. **References:** None

OP-473

Bone Marrow Dosimetry for Peptide Receptor Radionuclide Therapy using Patient-specific Pharmacokinetic Models

L. Carnegie-Peake, J. Taprogge, J. Gear, G. Flux;
Royal Marsden Hospital NHS FT, London, UNITED KINGDOM.

Aim/Introduction: A bone marrow (BM) absorbed dose limit of 2 Gy is typically prescribed in peptide receptor radionuclide therapy (PRRT) due to the radiation-induced haematological toxicity [1,2]. BM dosimetry is therefore necessary to ensure this limit is not exceeded. According to EANM guidance, the activity retention in blood can be used as a surrogate for the activity retention in bone marrow. However, if blood samples are not routinely acquired, whole-body (WB) and organ activity retention data can be used to develop patient-specific pharmacokinetic (PK) models to determine the activity retention in blood from which the BM dosimetry may be obtained. **Materials and Methods:** Bone marrow dosimetry for 9 patients treated with Y-90 DOTATATE was derived from the absorbed dose delivered to blood, calculated from patient-specific PK models constructed from activity retention data for liver, spleen, kidneys, whole-body and tumours [3]. Published OLINDA S-values were applied to the TIAs to calculate bone marrow absorbed doses. **Results:** Serum TIA values ranged from 1004MBq.h to 7411MBq.h (4030 ± 2217MBq.h) were determined. The serum TIAs ranged from 0.7% to 8.4% of the WB TIA (4.5±2.7%). WB and serum TIAs predicted by the PK model were used to perform bone marrow dosimetry. Bone marrow absorbed doses ranged from 0.5Gy to 2.1Gy (1.2±0.7Gy). The PK-derived serum activity retention curves and the bone marrow absorbed doses showed good agreement with previously published values. **Conclusion:** It has been shown that it is feasible to extract serum activity retention curves in PRRT using patient-specific PK models

in the absence of blood samples. Direct validation of PK-derived serum activity retention curves is required through prospective blood sample collection on future patients. **References:** [1] Bergsma, H., et al., Subacute haematotoxicity after PRRT with (177) LuDOTA-octreotate: prognostic factors, incidence and course. *Eur J Nucl Med Mol Imaging*, 2016. 43(3): p. 453-63. Improved prediction of haematological toxicity during [177Lu]Lu-DOTA-TATE therapy by optimising serial SPECT-CT red marrow dosimetry

J. Tipping¹, E. Page¹, N. Calvert¹, D. Hamilton¹, D. Cullen², E. Price², S. Pells², G. Needham², P. Manoharan¹;

¹The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM, ²The University of Manchester, Manchester, UNITED KINGDOM.

Aim/Introduction: This research compared red marrow absorbed dose estimations following Peptide Receptor Radionuclide Therapy (3D Image Based (IB) versus Blood Based (BB) methods), and dose correlations with haematological toxicity. **Materials and Methods:** Data were acquired during cycle 1 of [177Lu]Lu-DOTA-TATE therapy for a cohort of PRRT patients. Red marrow dosimetry was performed using BB methods and IB methods using serial SPECT/CT methods, with dose uncertainties estimated. The effect on total dose (due to self & cross-irradiation) was assessed for two different cross-irradiation models (simplistic versus realistic). The strength and significance of the correlation between dose and post therapy platelet toxicity were assessed for each dosimetry method. The effect of exposure to prior treatments on dose toxicity correlations was also assessed. **Results:** Early results indicate that IB methods delivered significantly higher red marrow absorbed doses than BB methods (mean increase of a factor of 3 when cross-irradiation was included). Choice of cross-irradiation model had a significant impact on total dose magnitude for both BB and IB techniques. Dose response analysis of these initial results indicate that the simplistic cross-irradiation model gave the strongest and most significant dose - toxicity correlations for both IB and BB methods. The most realistic activity distribution model produced significant correlations only with IB methods for therapy naïve patients. **Conclusion:** Red marrow absorbed doses measured from serial SPECT were significantly higher than those from serial blood measurements. IB absorbed doses produced stronger and more significant correlations for therapy naïve patients than BB absorbed doses.

Calculation of absorbed dose distribution for Selective Internal Radiation Therapy (SIRT) using Monte Carlo Method

M. Maciak¹, P. Piasecki², E. Iller³;

¹National Centre for Nuclear Research, Otwock, POLAND,

²Department of Interventional Radiology, Military Institute of Medicine, Warsaw, POLAND, ³National Centre for Nuclear

Research, Radioisotope Centre POLATOM, Otwock, POLAND.

Aim/Introduction: Radioembolization or Selective Internal Radiation Therapy, SIRT is one of the method applied to treat liver cancer, mainly hepatocellular carcinoma and colorectal metastases. Therapy involves the administration of microspheres containing beta radiation emitter directly to the liver circulatory system. Currently used dosimetry models assumes uniform distribution of the microspheres within the tumor volume but there are some evidences that heterogeneous distribution, especially in large metastases, results in ineffective treatment and finally shortening of the survival time. The aim of this study was to prepare a computational dosimetry model using Monte Carlo Method-based tool, to estimate the distribution of the absorbed dose at the cellular, microscopic level.

Materials and Methods: To build a computational dosimetry model the FLUKA simulation package was used [1,2]. The distribution of microspheres implemented in the model, based on microscopic images obtained for different relative concentration of resin microspheres used for different experiment described elsewhere. Microspheres were defined as pure yttrium spheres with diameter of 32,5 µm (median diameter of resin spheres) and sphere specific activity of 55 Bq per sphere. As the estimator for the absorbed dose calculation, the USRBIN estimator, defined as cuboid of dimensions of 1800 µm x 1300 µm times sphere diameter was used. **Results:** Monte Carlo model for calculation of the absorbed dose and the distribution of the absorbed dose at the microscopic level was prepared. For the microscopic data available for the preparation of the model absorbed dose distributions and total absorbed dose for the samples were calculated and biological studies of the samples were correlated with the doses calculated using the model. **Conclusion:** FLUKA is a valuable tool for preparation dosimetry model for absorbed dose calculation at the microscopic level and it seems to be possible to extend the application of the model to the macroscopic level using DICOM files of the patients who underwent the SIRT therapy to validate the relation of the heterogeneous distribution and the shortening of the survival time. **References:** [1] The FLUKA Code: Developments and Challenges for High Energy and Medical Applications, T.T. ²ImVIA, EA 7535, University of Burgundy, Dijon, FRANCE,

³Department of Vascular & Interventional Radiology, University hospital, Dijon, FRANCE, ⁴Gastroenterology Department, University hospital, Dijon, FRANCE.

Aim/Introduction: Selective internal radiation therapy (SIRT) with ^{90}Y microspheres is an effective option for treatment of advanced hepatocellular carcinoma (HCC). ^{99m}Tc MAA-SPECT-CT pre-treatment dosimetry is systematically performed to estimate the lung shunt fraction and the absorbed doses to tumor and healthy liver. However, the optimal method for determination of target (tumors) contours has not yet been validated. Our aim was here to correlate different ^{99m}Tc MAA-SPECT-CT based dosimetry data and contouring methods with overall survival (OS) in HCC patients treated with SIRT. **Materials and Methods:** 56 patients who underwent SIRT between 2012 and 2019 (33 resin microspheres and 23 glass microspheres) were retrospectively included. Tumours were delineated using 3 methods: MRI-based contours manually drawn by a radiologist and then registered on SPECT-CT via deformable registration (C_{MRI}); MAA-SPECT 10% threshold contouring (C_{SPECT}); overlapping of both volumes ($C_{\text{MRI/SPECT}}$). Three-dimensional voxel-based dosimetries were computed with a research workflow in MiM SurePlan 7.0.1 software. Doses were calculated with the Local Deposition Method. The mean absorbed dose (Dmean) and the Tumor-to-Normal liver uptake Ratio (TNR) were evaluated for all 3 contouring methods. Tumor Response was based on follow-up MRI using mRECIST criteria. Optimal cut-off for each parameter were determined with Receiver Operating Characteristic (ROC) method based on tumor response at 6 months. Univariate and multivariate Cox proportional hazard regression analyses were performed to identify associations with outcome. **Results:** Median follow-up was 34 months during which 24 patients died. The median (IQR) Dmean were 107 Gy (60–169), 134 Gy (76–181) and 164 Gy (106–222) for C_{MRI} , C_{SPECT} and $C_{\text{MRI/SPECT}}$, respectively. Areas under ROC curves were predictive for all 3 Dmean contouring methods, and for TNR with C_{MRI} method only. By multivariate analysis, only Dmean associated with TNR,

both based on C_{MRI} method, were independent prognostic factors for OS ($p < 0.05$ for both). Patients with Dmean $C_{\text{MRI}} > 107$ Gy had an OS = 48.6 vs 15.3 months for others, and patients with TNR $C_{\text{MRI}} > 7.7$ an OS = 48.6 vs 15.7 months ($p < 0.0037$). **Conclusion:** In advanced HCC treated with SIRT, dosimetry based on pre-treatment ^{99m}Tc -MAA SPECT/CT is predictive of tumor response whatever the contouring method. However, only Dmean and TNR determined with radiologic contours (C_{MRI}) are independent predictive factors of survival. The use of radiologic contours registered on ^{99m}Tc -MAA SPECT/CT images should be prospectively considered for helping therapeutic strategy. **References:** None

OP-477

Radioembolization of hepatocarcinoma: dose-response assessment with mRECIST and with a new densitometric method

C. Romanò¹, S. Mazzaglia¹, M. C. De Nile², S. Bhoori³, A. Gabutti⁴, G. Maffi⁴, V. Mazzaferro³, M. Maccauro¹, C. Spreafico⁴, E. Seregni¹, C. Chiesa¹;

Surgery, Hepatology and Liver Transplantation, Foundation

IRCCS Istituto Nazionale Tumori, Milan, ITALY, ⁴Radiology 2,

Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY.

Aim/Introduction: Radiological response evaluation after radioembolization of hepatocarcinoma is often difficult and uncertain with the current consolidated dimensional criteria. We studied a new densitometric response assessment method in comparison with mRECIST in a dose-response study of hepatocarcinoma patients treated with ^{90}Y glass microspheres. **Materials and Methods:** 106 lesions of patients treated 8 days after calibration day were retrospectively analysed. In all the cases, both pre- (^{99m}Tc -MAA SPECT) and post-therapy (^{90}Y -PET) voxel-based dosimetry parameters were computed. In particular, the following variables (Ψ) were considered: mean dose (D), Equivalent Uniform Dose (EUD), average of the Biologically Effective Dose (BEDave), Equivalent Uniform Biologically Effective Dose (EUBED), the minimal dose of the 98%, 70%, 50% and 2% of the VOI (D_{98} , D_{70} , D_{50} , and D_2), and homogeneity index (HI). The consolidated mRECIST and the proposed densitometric criterion were adopted to assess lesion responses. According to the densitometric criterion, the Hounsfield Units (HU) variation within a circular ROI lesion is considered. The response threshold was optimized at 20% of HU decrease in the arterial CT phase. The Ψ -response correlation was assessed. The area under the receiver-operating characteristic (ROC) curve (AUC) of responding/not responding lesions was evaluated. The analysis was repeated stratifying on lesion mass with the median lesion mass as cut-off value (56 g).

Results: The mRECIST method did not show statistically significant Ψ -response correlation, neither with ^{99m}Tc -MAA SPECT nor ^{90}Y -PET dosimetric data. On the contrary, the densitometric method returned statistically significant Ψ -response correlation for all the dosimetric variables with post-therapy ^{90}Y -PET data, and with D , BED_{ave} , $D_{50\%}$ and D_2 using pre-therapy ^{99m}Tc -MAA SPECT images. Higher AUC values were reported with the densitometric (0.71 ± 0.05) with respect to the mRECIST (0.57 ± 0.06) criterion. In all the cases, post-therapy data returned higher AUC values with respect to pre-therapy evaluations, for the low predictive accuracy of MAA simulation. After the stratification on mass, mRECIST gave higher AUC values with respect to the densitometric method when large lesions were considered (mass ≥ 56 g, 4.7 cm diameter if spherical), while the opposite situation was obtained when small lesions (mass < 56 g) were considered. **Conclusion:** The densitometric method gave better correlation between dose and response, and, in general, improved the dose separation between responding and non-responding lesions. Moreover it allowed measuring a higher number of lesions. After lesion mass stratification, it gave better AUC values for small lesions, whereas the mRECIST method showed better AUC for large lesions. **References:** None

OP-478

Radioembolization of hepatocarcinoma with ^{90}Y glass microspheres: clinical implications of low precision of ^{99m}Tc -MAA SPECT/CT dosimetry on lungs and lesions

C. Chiesa¹, S. Mazzaglia¹, M. Maccauro¹, M. C. De Nile², C. Romano¹, M. Mira¹, A. Marchiano³, E. Seregni¹, V. Mazzaferro⁴, C. Spreafico³;

¹Nuclear Medicine, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, ²Post graduate specialization school in Medical Physics, Milan, ITALY, ³Interventional Radiology, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, ⁴HPB Surgery, Hepatology and Liver Transplantation, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY.

Aim/Introduction: In order to define the most accurate individualised treatment planning strategy in radioembolization of hepato-carcinoma with ^{90}Y glass microspheres, we evaluated the frequency and the amount of differences between predicted and actual absorbed doses (AD). **Materials and Methods:** We evaluated two sequential groups of 43+189=232 hepato-carcinoma patients, with 56 and 309 lesions, respectively, with ^{99m}Tc -MAA SPECT/CT and ^{90}Y -PET. They were injected after a decay time of 3.75 and 7.75 days from the calibration time (therefore named “Few-spheres” and “Many-spheres”), with 1 and 2.8 million of microspheres per GBq, respectively. PET images were automatically coregistered to SPECT in order to copy identical VOIs. Incidence of presence of Lung Shunt Fraction (LSF) was compared between planar MAA and ^{90}Y -PET

scans. For patients showing MAA-LSF, lung was included in PET scan. In liver, the difference between paired AD values $\text{AD}^{(90\text{Y})} - \text{AD}^{(99m\text{Tc})}$ and their ratio $\text{ADR} = \text{AD}^{(99m\text{Tc})} / \text{AD}^{(90\text{Y})}$ of lesions and whole non-tumoural tissue were analyzed both as dichotomic and as continuous dependent variables. Independent covariates considered in the univariate analyses were: DA=Different catheter tip positions during Angiography (>2 mm), different interventional radiologist, the time interval between the two sessions; lesion location in anterior/posterior segment; VOI mass (39 g median value adopted as cut-off). **Results:** MAA-LSF was present in 82/232 (35%) patients, while PET-LSF in 16/232 (7%) ($p < 0.0001$). PET-LSF was clinically relevant ($>10\%$) in only 6/232 cases (2.5%). For lesions, Bland-Altman bias (mean difference) and [95% C.I.] were, for “Few-spheres” and “Many-spheres”, respectively: $-29[-324,+265]$ Gy and $-61[-416,+294]$ Gy for lesions; $0.7[-18,+20]$ Gy and $+5[-13,+22]$ Gy for non tumoural tissue. “Few-spheres” showed a significantly better bias, while only a non-significant reduction trend for the 95% C.I.. Exclusion of cases with biasing factors (DA, MAA-LSF, coregistration problem) did not improved these values significantly. The Lin Concordance parameter was affected by low precision (0.70-0.80) for lesions in both groups. Lesion dose difference was associated only with DA ($p=0.0009$) and with lesion mass, with larger ADR (overestimation in simulation) for small masses. ADR was also weakly but significantly correlated with lesion mass (Spearman $r=-0.17$, $p=0.04$), converging with an asymmetric bi-logarithmic funnel-shaped plot to 1 for large masses. **Conclusion:** For lung prediction, ^{99m}Tc -MAA is inadequate. In liver, ^{99m}Tc -MAA predictions on lesions are largely inaccurate on the individual case. The relatively limited mean lesion differences allow to improve average cohort properties (OS, PFS), as reported in literature. However, further improvement may be obtainable through planning on much more accurate whole non-tumoural liver AD. **References:** None

OP-479

Comparison of different voxel-S-value methods for quantitative Y-90 TOF PET dosimetry

G. Chen¹, Y. Dewaraja², G. Mok¹;

¹University of Macau, Taipa, MACAO, ²University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: Converting time-integrated activity to absorbed dose using voxel-S-values (VSV) is an efficient method for voxel-based dosimetry yet its limitation in heterogeneous media is recognized. This study aims to assess the differences among different VSV methods as compared to Monte Carlo (MC) methods for lung, liver, lung-liver interface and tumor absorbed dose based on Y-90 microsphere TOF PET/CT images. **Materials and Methods:** This study included four sets of Y-90 microsphere TOF PET/CT patient data available from the University of

Michigan Deep Blue Data Repository. The PET matrix size was 200*200*122 with a voxel size of 4.07*4.07*3 mm. VSV (Gy/MBq-s) were generated by GATE v.8.0 with a matrix size of 21*21*21 and same voxel size as PET images. Liver, lungs and tumors were manually segmented from CT images and mapped to the corresponding PET images. Tumors could only be delineated on two patients while liver and lungs could be segmented from all patients. Time-integrated activity maps were generated from PET images assuming only physical decay after the acquisition. Investigated VSV methods were liver kernel with density correction (LKD), constant liver kernel (LK), central voxel scaling kernel (CK), lung+liver kernels (LLK) and local deposition (LD). MC results were used as the gold standard. Mean absorbed doses were calculated for tumors, liver, lungs, lung-liver interface, i.e., liver_i and lung_i which are 1.5 cm slabs of liver and lungs extended from the interface, respectively. **Results:** LKD, LK, CK, LLK and LD methods were within 3% of MC for mean liver and tumor absorbed dose. Compared to MC, their average differences were 26%±4.6%, -47.6%±36.2%, -8.6%±34.4%, -8.5%±2.0% and 19.9%±3.6%, for mean lung absorbed dose, 53.2%±10.8%, -61.7%±2.7%, 24.9%±5.7%, -12.8%±3.2% and 46.4%±5.8%, for lung_i, and 4.4%±3.3%, -4.4±3.4%, 6.1%±1.7%, 19.2%±8.0% and -6.7%±4.8% for liver_i. **Conclusion:** Absorbed doses from five VSVs are similar to MC for liver and tumors which are located far from the lung-liver interface. LKD and LD overestimate lung absorbed dose whereas others underestimate it. For the interface, LKD and LK perform reasonably well on liver_i, while LLK performs better on lung_i as compared to others. VSV poses more errors in lung absorbed dose as compared to the liver, especially manifests in the interface. LLK is suggested to obtain the lung absorbed dose, and LKD or LK is suggested to obtain the liver or tumor absorbed dose. **References:** [1] Mikell et al. EJNMMI physics, 2015; 2(1): 16. Correlation Study between PET/MR Radiomics Features, Metabolic Parameters and Staging of Nasopharyngeal Carcinoma

J. Liang;

Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: The study aims to investigate the correlations between PET/MR radiomics features and three metabolic parameters: the maximum standardized uptake value(SUVmax), tumor metabolic volume(MTV), total lesion glycolysis (TLG) , as well as their correlation with TNM staging of Nasopharyngeal Carcinoma(NPC). **Materials and Methods:** The PET/MR imaging data of 100 NPC patients with undifferentiated carcinoma from a medical center were collected. The patients were randomly divided into training group (n = 70) and test group (n = 30). We measured the metabolic parameters (SUVmax, MTV, TLG) of the NPC primary focus with GE post-processing workstation, and used AK software to extract the most relevant radiomics features to NPC staging. Finally, we used the selected radiomics features to establish a logistic regression model. To analyze the correlation between radiomics features, metabolic parameters and the TNM staging, and analyze the correlation between radiomics features and metabolic parameters. **Results:** We extracted 396 radiomics features from the T2WI and the PET image respectively. After the

feature selection, 6 and 3 features were retained. The AUCs of the training and test group of the T2WI model were 0.85 and 0.83, the AUCs of the training and test group of the PET model were 0.84 and 0.82. Spearman correlation analysis showed that metabolic parameters (MTV, TLG), PET radiomics features (GLCMEnergy_AllDirection_offset1_SD, GLCMEntropy_angle0_offset4) were correlated with T stage, and the correlation coefficients were 0.608, 0.770, -0.752, 0.688, respectively; MTV, TLG, PET radiomics features (GLCMEnergy_AllDirection_offset1_SD, GLCMEntropy_angle0_offset4) were correlated with clinical stage, and the correlation coefficients were 0.430, 0.511, -0.470, 0.471, respectively; All metabolic parameters and radiomics features were not correlated with N stage. Pearson correlation analysis showed that T2WI radiomics feature (MinIntensity) was negatively correlated with MTV and TLG, and the correlation coefficients were -0.502, -0.566; PET radiomics feature (GLCMEntropy_angle0_offset4) was positively correlated with MTV and TLG, and the correlation coefficients were 0.692, 0.738, respectively; all features were not correlated with SUVmax. **Conclusion:** PET radiomics features (GLCMEnergy_AllDirection_offset1_SD, GLCMEntropy_angle0_offset4) and metabolic parameters (MTV, TLG) have a strong correlation with T staging and clinical staging of NPC, and all metabolic parameters and radiomics features have no correlation with N staging. T2WI radiomics features (MinIntensity), PET radiomics features (GLCMEntropy_angle0_offset4) are correlated with metabolic parameters (MTV, TLG), while the remaining features are not correlated with metabolic parameters. **References:** None

OP-487

Application Value of PET/MR Radiomics Analysis in Evaluating the Clinical Staging of Nasopharyngeal Carcinoma

J. Liang;

Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: To investigate the value of ^{18}F -FDG PET/MR radiomics model in evaluating the clinical staging of nasopharyngeal carcinoma (NPC). **Materials and Methods:** From June 2017 to October 2019, the clinical data and PET/MR imaging data of 100 NPC patients with undifferentiated carcinoma from a medical center were collected. The patients were randomly divided into training group (n = 70) and verification group (n = 30). All patients were divided into early stage (I - II stage) and advanced stage (III - IV stage). We measured the metabolic parameters (SUVmax, MTV, TLG) of the NPC primary focus with GE post-processing workstation, and used AK software to extract the most relevant radiomics features to NPC staging, then constructed the corresponding radiomics

signature. Multivariable logistic regression analysis was performed with radiomics signature and clinical variables for developing the prediction model. The receiver operating characteristic (ROC) analysis was used to evaluate the prediction model. **Results:** The established radiomics signature has better prediction efficiency for identifying the clinical stage of NPC. The AUCs were 0.749 (95% CI: 0.696 - 0.858) and 0.733 (95% CI: 0.631 - 0.835) in the training group and the verification group, respectively. On multivariable logistic regression, the radiomics signature and total lesion glycolysis (TLG) were considered to be independent and significant risk factors for the stage (I-II stage vs. III-IVb stage) of NPC. The prediction model showed good discrimination in both training group (AUC=0.851, 95%CI:0.799 to 0.893; sensitivity=0.801, specificity=0.734, positive predictive value=0.811, negative predictive value=0.890) and verification group (AUC=0.876, 95% CI: 0.781 to 0.903, sensitivity=0.893, specificity=0.718, positive predictive value=0.701, negative predictive value=0.912). **Conclusion:** The radiomics predictive model which integrated with the radiomics signature and metabolic parameters (TLG) can be used as a promising and applicable adjunct approach for predicting the clinical stage (I-II stage vs. III-IVb stage) of patients with NPC. **References:** None

OP-488

Impact of Primary Tumor Size, SUV_{max} of Primary Tumor and the Most Avid Neck Node on Baseline ^{18}F FDG PET/CT Upon Disease Recurrence in Head and Neck Oropharyngeal SCC using Standardized Imaging Protocol

M. Zaman¹, N. Fatima¹, A. Zaman², U. Zaman³, S. Zaman⁴, R. Tahseen¹;

¹AKUH, Karachi, PAKISTAN, ²Dow University of Health Sciences (DUHS), Karachi, PAKISTAN, ³Dept of Medicine Suny Downstate, Hospital, New York, NY, UNITED STATES OF AMERICA, ⁴Dow Medical College, Dow University of Health Sciences (DUHS), Karachi, PAKISTAN.

Aim/Introduction: Purpose of this prospective study was to find the impact of primary tumor size (Ts), standardized uptake values (SUVmax) of primary tumor and the most avid neck node on disease recurrence in patients with head and neck oropharyngeal squamous cell carcinoma (HNOP-SCC). **Materials and Methods:** We included patients with HNOP-SCC (without distant metastasis - M0 disease) who had pre and post-treatment ^{18}F FDG PET/CT using strict standardized imaging protocol from 2017-2019. Based on follow-up ^{18}F FDG PET/CT findings patients were categorized as disease free (no or minimal ^{18}F FDG uptake \leq background over surgical bed and no distant metastasis) and disease recurrence (^{18}F FDG uptake $>$ background over surgical bed with or without nodal and/or distant metastasis). Ts and SUVmax of primary tumor and the most avid neck

node were compared and impact of these were studied upon disease recurrence. **Results:** Total 112 patients were included. No significant difference was seen in mean age (overall: 60 ± 14 yr.), gender distribution (overall M:F: 69:31%), body mass index (overall: 25.20 ± 5.82) and history of diabetes (overall: 19%) between disease free and disease recurrence groups. Similarly, no significant difference was observed for fasting blood sugar (overall: 110 ± 28 mg%), ^{18}F FDG dose (overall: 169 ± 37 MBq) and uptake period (overall: 70 ± 12 min) between two groups ensuring strict adherence to standardized imaging protocol. Significant difference ($p < 0.05$) was observed between disease free and disease recurrence for Ts (25 ± 10 mm vs. 33 ± 14 mm), SUVmax of primary tumor (6.2 ± 6.8 vs 9.3 ± 7.2) and the most avid neck node (2.1 ± 3.3 vs. 4.7 ± 5.9) and median follow-up (13 ± 12 vs 08 ± 13 months) respectively. Using receiver operating characteristic (ROC) analysis, Ts > 29 mm, baseline tumor SUVmax > 4.6 and nodal SUVmax > 6.2 were found independent predictors for disease recurrence. Nodal SUVmax > 6.2 was found an independent predictor of shortest DFS than Ts and tumor SUVmax. **Conclusion:** We conclude that in HNOP-SCC, primary tumor size (> 29 mm), SUVmax of primary tumor (> 4.6) and the most avid neck node (> 6.2) in baseline ^{18}F FDG PET/CT using standardized imaging protocol are the independent predictors of disease recurrence. Furthermore, SUVmax > 6.2 of the most avid node predicts the shortest DFS than primary tumor size and SUVmax of primary tumor. **References:** None

OP-489

Comparison of 18F-FDG PET / MR and enhanced MR in skull-base bone invasion of nasopharyngeal carcinoma

Y. Xu, S. Wang;

Hangzhou Universal Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: To explore the value of 18F-FDG PET/MR in evaluating skull-base bone invasion of nasopharyngeal carcinoma **Materials and Methods:** 124 patients with NPC who underwent PET/MR and enhanced MR scan. Difference between GTV_{PET} (gross tumor volume), a tumor target region delineated with 30% of SUVmax as a threshold, and GTV_{MR} , a tumor target region delineated with fat suppression enhanced T2 sequence was compared. **Results:** 68 patients showed skull-base bone erosion, of the 68 patients, 24 showed osteolytic bone destruction and 44 showed bone marrow infiltration. The osteolytic bone destruction area is characterized by soft tissue mass signals. The bone marrow infiltration type is characterized by low signal intensity replaced high signal intensity in the bone marrow on the T1-weighted images or when hyperintensity was observed on the fat-suppressed T2WI, and a high signal was seen on DWI. All enhanced scans of the bone invasion area showed abnormal enhancement. The SUVmax [$3.31(1.64,4.95)$] of

the skull base lesion area was significantly lower than that [$9.77(6.47,11.54)$] of the main body of the nasopharyngeal lesion ($Z = -7.143, P < 0.01$). The SUVmax [$3.22(2.44,3.60)$] of bone lesions in bone marrow infiltrating cases was significantly lower than that [$6.18(4.72,7.45)$] of osteolytic bone destruction ($Z = -6.776, P < 0.01$). Among the 44 cases of bone marrow infiltration, FDG metabolism in the visible lesion area was higher than that in the contralateral or surrounding normal bone in 23 cases, and no intense high metabolic region was observed in 21 cases. The area under the ROC curve (AUC) for the evaluation of skull base invasion by SUVmax was 0.866, the SUVmax corresponding to the most approximate index was 1.5, and the sensitivity and specificity were 79.4% and 46.0%, respectively. In osteolytic bone destruction cases, 4.17% (1/24) of the cases of skull-base bone lesions were located outside the GTV_{PET} area, and 61.36% (27/44) of bone marrow infiltration cases were located outside the GTV_{PET} area, there were statistical differences ($\chi^2 = 20.97, P < 0.01$). GTV_{PET} [$35.46(25.27,43.56)$] is smaller than GTV_{MR} [$41.27(30.45,29.58)$] ($Z = -5.316, P < 0.01$). **Conclusion:** Although PET / MR is of great value for staging of nasopharyngeal carcinoma, FDG uptake in the area of skull base invasion is lower than that of nasopharyngeal lesions, and false negatives often occur in bone marrow infiltrating types. Evaluation of skull base bone invasion and radiotherapy target region with PET metabolic range may not be accurate, and enhanced MR is still a necessary detection method for pre-treatment evaluation and efficacy evaluation. **References:** None

18F-FDG PET/Low Dose CT as unique multimodality imaging method to assess bone involvement in Multiple Myeloma patients

C. Ferrari¹, A. Nappi¹, C. Minoia², M. Zappia³, G. Santo¹, P. Mammucci¹, N. Merenda¹, A. Guarini², L. Brunese³, N. Maggioletti³, G. Rubini¹;

¹Nuclear Medicine Department, University of Bari "Aldo Moro", Bari, ITALY, ²Haematology Unit, IRCCS Istituto Tumori "Giovanni Paolo II", Bari, ITALY, ³Radiology Department, University of Campobasso, Campobasso, ITALY.

Aim/Introduction: Imaging plays a crucial role to assess bone involvement in Multiple Myeloma (MM) patients. The International Myeloma Working Group recommends the use of Whole-body Low Dose CT (WBLDCT) instead of conventional skeletal survey in the baseline workup. In the last years, 18F-FDG PET/CT, including both functional and morphological evaluation, has changed the clinical approach to MM patients in staging, restaging and therapy response assessment, particularly in accurately distinguishing active from inactive bone lesions. We aimed to compare the performance of 18F-FDG PET-coregistrated low dose CT (PET/LDCT) with WBLDCT in MM patients.

Materials and Methods: Since July 2018 to September 2019, 33 consecutive MM patients (mean age 67y, range: 53–82y) were prospectively enrolled and underwent WBLDCT during their staging/restaging work-up and PET/LDCT within 30 days. CT acquisition parameters of both WBLDCT and PET/LDCT had been defined to reduce dose exposition (120kV, 50 mAs/rotation, Pitch 0.984, FOV/Matrix 500mm/512, thickness 3.75). WBLDCT and PET/LDCT were evaluated by two independent readers and assessed as positive in the presence of at least one lytic bone lesion, evaluating as both patient-based analysis and region-based analysis, including skull, cervical, dorsal, lumbo-sacral spine, thorax (ribs, sternum, scapula), pelvis, upper and lower limbs. Concordance between the two methods were analyzed by Cohen's k test. **Results:** According to patient-based analysis, WBLDCT and PET/LDCT resulted negative concordant in 3/33 (9%) patients and positive concordant in 29/33 (88%) ($k=0.841$, $p<0.001$). In region-based analysis, concordances in different anatomic regions were: skull ($k=0.937$, $p<0.001$), cervical ($k=1.000$, $p<0.001$), dorsal ($k=0.809$, $p<0.001$), lumbo-sacral spine ($k=0.878$, $p<0.001$), thorax ($k=0.756$, $p<0.001$), pelvis ($k=0.814$, $p<0.001$), upper limbs ($k=0.655$, $p<0.05$) and lower limbs ($k=1.000$, $p<0.001$). No statistically significance differences were found between the two exams both in patient-based analysis and region-based analysis. **Conclusion:** According our experience, PET/LDCT showed comparable performances to WBLDCT. Our preliminary data need to be confirmed in larger cohorts and, if confirmed, lead us to suggest the use of PET/LDCT to assess bone involvement in MM patients as unique morphological and functional imaging method in staging and restaging disease. The combined radiologist-nuclear physician report could allow to avoid further investigations, with impact on patient compliance, radiation exposure and health care spending. **References:** None

FDG-PET/CT in early assessment of immune-related adverse events during first treatment response assessment in melanoma patients treated with immune checkpoint inhibitors

K. Kudura^{1,2}, L. Nussbaumer², S. Bengts^{1,2}, A. Haider^{1,2}, D. A. Ferraro^{1,2}, L. Basler^{3,2}, R. Förster^{3,2}, M. Hüllner^{1,2}, L. Husmann^{1,2}, C. Deubelbeiss^{4,2}, F. Dimitriou^{4,2}, R. Dummer⁴, J. Mangana^{4,2};

¹Department of Nuclear Medicine University Hospital Zurich, Zurich, SWITZERLAND, ²University of Zurich, Zurich, SWITZERLAND, ³Department of Radiation Oncology University Hospital Zurich, Zurich, SWITZERLAND, ⁴Department of Dermatology University Hospital Zurich, Zurich, SWITZERLAND.

Aim/Introduction: The recently introduced immune checkpoint inhibitors already represent an important treatment option in advanced tumor stages including malignant melanoma. Immune checkpoint inhibitors favour

the onset of autoimmune manifestations, often termed immune-related adverse events (IRAEs). Considering their high frequency but also still controversial discussed presumed interaction with treatment outcome an early detection of IRAEs is essential. Aim of this retrospective study is to investigate whether early findings suspicious of common immune-related adverse events after immune checkpoint blockade initiation assessed by FDG-PET/CT performed for early treatment response assessment three months after treatment initiation can be validated by laboratory, radiological findings and/or occurrence of clinical symptoms under immune checkpoint blockade in metastatic melanoma patients. **Materials and Methods:** FDG-PET/CT scans at baseline, 3 months and 12 months after first drug infusion between 2015 and 2017 were retrospectively separately analyzed. Patients were enrolled when FDG-PET/CT scan at 3 months showed new signs of IRAEs compared to previous FDG-PET/CT at baseline. In total 25 patients with histologic proven malignant metastatic melanoma all treated with immune checkpoint blockade. The new findings suspicious of IRAEs on FDG-PET/CT at three months after the first drug infusion were then retrospectively validated by laboratory or radiological findings or onset of new symptoms. FDG-PET/CT scans at 12 months after first treatment were analyzed according to the PET/CT based immune-related response criteria and our cohort dichotomized into two groups: clinical benefit (CR, PR and SD) vs. no clinical benefit (PD). **Results:** Approximately half of our population ($n=12$) showed new findings suspicious of thyroiditis on FDG-PET/CT three months after first drug infusion, followed by 32 % ($n=8$) presenting signs of colitis, 12% ($n=3$) sarcoid-like lymphadenopathy, 4% ($n=1$) hypophysitis and 4% ($n=1$) hepatitis. In 80% ($n=20$) of our patients hybrid imaging based new findings suspicious of IRAEs could be verified by the onset of new symptoms, clinical or radiological findings ($p=0.003 < 0.05$). 68% ($n=17$) of our metastatic melanoma patients benefit from immune checkpoint blockade one year after first drug infusion. **Conclusion:** FDG-PET/CT enables an early reliable detection of immune-related adverse events three months after treatment initiation concordant with clinical, laboratory and radiological findings in metastatic melanoma patients under immune checkpoint blockade. In daily clinical practice, as part of an interdisciplinary tumorboard, FDG-PET/CT performed for first treatment response assessment can also help to detect and treat immune-related adverse events at an early stage and so potentially prevent from possible interaction with treatment outcome. **References:** None

OP-492

Can [18F]FDG PET/CT predict histopathologic response or recurrence after complete surgical resection in prior unresectable stage III melanoma patients treated with

neoadjuvant targeted therapy?

B. van der Hiel, S. Blankenstein, E. Aalbersberg, M. Stokkel, B. van de Wiel, W. Klop, A. van Akkooi, J. Haanen;
the Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.

Aim/Introduction: In unresectable stage III BRAF-mutated melanoma patients, neoadjuvant treatment with BRAF/MEK inhibitors enables surgical resection after sufficient downsizing of the tumour. However, recurrences after radical surgery still occur in these patients. The degree of pathologic (PA) response might act as a predictive biomarker for recurrent disease or survival. [18F]FDG uptake on PET/CT shows a rapid decrease in patients treated with BRAF/MEK inhibitors, even shortly after the initiation of treatment. With this study we aim to investigate whether response monitoring with PET/CT prior to- and during treatment with dabrafenib and trametinib can predict histopathological response or recurrence after complete surgical resection. **Materials and Methods:** Patients with BRAF-mutated, unresectable locally advanced stage III melanoma were included and treated with BRAF- and MEK-inhibitor dabrafenib and trametinib for eight weeks. [18F]FDG PET/CT was performed at baseline and two and eight weeks after the initiation of therapy. Pathological response was assessed on the dissection specimen after surgical resection. Body weight based SUVmax, SUVpeak, and Total Lesion Glycolysis (TLG) were measured. Tumour SUVmean and SULpeak were measured for response monitoring according to EORTC-criteria and PERCIST. Patients underwent PET/CT at follow up every 3 months for 2 years, then every 6 months for 2 years, and once in year 5. **Results:** Twenty patients were included in the study. In eighteen patients sufficient downsizing occurred to perform a resection and assess pathological response. Eight patients (44%) had a pathologic Complete Response (pCR) and ten patients (56%) had a non-pathologic Complete Response (non-pCR). EORTC or PERCIST response measurements did not correspond with pathologic outcome. Median and interquartile range of SUVmax, SUVpeak and TLG at baseline, 2 weeks or 8 weeks did not differ between the pCR and pPR/NR group, nor did absolute or percentage change between baseline and two weeks, baseline and eight weeks or two weeks and eight weeks. Recurrence was evaluated in sixteen patients with R0 resection and no evidence of disease elsewhere in the body. Eight (50%) patients developed recurrence. Six recurrences were detected with imaging only, four of which with PET/CT within 6 months after surgery. PET parameters prior to surgery could not predict recurrence. **Conclusion:** Baseline PET or (early) PET response in previous unresectable stage III melanoma patients could not predict pathologic response or recurrence after treatment with BRAF/MEK inhibitors. However, [18F]FDG PET/CT seems valuable in detecting

recurrence after surgery in these patients. **References:** None

OP-493

The use of [18F]FDG PET/CT to detect early recurrence after resection of high-risk stage III melanoma

B. van der Hiel, E. Stahlie, M. Stokkel, Y. Schrage, W. van Houdt, M. Wouters, A. van Akkooi;
the Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.

Aim/Introduction: To date, international consensus concerning the use of [18F]FDG PET/CT as a surveillance tool in the follow-up of high-risk melanoma patients after complete resection of disease is lacking. Moreover, with the rise of adjuvant therapy it seems appropriate to investigate the role of this imaging modality to exclude newly developed metastases after resection and prior to starting treatment. The aim of this study was to investigate the use of PET/CT in detecting (early) recurrences after complete resection of stage IIIB-D melanoma, either prior to starting adjuvant systemic therapy or within a surveillance program without adjuvant therapy in asymptomatic patients. **Materials and Methods:** Prospectively two cohorts were set up with stage III melanoma patients with complete resection of disease. In the first cohort (stage IIIB/C AJCC 7th) surveillance [18F]FDG PET/CT was performed 6-monthly for two years if patients stayed asymptomatic with normal serum S100B, with a final scan at three years. In the second cohort (stage IIIB/C/D AJCC 8th) patients underwent one screening [18F]FDG PET/CT after resection and prior to starting adjuvant treatment. **Results:** Thirty-five patients were included in cohort one (105 scans) with a median follow-up of 33 months. Twelve patients (34.3%) developed a recurrence which were all discovered by PET/CT, of which seven (20.0%) were detected at the first scan after six months. Seven recurrences occurred in stage IIIC patients, five in stage IIIB patients. Sensitivity and specificity were 92.3% and 100% respectively. Forty-two patients were included in cohort two. Recurrence was suspected on nine scans (21.4%), four (9.5%) of which were true positive. Five (11.9%) scans were false positive. The number of scans needed to find one asymptomatic recurrence were 8.8 and 10.5 in cohort one and two respectively. **Conclusion:** This study demonstrates that [18F]FDG PET/CT is useful for detecting recurrence in high-risk resected stage III melanoma patients, especially within the first six months after surgery. Therefore, PET/CT should be considered when monitoring these patients after complete resection either prior to starting adjuvant therapy and during follow-up protocols. **References:** None

OP-494**PET/CT Evaluation and Patterns of Response to Different Type of Therapies in Patients with Disseminated Melanoma**S. Divosevic¹, M. Sunjic²;¹Medikol Polyclinic, Zagreb, CROATIA, ²Clinical Hospital Centre Sisters of Mercy, Zagreb, CROATIA.

Aim/Introduction: To evaluate the benefit of F 18 FDG PET/CT in follow-up of efficacy of different types of therapy modalities in patients with disseminated melanoma.

Materials and Methods: We examined 171 patients, 91 men, 62 women, 70 on molecular targeted therapy (40 vemurafenib-kobimetinib, 30 dabrafenib-trametinib, group A), 101 patients on immunotherapy (91 pembrolizumab, 10 nivolumab, group B), and 16 on combined therapy (group C). The mean age of patients was 60 years, in the time of primary tumor excision 62 years, in the time of metastases appearance 62 years, approximately 3 years from the primary diagnosis to disseminated disease. We found totally 363 metastases, mainly in the lymph nodes, lung, subcutaneous tissue, skeleton, liver, brain, skin, muscles, spleen, adrenal glands and bowel, consecutively. We performed totally 132 FDG PET/CT scans (52 in group A, 80 in group B, 87 in group C), although 106 patients were followed every time with PET/CT, thus the numbers were 36 patients in group A, 54 in group B, and 16 in group C.

Results: In the group A, 89% of patients were in regression of the disease, 11% in progression, in group B we had 63% of patients in regression and 37% in progression, and in group C 31% of patients were in regression and 69% in progression of the disease. We found 5 pseudoprogessions in 3 immunotherapy patients, in the period of 4-19 months since the beginning of the therapy, which is in concordance to known results from previous studies, but we have only two patients with hypreprogression, which is significantly less than usually known. We found iatrogenic pneumonitis in 3 patients. **Conclusion:** Since the new modalities of therapy for melanoma patients are expensive, and because melanoma can spread throughout the whole body, including skin, subcutaneous tissue and muscles, our results support the importance of PET/CT in evaluation of all the modalities of specific therapy, evaluating the need for continuation or cessation of therapy, changing of treatment modalities, and diagnosis of different side-effects, thus influencing strongly on the quality of patient's life, being at the same moment cost-effective. **References:** None

OP-495**Clinical significance of FDG-PET/CT for Mucosal Melanomas**

K. Kitaguchi, Y. Nakamoto, T. Nomashi, S. Koyasu, K. Miyake, T. Ishimori, T. Saga;

Kyoto University Hospital, Kyoto, JAPAN.

Aim/Introduction: Mucosal melanoma (MM) is a rare and aggressive tumor, which arises in extracutaneous sites from melanocytes present in mucosal membranes of the respiratory, gastrointestinal and urogenital tracts. Clinical role of positron emission tomography/computed tomography (PET/CT) in skin melanoma has been established ¹. However, its utility for MM has not been fully investigated ². The aim of this study was to evaluate the clinical significance of FDG-PET/CT for MM. **Materials and Methods:** A total of 28 patients (median 65 yr, M: F= 15:13) with histologically-proven MM, who underwent PET/CT between May 2009 and September 2019 at our institution, were included in this study. PET/CT was performed for staging in 21 patients and for restaging in 7 patients. Based on the final diagnosis obtained by histopathology or clinical follow-up, the diagnostic performance of PET/CT was evaluated. The prognostic value of multiple PET parameters (SUVmax, SUVmean, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) for the primary tumor) with respect to progression free survival was assessed with the Cox proportional hazards regression model as a sub-analysis. **Results:** The 21 primary sites were as follows: nasal sinus (n=6), digestive tract (n=6), uterus (n=5), oral cavity (n=2), and tracheal bronchus (n=2). The sensitivity and positive predictive value (PPV) of FDG-PET/CT were all 100% for detection of primary sites. For metastases, sensitivity and PPV were 93% and 98%, respectively. There were some lesions identified only by FDG-PET/CT in palate(n=1), paranasal sinus(n=1), esophagus(n=1), small intestine(n=1), and bone(n=11), while brain (n=2) and liver (n=7) metastases were missed. In 18 patients who underwent surgical resection or chemotherapy for a primary tumor in our institution, 16 patients had a recurrence during follow-up (median time, 11.9 months). Higher MTV (p = 0.039) and TLG (p = 0.031) correlated with poorer progression free survival. However, SUVmax, SUVmean, number of lesions were not identified as a significant predictor. **Conclusion:** FDG-PET/CT is a valuable imaging modality for staging and re-staging in mucosal melanoma. Some PET quantitative parameters were suggested to be important prognostic factors for progression free survival. **References:** 1. Perng P, et al. AJR Am J Roentgenol. 2015 Aug;205(2):259-70.2. Increased cerebral glucose consumption during hypoglycemia in obese patients measured using dynamic bolus-injection ^{18}F -FDG PET/MR during hyperinsulinemic euglycemic and hypoglycemic clamp

M. Lubberink, S. Kvernby, N. Abrahamsson, K. Almy, M. Fahlström, M. Gingnell, S. Haller, J. Wikström, M. Sundbom, A. Karlsson, J. Eriksson;
Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Obese patients develop less symptoms and hormonal response during hypoglycemia after gastric bypass surgery (GBP) than before¹. However, it is not known whether cerebral glucose consumption and/or blood flow (CBF), and their response to hypoglycemia, change in obese patients after gastric bypass surgery. The aim of the present work was to develop methodology and assess glucose metabolism and cerebral blood flow (CBF) response to hypoglycemia in obese patients using simultaneous PET/MR. **Materials and Methods:** Eight non-diabetic obese subjects (BMI 35-45) underwent 120-min dynamic scans after bolus injection of 5 MBq/kg ^{18}F -FDG on a Signa PET/MR. Plasma glucose levels were stabilized using a hyperinsulinemic-euglycemic clamp, resulting in normal glycemia with a plasma glucose concentration of 5 mmol/L during the first 50 min of the scan. Between circa 50 and 80 min p.i., plasma glucose concentration was decreased to 2.7 mmol/L. Blood samples were taken to measure plasma glucose and radioactivity. Net uptake rate of ^{18}F -FDG (K_i) and metabolic rate of glucose (MRglu) during euglycemia and hypoglycemia were calculated using a dual-phase basis function implementation of the irreversible two-tissue compartment (2T3k) model allowing for a change in rate constants during the glucose reduction phase, both for whole brain grey matter and at the voxel level. Changes between euglycemic and hypoglycemic CBF were assessed using simultaneous pseudo-continuous arterial spin labelling (pcASL). Accuracy and precision of the dual-phase model were assessed using numerical simulations. **Results:** Mean K_i increased significantly from 0.025 ± 0.003 mL/cm³/min during normal glycemia to 0.059 ± 0.012 mL/cm³/min during hypoglycemia ($p=0.08$, Wilcoxon), corresponding to a significant increase of MRglu from 0.13 ± 0.01 to 0.16 ± 0.03 $\mu\text{mol}/\text{cm}^3/\text{min}$ ($p=0.015$). No significant changes in CBF were found. Agreement between K_i values for normal glycemia based on the dual-phase model and 2T3k was high. Simulations showed a high correlation and agreement

between simulated and fitted K_i values both at normal glycemia and hypoglycemia. Voxel-based results agreed well with whole brain gray matter results, showing a uniform significant increase in K_i in cortex but not in cerebellum. A significant decrease in K_i was found in hypothalamus. **Conclusion:** Simulations indicate that the dual-phase basis function method is able to robustly measure changes in glucose metabolism. Hypoglycemia appears to result in an overcompensation of cortical glucose uptake rate, but a reduction in hypothalamus, in obese patients. This results in slightly but significantly increased average whole brain glucose metabolism compared to normal glycemia. **References:** 1 Abrahamsson et al, Diabetes 2016

OP-508

The Assessment of Intrahepatic Islet Transplantation with Dynamic Exendin PET Imaging

T. J. P. Jansen¹, M. Buitinga^{1,2}, M. Boss¹, M. van der Graaf¹, E. J. P. de Koning³, M. A. Engelse³, M. F. Nijhoff³, I. Velikyan⁴, O. Korsgren⁴, O. Eriksson⁴, M. Brom¹, M. Gotthardt¹;
¹Radboudumc, Nijmegen, NETHERLANDS, ²KU Leuven, Leuven, BELGIUM, ³LUMC, Leiden, NETHERLANDS, ⁴Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Intrahepatic transplantation of islets is performed in patients with complicated type 1 diabetes (T1D) and unstable glycemic control. This procedure leads to improved glycemic control and quality of life. Graft function can however deteriorate over time due to various factors. A tool for the assessment of transplantation success and to measure islet survival in addition to functionality would be of great clinical value. We used dynamic PET imaging with the beta cell-specific tracer ^{68}Ga -exendin to study the presence of intrahepatic islet grafts in T1D patients. **Materials and Methods:** Dynamic PET scans were acquired after intravenous injection with [^{68}Ga]Ga-NODAGA-exendin-4 of 8 T1D patients with functional intrahepatic islet grafts (Tx-group: 4 men, 4 women), and 3 control patients with T1D awaiting islet transplantation (2 men, 1 woman). Islet functionality was biochemically assessed prior to imaging with a mixed-meal tolerance test (MMTT), and presented as C-peptide AUC and peak. Hepatic regions were identified with a minimum uptake (mean+2SD) based on controls. Kinetic modeling was applied to measure tracer accumulation in these regions to determine the distribution volume. Subsequently, the relation between PET signal and islet function was determined. Proton Magnetic Resonance Spectroscopy (1H-MRS) of a voxel positioned in the center of the liver was performed at 3T to check for hepatic steatosis. Relative lipid content was determined by time-domain fitting of the methylene lipid signal at 1.3 ppm and water signal at 4.7 ppm. **Results:** The control and Tx-group did not differ in age (58.7 ± 5.5 vs. 57.6 ± 9.1 years, $p=1.00$), BMI (24.5 ± 4.5 vs. 24.2 ± 3.8 kg/m², $p=0.92$) and HbA1c (62.3 ± 6.1

vs. 46.3 ± 10.0 mmol/mol, $p=0.052$), though C-peptide AUC (22.6 vs. 145.2 nmol.min/L, $p=0.01$) and peak C-peptide (0.24 vs. 1.69 nmol/L, $p=0.01$) significantly differed. The distribution volume (V_t) of the PET tracer was significantly higher in the Tx-group, indicating an increased retention of ^{68}Ga -exendin in the liver (0.43 ± 0.02 vs. 0.57 ± 0.08 , $p=0.01$). There was no significant correlation found in the Tx-group between V_t and C-peptide production, nor between V_t and islet equivalents. No hepatic steatosis was observed in the subjects using 1H-MRS. **Conclusion:** These preliminary data of this explorative study indicate that dynamic PET imaging using ^{68}Ga -labeled exendin is a highly promising tool to monitor survival of pancreatic islet grafts in T1D patients. Imaging can contribute to further elucidate the correlation between beta cell mass measurements and C-peptide production using larger datasets. **References:** None

OP-509

Pancreatic uptake of radiolabeled exendin as a measure of beta cell mass in T2DM before and after bariatric surgery

L. Deden¹, M. Boss², F. Berends³, H. de Boer³, E. Hazebroek^{1,4}, M. Gotthardt²;

¹Vitalys, Rijnstate, Arnhem, NETHERLANDS, ²RadboudUMC,

Nijmegen, NETHERLANDS, ³Rijnstate, Arnhem, NETHERLANDS,

⁴Wageningen University & Research, Wageningen, NETHERLANDS.

Aim/Introduction: An approach for in vivo beta cell imaging is targeting the glucagon-like peptide-1 (GLP-1) receptor by radiolabeled exendin-4. Currently, the role of beta cells in onset, course and remission type 2 diabetes mellitus (T2DM) is not clear. Beta cell mass (BCM) and function (BCF) might be related to T2DM remission after gastric bypass surgery (RYGB). The aim of this study is examining BCF and pancreatic uptake of ^{68}Ga -exendin-4 before and after RYGB in patients with T2DM. **Materials and Methods:** Thirteen patients were included between December 2017 and June 2019. Arginine stimulation test, oral glucose tolerance test (OGTT) and ^{68}Ga -exendin-4-PET/CT were performed pre- and one year post-RYGB. Total pancreatic uptake of ^{68}Ga -exendin-4 per injected activity (kBq/MBq) was measured quantitatively on PET/CT as marker for BCM.

Results: Preliminary analysis in nine patients with complete follow-up was performed. Six were female, mean age of 54 years and mean duration of T2DM was 12 years. Six patients were on insulin therapy (104 ± 53 IU/day), three on metformin (1-2g/day) preoperatively. Postoperatively, average BMI decreased from 39 ± 4.7 to 27 ± 3.7 kg/m² and HbA1c from 63 ± 10 to 47 ± 17 mmol/mol. Preoperatively, pancreatic uptake of ^{68}Ga -exendin-4 was lower in the insulin than in the metformin group; 1.55 [0.53 - 2.66] vs. 2.95 [2.47 - 3.20] kBq/MBq ($p=0.017$). Also, c-peptide response during OGTT was smaller in the insulin than the metformin group (1.1 vs. 2.9 nmol/l, $p=0.015$). Postoperatively, in

the insulin group, one patient had complete remission (no antidiabetics, normal HbA1c), two patients had little improvement (insulin or sulfonylurea, unchanged HbA1c), three patients had improvements in between. Pancreatic uptake increased to 2.29 [1.86 - 3.06] kBq/MBq ($p=0.025$) in this group, which seems to be related to the degree of improvement; relative increase of 56-340% in three patients with most improvement, and 8-30% in patients with least improvement. In the metformin group all patients had complete remission. Pancreatic uptake decreased or remained stable; the relative change varied from -47% to +13%. **Conclusion:** As could be expected, patients with insulin dependent T2DM have lower beta cell mass and function compared to patients with non-insulin dependent T2DM. In the metformin group, average pancreatic uptake of ^{68}Ga -exendin-4 decreased after RYGB, probably reflecting reduction of beta cell hyperplasia. Contrary, insulin-dependent patients with remission or large improvement of T2DM, had increased pancreatic uptake. This may indicate towards recovered beta cell mass and has not been observed in patients so far. Mechanisms of recovering BCM and increasing pancreatic ^{68}Ga -exendin-4 uptake need further investigation. **References:** None

University Hospital Würzburg, Würzburg, GERMANY.

Aim/Introduction: Neurofibromatosis type 2 (NF2) is a genetic disorder that is associated with multiple tumors of the nervous system and approximately one-half of patients present with meningiomas. For patients with multifocal disease, somatostatin receptor (SSTR)-targeted peptide receptor radionuclide therapy (PRRT) might be a suitable systemic treatment option. **Materials and Methods:** Between March 2015 and August 2017, eleven NF2 patients (7 females and 4 males; mean age, 39 ± 12 years) with multifocal, progressive meningiomas underwent a median of 4 cycles of PRRT (range, 2 - 6 cycles). Acute and chronic adverse events were recorded according to NIH Common Toxicity Criteria (CTC) version 5.0. Follow-up magnetic resonance imaging (every 3 to 6 months), using the Response Assessment in

Neuro-Oncology response criteria for meningiomas, were used to assess treatment responses. **Results:** PRRT was well tolerated in all patients without any relevant acute adverse effects. Transient hematologic toxicity (CTC grade 3) was observed in 2 subjects. SSTR-directed radiopeptide therapy resulted in radiological disease stabilization in 6 out of 11 patients. Median progression-free survival of the entire cohort was 12 months (range, 1 - 55 months), overall survival was 37 months (range, 5 - 61 months), respectively. **Conclusion:** PRRT is feasible and well-tolerated in NF2 patients. It might be a suitable treatment option in subjects with multifocal disease. **References:** None

OP-511

Radiosynovectomy is effective in patients with knee replacement and chronic synovitis

K. Liepe, M. Baehr;

Klinikum Frankfurt, Frankfurt (Oder), GERMANY.

Aim/Introduction: After knee replacement, therapy resistant, chronic synovitis is a common problem which causes effusion and pain. Even after arthroscopic surgery of synovitis the rate of relapse is high. It has been hypothesized that radiosynovectomy (RSO) is a useful therapeutic modality in patients with knee replacement and chronic synovitis. **Materials and Methods:** In a single center study, a cohort of 55 patients with 57 knee replacements and chronic synovitis underwent RSO. In summary, 101 joints were treated using 182 ± 9 MBq of ^{90}Y -citrate. The number of performed RSOs ranged from 1 to 4 (53%, 21%, 23%, and 4%). Every patient received a $^{99\text{m}}\text{Tc}$ -MDP scintigraphy before first RSO and three months after every RSO. Long-term follow-up ranged from 5.7 to 86.7 months with a mean of 23.2 months. For qualitative analysis, an established 4 steps scoring was used (0 = no response or worsening, 1 = slight response, 2 = good response, 3 = excellent response). For quantification, the uptake was determined within the $^{99\text{m}}\text{Tc}$ -MDP scintigraphy soft tissue phase before and after therapy. **Results:** At the end of long-term follow-up 27% of patients have an excellent, 24% a good, 30% a slight and 20% no response. The duration of response was 7.5 ± 8.3 months with a maximum of 27 months. In patients with repeated treatment, the effect after the first therapy was lesser than in patients who received a single treatment in total. However, three months after the last RSO, patients with repeated treatment showed a similar effectiveness than single treated patients. At the end of long-term follow-up, patients with repeated RSOs had a higher effectiveness at similar duration response. In the $^{99\text{m}}\text{Tc}$ -MDP scan 65% of patients showed a reduction of uptake. When comparing subjective and objective response 78% of patients showed a concordance in both, symptoms and scintigraphy. Pilot histological analysis revealed that the synovitis is triggered by small plastic particles. **Conclusion:** RSO is an effective

therapy in patients with knee replacement and chronic synovitis. It shows good subjective and objective response rates and long response duration. $^{99\text{m}}\text{Tc}$ -MDP scintigraphy is suitable for evaluation of response, since the results correlate with the symptoms. Repeated treatment leads to a stronger long-time response. The chronic synovitis is caused by plastic particles, which result from the abrasion of the polymeric inlay of endoprosthesis. Consequently, the effect of RSO is restricted by the amount of foreign material within the knee joint. **References:** None

OP-512

Off the beaten path in oncology: active BAT by virtue of ^{18}F -FDG PET/CT

W. Jalloul¹, I. C. Grierosu¹, T. Ionescu¹, C. Stolniceanu¹, R. Iacob², R. Tibu¹, A. Tarca¹, M. Gutu¹, D. Chetan², C. Ștefănescu¹, A. Naum²;
¹Biophysics and Medical Physics-Nuclear Medicine Laboratory, University of Medicine and Pharmacy „Grigore T. Popa”, Iasi, ROMANIA, ²Nuclear Medicine Laboratory, Regional Institute of Oncology, Iasi, ROMANIA.

Aim/Introduction: Brown Adipose Tissue (BAT) is a complex tissue which participates in the regulation of the whole body metabolism by producing a variety of adipokines. ^{18}F -FDG PET/CT, as a common imaging modality used in cancer assessment, can identify the hypermetabolic activity in activated BAT, also. The aim of this study is to emphasize the contribution of ^{18}F -FDG PET/CT to BAT detection, quantification and better understanding of this tissue biodistribution in oncological patients. **Materials and Methods:** After investigating ^{18}F -FDG PET/CT scans performed on the total number of patients, who were referred to our Nuclear Medicine Laboratory-between January 2018 and June 2019 for various oncological diagnoses, we selected the images with active BAT. We studied the BAT imaging pattern and measured SUV_{max} in multiple hyperfunctional tissue's localizations (cervical, supraclavicular, paravertebral, axillary, mediastinal and abdominal). **Results:** 42 positive scans were described in 38 patients with median age of 34.5 years. Female patients represented the highest rate of active BAT (57.89%). We noticed that 50% of patients were initially diagnosed with Hodgkin's Lymphoma (HL), 13.15% with Non-Hodgkin's Lymphoma (NHL), 10.53% with Cervical Cancer (CC), and with other cancer types under 5% each. ^{18}F -FDG high uptake in BAT was symmetric (sym) and homogeneous (hom), respectively, in 71.42% and 42.85% of images. The highest percentages were identified in NHL patients: 80% sym and 60% hom versus 66.7% sym and 38.1% hom in HL patients, versus 60% sym and 20% hom in CC patients. SUV_{max} in functional BAT ranged between 1.8 and 21.76 g/ml, with the highest median value of 5.98 g/ml in HL patients, followed by 5.68 g/ml in NHL patients and 4.73 g/ml in CC patients. Its maximum individual value was reached in supraclavicular localization in a HL patient (21.76

g/ml); however, the maximum uptake was identified in paravertebral region in a CC patient (8.67 g/ml). **Conclusion:** Biodistribution and SUV_{max} variation in different active BAT localizations raise a compelling hypothesis, of potential correlation between the oncological diagnosis and BAT activation, which needs further investigation. **References:** None

OP-513

The effectiveness predictive model of radioiodine therapy for Graves' disease in children and adolescents

A. Trukhin¹, P. Rumyantsev¹, V. Saenko², D. Dzeytova¹, M. Sheremeta¹, V. Degtyarev¹, V. Yasuchena¹, K. Slaschuck¹, S. Serzhenko¹, Y. Sirota¹, S. Zakharova¹;

¹Endocrinology Research Center, Moscow, RUSSIAN FEDERATION, ²Nagasaki University, Nagasaki, JAPAN.

Aim/Introduction: Graves' disease (GD) is a common cause of hyperthyroidism in patients of any age. In order to keep up with desirable effect and safety, radioiodine treatment (RIT) for hyperthyroidism accompanied by dosimetric estimations of therapeutic activity in children and adolescents requires preliminary risk assessment using predictive models. **Materials and Methods:** Study includes 55 children and adolescents (48 girls and 7 boys): age - 8÷17 (14.4±2.8) years; thyroid volume - 7.1÷94.5 (35.4±20.1) ml; Graves' orbitopathy in 32% patients; antithyroid drug (ATD) treatment - 3÷144 (38.9±26.3) months; thyrotoxicosis recurrence after ATD reduction - 40% patients; thyroid uptake 1.8÷41.2 (16.2±11.4) %; prescribed ¹³¹I activities - 534÷1396 (896±203) MBq; maximum thyroid ¹³¹I-uptake - 10÷60 (43.2±10.3) %; specific ¹³¹I activity - 4.1÷27.0 (14.3±5.5) MBq/ml; maximum thyroid absorbed dose rate - 0.44÷2.9 (1.6±0.6) Gy/h. Follow-up period ranged from 6÷36 months (18.8±2.8); TSH, fT3, fT4 before RIT. Follow-up: monthly - TSH, fT3 and fT4; half-annually - TRAb, thyroid volume. Effect evaluation: positive outcome - 6 months hypothyroidism. Predictors of RIT success evaluation - multivariate logistic regression modeling, cross-validation; quasi-complete separation of predictors: the Firth's penalized likelihood method. Effect achievement assessment - Cox proportional hazard model. **Results:** Effect: hypothyroidism - 45 (81.8%) patients; euthyroidism - 2 (3.6%) patients; hyperthyroidism - 8 (14.6%). Thyroid volume reduction - 12.2÷94.3 (70.0±15.7) %. Predictors of effect: age (OR=1.31, 95%CI 1.06-1.60), thyroid volume (OR=0.90, 95%CI 0.83-0.96); fT4 prior RIT (OR=1.23 95%CI 1.03-1.48). ROC analysis: continuous variables {age, thyroid volume, fT4} - AUC=0.94 (95%CI 0.88-1.00), accuracy=0.86, SE=0.93, SP=0.50, PPV=0.89, NPV=0.63; AUC cross-validated = 0.91 (95%CI 0.846-0.99); categorical variables {age ≥11 years, thyroid volume ≥43 ml, fT4 ≥13.5 pmol/l} - AUC=0.92 (95%CI 0.81-1.00), Accuracy=0.93, SE=0.93; SP=0.90, PPV=0.98, NPV=0.75; AUC cross-validated =0.87 (95%CI 0.73-1.00). The Cox modeling: volume affected

the achievement of hypothyroidism: continuous variable - HR=0.98 (95%CI 0.96-0.99), categorical ≥43 ml - HR=0.32 (95%CI 0.15-0.71). Chance of achieving hypothyroidism: decreases effect by 2% per each additional 1 ml of thyroid volume each month; 3-fold lower in patients with thyroid volume ≥43 ml. **Conclusion:** Developed models are useful instruments for RIT planning and prospective evaluation of outcome in children and adolescents with GD. Key efficacy predictors prior RIT - age, thyroid volume and fT4. Thyroid volume less than 43 ml, age older than 11 years and fT4 level higher than 13.5 pmol/l were associated with favorable result. Knowledge of pivotal factors of RIT efficacy provides broader opportunities for the exploration of more sophisticated predictive models. **References:** None

OP-514

¹⁸F-FDG -PET/MRI in patients with Graves'orbitopathy

M. Weber¹, J. Koenen², C. Deusch³, N. Bechrakis², K. Herrmann¹, A. Eckstein², I. Binse¹, M. Oeverhaus²;

¹Department of Nuclear medicine, University Hospital Essen, Essen, GERMANY, ²Department of Ophthalmology, University Hospital Essen, Essen, GERMANY, ³Institute for Diagnostic and Interventional Radiology and Neuroradiology University Hospital Essen, Essen, GERMANY.

Aim/Introduction: Currently therapeutic management of patients with Graves' orbitopathy (GO) relies on clinical assessments and MRI scans. However, monitoring of inflammation remains difficult since external inflammatory signs like injection and chemosis do not necessarily represent the orbital disease activity and MRI scans cannot be used for follow-up examinations. Therefore, we aimed to evaluate the diagnostic value of ¹⁸F-FDG-PET/MRI to assess the inflammation of GO patients. **Materials and Methods:** Patients with new onset of GO who were examined in our EUGOGO tertiary referral center were enrolled in this trial. All patients underwent ophthalmological and orthoptic examinations to evaluate the activity and severity of GO, as well as an ¹⁸F-FDG-PET/MRI (Siemens Biograph mMR) with dual-time-point-imaging (immediately post injection and 60 minutes p.i.). A subset of PET parameters including maximum standardized uptake value (SUVmax), metabolic target volume (MTV), and total lesion glycolysis (TLG) were obtained separately per-eye and per-extraocular eye muscle (EOM). EOM thickness was measured on the co-registered MRI. Subsequently, differences in PET parameters among severity grades were analyzed and correlation with clinical findings assessed using Pearson's correlation coefficient (R²). **Results:** Fourteen GO patients were enrolled and analyzed. Three showed mild, seven moderate-to-severe and four sight-threatening GO. Patients with severe GO showed statistically significant higher TLG than patients with mild GO (11.5 vs. 4; p=0.02) and higher MTV than patients with mild (11.8 vs. 4.7; p=0.03) and moderate (11.8

vs. 6.3; $p=0.04$) GO on the per-eye analysis of early static images. PET parameters did not show statistically significant differences among groups on the late acquisition images. Correlation between NOSPECS on one hand and MTV and TLG on the other was comparable among early and late static images ($R^2= 0.49-0.61$). Parameters obtained from individual EOMs were not correlated with its motility ($p=0.17-1.0$). **Conclusion:** TLG and MTV appear to be good discriminators for severe vs. mild/ moderate GO and show a significant correlation with NOSPECS. Whereas early PET acquisition compares favorably for GO severity assessment, the correlation of NOSPECS with PET parameters was equal for both time points. As expected, PET parameters of individual eye muscles were not correlated with associated eye motility, since fibrosis and not inflammation is mainly responsible for motility disorders. In conclusion, ^{18}F -FDG-PET/MRI is a promising modality for the assessment of GO severity with the potential to address limitations of current diagnostic standard procedures. Therefore, its diagnostic value should be subject of further studies on larger collectives. **References:** None

OP-515

Level of Thyrotropin Receptor Antibodies after Treatment with Radioactive Iodine

S. Gaberscek^{1,2}, D. Šfiligoj Planjšek¹, E. Pirnat¹, K. Zaletel¹, P. Jaki Mekjavič^{3,2};

¹Department of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA, ²Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA, ³Department of Ophthalmology, University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: For decades, radioiodine (I-131) therapy is effectively used for the treatment of Graves' disease (GD). It is known, that after I-131, serum level of thyrotropin (TSH) receptor antibodies (anti TSH-R) usually increases. Our aim was to evaluate the dynamic of this increase, since antiTSH-R may influence the course of Graves' orbitopathy. **Materials and Methods:** We reviewed medical records of all patients who were for the first time diagnosed with GD between the years 2005 and 2009. After initial treatment with antithyroid drugs, all patients were eventually treated with I-131. With respect to thyroid volume they received 555, 740, 925 or 1110 MBq of I-131. Serum level of antiTSH-R was measured with a second-generation human TRAK RIA kit (Brahms, Hennigsdorf, Germany). Values above 1.5 U/L were considered positive. Only patients with the known antiTSH-R value were included in the study. Results are expressed as median values and range. **Results:** Out of 724 patients, 335 patients, 253 females and 82 males, aged 45 (16-87) years had the known value of antiTSH-R before the first dose of I-131, 6 (2-12) weeks, 3 (2-10) months, 6 (3-15) months, 9 (3-43) months, and 12 (1-71) months after the first dose of I-131. Treatment with I-131 was performed 9

(0-31) months after the first presentation of GD. Out of 335 patients, 295 (88.1%) patients were cured with the first dose of I-131, while 40 (11.9%) patients needed the second dose of I-131 to achieve hypothyroidism or euthyroidism. When compared with the level before I-131 therapy (6.2 (0-41) U/L), level of antiTSH-R was significantly higher ($p<0.001$ for all) six weeks after I-131 therapy (10, (0-40) U/L), three months after I-131 therapy (31, (0-40) U/L), six months after I-131 therapy (30, (0-40) U/L), nine months after I-131 therapy (21, (0-40) U/L), as well as twelve months after I-131 therapy (12, (0-40) U/L). When compared with the highest level three and six months after I-131 therapy, level of antiTSH-R was significantly lower nine and twelve months after I-131 ($p<0.001$ for all). When compared with the level nine months after I-131, level of antiTSH-R was significantly lower twelve months after I-131 ($p<0.001$). **Conclusion:** Level of antiTSH-R increases up to six months after I-131 therapy and, afterwards, gradually decreases. This finding helps to plan a successful follow-up strategy for patients with GD, treated with I-131 therapy. **References:** None

OP-516

Therapeutic ^{131}I dose for the treatment of hyperthyroidism due to unifocal autonomy in compliance with the optimization principle of Council Directive 2013/59/EURATOM

C. Canzi, V. Longari, L. Florimonte, F. Buffoni, M. Castellani; Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, ITALY.

Aim/Introduction: European guidelines for hyperthyroidism radiometabolic treatment suggest a target dose of 300-400Gy for unifocal autonomy. Aim of this study was to demonstrate that a lower dose and a personalised pretreatment dosimetric study can be effective in obtaining a stable euthyroid status avoiding both hyperthyroidism persistence and onset of hypothyroidism and in complying with the Council Directive 2013/59/Euratom optimization principle. **Materials and Methods:** We considered 123 patients with a minimum follow-up of 12 months (85F, mean age 61 ± 13 y, 78 with subclinical hyperthyroidism and 45 with overt hyperthyroidism) with a single nodule of mean weight of 14.6 ± 10.4 g (range: 3.8-57.3g). They were studied with a pretreatment patient-specific dosimetric study (based on administration of 48-111MBq of ^{123}I , on multiple uptake measurements with a gammacamera and on the MIRD formula corrected for the reduced uptake in therapy with respect to dosimetry) in order to calculate the therapeutic ^{131}I activity necessary to release to the nodule a dose of 140Gy. Afterwards, the dose released after the administration of the calculated ^{131}I therapeutic activity was evaluated by means of 6 uptake measurements at 2, 4, 24, 48, 96 and 168 hours and the use of the MIRD formula. Uptake measurements were performed with a gammacamera

equipped with a high energy collimator. After the first 12 months each patient clinical outcome was monitored with biochemical analysis (TSH, FT3 and FT4) once a year. Two subgroups of 72 and 41 patients had a follow-up of 5 and 10 years, respectively. **Results:** All patients were given a single therapeutic ^{131}I administration with a mean activity of $292 \pm 146 \text{ MBq}$ [range: 87–625 MBq]. The mean dose released to the nodule was $143 \pm 37 \text{ Gy}$. Twelve months after therapy hyperthyroidism was healed in 97% of the patients and 8% were hypothyroid (serum TSH level over 4.2 uU/ml). In the subgroup followed for 5 years, 100% of the patients solved hyperthyroidism and 22% became hypothyroid and in the subgroup followed for 10 years they were 29%. **Conclusion:** This study demonstrated that a released target dose of about 140 Gy is effective in solving hyperthyroidism due to unifocal autonomy and in maintaining a long lasting euthyroid state in the most of the patients. This dose is quite lower than the value indicated by the European guidelines for hyperthyroidism treatment. The wide range of administered activity indicates the importance of a personalized pretreatment dosimetric study in order to obtain the clinical goal with the lowest activity. **References:** None

OP-517

Hyperactive thyroid nodules treated by radiofrequency ablation

F. Joosten, H. de Boer, P. Veendrick, W. Bom, E. Bom, M. van Borren; Rijnstate Hospital, Arnhem, NETHERLANDS.

Aim/Introduction: Toxic thyroid nodules are usually treated with radioactive iodine. This is associated with a high risk of permanent hypothyroidism. Radiofrequency ablation (RFA) may be a good alternative. **Materials and Methods:** Patients with a symptomatic toxic thyroid nodule, documented by suppressed TSH levels and a hot nodule on I-123 scan were treated by transisthmic, ultrasound-guided RFA, in an outpatient setting under local anesthesia. Follow-up was at least one year. **Results:** Over 40 patients were included, ranging in age from 37 - 75 years. All subjects had suppressed TSH levels. RFA was not associated with clinically significant adverse effects. Euthyroidism was achieved in the first 21 patients 11/21 patients (52%). A partial response with normalization of FT4 and FT3, and an incomplete improvement of TSH levels was observed in 6/21 patients (29%). During the meeting the data of 20 more patients with a follow up of 1 year at least will be presented. Recurrence of hyperthyroidism has not been observed so far. **Conclusion:** These data suggest that radiofrequency ablation is a safe and promising treatment for symptomatic toxic thyroid nodules, with a low risk of permanent hypothyroidism. The recurrence risk of hyperthyroidism cannot be established due to the short follow up, however did not occur in this group of patients **References:** None

OP-518

HIFU For Thyroid Nodules An Effective Therapy For The Volume Reduction Of Thyroid Nodules

C. Körber, N. Körber-Hafner; Nuclearmedicine, Fulda, GERMANY.

Aim/Introduction: Thermoablative therapies have been established as additional therapy options for thyroid nodules with local symptoms in comparison to thyroid surgery or radioiodine therapy in the last years. Therefore we used and analysed the HIFU therapy as a mean for the volume reduction of thyroid nodules. **Materials and Methods:** Since January 2019 we used the HIFU device of Theraclion SA (92240 Malakoff, France) for the therapy of thyroid nodules and fibroadenomas of the female breast. Only patients with local symptoms and often visible cervical protrusion underwent a therapeutic procedure. The volume of the thyroid nodules were analysed by two independent investigators 4, 12 and 36 weeks after therapy using ultrasound (My lab 9, Esaote, 15 MHz) and the results were compared to the nodule volume before echotherapy. All possible side effects were registered as well as a possible palsy of the N laryngeus recurrens. We further analysed the statistical relation between the dose administered and the pretherapeutic volume. The statistical analysis was performed using Statistica 10, the significance level was defined with $p < 0,05$. **Results:** 75 patients were treated in the time period. 36 weeks after the therapy 52 patients could be analysed (male 6, female 46). The pretherapeutic volume of the total volume was $26 \pm 10 \text{ (ml)}$, the pretherapeutic volume of the thyroid nodules volume was $4,9 \pm 2,6 \text{ (ml)}$, after 4 weeks $2,6 \pm 0,76 \text{ (ml)}$ and after 36 weeks $0,6 \pm 0,1 \text{ ml}$. (t-Test pretherapeutic volume//thyroid nodule volume after 36 weeks $p > 0,0003$). The mean volume reduction was $58 \pm 12 \%$. Furthermore a good correlation between the administered dose and the pretherapeutic volume could be shown. A significant drop of the administered dose could only be found for thyroid volume greater than 16 ml. **Conclusion:** HIFU therapy is a great non surgical therapy for thyroid nodules without any side effects discovered. After 36 weeks a good reduction of the thyroid nodule could be seen, even with thyroid volumes up to 16 ml. At all patients an improvement of the local symptoms could be observed without recognizable side effects. **References:** None

EPS-086

Assessment of high-speed recording lung perfusion images provided by a high sensitivity 360° whole-body CZT camera in the pre-operative workup of lung cancer

S. Melki, A. Verger, G. Karcher, P. Marie, L. Imbert;
CHRU Nancy, Vandoeuvre-lès-Nancy, FRANCE.

Aim/Introduction: The whole-body Veriton® 360° CZT-camera (Spectrum Dynamics Medical) is equipped with high-resolution detectors which can be positioned in close proximity to the chest, allowing high-speed recordings and further reconstructions of SPECT images using CT-based attenuation correction, not only for 3D images, but also for retro-projected images in a 2D planar mode (i.e. the multi-view planar (MVP) images). This study aimed to assess the relative percentages of right- and left lung-perfusions obtained with these MVP images, as well as with the 3D CZT-SPECT images, in comparison with those provided by conventional planar images from an Anger camera (Symbia, Siemens Healthineers), in lung cancer patients undergoing pre-operative workup. **Materials and Methods:** A SPECT/CT acquisition of less than 5 minutes was obtained with the 360° whole-body CZT camera after 370 MBq injection of ^{99m}Tc-labelled macroaggregate of albumin, and was immediately followed by a conventional Anger camera planar scintigraphy acquisition in 41 consecutive patients (66±12 years, 16 women) for whom this investigation was planned as part of pre-operative workup of a lung cancer. Right- and left-lung counts, obtained using dedicated software, were expressed in percentages of total pulmonary counts and comparisons made between values provided by the Anger camera planar views, and both the MVP and the SPECT images from the CZT-camera. **Results:** The percentages of lung perfusion obtained with the MVP images from the CZT-camera were strongly linked to those obtained with conventional planar images ($y = 0.99x + 0.38$, $R^2 = 0.98$), as well as to those obtained from the 3D CZT-SPECT images ($y = 1.02x - 1.46$, $R^2 = 0.99$). Values obtained with the 3D CZT-SPECT images and the conventional planar images were also strongly inter-correlated between each other ($y = 0.97x + 2.07$, $R^2 = 0.98$). Finally, each of the 3 image methods identified the same 21 patients, and no additional patients, as having an asymmetrical lung function (i.e. with a relative right lung function setting outside the 45 to 55% normal range). Additionally, high-speed 3D CZT-SPECT enabled per lobe assessment. **Conclusion:** Both MVP and

native 3D SPECT images from this CZT-camera may be used instead of conventional planar scintigraphy for quantitative assessment of relative lung perfusion and function in the pre-operative workup of lung cancer. However, only the 3D images provide additional values at the lobar scale.

An Assessment of the Accuracy of Quantitative SPECT/CT Imaging Using Tc99m and Lu177

J. Johnson, K. Adamson, T. Alkahtani;
Guy's and St Thomas' Hospitals NHS Foundation
Trust, London, UNITED KINGDOM.

Aim/Introduction: Quantitative SPECT imaging is a valuable tool in the diagnosis and staging of disease, and for assessing therapeutic response. An increasing number of such commercial applications are being developed and it's important that the accuracy, precision and source of errors for quantitative data is known. Calibration of the imaging system and optimisation of imaging and reconstruction parameters ensures the uncertainties are established. This study validated quantitative data for Tc99m and Lu177 acquired on two Siemens Symbia Intevo Bold SPECT/CT systems, using Siemens xSPECT Broad Quantification. **Materials and Methods:** The imaging systems were calibrated for each isotope using a point source and a homogeneous cylindrical source of known Tc99m and Lu177 activity. An IEC NEMA Image Quality phantom comprising 6 spherical inserts of 10mm-37mm diameter was filled with an activity concentration ratio of 10:1 between the spheres and background for Tc99m and Lu177 on separate occasions. Following imaging using a clinical protocol and reconstruction using xSPECT Broad Quantification workflows, SUV-based quantitative analysis was performed and resolution recovery coefficient (RRC) curves generated. RRC is defined as the ratio of the measured to expected SUV. Two SUV parameters were calculated for each sphere; SUV_{max} and $SUV_{50,meas}$. $SUV_{50,meas}$ is defined as the average SUV in the VOI defined by the 50% isocontour of the sphere. **Results:** The SUV_{max} and $SUV_{50,meas}$ for Tc99m and Lu177 clearly exhibited the impact of the partial volume effect for smaller volumes. The RRC results show that for the smallest volume (10mm) using $SUV_{50,meas}$ the uptake of Tc99m was underestimated by up to 83%, and 89% for Lu177. For SUV_{max} RRC for the 10mm sphere was 0.182 and 0.174 for Tc99m images on each of the systems, and 0.134 and 0.110 for Lu177. For the largest sphere (37mm), the RRC using SUV_{max} for Tc99m was 1.298 and 1.208, and for Lu-177 0.687 and 0.629. For Tc99m, for spheres between 10mm and 37mm, the RRC using SUV_{max} ranged from a significant underestimation to an overestimation. The great variation in results for volumes comparative to those in clinical images could greatly

impact conclusions drawn. For Lu177, the RRC shows the significant underestimation of Lu177 uptake for all spheres. This understanding is key for accurately reporting clinical images and assessing therapeutic response. **Conclusion:** Validation of software providing quantitative data from SPECT/CT imaging is essential before its application in clinical setting to ensure understanding of accuracy and impact on patient management. **References:** None

EPS-088

Can Half-Time Bone SPECT Replace the Standard Bone SPECT?

M. El-Sayed, J. O'Brien, T. Jones, A. D'Sa, A. Notghi;
Sandwell & West Birmingham Hospitals NHS
Trust, Birmingham, UNITED KINGDOM.

Aim/Introduction: At our centre, SPECT-CT is performed as an add-on to planar bone scan (BS) in oncology patients who have focal increased uptake of unclear cause. The additional SPECT-CT increases the total scan time which affects the patient throughput. This study evaluates if add-on SPECT-CT with reduced scan time can replace standard time SPECT-CT for oncology patients. **Materials and Methods:** 20 BS for oncology patients who had add-on SPECT-CT were selected. Images were acquired using a dual-head gamma camera. Acquisition parameters were as follows: imaging performed 2 hours after 550-650 MBq [^{99m}Tc]-HDP injection, 128 x 128 matrix, 120 steps, 10 seconds/step. Poisson resampling was used to mimic reduced scan time of 5 seconds/step & 3 seconds/step. The scans were processed using GE Xeleris resolution recovery software producing 3 data sets; SPECT-CT10, SPECT-CT5 & SPECT-CT3. This resulted in 60 scans. These were anonymised, randomised, then reported by 2 radionuclide radiology consultants. The number of lesions on SPECT-CT and final diagnoses were recorded. Using a visual analogue scale (1-10), the scans were scored for quality and reporter confidence. Wilcoxon signed-rank test was used for comparisons. **Results:** Comparing SPECT-CT10 (gold standard) to SPECT-CT5, the latter showed statistically significant inferior quality ($p=0.027$). However, all lesions were detected and there were no errors in the final diagnosis. There was no difference in reporter confidence ($p=0.982$). Comparing SPECT-CT10 to SPECT-CT3, 12/20 SPECT-CT3 had interpretation errors (missed lesions=58%. False positive lesions=42%). SPECT-CT3 was significantly inferior in quality and reporter confidence ($p=0.000$ & 0.019 respectively). **Conclusion:** We conclude that SPECT-CT5 can replace SPECT-CT10 as add-on to inconclusive planar BS in oncology patients at our centre. This will reduce SPECT acquisition time by 50% without compromising the clinical diagnosis or reporter confidence. However, SPECT-CT3 is not acceptable with our current scanning protocol. **References:** None

EPS-089

Design and implementation of a network-based educational platform for simulation of a benchtop PET system

I. Mohammadi^{1,2}, P. M. M. Correia¹, I. F. C. Castro¹, P. M. C. C. Encarnação¹, A. L. M. Silva¹, J. F. C. A. Veloso¹;
¹i3N-Physics Department, University of Aveiro, 3810-193, Aveiro, PORTUGAL, ²Department of Basic Sciences, Faculty of Medicine, Sari Branch, Islamic Azad University, Sari, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Nuclear medical imaging has the power of bringing together different areas of scientific knowledge: mathematics, physics, biochemistry, engineering and medical sciences. Using an efficient way to deliver medical imaging knowledge and establishing an effective learning environment for students, technologists and medical specialists has long been a goal for educators. Limited efforts have been made for step-by-step interactive education of the nuclear medical imaging data generation process, the fundamental education component of tomographic imaging. Based on this idea, a network-based user-interactive learning system including a graphical user interface simulation script creator to run on GATE platform was implemented, featuring text, animation, data acquisition, mathematical concepts of image creation, simulation and image reconstruction courses, so as to optimally fulfill PET imaging education tasks. **Materials and Methods:** A benchtop PET scanner considered for training and entry-level research. Using SQL as database and ASP.NET as server-end language, ADO.NET database access technology was adopted to design and implement the educational platform's structural functions, question/answer module and exam creation with hierarchical subject categorization. In addition, a dedicated graphical interface webform page provides flexibility and simplicity in defining an input file for simulating a benchtop PET system on the already popular GATE Monte Carlo simulation platform, benefiting from the existing capabilities and large selection of underlying Geant4 libraries for physical processes. **Results:** The system's interactive learning environments provided multiple means of representation and expression for the learner through text and graphics, animated simulations and other media combinations. Interactive education aids in increasing students' comprehension, motivation level and learning perception. The implemented system is widely accessible using any web browser and multiple users can work individually and simultaneously. Furthermore, to simplify the selection of parameters like phantom materials, source type, position and activity, a single configuration page lets the user control simulation parameters by setting their respective values, replacing aliases in correspondent macro files. Default properties will be used when undefined by the user. GATE macros are

subdivided into major parts, describing the phantom(s), source selection, digitizer, selection of physics models and visualization options. Scripts that used to be entered in GATE have been generated and compiled by the program as a single compressed file accessible by authenticated users. **Conclusion:** This system allows generalizing the practical learning of PET imaging, a valuable resource for students, technologists and researchers of nuclear medicine, medical imaging, biomedical engineering and other fields that imply the knowledge of PET imaging. **References:** None

Emission time optimisation for [⁶⁸Ga]Ga-PSMA-11 with a SiPM PET/CT based on phantom measurements

P. Frago Costa¹, W. Jentzen¹, F. Süßelbeck¹, W. P. Fendler^{1,2}, C. Rischpler¹, K. Herrmann¹, M. Conti³, D. Kersting¹, M. Weber¹;

¹Department of Nuclear Medicine, University Hospital Essen, University of Duisburg-Essen, Essen, GERMANY,

²German Cancer Consortium (DKTK)-University Hospital Essen, Essen, GERMANY, ³Siemens Medical Solutions, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: In clinical routine protocols with [⁶⁸Ga]Ga-PSMA-11, the emission time per bed position is currently 2-4 min. The potential for reducing the total acquisition time is particularly valuable for prostate cancer patients undergoing [⁶⁸Ga]Ga-PSMA-11 PET/CT examinations enhancing patient comfort and throughput. The aim of this study was to identify the optimal reconstruction parameters allowing a minimal acquisition time in [⁶⁸Ga]Ga-PSMA-11 examinations on a Biograph Vision using silicon photomultipliers (SiPM) PET/CT, preserving acceptable lesion detectability and spatial resolution. **Materials and Methods:** Two phantoms were used: a soft-tissue tumour phantom consisting of six spheres (ranging from 6.5 mm to 28.0 mm in diameter) mounted in an abdominal cavity, and a line phantom to estimate the reconstructed PET spatial resolution. The soft-tissue tumour spheres were filled with activity concentrations (ACs) that were derived from clinical data. Phantom data were acquired in list-mode, single bed position. Images with emission data ranging from 30 to 300 s, in 30-s increments, and a reference image with 10-min emission data were reconstructed. Iterative image reconstruction (OSEM) with and without point-spread-function (PSF) and/or time-of-flight (TOF) options were applied using different iterations, Gaussian filters, and voxel sizes. The resulting image quality was assessed using the following metrics: lesion detectability of each sphere was assessed using the contrast-to-noise ratio (CNR); a CNR equal or larger than 8 was considered acceptable. For image quantification, the percentage maximum AC (AC-max) deviations between the images at different emission times and the reference image were calculated; a percentage deviation range of ±20% was considered acceptable.

Results: Sphere and background ACs of 20 kBq/mL and 1 kBq/mL were selected, respectively. The line sources were filled with an AC of 10 MBq/mL (approximately 30 MBq in the field-of-view). The optimized emission time duration was 60 s using OSEM-TOF or OSEM-TOF+PSF (4 iterations, 4-mm Gaussian filter, and almost isotropic voxel size of 3-mm side length), resulting in a PET spatial resolution of 6.3 mm. The metrics at 60 s were $CNR_{OSEM+TOF}=15$ and $CNR_{OSEM+TOF+PSF}=24$; AC-max deviations were below 20%. **Conclusion:** Based on the phantom data, acquisition time on a SiPM PET/CT can be reduced by a factor of 2-3, while maintaining lesion detectability similar to our standard clinical protocol. Spatial resolution was maintained at the same order than the smallest lymphatic lesions in prostate cancer. Impact of reduced acquisition time on patient comfort, image quality/pelvic urine background, and throughput will be assessed in future clinical studies. **References:** None

Optimization of 18F-FDG oncological examination on a TOF-PET/CT scanner: results of a multicenter preliminary study

A. Zorz¹, E. Richetta², M. Poli², M. A. Rossato¹, R. E. Pellerito², G. M. Sacchetti³, M. Burei¹, R. Matheoud³;

¹Istituto Oncologico Veneto IOV - IRCCS, Padua,

ITALY, ²AO Ordine Mauriziano di Torino, Turin, ITALY,

³AOU Maggiore della Carità, Novara, ITALY.

Aim/Introduction: In PET/CT 18F-FDG oncology practice, image quality is influenced by different factors, such as the administered activity, patient dimension, acquisition and reconstruction parameters. The aim of this study was to investigate the possible dependence of image quality and lesion detectability on emission scan duration and patient Body Mass Index (BMI), in order to optimize oncological acquisition protocol. **Materials and Methods:** 30 oncological patients were selected for the study (15 with BMI<25 kg/m² (L) and 15 with BMI>25 kg/m² (H)) and acquired on three Philips Ingenuity TF PET/CT scanners installed in different Italian hospitals. Patients were injected with 3 MBq/kg of 18F-FDG. PET images were acquired in list-mode with an emission scan duration (ESD) of 120 seconds per bed position and retrospectively reconstructed at 120, 90, 75, 60 (default scan time), 45 and 30 seconds. Images were reconstructed by using the default clinical protocol. Image quality was described by using the Coefficient of Variation (CV), defined as the ratio between the standard deviation and the average activity concentration on a 1500 mm² ROI placed in the central part of the liver. For the lesions outlined in whole body examinations, Contrast-to noise ratio (CNR) was evaluated as $((CL-CB)/CB)/(\sigma B/CB)$, where CL, CB and σB are the average concentration in the lesion, the average concentration in the background and the standard deviation in the background, respectively. Overall,

31 lesions were analysed. The impact of ESD and BMI as independent variables was assessed separately on CV and CNR by means of the ANOVA test ($p < 0.05$). **Results:** Both ESD and BMI resulted to be predictors of CV and CNR. In particular, CV decreases by increasing ESD ($p < 0.05$), though a significant increase in CV can be observed only between ESD=60s vs ESD=120s and ESD=60s vs ESD=30s. As expected, CV increases by increasing the patient's BMI, with an average increase of 22% from L to H BMI group. As for CNR, ANOVA showed a significant increase with increasing ESD and by decreasing patient's BMI (+23%). **Conclusion:** Our preliminary data suggest that an improvement in image quality in terms of noise and contrast-to-noise ratio is still achievable on a TOF-PET/CT scanner by increasing ESD. Overweight patients will further benefit from such protocol optimization. **References:** None

EPS-092

The impact of patient's body shape on PET image quality in digital and analogic PET/CT

K. Weyts, E. Quak, I. Licaj, C. Lasnon, R. Ciappuccini, J. Savigny, G. Foucras, S. Bardet, C. Jaudet;
Centre François Baclesse, Caen, FRANCE.

Aim/Introduction: New digital PET shows higher temporal resolution and more stable count rate than analogic PET. This could limit PET image quality degradation with increasing patient's body mass (index) (BMI) observed in analogic PET/CT. We wanted to describe patient's body shape's influence on PET image quality in digital (dPET/CT) and analogic PET/CT (aPET/CT). The robustness was tested by using 2 different protocols for dPET/CT. **Materials and Methods:** We retrospectively studied the relation between patient's weight, BMI, fatty mass and FDG PET image quality, evaluated by liver coefficient of variance (CV_{liv}) and visually by 2 specialists. 177 unique patients and exams were performed on dPET/CT (weight 35-127 kg; BMI 15-44 kg/m²): with Protocol 1 (N=52) : 3MBq/kg FDG ($\pm 8\%$) - 2min/bed position- 3D OSEM with point spread function (PSF) reconstruction; 2 iterations 10 subsets (2i10s) and 2mm voxel size diameter, or Protocol 2 (N=125): 4MBq/kg FDG ($\pm 8\%$) -1min/bed position-3D OSEM PSF reconstruction ; 4i4s, 2mm voxel size diameter), implemented in a period of increased patient number scanning. 77 different patients and exams were analyzed on aPET/CT (weight 38-130 kg; BMI 14 -52 kg/m²) with following imaging protocol: 4MBq/kg FDG ($\pm 8\%$) - 2min40s/bed position if BMI < 25 kg/m² and 3min40s/bed position if BMI \geq 25 kg/m² - 3D OSEM PSF reconstruction ; 3i21s, 4mm voxel size diameter. We used STATA version 15 for statistical analyses, with two sided $p < 0.05$ considered to be statistically significant. **Results:** In multivariable analyses we found a positive association between weight, BMI, fatty mass and CV_{liv} on each camera and in each protocol ($p \leq 0.004$ for dPET/CT; $p \leq 0.04$ for aPET/

CT). Best linear fit ($r^2 = 0,61$) and highest correlation Pearson coefficient ($R = 0,78$) was obtained between CV_{liv} and weight as well as fatty mass on dPET/CT with 3MBq protocol 1; $p \leq 0,046$. No significant inferiority was observed between dPET/CT protocol 2 (Pearson $R = 0,61$ for weight) and aPET/CT (Pearson $R = 0,42$ for weight) with substantially longer scanning time ($p = 0,07$). For dPET/CT a significant increase by 23% of mean CV_{liv} was found in weight category ≥ 90 kg ($CV_{liv} = 0,149 \pm 0,018$) versus < 70 kg ($CV_{liv} = 0,121 \pm 0,009$) for the 3MBq protocol 1 ($p = 0,0001$), and 25% with the 4MBq protocol 2 ($CV_{liv} = 0,142 \pm 0,014$ versus $0,113 \pm 0,013$; $p < 0,0001$). A concordant, inverse association was found between body shape and visual scores on each camera ($p \leq 0,001$). **Conclusion:** FDG PET image quality decreases especially with increasing patient's weight on digital and analogic PET/CT, imposing an adaptive imaging protocol also on digital PET/CT. **References:** None

EPS-093

Emission time reduction for 2-[¹⁸F]FDG examinations in lymphoma patients with a PET/CT with SiPM - a feasibility phantom study

P. Frago Costa¹, A. Bramer¹, M. Weber¹, D. Kersting¹, M. Conti², W. P. Fendler^{1,3}, C. Rischpler¹, K. Herrmann¹, W. Jentzen¹;

¹Department of Nuclear Medicine, University Hospital Essen, University of Duisburg-Essen, Essen, GERMANY,

²Siemens Medical Solutions, Knoxville, TN, UNITED STATES OF AMERICA, ³German Cancer Consortium (DKTK)-University Hospital Essen, Essen, GERMANY.

Aim/Introduction: A new generation of PET/CT scanners, equipped with silicon photomultipliers (SiPM), provide increased sensitivity and faster coincidence timing resolution. These improvements may translate in reduced acquisition time or administered activity without compromising lesion detectability and quantitative accuracy. In the case of paediatric patients undergoing 2-[¹⁸F]FDG PET/CT for malignant lymphomas, a decrease of either acquisition time or administered activity is particularly beneficial for the patient. The aim of this study is to optimise the standard emission time (140-s emission time per bed, 70-kg patient and 210-MBq tracer activity) from 2-[¹⁸F]FDG PET/CT procedures in lymphoma patients on a Biograph Vision using SiPM PET/CT using an abdominal tumour phantom. **Materials and Methods:** The phantom consists of 6 spheres with inner diameters of 6.5 to 28.0 mm inserted on a torso-like background cavity. Injected sphere and background activity concentrations (ACs) were derived from clinical data. Phantom data were acquired in list mode with a scan time duration of 10 min. Different image reconstructions with varying iterations and Gaussian filters were performed using emission data between 30 and 300 s in 30-s increments. A reference image was reconstructed with 10 min emission time per bed position. Detectability was assessed using the

contrast-to-noise ratio (CNR); a CNR equal or larger than 8 was considered to be sufficiently visible. Quantification was assessed using the maximum AC (AC-max). The percentage AC-max deviations were calculated between the images at different emission times and the reference image; a percentage deviation range of $\pm 20\%$ was considered acceptable. **Results:** A representative signal-to-background ratio of 5:1 and a sphere AC of approximately 13 kBq/mL was selected based on the clinical data. The smallest lesion identified on the clinical dataset was comparable to the 9.7-mm diameter sphere. The following metrics refer to the 9.7-mm diameter sphere as larger spheres possess CNR values above 8, irrespective of image reconstruction methods and parameters. The optimised emission time per bed position was 60 s using OSEM+TOF or OSEM+TOF+PSF (4 iterations, 4-mm Gauss and 2-mm nearly cuboid voxel size). At 60 s emission time, $CNR_{OSEM+TOF}$ and $CNR_{OSEM+TOF+PSF}$ values were 8 and 12, respectively. Absolute AC-max percentage deviations were below 20%. **Conclusion:** In this phantom study, acquisition time on a PET/CT with SiPM allows a reduction of approximately a factor 2-3 while maintaining lesion detectability. Impact on a reduced acquisition time will be assessed in future clinical studies. **References:** None

EPS-094

Gender related difference in PET SUV in overweight and obese people

I. Sarikaya¹, A. Sarikaya², A. N. Albatineh¹;

¹Kuwait University Faculty of Medicine, Kuwait, KUWAIT,

²Trakya University Faculty of Medicine, Edirne, TURKEY.

Aim/Introduction: It is well known that standardized uptake value (SUV) is overestimated in patients with high body mass index (BMI). In this study we aimed to determine the gender related difference in SUV in overweight and obese patients. **Materials and Methods:** F-18 fluorodeoxyglucose (FDG) whole body positron emission tomography/computed tomography (PET/CT) images of the patients with BMI higher than normal (overweight: 25-29.9 and obese: 30 and above) were analyzed retrospectively. SUV_{max} and SUV_{mean} of the liver and blood pool were measured. BMI and lean body mass (LBM) were measured via online calculators. SUVs were corrected by LBM to obtain SUV_{LBM} (SUL). **Results:** Thirty four (34) females (mean age 58 ± 9 years) and 33 males (mean age 63 ± 7 years) were included. Among females, 31 were obese and 3 overweight. Among males, 20 were overweight and 13 obese. There was a significant difference between median SUV-SUL differences among males and females in all patients (overweight and obese) and also in obese patients (P value < 0.001). Including all patients, SUVs were approximately 43.4% higher than SULs in females and 35.5% higher than SULs in males. Including only obese patients (31 female and 13 male), SUVs were approximately 45.3% higher than SUL in

females and 39.5% higher than SULs in males. Mean weight of the patients was 86.8 kg (44.9% fat) in obese females and 103 kg in obese males (39.9% fat). **Conclusion:** SUVs are overestimated in both genders who are overweight and obese but overestimation of SUVs is higher in females as compared to males. This is mainly due to higher percentage of body fat in females. **References:** 1. Lucignani G, Paganelli G, Bombardieri E. Study on the difference between peripheral lung cancer and inflammatory pseudotumor based on the method of image histology

C. Ma;

Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Me, Jinan, CHINA.

Aim/Introduction: This study is to distinguish peripheral lung cancer and pulmonary inflammatory pseudotumor using CT-radiomics features extracted from PET/CT images. **Materials and Methods:** In this study, the standard 18 F-fluorodeoxyglucose positron emission tomography/computed tomography (18 F-FDG PET/CT) images of 21 patients with pulmonary inflammatory pseudotumor (PIPT) and 21 patients with peripheral lung cancer were retrospectively collected. The dataset was used to extract CT-radiomics features from regions of interest (ROI), using, then, statistical methods to screen CT-radiomics features, which could distinguish peripheral lung cancer and PIPT. And the ability of radiomics features distinguished peripheral lung cancer and PIPT was estimated by receiver operating characteristic (ROC) curves. **Results:** A total of 435 radiomics features were extracted, of which 20 could difference between peripheral lung cancer and PIPT. these features were seen in 16 of 330 Gray-Level Co-occurrence Matrix features, 1 of 49 Intensity Histogram features, 1 of 5 Neighbor Intensity Difference features, 2 of 18 Shape features. area under the curve (AUC) of these features were 0.7310.075, 0.717, 0.737, 0.7480.038, respectively. **Conclusion:** Radiomics features extracted from non-contrast CT based on PET/CT images can help distinguish peripheral lung cancer and PIPT. **References:** [1] Vanderhoek M, Perlman SB, Jeraj

Development of an anthropomorphic rodent phantom

W. McDougald¹, N. Weir², R. Collins³, A. Tavares¹;

¹BHF-Centre for Cardiovascular Science, College of Medicine & Veterinary Medicine, Edinburgh, UNITED KINGDOM, ²Department of Medical Physics, NHS Lothian, Edinburgh, UNITED KINGDOM, ³University of Edinburgh College of Arts, Edinburgh School of Architecture and Landscape Architecture, Edinburgh, UNITED KINGDOM.

Aim/Introduction: Develop a 3D printed tissue equivalent material (TEM) anthropomorphic rodent phantom with the intent to replace using animals when optimizing imaging protocols and assist in accurate scanner quality control validation. Research using positron emission tomography/computed tomography (PET/CT) continues its rapid increase as a key imaging technique across multiple biomedical preclinical research fields. Preclinical PET/CT is a powerful, pivotal imaging tool supporting investigations and evaluations of underlying biological mechanisms. Preclinical PET/CT is fully quantitative, providing biological functional information, whilst CT provides anatomical information. Additionally, the expansion of utilizing CT, as a dedicated system and with PET, SPECT or optical increases the need for new imaging protocols in several biomedical research fields. When designing or optimizing a preclinical experimental imaging protocol, usually, a priori knowledge of obtainable optimization is not known. To gain this information, small laboratory animals are generally used for testing. **Materials and Methods:** A CT acquisition of a scheduled 1 rodent was exported into OsiriX and PMOD for volume and surface rendering. The rodent's brain, heart, liver, kidney and lungs were imaged and exported in the same manner. All files were exported into Rhinoceros 3D CAD software. The prepared CAD files were used for 3D printing the anthropomorphic TEM rodent phantom. Phantoms were made with combinations of Tango Black Plus M, Vero Clear and Vero White Plus M 830. Furthermore,

the phantom was designed with a void for lungs and a calcium hydroxyapatite (CaHA) skeletal insert. HU values were extracted by drawing volumes of interest using PMOD. Calculated 3D material linear attenuation coefficient were compared to tissue. **Results:** Selected commercially available 3D printing materials produced measured HUs within accepted ranges for soft tissue. Calculated 3D material linear attenuation coefficient compared well to measured attenuation coefficients. Tango Black Plus M measured the lowest values at -38HU. Perspex and Vero Clear measured -12HU and -17HU, respectively. Vero White Plus measured the greatest at 22HU. No tissue measured HUs for lung or cortical bone at the preclinical tube voltage. **Conclusion:** X-ray properties and HUs of materials corresponded to those of human tissues at diagnostic and preclinical energies for soft tissue. No 3D material measured a close similarity to lung or cortical bone. Collected data and the developed 3D printed TEM phantom support the usage of an anthropomorphic rodent phantom for preclinical protocol optimizations and quality control; replacing the use of animals. **References:** None

Optimization of Quantitative ¹⁸F-DCFPyL PET using a Realistic Anthropomorphic Phantom with Shell-less Radioactive Epoxy Lesions

R. Fedrigo^{1,2}, D. Kadrmas³, P. Edem⁴, L. Fougner⁴, I. S. Klyuzhin^{1,2}, M. P. Petric⁴, F. Bénard^{1,2,4}, A. Rahmim^{1,2,4}, C. Uribe^{2,4};

¹BC Cancer Research Centre, Vancouver, BC, CANADA,

²University of British Columbia, Vancouver, BC, CANADA,

³University of Utah, Salt Lake City, UT, UNITED STATES

OF AMERICA, ⁴BC Cancer, Vancouver, BC, CANADA.

Aim/Introduction: Block sequential regularized expectation maximization (BSREM), as compared to OSEM reconstruction, has received significant interest for its ability to reach convergence with minimal noise amplifications. PET images with ¹⁸F-DCFPyL (a PSMA-based tracer) have shown superior results in detecting prostate cancer. However, few phantom studies have evaluated the quantitative accuracy of BSREM for high contrast, small diameter (sub-10mm) lesions observed in ¹⁸F-DCFPyL scans. This study aimed to design a realistic phantom experiment to optimize the reconstruction parameter (β) of the BSREM algorithm for quantification of prostate cancer metastasis imaged with ¹⁸F-DCFPyL. In addition, the quality of the reconstructed images was also evaluated. **Materials and Methods:** Twenty-seven spherical lesions (diameters 3mm-16mm) were cast using Epoxy resin infused with 3 activity concentrations of ²²Na-NaCl. The diameters and concentrations were chosen based on an analysis of 10 prostate cancer patients imaged with ¹⁸F-DCFPyL. A highly realistic anthropomorphic phantom [1] which features a liver, lungs, bladder, and ureters, was filled with ¹⁸F-FDG

to achieve target concentrations determined from the patient segmentations. Ten scans were performed at 30min intervals using a GE Discovery D690 PET/CT scanner. Bed and scan durations were scaled to maintain similar count statistics. Images were reconstructed with OSEM (24,32 subsets, 1-4 iterations) and BSREM (32 subsets, 25 iterations, $\gamma=2$, $\beta=100,150,200,250,300,400,500,650,800$). Regions-of-interest were drawn with MIM (MIM Software Inc.) using a 40% of SUV_{max} fixed threshold and MIM's PET Edge+ method. ^{22}Na lesion ground truth activity concentrations were determined from a scan with fully decayed background. Metabolic tumour volume (MTV), contrast, signal-to-noise ratio, and recovery coefficients (max, mean, and peak) were calculated for each sphere size. **Results:** SUV_{mean} recovery coefficients were $130.4\pm 13.5\%$ and $98.3\pm 6.9\%$ (16mm), and $99.7\pm 4.7\%$ and $69.4\pm 0.8\%$ (10mm), for $\beta=150$ and $\beta=300$ respectively. Contrast-to-noise ratios for $\beta=150$ and $\beta=300$ were 55.3 ± 14.4 and 65.3 ± 5.6 (16mm), and were 15.4 ± 1.8 and 4.6 ± 1.4 (6mm). Signal-to-noise ratios were comparable with maximum values 81.2 ± 1.0 ($\beta=150$) and 105.2 ± 0.07 ($\beta=300$). PET Edge+ MTV bias was $0.2\pm 0.01\%$ at 6mm, but deviated $56.2\pm 1.7\%$ at 12mm. The 40% threshold deviated by over 176% for spheres smaller than 10mm, but reduced to 14.9% at 12mm. **Conclusion:** Our results suggest that $\beta=150$ and $\beta=300$ are optimal parameters for quantification of ^{18}F -DCFPyL PET scans for lesions of sizes of 3-10mm and 12-16mm, respectively. PET Edge+ segmentation is recommended for segmenting lesions of 3-10mm, while the 40% threshold showed better results on larger 12-16mm lesions. **References:** [1] Kadrmas, et al. J. Nucl. Med., 50, 8, 1315-1323, 2009.

EPS-098

Dose-scan-time optimization for ^{18}F -PSMA-PET using a digital PET scanner

P. Bergwerff^{1,2}, D. Koopman², B. N. VendeP, C. H. Slump³, J. A. van Dalen⁴;

¹Technical Medicine, University of Twente, Enschede, NETHERLANDS, ²Department of Nuclear Medicine, Isala hospital, Zwolle, NETHERLANDS, ³TechMed Centre, University of Twente, Enschede, NETHERLANDS, ⁴Department of Medical Physics, Isala hospital, Zwolle, NETHERLANDS.

Aim/Introduction: There is an increasing use of prostate specific membrane antigen (PSMA) in PET imaging of patients with prostate cancer. Current literature suggests to use a tracer dose of typically 2 MBq/kg without specifying the scan-time. We aimed to determine the dose-scan-time product (DSTP) that is needed for adequate ^{18}F -PSMA-PET imaging using a digital PET/CT scanner. **Materials and Methods:** ^{18}F -PSMA-1007 PET/CT scans (Vereos, Philips Healthcare) of 10 consecutive patients (mean weight 81 kg, range 54-100kg) with initial or recurrent prostate cancer were used. Data were acquired using 2 MBq/kg and 4 minutes

per bed position (DSTP=8). Previously, we determined optimal image reconstruction settings using ordered subset expectation maximization and DSTP=8 for ^{18}F -PSMA-PET, and we applied those optimized parameters in this study: 3 iterations, 7 subsets and point spread function modelling. Images based on DSTPs of 4, 5, 6 and 7 were simulated by reconstruction of clipped list-mode data. Three nuclear medicine physicians assessed the image quality based on a 4-point scale. Moreover, a semi-quantitative assessment was performed by measuring the SUV of reported lesions and background noise in the aorta. **Results:** Visual assessment of 50 ^{18}F -PSMA-PET datasets (10 patients \times 5 reconstructions) showed comparable and adequate image quality for all DSTPs ($p=0.72$, $p=0.72$, $p=1.0$, $p=1.0$ for DSTPs of 4, 5, 6 and 7, respectively). There was a tendency towards lower scores for patients with the highest body weight. Reducing DSTP resulted in a noise increase up to 20% for DSTP=4, but SUVs of reported lesions ($n=32$) remained stable. The standard deviation of differences in SUV between default and reduced DSTPs increased up to 14%. **Conclusion:** Using optimized reconstruction settings for ^{18}F -PSMA-PET, the dose-scan-time product can be reduced to at least 4 MBq/kg/min for the Vereos PET/CT scanner. For example, when applying a tracer-dose of 2 MBq/kg, an acquisition time of 2 minutes is suggested. Future studies could investigate the relation between patient's bodyweight and ^{18}F -PSMA tracer dose for a constant image quality across all patients. **References:** None

EPS-099

Results of different formulations on hepatic Standardized Uptake Value in pediatric FDG PET

B. de Keizer^{1,2}, A. F. van der Hoeven¹, L. Miltenburg¹, R. van Rooij¹;

¹UMC Utrecht, Utrecht, NETHERLANDS, ²Prinses Maxima Center for Pediatric Oncology, Utrecht, NETHERLANDS.

Aim/Introduction: [^{18}F]FDG PET is increasingly used in diagnosis and follow-up of pediatric cancer patients(1). For quantification of FDG uptake in tissue, the standardized uptake value (SUV) is used. SUV can be calculated using different formulations. The body weight (BW) corrected formulation and lean body mass (LBM) corrected formulations (according to James or Janmahasatian) are mostly used. For measurements in adults the LBM janmahasatian formulation is advised(2). It is not known which formulation is best for use in pediatric patients. To investigate results of different formulations for hepatic SUV in paediatric patients, a retrospective analysis was performed. **Materials and Methods:** Consecutive [^{18}F]FDG PET performed in pediatric aged <16 years between December 2018 and April 2020 were retrospectively reviewed. Liver SUV was measured with a 3-cm-diameter spheric region of interest in the right liver lobe. SUV was calculated using BW (SUVbw) and sex specific LBM formulations according to James and

Janmahasatian (SULjames and SULjanmaha). **Results:** A total of 236 patients were reviewed (92 female and 144 male). Mean age was 9.9 (range 0.8 - 15.8) and 9.8 (range 0.4 - 15.7) for female and male patients respectively. Mean weight was 36.5 (range 7 - 96) and 38.9 (range 7 - 99) for female and male patients respectively. Mean SUVbw was 1.41 (1.46 female; 1.37 male), mean SULjames was 1.21 (1.26 female; 1.18 male), mean SULjanmaha was 1.22 (female 1.30; male 1.19). All measurements had a positive correlation with weight ranging from $r = 0.71$, for SULjanma for male patients till $r = 0.82$ for SUVbw for female patients. **Conclusion:** The used formulations lead to different mean hepatic SUV, with highest values for SUVbw and lower values for SULjames and SULjanma. All formulations have positive correlation with weight, leading to increasing liver SUV with increasing weight. **References:** 1. Uslu L, Donig J, Link M, Rosenberg J, Quon A, Daldrup-Link HE. SPECT/CT with $^{99\text{mTc}}$ MIBI Diagnostic Value In Hyperparathyroidism Comparison To Other Alternative Ultrasound & Four-dimensional parathyroid CT

M. Algarni; KFMMC, Dhahran, SAUDI ARABIA.

Aim/Introduction: Accurate preoperative anatomic localization of hyperfunctioning parathyroid adenoma (HTP) critical importance in surgical planning for minimally invasive parathyroidectomy. SPECT/CT with $^{99\text{mTc}}$ -sestamibi ($^{99\text{mTc}}$ -MIBI) important for detection of any metabolic active hyperfunctioning gland(s) localized in the neck or mediastinum. Ultrasonography (US) and Four-dimensional parathyroid CT (4D CT) increasingly offers potential advantages as an alternative primary investigation and is a common second-line investigation. **Materials and Methods:** Retrospective study included 28 patients aged 26 - 87 years (mean age 49 ± 7). Female to male ratio was 4:1. The follow-up period ranged from 3 to 12 months, the mean being 6 months. In all cases of biochemically confirmed hyperparathyroidism, the average levels were: Ca total - $2.65 \pm 0.05 \text{ mmol/l}$ (NV 2.12-2.52), PTH = $72 \pm 32 \text{ pg/ml}$ (NV 1.5-9.2). All underwent parathyroidectomy, and an adenoma was confirmed. Scintigraphy was performed with SPECT/CT (GE model 670pro NM/CT). 4D CT done with Toshiba Aquilion 64. Ultrasonography (US) was done with ACUSON SC2000 by means of 10MHz linear probe. **Results:** The exact localization hyperfunctioning parathyroid gland was identified 23 (82.2%) out of 28 patients by means of SPECT/CT. The remaining 5 patients need an alternative investigation and second-line investigation which we started with US parathyroid adenoma was

identified 2 (40%) out of 5 patients. All remaining 5 patients further investigated with 4D-parathyroid CT scan hyperfunctioning parathyroid gland was identified 4 (80%) out of 5 patients. One patient (3.5%) out of 28 patients was diagnosed intraoperatively. **Conclusion:** SPECT/CT with $^{99\text{mTc}}$ -sestamibi appears promising with an important key role in diagnosis hyperfunctioning parathyroid gland but further imaging with 4D-parathyroid CT scan may be needed particularly when we attempt to diagnose the precise site of disease localization in presurgical planning. **References:** 1- Casara D et al. $^{99\text{mTc}}$ -MIBI radio-guided minimally invasive parathyroid surgery planned basis of a preoperative $^{99\text{mTc}}$ -pertechnetate/ $^{99\text{mTc}}$ -MIBI and ultrasound. *Eur J Nucl Med* 2000;27:1300-4. 2- Casara et al. $^{99\text{mTc}}$ -MIBI radio-guided minimally invasive parathyroidectomy: *Nucl Med Commun* 2019;40:96-105. 3- Beheshti M et al. Aim/Introduction: Radio Guided Surgery (RGS) is a technique helping the surgeon to achieve complete resection of tumours, using a radio tracer injected to the patient before surgery, and detecting emitted radiation by means of a dedicated probe. This technique today uses gamma emitting isotopes together with gamma detectors. A novel approach to RGS using pure beta- decaying isotopes

was recently proposed [1], aiming at overcoming major limitations of the current one, that are given by the high penetration of gamma particles. First validation case has been Y90 as radio isotope (pure B- decay, $E_{max}=2.23\text{MeV}$) and an organic scintillator as detector element of the probe. Despite having shown a good sensitivity and high efficacy in Y90-DOTATOC applications, in particular in Meningioma and gastrointestinal NET ex-vivo samples, the limited number of pure beta- emitting radio pharmaceuticals limits the applicability of this promising technique **Materials and Methods:** In this context, i.e. to increase the number of application cases of the beta-RGS technique, we have been investigating new detector technologies/solutions (including solid state detectors), aimed at increasing the sensitivity to low energy particles, that would allow the technique to be performed also with lower-endpoint radio pharmaceuticals. Moreover, we also investigated the possibility to use positron emitting radio pharmaceuticals, exploiting the high sensitivity to beta particles of our detector, together with its substantial transparency to photons. In parallel with an experimental campaign of ex-vivo tests on Ga-PSMA prostate tumor samples, we developed laboratory measurements and Monte Carlo simulations regarding a possible application with F18 and Cu isotopes (64-67), in particular in gynaecologic applications. Also a possible application to pancreatic tumours is under study, using 90Y-DOTATOC. **Results:** The novel approach to beta RGS demonstrated to be highly effective if performed with pure beta- emitting radiopharmaceuticals in meningioma and gastrointestinal NET ex vivo samples. Moreover, pancreatic NETs are expected to be a possible application case. Furthermore, improved detectors allow also the use of positron emitting radio pharmaceuticals, as demonstrated by Ga-PSMA prostate cancer ex-vivo tests, and the use of 18F is also likely to be a possibility. **Conclusion:** The novel approach to beta RGS we proposed in the past years, initially tailored at pure beta- emitting isotopes, thanks to retrospective studies, ex-vivo tests and detector optimisation is now expanding towards a higher number of application cases. **References:** [1] E. S. Camillocci et al., Scientific Reports, 4 (2014), "A novel radioguided surgery technique exploiting beta- decays" 4401.

An IAEA tool to assess staffing needs in Nuclear Medicine

M. Marengo¹, M. Dondi², J. Bomanji³, S. A. Baigorria⁴, S. Bouyoucef⁵, E. W. Elias⁶, T. E. Pascual⁷, D. Paez²;

¹University of Bologna, Bologna, ITALY, ²Nuclear Medicine and Diagnostic Imaging Section - IAEA, Vienna, AUSTRIA, ³Institute of Nuclear Medicine - University College of London, London, UNITED KINGDOM, ⁴Fundacion Escuela Medicina Nuclear, Mendoza, ARGENTINA, ⁵Department of Nuclear Medicine CHU Bab el Oued, Algiers, ALGERIA, ⁶Department of Nuclear Medicine - Singapore General Hospital, Singapore,

SINGAPORE, ⁷Philippine Nuclear Research Institute - St Lukes Medical Center, Global City, PHILIPPINES.

Aim/Introduction: Staff costs are one of the most expensive components of nuclear medicine services (NMS). Introduction of new imaging modalities or therapies, new roles and responsibilities, let alone a fresh new start of a new NMS, may require assessment or re-assessment of staffing needs to ensure the most efficient use of resources. To the best of our knowledge, there are no models, applicable to NMS of different complexity, to assess staffing needs. **Materials and Methods:** A model was created, based not only on clinical workload but also on "infrastructure" parameters, such as number and type of equipment; level of Radiopharmacy activity and presence of in-house cyclotron. Indeed, additionally to the clinical work, which include attendance to multidisciplinary meetings and discussion with referring physicians, staff need to spend time for setting the equipment; run QA/QC and user-operated maintenance and patient- and equipment-related administrative tasks. In case of teaching hospitals, a slightly higher weight has been given. In our model, considering annual leaves, sick leaves, absences for training, working time is set at 1640 hours/year, down from an average of 2000 hours, and is consistent with a replacement factor of 1.22, frequently used by Human Resources. The most relevant factor, however, is the amount of time required to carry out clinical procedures, i.e. their "weight". As suggested by the Center for Medicare and Medicaid Services, a standard basic "work unit" has been set at 15 min. Then weights of each procedure consider the number of "15-minutes work units", needed to covering all aspects, from patient admission and interview, discussion with referring physicians and attendance to meetings, through administration of radiopharmaceuticals and other medication, reporting, patients assistance, data processing, storing, archiving, etc. The needs for Radiopharmacy staff are based on previous IAEA publication, while contribution of medical physicists is not included, since another IAEA tool already exists. **Results:** This model was tested on data existing in an IAEA data base for NMS of different levels and by an international panel, considering their own Departments and other simulated or real configurations. The agreement between existing staff and calculated needs was found to be within 15 %. **Conclusion:** This model calculates staffing needs in term of FTE nuclear medicine physicians, radiopharmacists, NM technologists, and nurses and could be used for planning new departments, before introduction of new technologies or for periodical reviews of resources utilization. **References:** None

OP-532**¹⁸F]Crizotinib PET imaging to address the impact of the P-glycoprotein transport function at the blood-brain barrier on the brain delivery of the drug**

F. Caillé¹, M. Sardana², M. Goislar¹, L. Breuil¹, M. Schou³, G. Wrigley⁴, N. Tournier¹, C. Elmore², B. Kuhnast¹;

¹CEA, Orsay, FRANCE, ²Astra Zeneca, Gothenburg, SWEDEN, ³Astra Zeneca, Stockholm, SWEDEN, ⁴Astra Zeneca, Cambridge, UNITED KINGDOM.

Aim/Introduction: Crizotinib is a tyrosine kinase inhibitor approved for non-small cells lung carcinoma. The brain accumulation of crizotinib is mainly restricted by the P-glycoprotein (P-gp, ABCB1), a major efflux transporter at the blood-brain barrier, which limits its efficacy against CNS metastases. We hypothesized that the brain delivery of crizotinib can be improved using a clinically feasible pharmacological protocol of P-gp inhibition. We report the preparation of an original precursor for isotopic radiolabelling of [¹⁸F](R,S)-crizotinib and the first brain PET images in rats with and without ABCB1 inhibition. **Materials and Methods:** A racemic spirocyclic hypervalent iodine(III) complex was synthesized for radiosynthesis with [¹⁸F] fluoride. Radiofluorination was realized using a TRACERlab FX_{FN} module and conditions were optimized monitoring the conversion rate by radio-TLC. The crude radiotracer was purified by semi-preparative HPLC. Radiochemical yield (RCY) and molar activity (A_m) were assessed by radio-HPLC. Dynamic PET acquisitions were performed in anesthetized rats during 60 min after [¹⁸F](R,S)-crizotinib injection (37 ± 5 MBq) with or without ABCB1 inhibition using tariquidar (8 mg/kg, 15 min i.v. prior to radiotracer injection). **Results:** The racemic precursor was synthesized from 2,4-dichloro-1-iodobenzene in 5 steps and 2% yield. Up to 52% radiochemical conversion was obtained using fluorine-18 and tetraethylammonium bicarbonate as a base in DMF at 160 °C for 10 minutes. Deprotection with 3 M HCl_(aq) at the same temperature for 10 minutes was quantitative. Ready-to-inject [¹⁸F](R,S)-crizotinib was obtained in 5 % RCY and 60 ± 10 GBq/μmol (n = 7) A_m. PET baseline experiments showed no penetration in the rat brain whereas [¹⁸F](R,S)-crizotinib enters the brain under ABCB1 inhibition using tariquidar. **Conclusion:** An original precursor for crizotinib radiofluorination was synthesized and [¹⁸F](R,S)-crizotinib was successfully radiolabelled. The first PET images of [¹⁸F](R,S)-crizotinib in the rat brain demonstrated the relevance of P-gp inhibition to improve its brain delivery. Investigation with the enantiomerically pure [¹⁸F](R)-crizotinib are ongoing. **References:** None

OP-533**Validation of [¹¹C]glyburide as PET probe for imaging OATP function in humans**

S. Marie^{1,2}, L. Breuil¹, Z. Chalampalakis¹, L. Becquemont², M.

Goislar¹, F. Caillé¹, C. Comtat¹, M. Bottlaender¹, N. Tournier¹;

¹Laboratoire d'Imagerie Biomédicale Multimodale (BIOMAPS), Université Paris-Saclay, CEA, CNRS UMR9011, Inserm UMR1281, Service Hospitalier Frédéric Joliot, Orsay, FRANCE, ²Hôpital Bicêtre, Assistance Publique des Hôpitaux de Paris, Le Kremlin Bicêtre, FRANCE.

Aim/Introduction: Organic Anion Transporting Polypeptides (OATP, SLCO) transporters control the influx of many endo/exogeneous compounds across biological membranes. OATPs are mainly expressed in hepatocytes (OATP1B1/1B3/2B1) where they mediate the hepatic uptake of many drugs and control hepatobiliary elimination. OATPs have also been detected at other blood-tissue interfaces (OATP1A2/2B1) suggesting a role for drug distribution to tissues. Imaging probes with improved pharmacokinetic properties are needed for determination of OATP function at the blood-tissue interface. Glyburide (GLB) is transported by OATP1B1/1A2/2B1 and [¹¹C]GLB successfully revealed OATP function using PET imaging in non-human primates¹. **Materials and Methods:** Three healthy male volunteers (< 30 years) underwent two consecutive [¹¹C]GLB dynamic PET/MR scans (126±55 MBq i.v.; 30 min), before and after an injection of the prototypical OATP-inhibitor rifampicin (9 mg/kg i.v.). Time-activity curves (TAC) were obtained in the liver and the arterial blood-pool (left ventricle + aorta). During PET acquisitions, venous blood samples were withdrawn to test [¹¹C]GLB metabolism and binding to plasma proteins. Liver distribution was estimated by the ratio of areas under the curves $AUC_R = AUC_{liver} / AUC_{blood}$. The initial uptake clearance of [¹¹C]GLB from blood to liver (CL_{uptake}) was estimated using an integration plot analysis. Paired t-test were used to compare outcome parameters obtained in each subject. **Results:** PET images revealed the predominant uptake of [¹¹C]GLB in the liver. Rifampicin drastically decreased the PET signal in the liver while obviously increasing radioactivity in the vasculature. With or without rifampicin-pretreatment, [¹¹C]GLB was slowly metabolized with >90 % parent compound at 30 min and binding to plasma proteins was >99 %. There was a significant 2.62±0.24-fold decrease in AUC_R consistent with the 3.90±0.99-fold decrease in CL_{uptake} obtained after rifampicin inhibition. **Conclusion:** [¹¹C]GLB benefits from suitable in vivo stability and its liver uptake is inhibited by rifampicin, thus demonstrating an importance of OATP-mediated transport. The decrease in CL_{uptake} induced by rifampicin is higher than that of previous PET radioligands used for imaging OATP in humans. This may be explained by the limited passive diffusion of [¹¹C]GLB, probably related to highly lipophilic physico-chemical properties and high binding to plasma proteins. Thus, transport of [¹¹C]GLB across membranes is predominantly governed by OATP-mediated transport which makes it a sensitive and quantitative probe to investigate the importance of extra-

hepatic OATP-function in humans. **References:** 1. Tournier and al. Effects of Selected OATP and/or ABC Transporter Inhibitors on the Brain and Whole-Body Distribution of Glyburide. *AAPS J.* 15, 1082-1090 (2013).

OP-534

¹⁸F-VUIIS1008 as a potential novel PET probe for PET imaging of rheumatoid arthritis in a rat model

X. Su¹, L. Wang¹, W. Dong¹, Z. Guo²;

¹Department of Nuclear Medicine, Zhongshan Hospital Xiamen University, Xiamen, CHINA, ²Center for Molecular Imaging and Translational Medicine, Xiamen University, Xiamen, CHINA.

Aim/Introduction: Early diagnosis and therapy are crucial to control optimally disease progression and achieve good prognosis in Rheumatoid arthritis (RA). Currently, it is difficult to efficiently diagnose and monitor early-stage RA. The aim of the present study is to develop ¹⁸F-labeled TSPO ligand VUIIS1008 (¹⁸F-VUIIS1008) as a novel PET probe for imaging of rheumatoid arthritis. **Materials and Methods:** The tosylate substrate was labeled with fluorine-18 at its 2-fluoroethyl moiety using a tosyloxy-for-fluorine nucleophilic aliphatic substitution labeled to obtain ¹⁸F-VUIIS1008. The labeling efficiency, radiochemical purity, lipophilicity and stability were determined in vitro. In vitro cellular uptake and competitive binding assays were performed on RAW264.7 macrophage cells. Micro-PET studies were conducted on mice with rheumatoid arthritis induced by Complete Freund's Adjuvant. **Results:** The labeling yields and radiochemical purity of ¹⁸F-VUIIS1008 were (41±5)% and more than 98%, respectively. Lipophilicity was 1.58±0.03 and specific radioactivity was 4107 Ci/mmol. ¹⁸F-VUIIS1008 displayed good stability, which the radiochemical purity was more than > 98%, in saline at 4 h. It also exhibited high specific TSPO binding in RAW264.7 macrophage cells in vitro. The uptake ratio was (14.0 ± 0.3) % at 1 h after incubation, and decreased significantly after adding cold ligand (Figure 1). The competitive binding study showed that ¹⁸F-VUIIS1008 has high affinity for TSPO with IC₅₀ 0.05nM (Figure 2). Micro-PET imaging demonstrated uptake of ¹⁸F-VUIIS1008 on the left arthritic ankles was gradually increased from 0.5 h to 1 h, which was (1.33±0.01) % ID/g at 1 h. The uptake was 2-2.5 times compared with contralateral normal ankles. The uptake of ¹⁸F-VUIIS1008 Micro PET imaging showed different levels at various days in inflammation models, with a peak of inflammation at day 7 and 29 (Figure 3), suggesting that it was associated with the mechanism that the inflammation model was performed by CFA. ¹⁸F-VUIIS1008 Uptake in the arthritic ankles could be largely blocked by PK11195 or cold ligand (VUIIS1008) (Figure 4). **Conclusion:** ¹⁸F-VUIIS1008 can be readily radiolabelled, clearly visualized arthritis and exhibited low background, suggesting its potential as a novel promising molecular probe targeting TSPO for

arthritic PET imaging. **References:** None

OP-535

Preliminary evaluation of a novel PET tracer for fatty acid oxidation, ¹⁸F-AS3504073-00

Y. Ohshima^{1,2}, Y. Yagi^{1,2}, X. Chen^{1,2}, S. Mühlig^{1,2}, H. Fushiki³, Y. Murakami³, T. Higuchi^{1,2,4};

¹Department of Nuclear Medicine, University Hospital, University of Würzburg, Würzburg, GERMANY, ²Comprehensive Heart Failure Center, University Hospital, University of Würzburg, Würzburg, GERMANY, ³Bioimaging Research Laboratories, Astellas Pharma Inc., Tsukuba, JAPAN, ⁴Okayama University, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, JAPAN.

Aim/Introduction: Fatty acid oxidation (FAO) is a major process to satisfy the high-energy requirement of the myocardium and is a promising therapeutic target for heart failure. Radiolabeled thia-substituted fatty acid, such as 18-¹⁸F-fluoro-4-thia-oleate (FTO), has been introduced as a marker of myocardial FAO. A newly developed FTO analogue ¹⁸F-AS3504073-00 has been reported aiming to improve tracer characteristics for cardiac imaging. In this study, the subcellular kinetics of uptake and trapping of ¹⁸F-AS3504073-00 was characterized and compared to ¹²⁵I-15-(p-iodophenyl)-3(R,S)-methylpentadecanoic acid (¹²⁵I-BMIPP) and 1-¹⁴C-palmitate in freshly isolated mouse cardiomyocytes. Furthermore, biodistribution studies were performed with ¹⁸F-AS3504073-00 in mice. **Materials and Methods:** All animal experiments were conducted in compliance with the current laws of the Federal Republic of Germany. Cardiomyocytes were freshly isolated from healthy mice according to the previous reports with some modifications (1). Cardiomyocytes were treated with ¹⁸F-AS3504073-00, ¹²⁵I-BMIPP or 1-¹⁴C-palmitate in 0.5% BSA/DMEM at 37°C or 4°C. CD36-dependent uptake and metabolic trapping were examined by treating cardiomyocytes with each tracer in the presence of specific inhibitors. For biodistribution studies, mice were euthanized at 60 min after intravenous injection of ¹⁸F-AS3504073-00 and the radioactivity in the tissues of interest was measured. **Results:** ¹⁸F-AS3504073-00, ¹²⁵I-BMIPP, and 1-¹⁴C-palmitate were time-dependently taken up into cardiomyocytes, while CD36 inhibitor, sulfo-succinimidyl oleate, could significantly inhibit the uptake of these tracers (P<0.01). The cell-associated radioactivity of three tracers was significantly reduced in the presence of etomoxir, a specific inhibitor for carnitine palmitoyltransferase-1 (CPT-1) (P<0.05). These results indicate that ¹⁸F-AS3504073-00, as well as ¹²⁵I-BMIPP and 1-¹⁴C-palmitate, was taken up into cardiomyocytes via CD36, then transported into mitochondria via CPT-1. Extracellular release after exposure of the tracers in the presence or absence of etomoxir showed that ¹⁸F-AS3504073-00 was rapidly washed out from

cytosol, but remained in mitochondria. While ^{125}I -BMIPP and $1\text{-}^{14}\text{C}$ -palmitate remained in both cytosol and mitochondria. Biodistribution studies showed that ^{18}F -AS3504073-00 was rapidly cleared from the blood and accumulated significantly in the heart and liver. The SUV in the heart, heart-to-blood ratio, and heart-to-muscle ratio were 4.9 ± 0.5 , 22.0 ± 3.2 , 27.8 ± 1.2 , respectively. **Conclusion:** ^{18}F -AS3504073-00 was taken up into cardiomyocytes via fatty-acid transporter CD36 and specifically trapped in mitochondria due to FAO. Furthermore, biodistribution study with ^{18}F -AS3504073-00 showed high heart-to-background ratios. Therefore, the new class of PET tracer ^{18}F -AS3504073-00 is worthy of further pursuit as a marker of altered cardiac metabolic phenotype in heart failure. **References:** (1) O'Connell TD, et al. *Methods Mol Biol* 2007;357:271-96.

OP-536

Characterization of a new panel of ^{89}Zr -labeled RON targeting monoclonal antibodies as a targeting agent for molecular imaging

D. Spiegelberg^{1,2}, P. Jha¹, X. Y. Koh³, D. Lane^{3,4}, M. Nestor¹;

¹Dep of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, ²Dep of Surgical Sciences, Uppsala University, Uppsala, SWEDEN, ³P53 Laboratory, Agency for Science, Technology and Research (A*STAR), Singapore, SINGAPORE, ⁴Dep of Microbiology, Tumor and Cell Biology, Science for Life Laboratory, Karolinska Institutet, Stockholm, SWEDEN.

Aim/Introduction: The tyrosine kinase of the Recepteur D'origine Nantais (RON) receptor, also called macrophage-stimulating protein receptor (MST1R), is associated with the progression and metastasis of cancer. Only expressed in small amounts on epithelial cells, it is often overexpressed and alternatively spliced in cancer, including constitutively active isoforms. In addition, aberrant glycosylated RTKs like RON tend to increase the kinase activity of the receptor and lead to poor outcomes. RON is therefore an attractive target for diagnostic imaging and cancer therapeutics. Particularly, RON targeting monoclonal antibodies that also inhibit aberrantly glycosylated RON, which might have greater therapeutic efficacy in the treatment of cancer, is of great value. The objective of the present study was to evaluate for the first time the in vitro and in vivo binding properties of a new panel of RON targeting monoclonal antibodies to assess their utility as a targeting agent for molecular imaging using PET/CT. **Materials and Methods:** In the current study we examined a new panel of monoclonal antibodies binding not only of the glycosylated RON but also of the non-glycosylated and aberrant glycosylated RON receptor. The antibodies were labeled with ^{89}Zr using the siderophore-derived chelator desferrioxamine (DFO) and the stability was evaluated by chromatography. In vitro binding properties were assessed by LigandTracer measurements and cell specificity studies. For the in vivo

investigations, tracer distribution was studied in a double tumor model with RON knockout and RON-overexpressing colon cancer xenografts using PET/CT imaging, followed by biodistribution and autoradiography. **Results:** The in vitro characterizations of the tracers demonstrated long shelf life and antigen specific binding. Repeated PET/CT imaging after 24, 48 and 72 hours demonstrated excellent imaging properties for all tested tracers, with the best contrast images occurring 48 hours post injection. The highest uptake was detected in the RON expressing tumor with no uptake in healthy tissue. The biodistribution data and ex vivo autoradiography results confirmed the specific binding of the novel tracer to the RON-positive tumors, significantly higher than for the negative control tumors. **Conclusion:** PET imaging with ^{89}Zr -DFO-anti RON Ab's is a promising approach for cancer diagnostics and could be further utilized for patient stratification and treatment response monitoring of RON targeting therapeutics. **References:** None

OP-537

D-Peptide-based probes for CXCR4-targeted molecular imaging and radionuclide therapy

F. Cleeren¹, C. Cawthorne², T. Van Loy³, J. Kleynhans⁴, K. Leys¹, M. M. Sathekege⁴, D. Schols³, C. M. Deroose⁵, G. Bormans¹;

¹Radiopharmaceutical Research, Department of Pharmacy and Pharmacology, KU Leuven, Leuven, BELGIUM, ²Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM, ³Rega Institute for Medical Research, KU Leuven, Leuven, BELGIUM, ⁴Department of Nuclear Medicine, University of Pretoria & Steve Biko Academic Hospital, Pretoria, SOUTH AFRICA, ⁵Nuclear Medicine, University Hospitals Leuven; Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM.

Aim/Introduction: Attempts to make a suitable fluorine-18 derivative of [^{68}Ga]Pentixafor¹ were unsuccessful due to the pronounced sensitivity of the Pentixafor scaffold towards even minor structural modifications, leading to strongly decreased CXCR4 binding affinity. Results with the therapeutic companion radiopharmaceutical [^{177}Lu]Pentixather are promising, but there is still room for improvement regarding pharmacokinetics and dosimetry profile.² Moreover, an anti-CXCR4 radiopharmaceutical labelled with an α -emitter might present a breakthrough in therapy of various CXCR4-expressing tumours. Therefore, the aim of this study is to develop innovative CXCR4 radiopharmaceuticals, both for diagnostic and therapeutic purposes, starting from D-Peptide-based probes (vMIP-II-derived CXCR4 antagonists composed entirely of D-amino acids)³ that have not been explored yet for nuclear medicine applications. **Materials and Methods:** The high affinity (~4.6 nM) bivalent construct DV1-K-(DV3)³ was site-specifically derivatised with 2tBu-NOTA and 3tBu-DOTA to obtain NOTA-DV1-K-(DV3) and DOTA-DV1-K-(DV3), after deprotection

respectively. After purification and characterization, the CXCR4 binding affinity of the derivatized peptides was determined before and after complexation of stable gallium and lutetium. NOTA-DV1-K(DV3) was labelled using the Al¹⁸F-method (NaOAc 0.1M, pH 4.1, 15 min 95°C) on an automated synthesis platform (Trasis AllinOne). DOTA-DV1-K-DV3 was labelled manually with gallium-68 (NH₄OAc 0.1M, pH 3.5), lutetium-177 (0.1M NaOAc, pH 4.1, 15 min 95°C) and actinium-225 (Tris 0.1M, pH 9, 5 min μ wave 95°C). The in vitro stability of the radiopharmaceuticals was determined in human serum at 37°C (iTLC and HPLC). Finally, the pharmacokinetic properties and specificity of the Al¹⁸F-labeled anti-CXCR4 radiopharmaceutical was evaluated in healthy mice using μ PET/CT with or without co-injection of 5 mg/kg AMD3100, followed by ex vivo biodistribution at 75 min. **Results:** The probes were successfully radiolabelled with [¹⁸F]AlF, [⁶⁸Ga]Ga, [¹⁷⁷Lu]Lu or [²²⁵Ac]Ac and demonstrated high in vitro stability (>95% after 2h). [¹⁸F]AlF-NOTA-DV1-K-(DV3) showed excellent pharmacokinetic properties with fast renal clearance and high and specific targeting of CXCR4 expressing tissues such as liver (SUV 7.38±0.49 vs. 0.96±0.13) and spleen (SUV 3.15±0.80 vs. 0.88±0.25). Moreover, in vitro binding studies of the probes confirmed high-affinity binding (5–15 nM) towards human CXCR4. Tumour targeting studies in CXCR4-positive xenografts and further affinity studies (AlF, La complex) are ongoing. **Conclusion:** The new probes demonstrated excellent pharmacokinetic properties and are expected to have a strong impact on CXCR4-targeted diagnostic imaging and targeted radionuclide therapy. **References:** 1. OP-538

Development of a specific PET radiotracer of APJ: in vitro and in vivo evaluation in a colon adenocarcinoma model

B. Louis¹, A. Moyon², A. Bouhlel¹, L. Balasse¹, S. Fernandez¹, S. Simoncini³, G. Hache², F. Dignat-George⁴, P. Garrigue², B. Guillet²; ¹C2VN INSERM 1263 INRA 1260 CERIMED Aix-Marseille Université, Marseille, FRANCE, ²C2VN INSERM 1263 INRA 1260 CERIMED, APHM, Aix-Marseille Université, Marseille, FRANCE, ³C2VN INSERM 1263 INRA 1260 Aix-Marseille Université, Marseille, FRANCE, ⁴C2VN INSERM 1263 INRA 1260, APHM, Aix-Marseille Université, Marseille, FRANCE.

Aim/Introduction: APJ receptor has been recently identified as overexpressed in various cancer cell lineages. To date, several APJ-targeted antitumor strategies are explored. We developed [⁶⁸Ga]Ga-AP747 as an APJ-targeted PET radiotracer, evaluated its biodistribution in healthy animals, and its specificity towards APJ in vitro and in vivo in a human colon carcinoma mouse model. **Materials and Methods:** AP747 was synthesized and radiolabeled with gallium-68.

Radiochemical stability in 0.9% NaCl and in human serum was validated up to 2h after synthesis by radioTLC (iTLC-SG, sodium citrate 0.1M pH5). To evaluate [⁶⁸Ga]Ga-AP747 biodistribution, 4.3±0.44MBq/50 μ L (0.17 μ g) of [⁶⁸Ga]Ga-AP747 were IV injected to healthy mice (n=3), and μ PET/CT acquisition was performed. In vitro characterization of [⁶⁸Ga]Ga-AP747 specificity towards APJ was performed on APJ-overexpressing human colon carcinoma T84 cells, as verified by western-blot. Blocking was performed using a 50-fold excess of APJ natural ligand. Quantification of radioactivity was realized on background-corrected autoradiographs (n=6). Mice (n=6) were subcutaneously xenografted with human colon adenocarcinoma T84 cells. 5.1±1.1MBq/50 μ L (0.17 μ g) of [⁶⁸Ga]Ga-AP747 were IV injected to the mice (n=3), and a μ PET/CT acquisition was performed. In vivo blocking was realized by injecting a large excess of 50 μ g apelin 30min before injecting 5.3±0.9MBq/50 μ L (0.17 μ g) of [⁶⁸Ga]Ga-AP747 (n=3) and a μ PET/CT acquisition was performed 1h after injection. μ PET/CT acquisitions were performed on a Nanoscan PET/CT camera. PET signal quantification was corrected by physical decay and expressed as percentage of injected dose per gram of tissue (%ID/g) for the biodistribution study, and as tumor-to-background ratios (t/b) for the in vivo blocking study, the gastrocnemius muscle taken as reference for background. **Results:** [⁶⁸Ga]Ga-AP747 was produced with a radiochemical purity of 96.7±2.0% and a radiochemical stability confirmed in serum up to 2h after synthesis (95.0±1.5%). In healthy animals, [⁶⁸Ga]Ga-AP747 was rapidly cleared from the circulation through early renal elimination with a resulting low background signal as soon as 30min after injection and notably a low hepatic uptake. In vitro blocking resulted in a significant 65% signal abolishment compared to non-blocked condition (***P= 0.0003). In T84-tumor bearing mice, [⁶⁸Ga]Ga-AP747 showed a high tumor uptake (t/b : 7.93±2.17) nearly totally abolished in blocking conditions (t/b: 1.03±0.32, n=3, *P=0.0235). **Conclusion:** [⁶⁸Ga]Ga-AP747 presents a highly favorable biodistribution profile for PET imaging. Specificity of AP747 PET imaging signal towards APJ was demonstrated in vitro and in vivo. Evaluating in vivo tissue APJ overexpression may represent an efficient companion tool of experimental APJ-inhibiting therapies, to determine therapeutic eligibility or to monitor therapeutic follow-up. **References:** None

Preclinical evaluation of ⁶⁸Ga-Desferal for bacterial infection imaging

M. Petrik¹, E. Umlaufova¹, V. Raclavsky², A. Palyzova³, V. Havlicek³, J. Pfister⁴, Z. Novy¹, M. Popper¹, M. Hajduch¹, C. Decristoforo⁴; ¹Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University, Olomouc, CZECH REPUBLIC, ²Department of Microbiology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, CZECH REPUBLIC,

³Institute of Microbiology of the Czech Academy of Sciences, Prague, CZECH REPUBLIC, ⁴Clinical Department of Nuclear Medicine, Medical University Innsbruck, Innsbruck, AUSTRIA.

Aim/Introduction: Bacterial infections are a serious global healthcare problem. Early and accurate identification and localization of infection is the critical first step in effective patient care. Molecular imaging has the potential for specific and sensitive detection of infections. The siderophore-based iron acquisition system represents one of few fundamental differences between bacterial and mammalian cells. Bacteria possess dedicated transporters for uptake of siderophores. Siderophores are low-molecular mass, iron specific chelators secreted by microorganisms. We have recently demonstrated that siderophores can be radiolabelled, replacing iron by gallium-68 without loss of bioactivity and allowing molecular imaging of fungal infections by positron emission tomography (PET). Here we report on the preclinical evaluation of clinically used siderophore, deferoxamine, marketed under the brand name Desferal (DFO), radiolabelled with Ga-68 for imaging of bacterial infections. **Materials and Methods:** DFO was labelled with Ga-68 in sodium acetate. In vitro characterization of ⁶⁸Ga-DFO including the determination of partition coefficient, protein binding and stability in various media was performed. In vitro uptake of ⁶⁸Ga-DFO was tested in different microbial cultures. In vivo biodistribution was studied in healthy mice. PET/CT imaging of ⁶⁸Ga-DFO was performed in suitable animal infection models. **Results:** DFO was labelled with Ga-68 with high radiochemical purity. In vitro assays showed hydrophilic properties of ⁶⁸Ga-DFO with low protein binding and high stability in human serum and PBS. The high in vitro uptake of ⁶⁸Ga-DFO in selected strains of *Pseudomonas aeruginosa* (Pa.), *Staphylococcus aureus* (S.a.) and *Streptococcus agalactiae* (S.ag.) could be blocked with an excess of cold iron-DFO. Ex vivo biodistribution data and PET/CT imaging acquired from experiments with healthy mice displayed rapid excretion of ⁶⁸Ga-DFO via the renal system and showed minimal retention in blood and other organs. PET/CT images of animal infection models displayed high and specific accumulation of ⁶⁸Ga-DFO in both Pa. and S.a. infection with excellent image contrast. No uptake was found in sterile inflammation, heat inactivated Pa. or S.a. and *Escherichia coli* lacking DFO transporters. **Conclusion:** We have shown that DFO can be labelled with Ga-68 with high radiochemical purity. ⁶⁸Ga-DFO displayed suitable in vitro characteristics and excellent pharmacokinetics in healthy mice. The high and specific uptake of ⁶⁸Ga-DFO by Pa. and S.a. was confirmed both in vitro and in vivo, proving the potential of DFO for specific imaging of bacterial infections. Whereas DFO is accepted in clinic for many years, we believe that ⁶⁸Ga-DFO has a great potential to clinical translation. **References:** None

OP-540

Fluorine-18 isotopic radiolabelling of the MEK inhibitor drug Binimetinib as a new PET imaging tool

S. Specklin, R. Pelletier, C. Truillet, B. Kuhnast;
CEA, Orsay, FRANCE.

Aim/Introduction: Mitogen-activated protein kinases (MAPK) signaling pathway plays an important role in cell proliferation. Mutation of BRAF gene induces an upregulation of this pathway that is involved in the development of several cancers. Binimetinib is a selective inhibitor of the MEK kinase involved in this signaling cascade and has been approved by the FDA for the treatment of BRAF positive melanoma.^[1] Radiolabelling of this compound could thus lead to interesting PET imaging applications, from preclinical studies of the signaling pathway, to a potential selective clinical tracer to monitor BRAF mutation. However, the structure of Binimetinib exhibits two aromatic fluorine atoms located on unactivated positions, therefore making its isotopic labelling a strong radiochemistry challenge. **Materials and Methods:** The most promising radiofluorination position was selected and the labelling development was performed from a model derived from the Binimetinib whose hydroxamic ester was replaced by a methyl ester. A large number of aromatic radiofluorination methods was screened in an informative comparative benchmark. For each method, the corresponding labelling precursor was synthesized in a few steps from a commercial Binimetinib precursor. Evaluation of the radiofluorination was performed on the advanced intermediate and applied to the whole compound in case of success. **Results:** Seven labelling precursors of the model intermediate were synthesized in one to six synthesis steps. Most of the radiofluorination methods were ineffective, highlighting a significant electronic enrichment of the arene. A low radiochemical conversion (RCC) of 5% was surprisingly observed via a Balz-Schiemann reaction and the best results were observed from copper mediated radiofluorination from stannyl or boronate precursors. After a careful optimization of the conditions, the model intermediate was radiolabelled with RCC up to 70% from the boronate precursor. However, the translation of these conditions to the whole Binimetinib precursor was unsuccessful. This prompted us to develop an optimized labelling strategy starting from the radiofluorination of the model intermediate first, followed by the hydrolysis of the methyl ester, its activation and coupling to the corresponding alkyhydroxylamine prior to a final deprotection. **Conclusion:** Using copper mediated radiolabelling of a boronate precursor, [¹⁸F]Binimetinib was obtained in a fully automated radiosynthesis involving a 5 steps / one pot sequence with 6% RCY. These first results will enable the first preclinical evaluation of [¹⁸F] Binimetinib. **References:** [1] Specenier, P. An Overview of Binimetinib for the Treatment of Melanoma. Expert Opinion

Development of a new fluorine-18-labelled PET tracer targeting norepinephrine transporter and evaluation on rodent and large animal models

X. Chen^{1,2,3}, S. Mühlig^{2,3}, Y. Ohshima^{2,3,4}, Y. Yagi⁵, H. Kimura⁵, K. Koshino⁶, N. Nose⁷, C. Lapa¹, A. Buck², T. Higuchi^{2,3,7};

¹Department of Nuclear Medicine, University Hospital of Augsburg, Augsburg, GERMANY, ²Department of Nuclear Medicine, University Hospital of Würzburg, Würzburg, GERMANY, ³Comprehensive Heart Failure Center, University Hospital of Würzburg, Würzburg, GERMANY, ⁴Department of Radiation-Applied Biology Research, Quantum Beam Science Research Directorate, National Institutes for Quantum and Radiological Science and Technology, Gunma, JAPAN, ⁵Department of Analytical and Bioinorganic Chemistry, Kyoto Pharmaceutical University, Kyoto, JAPAN, ⁶Department of Systems and Informatics, Hokkaido Information University, Ebetsu, Hokkaido, JAPAN, ⁷Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, JAPAN.

Aim/Introduction: Norepinephrine transporter (NET) is one of the major targets for diagnosis of heart failure and neuroendocrine tumours. Exemplified by clinically used SPECT tracer MIBG, a few NET-targeting radiotracers structurally derived from norepinephrine have been reported. We intend to develop a new fluorine-18-labelled PET tracer, 1-(3-fluoro-4-(3-¹⁸F-(fluoropropoxy)phenethyl)guanidine, with convenient radiolabelling procedure and high yield while keeping the high NET affinity. **Materials and Methods:** Starting from 4-methoxy-3-fluorobenzaldehyde, followed with Wittig reaction and Mitsunobu reaction for the synthesis. The NET affinity of the non-radioactive (cold) reference was evaluated in neuroblastoma SK-N-SH cell lines against ¹³¹I-MIBG. Different fluorine salts, catalysts and reaction temperature were examined for optimal radiolabelling condition. After successful radiofluorination, the radiotracer was evaluated in both rodents (n=4) and large animals (n=4) for biodistribution and cardiac uptake studies. **Results:** The precursor and the corresponding cold reference were synthesized. The cold reference shows essentially identical affinity at NET as norepinephrine (1.38 vs 2.57 μM against ¹³¹I-MIBG). The radiofluorination of the tracer could be achieved using [¹⁸F]KF/K₂₂₂ in DMF with high yield (28 %) and specific activity (54 GBq/mol). The dynamic imaging of the ¹⁸F-labelled tracer in rats has demonstrated stable and long-term cardiac uptake. Specific uptake was confirmed by blocking studies (administration of phenoxybenzamine before the injection of the radiotracer, heart-to-liver ratio: blocking 1.30 ± 0.54 vs control 6.14 ± 0.35 p<0.001) in both ex vivo autoradiography and in vivo imaging. A further evaluation of the radiotracer in cynomolgus monkeys has

demonstrated desipramine-sensitive high cardiac uptake and long-term retention (standardized uptake value 60 min postinjection of the tracer: heart 1.47 ± 0.18 vs liver 0.91 ± 0.47, p<0.05). **Conclusion:** We have successfully developed a new ¹⁸F-labelled PET tracer targeting NET, which showed almost identical affinity as MIBG in cell uptake studies and favourable biodistribution in both rodents and large animals showing distinct heart delineation and long-term desipramine-sensitive cardiac uptake. It provides not only potentially new PET clinical option, but also alternatives to investigate insights into the structure-affinity relationships for NET. **References:** None

Aim/Introduction: GluN2B subunit-containing NMDA receptors are involved in various neurodegenerative pathologies and hence a critical therapeutic drug target. We have previously reported on a GluN2B PET radioligand codenamed [¹⁸F]PF-NB1. Despite the remarkable in vitro specificity and selectivity, [¹⁸F]PF-NB1 exhibited only moderately higher in vivo binding to GluN2B-rich brain regions, as compared to the GluN2B-deficient cerebellum. With the aim to improve the in vivo selectivity, we evaluated OF-NB1 and MF-NB1, both constitutional isomers of [¹⁸F]PF-NB1[1]. **Materials and Methods:** Multi-step synthesis of OF-NB1 and MF-NB1 was followed by in vitro binding affinity determination of both ligands towards GluN2B subunits and sigma-1 receptors (off-target binding). A two-step method involving radiofluorination and cleavage of the protecting groups was used for the radiosynthesis of [¹⁸F]OF-NB1. In vitro autoradiography using rat and postmortem human ALS brain tissue slices, confocal microscopy, PET imaging, ex vivo biodistribution and metabolite studies were performed. Receptor occupancy experiments were carried out using CP-101,606 (0.5-15 mg/kg), a GluN2B antagonist with documented clinical efficacy. **Results:** OF-NB1 and MF-NB1 were synthesized in 24% and 14% overall yields, respectively. OF-NB1 exhibited a binding affinity value of 10.4±4.7 nM towards GluN2B subunits and a 39-

Aim/Introduction: GluN2B subunit-containing NMDA receptors are involved in various neurodegenerative pathologies and hence a critical therapeutic drug target. We have previously reported on a GluN2B PET radioligand codenamed [¹⁸F]PF-NB1. Despite the remarkable in vitro specificity and selectivity, [¹⁸F]PF-NB1 exhibited only moderately higher in vivo binding to GluN2B-rich brain regions, as compared to the GluN2B-deficient cerebellum. With the aim to improve the in vivo selectivity, we evaluated OF-NB1 and MF-NB1, both constitutional isomers of [¹⁸F]PF-NB1[1]. **Materials and Methods:** Multi-step synthesis of OF-NB1 and MF-NB1 was followed by in vitro binding affinity determination of both ligands towards GluN2B subunits and sigma-1 receptors (off-target binding). A two-step method involving radiofluorination and cleavage of the protecting groups was used for the radiosynthesis of [¹⁸F]OF-NB1. In vitro autoradiography using rat and postmortem human ALS brain tissue slices, confocal microscopy, PET imaging, ex vivo biodistribution and metabolite studies were performed. Receptor occupancy experiments were carried out using CP-101,606 (0.5-15 mg/kg), a GluN2B antagonist with documented clinical efficacy. **Results:** OF-NB1 and MF-NB1 were synthesized in 24% and 14% overall yields, respectively. OF-NB1 exhibited a binding affinity value of 10.4±4.7 nM towards GluN2B subunits and a 39-

fold selectivity over sigma-1 receptors. MF-NB1 displayed a lower GluN2B subunit affinity of 590 ± 36 nM. [^{18}F]OF-NB1 was synthesized in isolated radiochemical yields of $5.5 \pm 0.1\%$ ($n=6$) and molar activities of 192 ± 33 GBq/ μmol . In rat autoradiographic experiments, [^{18}F]OF-NB1 displayed higher accumulation in GluN2B-rich regions (cortex, striatum, thalamus and hippocampus) than the GluN2B-poor cerebellar region, which was blockable with GluN2B ligands, EVT-101 and CERC-301, but not with sigma-1 receptor ligands, fluspidine and SA4503. These findings were corroborated by PET imaging in Wistar rats using CP-101,606. Only intact [^{18}F]OF-NB1 was found in the rat brain 60 min postinjection. Biodistribution studies indicated higher GluN2B-rich regions/cerebellum ratios when compared to our previously reported [^{18}F]PF-NB1. A dose-dependent blocking effect was observed with CP-101,606 and resulted in a D_{50} of 8.1 $\mu\text{mol/kg}$. Lower GluN2B subunit expression was observed in ALS brain tissue sections compared to healthy controls, as indicated by autoradiography and confocal microscopy. **Conclusion:** [^{18}F]OF-NB1 is by far the most promising fluorinated radioligand for the in vivo PET imaging of GluN2B-containing NMDA receptors and drug receptor occupancy studies, and has potential for PET imaging studies in ALS patients and GluN2B subunit-related brain disorders. **References:** [1] Ahmed H, et al. OP-543

Biodistribution and Pharmacokinetics of Long-acting Radiolabeled Cyclic RGD Peptide in MDA-MB-231 Breast Cancer Model

Y. Huang, M. Chen, S. Lee, S. Lo, S. Chen, L. Chen, M. Li, C. Chang;
Institute of Nuclear Energy Research, Taoyuan, TAIWAN.

Aim/Introduction: Integrin $\alpha_v\beta_3$ plays a very important role in tumor angiogenesis which is significantly up-regulated on activated endothelial cells during angiogenesis. The majority of integrin-targeted imaging tracers are based on the tripeptide Arg-Gly-Asp (RGD) acid sequence because of its high affinity and specificity for integrin $\alpha_v\beta_3$. Some studies had proved that the conjugation of an albumin-binding motif, truncated Evans blue (EB), to radiolabeled cyclic RGD peptides significantly enhance imaging performance and therapeutic efficacy in a glioblastoma model. Aims of this study were to evaluate the improvement of pharmacokinetics, nanoSPECT imaging performance and biodistribution of the novel ^{111}In -DOTA-EB-cRGDfK in MDA-MB-231 breast cancer model. We demonstrated that ^{111}In -DOTA-EB-cRGDfK may offer diagnostic images for triple-negative breast cancer in the future. **Materials and Methods:** After intravenous injection of ^{111}In -DOTA-EB-cRGDfK and ^{111}In -DOTA-cRGDfK, blood samples from

MDA-MB-231 tumor-xenografted mouse model were collected through cardiac puncture at various time points. The pharmacokinetic parameters were estimated with the WinNonlin. Comparative study of nanoSPECT/CT imaging was processed by manually drawing regions of interest (ROIs) on tumor/kidney/liver/muscle and calculating the value of ROIs in PMOD. For ^{111}In -DOTA-EB-cRGDfK biodistribution analysis, organs of interest were removed, washed and weighed, and the radioactivity was measured with gamma counter. **Results:** The radiochemical purity of ^{111}In -radiopharmaceuticals was more than 90% analyzed by using radio-TLC and radio-HPLC. The clearance rate (Cl) of ^{111}In -DOTA-cRGDfK was 12.9 g/h, which is 94.9-fold higher than that of ^{111}In -DOTA-EB-cRGDfK (0.136 g/h). The area under the time curve ($\text{AUC}_{0 \rightarrow \infty}$) of ^{111}In -DOTA-EB-cRGDfK and ^{111}In -DOTA-cRGDfK was 375 and 1.02 %ID/g*h. The results of nanoSPECT/CT imaging presented cRGDfK peptide with a truncated albumin-binding motif EB enhanced tumor accumulation. ^{111}In -DOTA-EB-cRGDfK showed the highest tumor uptake at 24 h postinjection (10.93 ± 3.22 %ID/g), whereas ^{111}In -DOTA-cRGDfK was almost washout at the same time point (0.32 ± 0.18 %ID/g). The tumor accumulation of ^{111}In -DOTA-EB-cRGDfK was maintained at least 96 h (9.22 ± 2.65 %ID/g). The biodistribution result showed the highest tumor uptake was found to be $7.19 \pm 0.45\%$ at 24 h after ^{111}In -DOTA-EB-cRGDfK administration. **Conclusion:** These results of pharmacokinetics and nanoSPECT/CT imaging showed albumin-binding motif could improve circulation time of cRGDfK peptide, and the slow release of ^{111}In -DOTA-EB-cRGDfK from albumin might allow continual uptake in MDA-MB-231 breast tumor. It has been proved that ^{111}In -DOTA-EB-cRGDfK provided high contrast for the diagnostic image of triple-negative breast cancer. We are going to evaluate the capability as a radiotherapy tool of DOTA-EB-cRGDfK for $\alpha_v\beta_3$ -positive tumors in the future. **References:** None

Environmental Medicine, Rome, ITALY, ⁴Nuclear Medicine Department, Jordanian Royal Medical Services, Amman, JORDAN, ⁵Unit of Thoracic Surgery, San Camillo Forlanini Hospital, Rome, ITALY, ⁶Fondazione Policlinico Universitario A. Gemelli IRCCS; UOC Medicina Nucleare-Università Cattolica S. Cuore, Rome, ITALY.

Aim/Introduction: In non-small-cell lung cancer (NSCLC) staging, the evaluation of lymph nodal status is of paramount importance for selecting the optimal therapeutic approach. Study aim is to evaluate the performance of artificial neural network (NN) applied to preoperatively ¹⁸F-FDG PET/CT for predicting pathological nodal involvement in NSCLC patients. **Materials and Methods:** We retrospectively analyzed clinical, anatomic, metabolic and histopathological data from 540 consecutive clinically resectable NSCLC patients (333M; mean age: 67.4±9 years), who underwent pre-operative ¹⁸F-FDG PET/CT and subsequent pulmonary resection with hilio-mediastinal lymphadenectomy. From a set of features, Boruta algorithm selects 13 relevant features as input parameters (>60% PET-derived): patients' age, tumor size (mm), PET tumor result (positive: uptake ≥mediastinal blood-pool; SUVmax, SUVmean, TLG, MTV), PET nodal result (positive: at least one node with uptake ≥mediastinal blood-pool), PET nodal staging (N0/N1/N2), tumor histotype and grading. The dataset was randomly splitted into 2/3 training and 1/3 testing, with no features differences (p>0.05) between the two groups. Both logistic regression (LR) and a 3-layers NN (with 12, 6 and 2 neurons, respectively) models were applied, with NN trained for 500 epochs with 150 batch size and 0.1 validation split. With surgically-proven nodal status as gold standard (pN0 vs pN+ patients), diagnostic performance of NN for nodal staging was calculated by ROC analysis and compared with LR in terms of area under the curve (AUC), accuracy (ACC), sensitivity (SE), specificity (SP), positive and negative predictive values (PPV, NPV); comparison with visual PET nodal staging was also performed. **Results:** Histopathological nodal involvement (pN+) was detected in 108/540 (20%) patients. Training NN performance (AUC=0.849): ACC=80%, SE=72%, SP=81%; PPV=50%, NPV=92%. Test NN performance (AUC=0.769): ACC=77%, SE=58%, SP=81%; PPV=44%, NPV=89%. Training LR performance (AUC=0.795): ACC=75%, SE=68%, SP=77%; PPV=43%, NPV=90%. Test LR performance (AUC=0.763): ACC=77%, SE=55%, SP=82%; PPV=43%, NPV=88%. Visual PET analysis performance: ACC=0.82, SE=32%, SP=94%; PPV=57%, NPV=85%. **Conclusion:** Application of artificial NN to preoperative ¹⁸F-FDG PET/CT provides overall good performance for predicting pathological nodal status in NSCLC patients candidates for surgical resection, especially for ruling out nodal metastases due to high specificity. In clinical practice, our results suggest that application of NN allows to reduce the chance of false negative results at visual ¹⁸F-FDG PET/CT analysis. This finding assumes greater relevance in a population of clinically resectable NSCLCs,

with "a priori" low probability of lymph nodal involvement. Further studies are ongoing on NN application for categorizing pathological nodal involvement in N1 vs N2 status. **References:** None

Aim/Introduction: Survival follow-up is often incomplete or missed in clinical trials, which restricts the availability of extensive data in the development of artificial intelligence (AI) in prognosis prediction. We aimed to develop a weakly-supervised deep learning technology to utilize incomplete survival data in the prognosis of extranodal natural killer/T-cell lymphoma, nasal type (ENKTL) based on pre-treatment ¹⁸F-FDG PET/CT. **Materials and Methods:** One hundred and twenty-three ENKTL patients underwent ¹⁸F-FDG PET/CT before the treatment for the purpose of staging were retrospectively collected. Among them, 72 were followed-up for at least 2 years and 20% (14 randomly selected) were reserved for the test. In order to use the 51 patients without follow-up data, positive-negative-unlabeled classification (PNU) was developed to create pseudo labels for the training of survival prediction. Deep learning features were extracted from the PET/CT images in a training set (n=109) and a prediction similarity index (PSI) was derived from these features. The sensitivity, specificity and accuracy of PSI based progression-free survival (PFS) prediction were calculated. It was compared with the no pseudo-labels data. Survival curves were obtained using Kaplan-Meier analysis, followed by multivariate analysis to assess the independent effects of PSI and clinical features of the disease on PFS. **Results:** Deep learning features were extracted and PSI>1 was set as positive. In the training set with PNU, PSI got an AUC score of 0.995 in prediction of PFS. The prognosis are significantly different between the two groups divided by PSI (P=0.000). Prognostic performances were validated with the corresponding AUC score of 0.875 in prediction of PFS in the test set. A prediction sensitivity, specificity and accuracy were 83.33%, 87.50% and 85.71%, respectively.

The prognosis are significantly different between the two groups divided by PSI ($P=0.019$). In the control group without PNU, PSI got an AUC score of 0.771 in the test set. A prediction sensitivity, specificity and accuracy were 66.67%, 87.50% and 78.57%, respectively. PNU group (0.708) achieved Youden's index higher than that of non-PNU group (0.542) in the test set. Multivariate analysis showed that PSI with PNU or without PNU remained independent significant factors for PFS. **Conclusion:** Data-enhanced deep learning can utilize the data of incomplete to improve survival prediction. The method revealed the potential of the AI-extracted ^{18}F -FDG PET/CT features as a surrogate for the prognosis prediction of ENKTL. Future prospective studies with external validation are needed to validate our findings. **References:** None

⁶Department of Urology, Hôpital Foch, Suresnes, FRANCE.

Aim/Introduction: The diagnosis of pelvic lymph node (LN) involvement of muscle invasive bladder cancer (MIBC) is critical to guide patients' management. Heterogeneous metabolic and morphological criteria have been suggested in the literature. In this study, we aimed to develop and validate an PET/CT-based decision-making algorithm for use by the non-expert clinician that helps diagnose LN extent in patients with MIBC. **Materials and Methods:** Out of 238 screened patients retrospectively screened, 173 were included. All 18F-FDG PET/CT were performed within 90 days before radical cystectomy and extended pelvic LN dissection, and were reviewed independently by two nuclear medicine physicians. Morphological and metabolic features were collected for visible LN in each pelvic area, as well as physician the subjective conclusion regarding LN involvement. The reference standard was pathological examination of LN dissection samples. Patients were randomly assigned to the training set ($n=115$) or the validation set ($n=58$). Using machine learning (random forest tree algorithm) with 20 features, a multivariable prediction model (the signature) was developed and validated for diagnosing LN involvement. Signature performance

was evaluated using area under a receiver operating characteristic curves (AUCs). **Results:** Thirty (26%) patients presented pelvic LN involvement in the training set, and twelve (21%) in the validation set. In a per-patient analysis in the training set, the top 5 features for the diagnosis of LN involvement were LN SUVmax, product of diameters of the largest LN, the sum of the products of diameters of LN, the bladder tumor largest diameter and the SUVmax of urine. In the training set, the signature reached an AUC of 79.2 (95%CI 70.5-87.9) and the consensus of expert an AUC of 71.5 (95%CI 62.0-81.0), $p = 0.24$. In the validation set, AUCs were 66.7 (95%CI 49.7-83.6) and 62.3 (95%CI 47.8-76.8) $p = 0.70$, respectively. **Conclusion:** A PET/CT-based signature was developed with machine learning and validated for diagnosis of LN involvement on a per patient analysis, in patients with MIBC. The diagnostic performance of 18F-FDG PET/CT provided by this tool was not significantly inferior to a consensus of experts, and could be used for enhanced decision-making. **References:** None

⁴Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, GERMANY, ⁵Klinik für Radiologie und Nuklearmedizin, Universitätsklinikum Magdeburg A.ö.R., Magdeburg, GERMANY.

Aim/Introduction: The standardized uptake value (SUV) is widely used for quantitative evaluation in oncological FDG-PET but has well-known shortcomings as a measure of the tumor's glucose consumption. The standard uptake ratio (SUR) of tumor SUV and arterial blood SUV (BSUV) possesses an increased prognostic value [1,2] but requires image-based BSUV determination, typically in the aortic lumen. However, accurate manual ROI delineation requires care and imposes an additional workload which makes the SUR approach less attractive for clinical routine. The goal of the present work was the development of a fully automated method for BSUV determination in whole-body PET/CT. **Materials and Methods:** Automatic delineation of the aortic lumen was performed with a convolutional neural network (CNN), using the U-Net architecture. 946 FDG PET/CT scans from several sites were used for network training ($N=366$) and testing ($N=580$). For all scans, the aortic lumen was manually delineated, avoiding areas affected by motion-

induced attenuation artifacts or potential spill-over from adjacent FDG-avid regions. Performance of the network was assessed using the fractional deviations of automatically and manually derived BSUVs in the test data. **Results:** The trained U-Net yields BSUVs in close agreement with those obtained from manual delineation. Notably, using both CT and PET data as input for network training allows the trained network to derive unbiased BSUVs by detecting and excluding aorta segments affected by attenuation artifacts or spill-over. Comparison of manually (M) and automatically (A) derived BSUVs shows excellent concordance: the mean paired M-A difference was (mean \pm SD) = (-0.5 \pm 3.1)% with a 95% confidence interval of [-7.0, 6.6]% and a total range of [-10.2, 13.3]%. For four test cases the derived ROI volume was below the predefined threshold (< 1 ml). **Conclusion:** CNNs offer a viable approach for automatic BSUV determination. Our trained network exhibits a performance comparable to an experienced human observer and might already be considered suitable for supervised clinical use. **References:** [1] van den Hoff J, Oehme L, Schramm G, Maus J, Lougovski A, Petr J, et al., *EJNMMI Res.* 2013;3(1):77 [2] Hofheinz F, Li Y, Steffen IG, Lin Q, Lili C, Hua W, et al., *EJNMMI* 2019;46(7):1485

OP-548

Deep Learning-Enabled Comprehensive Detection and Quantification of 18FDCFPyL (PyL-PSMA) PET/CT

J. Brynolfsson¹, K. Johnsson¹, H. Sahlstedt¹, J. Richter¹, K. Sjöstrand¹, N. G. Nickols², M. B. Rettig², L. Edenbrandt^{1,3}, A. Anand¹; ¹Exini Diagnostics AB, Lund, SWEDEN, ²VA Greater Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA, ³University of Gothenburg, Gothenburg, SWEDEN.

Aim/Introduction: Comprehensive and automated quantification of PyL-PSMA PET/CT findings has the potential to be of great value in routine clinical practice as well as in clinical trials. We have developed the automated Prostate Cancer Molecular Imaging Standardized Evaluation (aPROMISE): a tool for automated, structured, and quantitative reporting of PET/CT findings. aPROMISE is based upon, but extends the PROMISE framework (Eiber et al, 2017). aPROMISE automates the process of lesion identification and quantification of e.g. Standard Uptake Values (SUVs). It may improve consistency of both inter- and intra-physician PSMA PET/CT assessments of disease. **Materials and Methods:** aPROMISE creates a deep-learning based semantic segmentation of the CT image. The segmentation is transferred to the PET image where reference SUVs for liver and blood pool are calculated. Suspicious hotspots, i.e., regions with high uptake in the PET image that may be consistent with disease, are identified and their volumes outlined. For each identified hotspot a range of quantitative measurements are generated, e.g., SUV max and lesion volume, as well as the miPSMA

index (Johnsson et al, 2020). Finally, a structured report is generated, summarizing the study data of the patient, together with a detailed list of detected lesions and their respective quantitative measurements. For development of the hotspot detection and delineation algorithm, a data set comprised of 266 PyL-PSMA PET/CT scans with manually annotated lesions was used. Evaluation of reference value computation was performed on 86 independent PyL-PSMA PET/CT images and compared with values estimated by 3 manual readers. **Results:** For bone, lymph and prostate lesions respectively, 91%, 92% and 93% were automatically detected. The Pearson correlation coefficient between reader-generated reference values were in the range 0.73-0.78 for blood pool and 0.78-0.97 for liver. The correlation between the software and reader generated reference values were in the range 0.82-0.88 for blood pool and 0.81-0.95 for liver. The standard deviation of manually generated reference values were 0.24 and 1.29 for blood pool and liver, respectively, whereas the corresponding standard deviations for aPROMISE were 0.21 and 1.15. **Conclusion:** An efficient automatic detection coupled with delineation of lesions in aPROMISE can enable standardized comprehensive quantification. Computation of reference SUVs with aPROMISE demonstrated better consistency than the manual readers. Future work would focus on evaluating the consistent and quantitative reporting of aPROMISE in management of patients with prostate cancer. **References:** None

OP-549

Whole-body lesion detection and prostate cancer staging in ⁶⁸Ga-PSMA-11 PET/CT using deep learning

N. Capobianco¹, A. Gafita², G. Platsch¹, L. Sibille³, B. Spottiswoode³, M. Eiber², W. A. Weber², N. Navab⁴, S. G. Nekolla²; ¹Siemens Healthcare GmbH, Erlangen, GERMANY, ²Department of Nuclear Medicine, Klinikum rechts der Isar, Technical University of Munich, Munich, GERMANY, ³Siemens Medical Solutions USA Inc., Knoxville, TN, UNITED STATES OF AMERICA, ⁴Computer Aided Medical Procedures (CAMP), Technical University of Munich, Munich, GERMANY.

Aim/Introduction: PSMA-ligand PET/CT has shown high accuracy for prostate cancer staging. Nevertheless, accurate interpretation of ⁶⁸Ga-PSMA-11 PET/CT images can be challenging with possible tracer uptake in sub-milliliter lesions and known pitfalls (1). We developed and evaluated a deep learning method to detect lesions in whole-body ⁶⁸Ga-PSMA-11 PET/CT and classify them following a standardized staging framework. **Materials and Methods:** ⁶⁸Ga-PSMA-11 PET/CT images of 93 patients with proven prostate cancer were annotated by two expert physicians (AG, GP). Each region with increased tracer uptake was segmented, labeled as physiological or suspicious and assigned an anatomical localization from a set of physiological uptake

sites and sites relevant for staging according to the PROMISE framework (2). PET/CT images and expert annotations were used for training a convolutional neural network (CNN) to detect and classify sites of suspicious tracer uptake. A hold-out set of 30 patients was used exclusively to evaluate performance. The CNN detection accuracy was evaluated by the fraction of suspicious sites successfully detected per subject (sensitivity) and the number of false positive sites identified per subject; compared to expert visual assessment. The CNN anatomical localization performance was evaluated by the ability to predict miN0 or miN1 stage, as presence or absence of suspicious pelvic lymph nodes, and miM0 or miM1 stage, as presence or absence of lesions in extrapelvic lymph nodes, bone or other organs. **Results:** In total, 2919 regions with elevated tracer uptake were annotated (average 31.4 per subject), including 2589 physiological uptake regions and 570 suspicious regions, of which 81 were pelvic lymph nodes, 157 were distant lymph nodes and 295 were bone lesions. The median segmented volume of suspicious lesions was 1.2 mL [interquartile range (IQR) 0.6–2.9mL]. The CNN showed good ability to detect suspicious sites, with 0.84 average sensitivity per subject (IQR 0.74–1) and a median of 2.5 false positives per subject (IQR 1.2–7.8). Based on the anatomical localization of lesions determined using the CNN, miN0 stage was correctly predicted in 18/22 subjects, miN1 in 8/8 subjects, miM0 in 2/5 subjects, miM1 in 25/25 subjects. **Conclusion:** The investigated deep learning method showed promising results for detection and anatomical localization of suspicious uptake sites in whole-body PSMA-targeted PET/CT, including sites with small volume. The anatomical localization is shown to have utility in providing staging support for prostate cancer. **References:** (1) Hofman MS, et al. *Radiographics*. 2018;38:200–217. Improved 3D Tumour Definition and Quantification of Radiotracer Uptake Using Deep Learning

L. Dal Toso¹, Z. Chalampalakis², I. Buvat², C. Comtat², J. A. Schnabel¹, P. K. Marsden¹;

¹King's College London, London, UNITED

KINGDOM, ²CEA, Paris, FRANCE.

Aim/Introduction: Positron Emission tomography (PET) is used in oncology to detect and stage tumours. Quantification of tumour radiotracer uptake is often performed using the standardized uptake value. However, its accuracy is limited by the poor spatial resolution and noise properties of PET images. There is need for new methods that allow for accurate and reproducible quantification of radiotracer uptake. We developed a deep learning approach using a 3D convolutional neural network (CNN), trained on simulated data, to improve uptake quantification and

tumour shape definition. **Materials and Methods:** Tumours with different shapes and dimensions, spanning 0.01 to 200 ml, were simulated. We generated 1000 tumours with uniform activity, 700 tumours split into halves, with different activities, and 700 hollow tumours. Each tumour was pasted in a random position within a lung of an anthropomorphic phantom. 'Ground truth' images with 2.08x2.08x2.03 mm³ voxels were generated by assigning appropriate activities to each organ, then input to an analytical simulator with the corresponding attenuation maps to create realistic PET data. PET images were reconstructed using CASToR, with the OSEM algorithm including PSF modelling. Small regions (50x50x50 voxels) cropped from the ground truth images and reconstructed PET images were used to train a CNN with six convolutional layers, each followed by batch normalisation except for the final layer. **Results:** The CNN was first trained and tested on 980 tumours with uniform activity and 580 hollow tumours. The network yielded denoised images, with sharper tumour edges. Improved estimates of the maximum activity were extracted from the predicted tumours and increased values of mean structural similarity (MSSIM) were measured between ground truth and predicted tumours. When testing this network on tumours divided into halves, similar improvements of tumour shape and maximum activity were observed, but some predicted tumours contained areas with non-uniform activities, in regions where the ground truth activity distribution was uniform. When training and testing this network on 2200 simulated tumours, better defined tumours were predicted but non-uniform activities could be observed. The average percentage difference between the maximum tumour intensity, extracted from the reconstructed PET and from the ground truth images was 75%±43%. The average percentage difference between maximum activities calculated using the predicted and ground truth images was 25%±33%. **Conclusion:** This approach improved the estimation of maximum activity in the simulated tumours and yielded better defined tumours. Future plans include applying the CNN on phantom PET images and on real patients. **References:** None

Influence of delineation modality on overall accuracy of machine learning predictive model on colorectal carcinoma

M. Grahovac, L. Papp, C. P. Spielvogel, D. Krajnc, A. Leisser, A.

Strassl, J. Bozic-Pavletic, T. Beyer, M. Hacker, A. Haug;

Medical University Vienna, Vienna, AUSTRIA.

Aim/Introduction: Positron Emission Tomography (PET) / Computer Tomography (CT) support diagnosis and follow-up of patients with colorectal cancer (CRC). To date, the association of the PET and CT-driven in vivo radiomics features with the overall survival (OS) is not well explored.

The aim of this study was to investigate the differences in the performance of predictive models depending of PET- and CT-driven delineation with the help of machine learning.

Materials and Methods: 73 ^{18}F -FDG PET/CT patients were included in this study. 319 lesions were delineated twice: once based on PET and once based on contrast enhanced CT. Optimized radiomics feature extraction in both cases was performed from the PET/CT images [1]. Additionally, demographic information (gender, weight, height and age group), clinical features (TNM staging, location of primary tumor, treatment response, K-ras mutation status, grading, number and location of metastases) and laboratory findings, which may be associated with worse outcome (elevated creatinine, LDH- and CRP values, leukocytopenia, thrombocytopenia and anemia), were merged with the extracted imaging features. 12-month OS predictor models were established utilizing embedded feature selection [2] for both the PET and CT-driven delineation approaches. Monte Carlo cross-validation with 90% training and 10% validation sets in 100-fold cross-validation scheme was performed to estimate the sensitivity (SENS), specificity (SPEC), accuracy (ACC), positive-predictive-value (PPV) and negative-predictive-value (NPV) of both predictive models. Class imbalance was handled with random undersampling.

Results: The predictive model based on PET-driven delineation outperformed the CT-driven predictive model (ACC: 74% vs 66%, SENS: 69% vs 68%, SPEC: 78% vs. 64%, PPV: 76% vs 65%, NPV: 72% vs 67% respectively). **Conclusion:** The PET-driven delineation approach outperformed the CT-driven approach. This indicates that PET heterogeneity combined with including the surrounding tissue of the lesions in CT - due to larger PET delineation masks as of the partial-volume effect - seems to provide additional supporting information for survival prediction in colorectal cancer patients. **References:** 1.Papp L, et al: Optimized feature extraction for radiomics analysis of ^{18}F -FDG-PET imaging. Deep learning radiomics for prediction of Alzheimer disease by using amyloid PET images

G. Giovacchini¹, E. Giovannini¹, M. Riondato¹, O. Ferrando², F. Foppiano², M. De Biasi³, C. Passera³, A. Tartaglione³, P. Lazzeri¹, A. Ciarmiello¹;

¹Nuclear Medicine Unit, S. Andrea Hospital, La Spezia, ITALY,

²Medical Physics Unit, S. Andrea Hospital, La Spezia, ITALY,

³Neurology Unit, S. Andrea Hospital, La Spezia, ITALY.

Aim/Introduction: Preliminary data suggest that radiomics may be used as a non invasive tool for diagnosis prediction

among normal control (NC), mild cognitive impairment and Alzheimer's disease (AD). This study was aimed to predict different disease stages and disease progression using deep learning approach and radiomic textural data derived by amyloid PET images. **Materials and Methods:** 328 subjects from ADNI database and EudraCT 2015-001184-39 trial (159 male, 169 female), mean age 72 ± 7.4 years underwent PET/CT with ^{18}F -Florbetaben. Study subjects cohort consisted of normal controls (n=149), MCIs (n=144) and AD (n=35). A total of 42 radiomics features and SUV were extracted from PET/CT studies on the whole brain and at lobar level. Whole cortical burden (A β burden) was defined by frontal, parietal, temporal, occipital and cingulate VOIs. SUV was corrected for cerebellar activity (SUVr). The neighborhood component analysis (NCA) was applied to reduce the high features dimensionality and selecting the most powerful for diagnosis prediction. NCA weighs each feature according to classification accuracy using Leave-One-Out (LOO) approach. The features selected were grouped in all possible combination and tested for the accuracy to discriminate among subject's group. Support vector machine (SVM) was used to estimate the performance of each feature combination by using misclassification error (MCE) as classifier. General linear model (GLM) was used for testing the relationship of SUV and radiomic model on Minimal State Examination (MMSE) and Clinical Dementia Rate scale Sum Of Boxes (CDR-SB). Significant differences between AUCs computed using different prediction models were tested using the Hanley and McNeil method. Effect size was assessed with Cohen's f statistic and evaluated as f: 0.10 = small, 0.25 = medium, and 0.40 = large. Analysis was implemented under Matlab 2019b using Deep Learning Toolbox. **Results:** Eight of 42 textural features were selected by NCA algorithm. Feature combination with the best diagnostic performance included the following 4 textural variables: (Global_Skewness, GLCM_AutoCorrelation, GLRLM_LRHGE, GLSZM_LZHGE) which emerged as being more useful to distinguish between groups as compared to the SUVmax (AUC: 0.74 vs. 0.63, P<0.01). Radiomic model compared to SUVmax significantly improved the relationship with MMSE (R²=0.28 vs. 0.20; cohen's f=0.28 vs. 0.25) and CDR-SB (R²=0.26 vs. 0.20; cohen's f=0.35 vs. 0.26). **Conclusion:** Deep-Learning radiomics is a promising approach for prediction of diagnosis and disease progression in AD. Although there results require validation in a larger population, this technique may support clinical decision strategy with complementary information. **References:** None

OP-553

In-vivo survival prediction of glioma patients from [^{11}C]MET-PET using advanced data pre-processing and machine learning

D. Krajnc, L. Papp, C. P. Spielvogel, M. Grahovac, T. Beyer, M. Hacker, T. Traub-Weidinger;

Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: [¹¹C]Methionine (MET) PET is an established nuclear medicine procedure for glioma imaging. 3-years survival built on in vivo features extracted from MET-PET glioma patients was demonstrated with moderate performance [1]. We hypothesize that such performance was biased by lack of proper data pre-processing of training datasets utilized for machine learning. Here, we compare predictive performance of 3-years survival of glioma patients with and without a novel data pre-processing approach. **Materials and Methods:** 105 MET-PET positive glioma cases were included. Primary tumour volume of interest (VOI) and a contra-lateral reference background region were defined using a semi-automated delineation procedure. Following tumour-to-background ratio normalization 49 radiomics feature were extracted per case. A 100-fold Monte Carlo cross-validation scheme was executed resulting in 90% training and 10% validation set in each MC fold. The training dataset of the MC folds were inputs of ensemble learning to establish 3-years survival predictive models in two schemes, without data preparation and after applying data pre-processing algorithms. We performed class imbalance correction, sample and feature redundancy cleansing, as well as outlier detection. Predictive performance was estimated for both executions over the validation cases of each MC fold by confusion matrix calculations (SENS, SPEC, ACC, PPV and NPV). **Results:** The validation performance of ML models with the original training data was 76% (SENS), 64% (SPEC) and 71% (ACC). In contrast, the performance with ML models built on the pre-processed training data was 71% (SENS), 82% (SPEC) and 80% (ACC), where we recorded sensitivity decrease due to original model overfitting when building on imbalanced dataset, while specificity and overall accuracy increased significantly. **Conclusion:** The accuracy of 3-y survival prediction in glioma patients, built on in vivo features, undergoing MET-PET can be improved significantly following advanced data preparation methods. **References:** 1. Papp L, et al: Glioma Survival Prediction with Combined Analysis of In Vivo ¹¹C-MET PET Features, Ex Vivo Features, and Patient Features by Supervised Machine Learning. Data-driven identification of diagnostically useful extrastriatal signal in dopamine transporter SPECT using explainable AI

M. Nazari^{1,2}, I. Apostolova³, A. Kluge², S. Kimiaei², R. Buchert³;
¹TU-Dresden, Dresden, GERMANY, ²ABX-CRO, Dresden, GERMANY, ³University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY.

Aim/Introduction: In clinical routine, the interpretation of dopamine transporter (DAT) SPECT for the diagnosis

of clinically uncertain parkinsonian syndromes usually is entirely based on striatal tracer uptake. However, there is some evidence that tracer uptake in other brain regions including insula, cingulate cortex, ventromedial prefrontal cortex, thalamus, hypothalamus and brain stem might also provide clinically useful information. The aim of the present study was to use explainable artificial intelligence (AI) for purely data-driven identification of extrastriatal brain regions that can contribute to the classification of DAT-SPECT beyond the striatal signal. **Materials and Methods:** Projection data from 1306 DAT-SPECT studies performed in clinical routine during 12/2008 and 01/2020 at a single center using 3 different SPECT camera models from two different manufactures equipped with low-energy-high-resolution collimators were retrieved from the PACS. Images were reconstructed by filtered backprojection using MATLAB. Reconstructed SPECT images were stereotactically normalized into the anatomical space of the Montreal Neurological Institute using SPM12 and a custom-made DAT-SPECT template. From each SPECT, a 2-dimensional slab view image of 12mm thickness was obtained by adding transaxial slices through the striatum. A convolutional neuronal network was trained with 1006 randomly selected slab views using visual binary interpretation as 'normal' or 'reduced' by an experienced reader as standard of truth. The convolutional neuronal network consisted of 14 convolutional layers followed by 3 fully connected neural network layers and had a total of 1,459,266 trainable parameters. The independent test set comprising the remaining 300 slab views was used to assess classification performance of the network. Layer-wise relevance propagation was used to quantify the relevance for the classification on a voxel-by-voxel base for each of the 300 slab views in the test set. A mean relevance map was obtained by averaging the relevance maps over all test slab views. **Results:** Overall accuracy, sensitivity, and specificity of the convolutional neuronal network were 97.0, 94.4, and 99.4%, respectively. Prominent contribution in the relevance map beyond the striatum (mainly putamen) was located in lateral frontal and lateral occipital cortex. Neither insula nor thalamus contributed relevantly. **Conclusion:** These findings suggest that tracer uptake in lateral frontal and lateral occipital cortex but not in insula and thalamus provides useful independent information for the interpretation of DAT-SPECT beyond striatal tracer uptake. **References:** None

OP-555

Evaluation of quantum-encoding for machine learning features in neural network-based predictive models

C. Spielvogel, M. Grahovac, D. Krajnc, M. Hacker, T. Beyer, A. R. Haug, L. Papp;
 Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Quantum neural network machine

learning approaches have been recently proposed [1]. The goal of the study was to compare the performance of predictive models established by quantum neural network and classic neural network approaches including three different radiomic cohorts. **Materials and Methods:** Three study cohorts were selected: 73 PET/CT cases of colorectal cancer patients, 120 CT cases of pancreatic cancer patients and 84 PSMA-11 PET cases of prostate cancer patients. The binary prediction targets were tumor presence for the colon cancer and the pancreatic cancer cohorts. For the prostate cohort the prediction target was low versus high risk. The class ratio was balanced for the prostate and pancreatic cohort while for the colon cancer cohort, 77 % of the samples corresponded to the non-tumor class. The radiomics features were scaled to values between 0.0 and 1.0 before executing both quantum and classic neural network approaches. The evaluation was performed using a nested, stratified Monte-Carlo cross-validation with 10 folds with a validation ratio of 25 % and a test ratio of 10 % in each predictive model. Evaluated performance metrics on the independent test set included sensitivity, specificity and accuracy for all predictive models. **Results:** The classic neural network models outperformed the corresponding quantum approaches in all cohorts. The accuracies were 0.69, 0.54 and 0.51 for the quantum approach for the colon cancer, pancreatic cancer and prostate cancer respectively while they were 0.74, 0.90 and 0.84 for the classic neural network respectively. The performance in the classic neural network was 17 % and 30 % higher for sensitivity and specificity respectively. **Conclusion:** Current solutions to perform quantum encoding of radiomics features appear to be inferior for neural network-based predictive models. Future approaches shall further optimize the way of encoding radiomics features to the quantum problem domain. **References:** [1] Broughton, Michael, et al. Patients with Progressive Paraganglioma Consecutively Treated with ¹⁷⁷Lu-Dotatate or ⁹⁰Y-Dotatoc PRRT. Toxicity, Efficacy and Prognostic Biomarker Results after Long-Term Follow-Up

S. Severi¹, S. Zovato², S. Nicolini¹, I. Grassi¹, M. Sansovini¹, E. Tardelli³, E. Scarpi¹, E. Mezzenga¹, V. Di Iorio¹, G. Paganelli¹; ¹IRST IRCCS, Meldola, ITALY, ²Familial Cancer Clinic, Istituto Oncologico Veneto (IOV) IRCCS, Padua, ITALY, ³Nuclear Medicine Unit, Department of Diagnostic Imaging, San Luca Hospital, Lucca, ITALY.

Aim/Introduction: At present there are no active therapies available for patients with progressive paraganglioma (mPPGLs) in either post-surgery or inoperable settings. However, these rare tumors overexpress somatostatin receptors and can thus be treated with peptide receptor radionuclide therapy (PRRT). We present our 10-year experience treating 46 consecutive mPPGL patients with ⁹⁰Y-Dotatoc or ¹⁷⁷Lu-Dotatate. **Materials and Methods:** All patients (20 men and 26 women, median age 52 years) showed positive scintigraphic imaging at ¹¹¹In-octreoscan or ⁶⁸Ga-Dotatoc PET/CT. ⁹⁰Y-Dotatoc was administered in 12 patients, with cumulative dosages ranging from 7.4 GBq to 11 GBq, while 34 patients received 18.5 GBq or 27.5GBq of ¹⁷⁷Lu-Dotatate. We used SWOG/RECIST criteria to evaluate treatment efficacy and CTCAE criteria to assess toxicity. The prognostic role of primary tumor site, hormone secretion, SDHx mutation, disease extension and metastatic involvement was also evaluated. **Results:** Both ⁹⁰Y-Dotatoc and ¹⁷⁷Lu-Dotatate PRRT were well tolerated by patients, without renal or bone marrow toxicity. The median follow-up was 60 months (range 11-146). The overall disease control rate (DCR) was 80.4% (95% CI 68.9-91.9) and was similar for both treatments. However, ¹⁷⁷Lu-Dotatate patients showed a better median overall survival (mOS) than those receiving ⁹⁰Y-Dotatoc and a better DCR when higher dosages were administered (P=0.03). Syndromic patients had a poorer mOS, and SDHx mutations did not interfere with treatment efficacy. **Conclusion:** PRRT is safe and effective for the treatment of patients with progressive mPPGL, especially at higher dosages. The better outcome

of ^{177}Lu -Dotatate-treated patients indicates the former radiopharmaceutical as the best candidate for further clinical application. **References:** None

Personalized Thera(g)nostic Approach in Patients with Pheochromocytoma and Paraganglioma: ^{131}I -mIBG and / or Peptide Receptor Radionuclide Therapy

H. Svirydenka, B. Nilica, C. Mair, L. Rossetti, A. Kroiss, G. Di Santo, S. Buxbaum, C. Decristoforo, C. Uprimny, M. Gabriel, I. Virgolini; Universitätsklinik für Nuklearmedizin, Innsbruck, AUSTRIA.

Aim/Introduction: The experience with ^{131}I iodine metaiodobenzylguanidine (^{131}I -mIBG) and somatostatin-receptor (SSTR)-based-peptide-radionuclide therapy (PRRT) in patients with pheochromocytomas (PCC) and paragangliomas (PGL) is limited. We report our experience for the treatment of malignant PCC and PGL (PPGL). **Materials and Methods:** Malignant PPGL patients treated at the Medical University Innsbruck, Department of Nuclear Medicine between 2006-2019 with ^{131}I -mIBG / ^{90}Y -DOTATOC / ^{177}Lu -DOTATATE, were retrospectively reviewed. Response to treatment was evaluated according to RECIST 1.0/ PERCIST 1.1 Criteria: Complete Response (CR), Partial Response (PR), Stable Disease (SD) and Progressive Disease (PD). The observation time was at least 1 year after completion of PRRT. As long term predictors we calculated the Progression-Free-Survival (PFS) and Overall-Survival (OS) since initialization of PRRT by Kaplan-Meier. **Results:** Twenty-seven patients (age range 18-74 years) with PPGL (8 PCC, 19 PGL) were analyzed. Pre-therapeutic scanning was positive in 7/8 PCC-patients with ^{123}I -mIBG and in 7/8 PCC-patients with ^{68}Ga -DOTATOC. 5/8 PCC-patients received ^{131}I -mIBG therapy (accumulated activity (ACC) range 3.6-47.48 GBq, absorbed tumour dose (ATD) range 0.8-673.2 Gy), from those 2 patients received additional tandem therapy with ^{90}Y -DOTATOC (ACC 11.2 and 15.5 GBq, ATD range 10.5-225.7 Gy). 2/8 PCC-patients were treated with ^{177}Lu -DOTATATE (ACC 25.8 and 30.4 GBq, ATD range 92-191.7 Gy) and 1/8 patients refused the therapy after performing dosimetry with ^{131}I -mIBG. 6/8 patients demonstrated PD, 1/8 PR, 1/8 CR by RECIST 1.0/ PERCIST 1.1 Criteria. The median PFS and OS of PCC-patients was 10 (range 8-108) and 30 months (range 12-156), respectively. Pre-therapeutic scanning was positive in 19/19 PGL-patients with ^{68}Ga -DOTATOC. However, 5/19 PGL-patients performed ^{123}I -mIBG, only in 1/5 patients, a positive uptake was observed. Additionally, 7/19 patients performed ^{18}F -DOPA and ^{18}F -FDG PET/CT, with evidence of positivity in 7/7 and 5/7 patients, respectively. 13/19 PGL-patients received ^{90}Y -DOTATOC (ACC range 8.07-16.44 GBq, ATD range 4.6-152.8 Gy), 4/19 PGL-patients ^{177}Lu -DOTATATE (ACC range 8.49-55.42 GBq, ATD range 14.1-235.3 Gy). 2/19 patients were lost to follow-up. In 16/17 patients SD and in 1/17 PD were recorded by RECIST 1.0/ PERCIST 1.1 Criteria.

The median PFS and OS of PGL-patients was 96 (range 10-180) and 99.5 months (range 24-180), respectively. **Conclusion:** Both ^{131}I -mIBG and ^{90}Y / ^{177}Lu -SSTR-targeting peptides may be beneficial for long-term disease control in some patients with locally advanced or metastatic PPGL when applied in several treatment cycles that could reach meaningful absorbed tumour doses. Pretherapeutic imaging allows a personalized, tailored treatment by selecting the radiopharmaceutical resulting in the highest tumour dose. **References:** None

OP-564

Transarterial radioembolization of unresectable intrahepatic cholangiocarcinoma with ^{90}Y glass microspheres: results of a single institution study

A. Lorenzoni, S. Mazzaglia, C. Spreafico, F. Scalorbi, G. Argiroffi, S. Bhooi, C. Chiesa, V. Fuoco, T. Cascella, E. Seregni, V. Mazzaferro, M. Maccauro; Fondazione IRCCS Istituto Nazionale Tumori, Milan, ITALY.

Aim/Introduction: To investigate safety and efficacy of yttrium-90 transarterial radioembolization (^{90}Y -TARE) in patients with unresectable intrahepatic cholangiocarcinoma (ICC). **Materials and Methods:** We retrospectively evaluated data of 23 consecutive patients (10 males, 13 females; mean 66, range 45-83 years) with locally advanced ICC treated with ^{90}Y glass microspheres as first-line therapy or after chemotherapy failure. Macroaggregated albumin (MAA)-based SPECT/CT dosimetry was used to plan treatment through tumor dose (TD) and non-tumoural whole liver dose (NTWLD). Tumor response was assessed using mRECIST criteria 3-6 months after each TARE. Side effects were assessed using NCI-CTCAE version 5 criteria. Overall Survival (OS) and Progression-Free Survival (PFS) were evaluated from the first TARE (Kaplan-Meier methodology). **Results:** ^{90}Y -TARE was administered 30 times (7 repeated administrations), for a total of 35 lesions treated. Eight out of 30 treatments were performed as first line therapy. The mean ^{90}Y -loaded glass microsphere injected activity was 2.5 GBq (95% CI: 2.1-2.9). Mean NTWLD was 42.4 Gy (95% CI: 34.5-50.3). One grade 3 treatment-related irreversible liver toxicity was observed. No clinically relevant extrahepatic toxicity was recorded. We obtained 1 complete response (CR 1/30=3%), 1 partial response (PR 1/30=3%), 26 stable disease (SD 26/30=87%) and 2 progression of disease (PD 2/30=7%). Objective response rate (CR+PR) was 7%; disease control rate (CR+PR+SD) was 93%. Two patients underwent post-TARE tumor resection and 1 patients orthotopic liver transplantation. Median OS was 21 months (95% CI: 12-34), median PFS was 9 months (95% CI: 6-17). Single-lesion dosimetric data were available in 25 out of 35 lesions (single-lesion response: 1 CR, 2 PR, 22 SD). Mean TD of all lesions was 309 (95% CI: 235-384) Gy, mean TD to responding lesions (CR+PR) was 384 (95% CI:

-129-898) Gy and mean TD to stable lesions was 280 (95% CI: 206-354) Gy. **Conclusion:** Our results show that ^{90}Y -TARE was safe and effective in controlling the disease. Dosimetric data of NTWLD suggest the possibility to increase ^{90}Y - glass microsphere administered activity to safely improve efficacy

Effectiveness of high-dose ^{131}I -MIBG as consolidation therapy for the patients with high-risk neuroblastoma

A. Inaki, R. Kuroda, H. Wakabayashi, N. Akatani, T. Yamase, Y. Kunita, S. Watanabe, T. Hiromasa, H. Mori, S. Saito, Y. Ikawa, D. Kayano, S. Kinuya;
Kanazawa University Hospital, Kanazawa, JAPAN.

Aim/Introduction: High-risk neuroblastoma is a childhood solid tumor with poor prognosis despite modern multimodality therapy. We have performed ^{131}I -metaiodobenzylguanidine (^{131}I -MIBG) internal radiotherapy with myeloablative dose combined with high-dose chemotherapy and blood stem cell transplantation as consolidation therapy for these patients. The aim of this study is to investigate whether our treatment protocol improved the remission induction rate and the long-term survival rate compared with conventional treatments.

Materials and Methods: A total of 16 patients with primary or first-relapsed high-risk neuroblastoma were enrolled. Patients received high-dose (666 MBq/kg as a target dose) ^{131}I -MIBG and then received high-dose chemotherapy and stem cell transplantation after conventional induction chemotherapy. **Results:** The mean age was 3.6 ± 2.8 (range 0 - 10 years old) and the mean ^{131}I -MIBG dose was 648.1 ± 49.3 MBq/kg (range 526.9 - 730.3 MBq/kg). Thirteen and 3 patients received MEC (melphalan, VP-16 and carboplatin) and BuMel (busulfan and melphalan) as high-dose chemotherapy, respectively. Fourteen and 2 patients received peripheral blood stem cell transplantation and cord blood transplantation, respectively. Fourteen patients (87.5%) succeeded to reach complete remission. The mean follow-up period was 1460.8 ± 999.5 days. Two patients relapsed and 1 patient died of the primary disease. Nine patients were followed up over 3 years and 3-year overall survival rate was 100%. **Conclusion:** ^{131}I -MIBG therapy increased the success rate of consolidation therapy and may improve the long term prognosis in patients with high-risk neuroblastoma. **References:** None

PRRT Efficacy of ^{111}In -DTPA-Octreotide Auger and Internal Conversion Electron Emission after Intra-arterial Implementation in Liver Metastasized Colorectal NETs

G. Limouris¹, V. Krylov², M. B. Dolgushin³, I. Kyriazanos⁴, A. Zafeirakis⁵;

¹Nuclear Medicine, Medical School, National and Kapodistrian

University of Athens, Athens, GREECE, ²Nuclear Medicine Dpt. "A. Tsyb Research Center", Obninsk, RUSSIAN FEDERATION, ³N.N. Blokhin Russian Oncological Research Center, Moscow, RUSSIAN FEDERATION, ⁴I Surgery Clinic, Army Naval and Veterans Hospital of Athens, Athens, GREECE, ⁵Army Share Fund Hospital of Athens, Athens, GREECE.

Aim/Introduction: Colorectal originated NETs are less commonly metastatic; however, when present, patients' survival is rather mediocre. Evidence guiding optimal treatment of such patients is practically lacking. By the present it was aimed to evaluate the efficacy of ^{111}In -DTPA-Octreotide Auger and Internal Conversion Electron Emission by assessing PRRT outcomes in patients with somatostatin receptor (SSTR) positive liver metastasized colorectal NETs.

Materials and Methods: Eleven patients (m=3, f=8, age range 49-79 years) were included in the study. All eleven had ^{111}In -DTPA-Octreotide avid disease (visual score IV). Patients treated with PRRT were retrospectively reviewed. Morphologic (RECIST 1.1), SSTR imaging responses and toxicity were assessed, three-monthly post-PRRT. Kaplan-Meier estimate was used to determine progression-free survival (PFS) and overall survival (OS) from the beginning of the therapy. ^{111}In -DTPA-Phe¹-Octreotide was implemented after selective catheterization of the hepatic artery, in an average activity of 6.3 ± 1.3 GBq per patient/per session, consecutively, with a time interval between sessions of 6-8 weeks. Infusion repetition did not exceed the 12 fold.

Results: None of the eleven treated patients resulted in complete response and partial response was assessed in eight cases (72.72%), disease stabilization in one (9.10%) and progressive disease in two (18.18%). The median PFS and OS were estimated to be 36 and 48 months, respectively. The organ average radiation dose was estimated as follows: (a) Liver Tumor 15.2 mGy/MBq, (b) Liver 0.14 mGy/MBq, (c) Kidneys 0.41 mGy/MBq, (d) Spleen 1.4 mGy/MBq and (f) Bone marrow 0.0032 mGy/MBq. The average absorbed dose per session to a tumour for a spherical mass of 10 gr was estimated to be 15 mGy/MBq, depending on the histotype of the tumour. Distinctive side effects were not noticed except a WHO toxicity grade 1 to 2 erythro-, leuko- and thrombocytopenia occurred in 9 (81.81%) cases observed about after the 9th session. **Conclusion:** The study indicates the high efficacy of ^{111}In -DTPA-Octreotide Auger and Internal Conversion electron emission due to their high LET, the morphologic responses with minimal toxicity and the very encouraging survival in patients with metastatic colorectal NETs despite the mediocre prognostic features of this cohort. Further larger prospective PRRT trials are warranted in this NET-subgroup. **References:** None

OP-567**Feasibility, Biodistribution and Preliminary Dosimetry in Peptide-Targeted Radionuclide Therapy (PTRT) of Diverse Adenocarcinomas using ¹⁷⁷Lu-FAP-2286: First-in-Human Results**

H. Kulkarni¹, C. Smerling², C. Schuchardt¹, A. Singh¹, F. Robiller¹, M. Chantadisa^{1,3}, A. Eismant¹, D. Mueller¹, D. Zboralski², F. Osterkamp², A. Hoehne², U. Reineke², R. P. Baum¹;

¹Zentralklinik Bad Berka, Bad Berka, GERMANY, ²3B Pharmaceuticals GmbH, Berlin, GERMANY, ³King Chulalongkorn Memorial Hospital, Bangkok, THAILAND.

Aim/Introduction: Fibroblast activation protein (FAP) is of great interest as target for diagnosis and therapy of numerous malignant tumors. In preclinical models, FAP-2286 has shown high uptake and long retention in tumors. Here we present first-in-human results. **Materials and Methods:** PTRT was performed in 11 patients with advanced adenocarcinomas using 2.5 - 9.9 GBq ¹⁷⁷Lu-FAP-2286 after prior confirmation of significant tumor uptake (SUV tumor-to-background ratio > 3) on ⁶⁸Ga-FAP (n =10)/FAPI PET/CT. A second cycle was administered to 9 patients, one patient underwent 3 cycles. Laboratory parameters including tumor markers were monitored. Biodistribution was analyzed by post-therapy planar and SPECT/CT images. Preliminary dosimetry estimations were performed in 7 patients. Clinical parameters including laboratory findings were monitored. **Results:** Metastases from adenocarcinomas of the pancreas (n=5), breast (n=4), rectum (n=1) and ovary (n=1) were present in the following localization: lymph node (n=6), lung (n=3), pleura (n=1), peritoneum (n=3), liver (n=7) and bone (n=5). Significant uptake and long tumor retention on delayed ¹⁷⁷Lu-FAP-2286 imaging (72h to 10 days post-injection) was observed in all patients. The mean absorbed whole body dose ranged from 0.05 - 0.1 Gy/GBq, red marrow received 0.04 - 0.09 Gy/GBq, and kidneys 0.6 - 0.9 Gy/GBq (comparable to ¹⁷⁷Lu-DOTATOC). Intensification of pre-existing abdominal pain with nausea and vomiting was noted in a pancreatic carcinoma patient with coeliac lymph node metastases, whereas short-lasting, severe headache was seen in a patient with skull metastases. There was mild, self-limiting headache in 3 patients, otherwise no relevant short-term side effects occurred. Pain decreased in 3 patients, one patient reported long-term clinical improvement. CTCAE v5.0 grade (G) 1 anemia emerging after treatment was noted in three patients. Anemia and leukocytopenia worsened from pre-existing G2 to G3 in one patient with bone-marrow involvement, who also experienced G3 renal insufficiency on follow-up (considered not related to PTRT). There was one new G3 thrombocytopenia. Follow-up using molecular imaging with ⁶⁸Ga-FAP-2286 PET/CT, RECIST 1.1 (CT/MRI) and tumor markers revealed stable disease in 3, and progressive disease in 8 patients. One patient with pre-existing, very advanced disease died of progression

4 weeks after the second cycle. **Conclusion:** FAP-targeted theranostics appears to be feasible and relatively safe. ⁶⁸Ga-FAP-2286 PET/CT can be used for patient selection and follow-up. Due to long tumor retention, PTRT using ¹⁷⁷Lu-FAP-2286 seems to be a promising treatment option in a broad spectrum of cancers. Further follow-up of patients as well as prospective clinical studies are warranted. **References:** None

OP-568**IPAX-1: Phase 1/2 study of 4-L-[¹³¹I]-iodo-phenylalanine (¹³¹I-IPA) administered concomitantly to second line external radiation therapy (XRT) in patients with recurrent glioblastoma multiforme (GBM)**

T. Traub-Weidinger¹, R. Wilson², J. Pichler³;

¹Medical University of Vienna, Vienna, AUSTRIA, ²Telix Pharmaceuticals, Melbourne, AUSTRALIA, ³Kepler Universitätsklinikum, Linz, AUSTRIA.

Aim/Introduction: Many tumour types, including GBM, overexpress the L-type amino transporter 1 (LAT-1). ¹³¹I-IPA is a small-molecule amino acid derivative internalised by LAT-1. Preclinical studies showed additive cytotoxic effects of ¹³¹I-IPA + XRT¹. Tumour accumulation of ¹³¹I-IPA was shown in a proof-of-principle study² and confirmed with single dosing of 2-7 GBq ¹³¹I-IPA in combination with XRT in patients with recurrent GBM³. The ¹³¹I-IPA + XRT in Recurrent GBM (IPAX-1) study evaluates safety, dosing schedule and preliminary efficacy of ¹³¹I-IPA combined with second-line XRT in patients with recurrent GBM. **Materials and Methods:** IPAX-1 is a multicentre, open-label, Phase 1/2, dose-finding study ¹³¹I-IPA + XRT in patients with histologically confirmed GBM experiencing first recurrence. Three dosing regimens are being evaluated at 2.0 GBq with subsequent dose escalation: Single dose ¹³¹I-IPA administered 1-3 days prior to 1st XRT (N=3). Fractionated (parallel) ¹³¹I-IPA in three fractions (3 x 0.67 GBq) administered throughout XRT, commencing 1-3 days prior to 1st XRT and subsequently every 5-9 XRT fractions (N=3). Fractionated (sequential) ¹³¹I-IPA in three fractions (3 x 0.67 GBq) with fraction 1 administered 1-3 days prior to 1st XRT and fractions 2 and 3 administered after completion of XRT (N=3). 36 Gy of XRT will be delivered in 18 fractions of 2 Gy. The best regimen at 2.0 GBq will proceed to dose escalation in 2.0 GBq increments, up to 8.0 GBq or until the maximum tolerated dose (MTD) is reached (N=3 per cohort). The primary study objective is to assess safety and tolerability of ¹³¹I-IPA + XRT. Secondary objectives include establishing MTD and optimal dosing schedule, dosimetry, biodistribution and preliminary efficacy. IPAX-1 will enroll up to 44 patients in Europe and Australia. Clinical trial number: NCT03849105. **Results:** As of May 2020, four patients have been randomised to the single dose and fractionated parallel groups. Up to 9.6 months post-treatment, one patient has stable disease

(SD, 9.6 months) and three patients have progressed (PD, 7.1, 4.8 and 2.5 months) using the Revised Assessment in Neuro-Oncology (RANO) criteria. No serious adverse events have been reported. **Conclusion:** ^{131}I -IPA (2 GBq) + XRT is safe and well tolerated. Preliminary results in the first 4 patients evaluated show best tumour response of SD up to 9.6 months post-treatment. **References:** 1. Israel et al. Nucl Med Biol 20112. Baum et al. OP-569

Comparison of 99mTc-MAA SPECT/CT predictive dosimetry and 90Y PET/CT posttreatment dosimetry in Radioembolization of Hepatic Tumours

O. Ferrando¹, F. Foppiano², A. Ciarmiello³;

¹ASL5 Spezzino, La Spezia, ITALY, ²Medical Physics

Department - ASL5 Spezzino, La Spezia, ITALY, ³Nuclear

Medicine Department - ASL5 Spezzino, La Spezia, ITALY.

Aim/Introduction: The aim of this study was to evaluate the agreement between the predictive dosimetry based on 99mTc-MAA SPECT/CT and the post-treatment dosimetry based on 90Y PET/CT acquisitions. **Materials and Methods:** The study was applied to 20 patients with hepato-cellular carcinoma who underwent radioembolization with 90Y-resin spheres. We compared pre-treatment dosimetry based on 99mTc-MAA SPECT/CT and post-treatment dosimetry based on 90Y PET/CT. 3D dose maps and dose-volume histograms (DVH_{spect}, DVH_{pet}) were calculated using the methodology proposed in [1]. Mean absorbed dose in tumour volumes (D_{spect} and D_{pet}) were calculated using the MIRD method [2]. SPECT and PET volumes of interest (tumour volume) were delineated with a thresholding method using the AMIDE software [3], lobar and whole liver volumes were determined from CT images. Patient administered activity was calculated using the Body Surface Area method as recommended by the sphere manufacturer. Concordance between D_{spect} and D_{pet} , DVH_{spect} and DVH_{pet} were evaluated with the Wilcoxon Signed Ranked test. **Results:** Patient administered activity ranged from 0.4 GBq to 2.2 GBq. Tumour volumes ranged from 75mL to 1012 mL. The mean absorbed doses for tumour volume were 161 ± 66 Gy (D_{spect}) and 173 ± 79 Gy (D_{pet}). The comparison between D_{spect} and D_{pet} and the comparison between DVH_{spect} and DVH_{pet} evaluated with the Wilcoxon Signed Ranked test were statistically significant with $\alpha=0.01$. **Conclusion:** Even if our results are limited to the restricted population analysed in this study, we have found a quantitative agreement between predictive and post dosimetry of 90Y-radioembolisation. From our point of view predictive dosimetry with 99mTc-MAA SPECT/CT can provide valuable estimation of tumour and non-tumour tissues absorbed doses and these information can help in the decision of a more personalised activity

administration. **References:** [1] A.C. Traino et al. OP-570

Effectiveness and safety of multiple 90Y-radioembolization in patients with primary and secondary liver tumors

A. Di Palo, C. Ferrari, C. D'Alò, P. Mammucci, M. Frugis, R. Ruta, V. Lavelli, G. Rubini;

Nuclear Medicine Department, University of Bari "Aldo Moro", Bari, ITALY.

Aim/Introduction: The purpose of this study was to assess the effectiveness and safety of multiple 90Y radioembolization with microspheres (TARE) in patients with primary and secondary liver tumors to complete the first treatment. **Materials and Methods:** Between 2016 and 2020, 20 patients (9 women, 11 men; mean age, 70 y) with nonresectable advanced liver tumors (6 colorectal liver metastases; 12 hepatocellular carcinoma; 2 cholangiocellular carcinoma) were treated by TARE twice. 12/20 patients received a whole-liver treatment with sequential TARE sessions of the left and right liver lobes (group A) while an uni-lobar treatment was performed in 8/20 patients (group B) within a mean of 6 months. Safety was the primary endpoint. Toxicity was documented according to Common Terminology Criteria for Adverse Events 4.0 (CTCAE) criteria based on laboratory parameters and clinical examinations 3 days, 6 weeks, and every 3 months after every TARE session. Response to treatment was assessed by CT scan according to RECIST criteria. Both CT scan and PET/CT imaging were used for patients' follow up to evaluate time to progression disease (TTP). TTP was estimated by the Kaplan-Meier method and results were compared using long-rank test. **Results:** In group A, after the first treatment 8/12 were PR, 2/12 SD and 2/12 PD, while in group B all patients (8/20) presented PR. After the second treatment, in group A 1/12 patients was CR, 2/12 were PR, 2/12 were SD and 7/12 were PD; in group B, 2/8 patients were CR, 1/8 were PR, 2/8 were SD and 3/8 were PD. No radioembolization-induced liver disease was observed. The most common adverse effects were ascites, reversible increasing of bilirubin and liver enzymes levels and transient abdominal pain. According to CTCAE criteria 3/20 patients showed reversible grade III to IV toxicities based on laboratory values, which returned to pretreatment levels after 6 weeks. Dorsal radiodermatitis occurred in 2/20

patients due to the interventional procedure. No case of RE-induced liver disease was registered. Median of TTP after the first treatment was 12,5 months. In particular a statistically significant difference was found in TTP and the patients' response to TARE ($p=0,002$), while no statistically significant difference was found in TTP and the number of lobes undergoing the treatment. **Conclusion:** In advanced liver tumors, multiple treatments with ^{90}Y radioembolization can be performed with an acceptable toxicity profile. Furthermore, multiple treatments do not affect the disease control both in unilobar and whole-liver TARE. **References:** None

OP-571

Role of ^{90}Y - microspheres PET based tumor to normal (T/N) dosimetry to assess response in HCC selective internal radiation therapy

R. B. Martinez, S. Gavane, K. Knesaurek;
Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: The aim of our work is to assess role of tumor-to-normal tissue (T/N) dosimetry ratios for predicting response in patients undergoing liver treatment with ^{90}Y microspheres. **Materials and Methods:** After treatment with ^{90}Y microspheres, 33 patients (5 females and 28 males, mean age $64.0 \pm 8.1\text{y}$), underwent PET/CT imaging. The low mA, non-diagnostic CT images from PET/CT were used for attenuation correction and localization of the ^{90}Y microspheres. Images were acquired for 15 min with the reconstruction matrix size of $200 \times 200 \times 75$ mm and voxel size $4.07 \times 4.07 \times 3.00$ mm. Local deposition method with known activity of ^{90}Y was used for dosimetry calculations. For each patient, volume-of-interest (VOI) for whole liver and tumor(s) was manually created and program automatically created normal tissue VOI. Response was assessed on MRI by mRECIST criteria done at a month post treatment and subsequently every 3 months after ^{90}Y treatment. **Results:** For 33 patients, the mean liver, tumor and normal tissue doses (mean \pm SD) were, 55.37 ± 25.83 Gy, 913.15 ± 796.54 Gy and 54.64 ± 25.55 Gy respectively. Among these patients, 29 (88%) have shown complete response (CR) and 4 (12%) have shown progression of disease (PD). For CR patients, the mean T/N dose ratio obtained was 20.14 (range 2.16 - 67.48) and for PD patients, the mean T/N dose ratio was significantly lower 6.57 (range 0.65-13.02). **Conclusion:** Our data indicates that patients with PD usually have T/N dose ratio lower than those with CR. However, further investigation is warranted because the number of PD cases was limited, and partial volume effect was not considered. **References:** None

Aim/Introduction: ^{68}Ga -FAPI serves as a promising alternative to ^{18}F -FDG for the assessment of malignant tumours and adds important diagnostic value in the context of challenging ^{18}F -FDG PET cancer subtypes. In this study, we evaluated the potential usefulness of ^{68}Ga -FAPI positron emission tomography/computed tomography (PET/CT) for the diagnosis of primary and metastatic lesions in various types of cancer, compared with ^{18}F -FDG PET/CT. **Materials and Methods:** A total of 75 patients with various types of cancer underwent contemporaneous ^{68}Ga -FAPI and ^{18}F -FDG PET/CT either for an initial assessment or for recurrence detection. Tumour uptake was quantified by the maximum standard uptake value (SUV_{max}). The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of ^{18}F -FDG and ^{68}Ga -FAPI PET/CT were calculated and compared to evaluate the diagnostic efficacy. **Results:** The study cohort consisted of 75 patients (47 male and 28 female; median age, 61.5 years; age range, 32–85 years). Fifty-four patients with 12 different tumour entities underwent paired ^{68}Ga -FAPI and ^{18}F -FDG PET/CT for initial assessment, while the other 21 patients underwent paired scans for recurrence detection. ^{68}Ga -FAPI PET/CT was able to clearly identify 12 types of malignant tumours with favourable tumour-to-background contrast, which resulted in a higher detection rate of primary tumours than did ^{18}F -FDG PET/CT (98.2% vs. 82.1%, $P=0.021$). Meanwhile, ^{68}Ga -FAPI PET/CT showed a better sensitivity than ^{18}F -FDG PET/CT in the detection of lymph nodes (86.4% vs. 45.5%, $P=0.004$) and bone and visceral metastases (83.8% vs. 59.5%, $P=0.004$). By contrast, ^{68}Ga -FAPI PET/CT was found to yield more false-positive findings compared to ^{18}F -FDG PET/CT, which resulted in its lower specificity for lymph nodes (76.5% vs. 58.8%, $P=0.250$) and bone and visceral metastases (58.3% vs. 41.7%, $P=0.500$). **Conclusion:** This study revealed that the primary tumour and most sites of

tumour involvement in patients with various cancers are well-visualised using ^{68}Ga -FAPI PET/CT. Tumour sites in the liver, abdomen, and brain were particularly evident because of the strong tumour uptake and low background uptake of ^{68}Ga -FAPI in these areas. ^{68}Ga -FAPI PET/CT was revealed to have better sensitivity and accuracy for the detection of both primary and metastatic lesions than did ^{18}F -FDG PET/CT. By contrast, ^{68}Ga -FAPI PET was found to yield more false-positive findings compared with ^{18}F -FDG PET, which resulted in its lower specificity for metastatic lesions (although this difference was not statistically significant).

^{18}F -FDG PET/CT in muscle-invasive urothelial bladder cancer: the role of functional imaging in neoadjuvant immunotherapy, an ancillary analysis of PURE-01 protocol

A. Capozza¹, L. Marandino², B. Padovano¹, G. Serafini¹, A. Briganti³, D. Raggi², E. Farè², F. Pederzoli³, A. Gallina⁴, M. Bandini³, U. Capitano³, M. Bianchi⁴, G. Gandaglia⁴, N. Fossati³, P. Giannatempo², A. Salonia⁴, F. Montorsi³, A. Necchi², E. Seregni¹, A. Alessi¹;

¹Nuclear Medicine Unit, IRCCS Istituto Nazionale dei Tumori di Milano, Milan, ITALY, ²IRCCS Istituto Nazionale dei Tumori di Milano, Milan, ITALY, ³Vita-Salute San Raffaele University, Milan, ITALY, ⁴IRCCS San Raffaele Hospital, Milan, ITALY.

Aim/Introduction: Nodal disease, in bladder cancer staging, has a significant impact on patients' prognosis; yet accurate lymph nodes (LN) staging is an ongoing challenge for oncologic imaging. In clinical practice, computed-tomography (CT) and magnetic-resonance are the standard staging methods, however conventional imaging is burdened by high false-negative rates. Currently, there are no consensus recommendations on the routine use of ^{18}F -FDG PET/CT in abdomino-pelvic nodal staging of bladder cancer. In this secondary analysis of PURE-01 clinical trial (NCT02736266), we exploited the role of ^{18}F -FDG PET/CT in patients with muscle-invasive bladder cancer (MIBC) treated with neoadjuvant immunotherapy and radical cystectomy. **Materials and Methods:** Enrolled MIBC patients were treated with 3 courses of 200 mg pembrolizumab, followed by radical cystectomy. They were assessed with thorax-abdomen CT scan and with ^{18}F -FDG PET/CT scan during screening and before surgery. All patients underwent extended pelvic LN dissection with packeted node submission. ^{18}F -FDG PET/CT results were compared with histopathological findings. ^{18}F -FDG PET/CT scans were reviewed to assess the onset of immune-related adverse events (irAEs) during pembrolizumab treatment, as well. **Results:** From 02/2017 to 08/2019, 106 evaluable patients were enrolled and treated; 212 PET/CT scans were internally performed and reviewed. Seven patients

(6%) had nodal uptake at baseline PET/CT; whereas eight patients (7%) had LN uptake at PET/CT post-neoadjuvant immunotherapy. After lymphadenectomy, the rate of pathologic LN was 15% (n=16). The performance of post-pembrolizumab PET/CT, in predicting pathologic LN, is as follows: Sensitivity 37% (15.2-64.6, 95% CI); Specificity 98% (91.9-99.7, 95% CI); Negative Predictive Value 89% (85.3-92.6, 95% CI); Positive Predictive Value 75% (39.9-92.6, 95% CI), Accuracy 88%. Overall, 4/6 patients (67%) with baseline FDG uptake revealed as true positive versus 12/97 (12%) false negative cases. As it concerns irAEs, a total of 40 patients (38%) developed inflammatory FDG-uptakes post-pembrolizumab in several target regions. Thyroid gland was the most frequently involved organ (n=21; 52%), followed by stomach (n=14; 35%), mediastinum (n=13; 32%) and lung (n=10; 25%). Only 15/40 (37%) patients had clinical manifestations of irAEs, i.e. signs, symptoms or laboratory alterations. **Conclusion:** ^{18}F -FDG PET/CT could find a role in bladder cancer LN staging, as it enforces conventional imaging in diagnosing nodal disease, especially in patients tested for eligibility in clinical trials, and to improve clinical management, as well. Immunotherapy determines profound inflammatory adverse events that could affect the safety profile of these treatments. ^{18}F -FDG PET/CT should be proposed to precociously recognize and diagnose irAEs.

^{18}F -PSMA-1007 PET/CT for response assessment in patients with metastatic renal cell carcinoma undergoing tyrosine kinase or checkpoint inhibitor therapy

L. Mittlmeier¹, M. Unterrainer², S. Rodler³, A. Todica¹, N. L. Albert¹, C. Burgard¹, C. C. Cyran², W. G. Kunz², J. Ricke², P. Bartenstein¹, C. G. Stief¹, M. Staehler³, H. Ilhan¹;

¹LMU Munich, Department of Nuclear Medicine, Munich, GERMANY, ²LMU Munich, Department of Radiology, Munich, GERMANY, ³LMU Munich, Department of Urology, Munich, GERMANY.

Aim/Introduction: The implementation of tyrosine-kinase and checkpoint inhibitors improved overall survival for metastatic renal cell carcinoma (mRCC). However, serum biochemistry is unable to predict therapeutic efficacy whereas early prediction of treatment response is highly desirable for the individualization of patient management and improvement of therapeutic outcome. Initial data showed promising results for PSMA-targeted PET imaging in mRCC due to a high PSMA-expression of the neovasculature of RCC. Therefore, we aimed at evaluating ^{18}F -PSMA-1007 PET imaging for response assessment in mRCC patients undergoing tyrosine-kinase or checkpoint inhibitor therapy compared to CT-based response assessment as the current imaging reference standard. **Materials and Methods:** ^{18}F -PSMA-1007 PET/CT was performed in 11 mRCC patients

prior to initiation of systemic treatment and 8 weeks after therapy initiation. Treatment response was evaluated separately on ^{18}F -PSMA PET and CT. Changes in uptake on PSMA-PET (SUV_{mean}) were assessed on a per-patient basis using a modified PERCIST scoring system. Complete response (CR_{PET}) was defined as absence of any uptake in all target lesions on posttreatment PSMA-PET. Partial response (PR_{PET}) was defined as decrease in summed SUV_{mean} of $>30\%$. The appearance of a new PET-positive lesion or an increase in summed SUV_{mean} of $>30\%$ was defined as progressive disease (PD_{PET}). A change in summed SUV_{mean} of $\pm 30\%$ was classified as stable disease (SD_{PET}). RECIST 1.1 criteria were used for response assessment on CT. Subsequently, results of radiographic response assessment on PSMA-PET and CT were compared. **Results:** At baseline PSMA-PET, every mRCC patient showed at least one PSMA-avid lesion. On follow-up PET, 3 patients showed CR_{PET} , 3 PR_{PET} , 4 SD_{PET} and 1 PD_{PET} . According to RECIST 1.1, 1 patient showed PR_{CT} , 9 SD_{CT} and 1 PD_{CT} . Overall, concordant classifications were found in only 2 cases (2 $\text{SD}_{\text{CT+PET}}$). Patients with CR_{PET} on PET were classified as 3 SD_{CT} on CT using RECIST 1.1. By contrast, the patient classified as PR_{CT} on CT showed PSMA-uptake without major changes during therapy (SD_{PET}). However, among 9 patients with SD_{CT} on CT, 3 were classified as CR_{PET} , 3 as PR_{PET} , 1 as PD_{PET} and only 2 as SD_{PET} on PSMA-PET. **Conclusion:** On baseline PSMA-PET, heterogeneous courses were observed during systemic treatment in mRCC patients with highly diverging results compared to RECIST 1.1. PSMA-PET for response assessment in mRCC patients undergoing tyrosine-kinase or checkpoint inhibitor therapy might provide additional information beyond the morphologic information on CT that might highly influence patient management. **References:** None

OP-576

Phosphoenolpyruvate Carboxykinase1 Reduces ^{18}F -FDG Uptake in Clear Cell Renal Cell Carcinoma

L. Shi¹, S. An², Y. Liu³, J. Liu², F. Wang¹;

¹Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA, ²Department of Nuclear Medicine, Ren Ji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA, ³Department of Nuclear Medicine, Shanghai Tenth People's Hospital, Tongji University School of Medicine, Shanghai, CHINA.

Aim/Introduction: Phosphoenolpyruvate carboxykinase (PCK1) plays an important role in gluconeogenesis. Suppressing gluconeogenesis is a component of glucose metabolism change in clear cell renal cell carcinoma (ccRCC). Fluorine 18 (^{18}F) fluorodeoxyglucose (FDG) positron emission tomography and computed tomography (PET/CT) is based on the abnormally high rate of glucose metabolism found in cancer cells and is widely used in diagnose and management of many malignant tumors. However, to date, the relationship between ^{18}F -FDG uptake

and PCK1 expression has not been investigated. **Materials and Methods:** Retrospective analysis was conducted on 68 patients with ccRCC who underwent ^{18}F -FDG PET/CT. The relationship between maximum standardized uptake (SUV_{max}) and the expression of PCK1, glucose transporter 1 (GLUT1) was analyzed with immunohistochemical analysis. PCK1 knockdown and overexpression in ccRCC cells were used to examine the role of PCK1 in tumor metabolism, tumorigenesis, and its effect on the expression of hypoxia inducible factor-1 α (HIF-1 α), GLUT1, and lactate dehydrogenase A (LDHA). **Results:** An inverse relationship between SUV_{max} and PCK1 expression ($P < 0.001$) was noted. The higher-grade ccRCC tumors exhibited a significantly greater SUV_{max} than lower-grade ccRCC tumors ($P < 0.001$). The PCK1 expression was also significantly lower in the patients with higher-grade ccRCC ($P = 0.001$) as revealed by ANOVA. PCK1 expression influenced glucose uptake, utilization and tumorigenesis in vitro and in vivo. PCK1 silencing-regulated expression of HIF-1 α mediates such metabolic reprogramming. **Conclusion:** PCK1 expression is inversely associated with SUV_{max} in patients with ccRCC, and PCK1 inhibits ^{18}F -FDG uptake and utilization via the HIF-1 α pathway. SUV_{max} is higher in patients with higher-grade ccRCC than in those with lower-grade ccRCC; this result may be due to the lower PCK1 expression in the former. **References:** None

OP-577

Auxiliary Diagnostic Utility of Partial ^{18}F -FDG PET/MR on Whole-Body ^{18}F -FDG PET/CT

Y. Xu;

Hangzhou Universal Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: To explore the value of selectively adding partial PET/MR after Whole-Body PET/CT. **Materials and Methods:** 296 cases of whole body PET/CT were analyzed retrospectively, those cases were all selectively added partial PET/MR due to the difficulty of diagnose on whole body PET/CT. 238 patients among those 296 patients were suffered from malignant tumor. Partial PET/MR covers multiple organs, which include 32 intracranial cases, 21 nasopharynx cases, 18 thoracic cases, 59 breast cases, 147 abdominal cases and 65 pelvic cases. The utility of adding partial PET/MR was valued according to the subsequent pathologic findings of those cases. **Results:** Partial PET/MR has a significant diagnostic value on most of the cases with a positive rate of 81.76%(242/296) among those cases, 14.86%(44/296)of the cases has no obvious value on further diagnose, yet another 3.38%(10/296) of the cases were misdiagnosed because of selectively adding partial PET/MR. 130 out of 216 cases which covers intracranial, breast, hepato, pancreas, renal and prostatic lesions have already acquired or changed the initial diagnose after partial PET/

MR was added, which covered 325 lesions including 191 malignant lesions. 81 cases have negative FDG uptake on PET-CT yet with a positive FDG uptake on PET-MR, mostly distributed in thoracic and abdominal areas. Among 80 cases of nasopharyngeal carcinoma, central primary bronchogenic carcinoma, rectal carcinoma and cervical carcinoma, 67 of those cases changed or pointed to a clear diagnose after adding partial PET-MR. **Conclusion:** Partial PET/MR has a significant value on those with diagnostic difficulties cases by only depending on whole body PET/CT. The appropriate timing, organ and sequences were highly depending on the experience of the radiologists. **References:** [1] Catalano O A, Rosen B R, Sahani D V, et al. Orsola Hospital, University of Bologna, Bologna, ITALY, ²Department of Medical and Surgical Sciences, University of Bologna, Bologna, ITALY, ³Radiodiagnostic and Radiotherapy Unit, Department of Medical and Surgical Sciences and Advanced Technologies, "GF Ingrassia", Catania, ITALY, ⁴Department of Nuclear Medicine, Würzburg University Hospital, Würzburg, GERMANY, ⁵Radiology Unit, S. Orsola Hospital, University of Bologna, Bologna, ITALY, ⁶Endocrinology Unit, S. Orsola Hospital, University of Bologna, Bologna, ITALY, ⁷Pathology Unit, S. Orsola Hospital, University of Bologna, Bologna, ITALY.

Aim/Introduction: Hormonal assessment (HA) and contrast-enhanced CT (ceCT) show insufficient sensitivity and specificity when staging adrenal lesions (AL), while FDG-PET does not hold an established role during the diagnostic work-up. We aimed at: 1) developing an imaging-based (ceCT and FDG-PET) score to predict the probability of malignancy and 2) identifying a diagnostic flow-chart able to possibly discriminate between malignant and

benign lesions by the means of a composite reference standard. **Materials and Methods:** From 2007 to 2018 we retrospectively enrolled patients referred to our hospital for evaluation of unilateral adrenal mass with: a) a ceCT made up of unenhanced, arterial, venous and delayed phase (15 minutes); b) FDG-PET within one month of the ceCT; c) HA if available; d) histopathology after adrenalectomy or if unavailable, a clinical follow-up of at least 2 years as reference standard. Firstly, multivariable logistic regression analysis was employed to determine predictors of malignant AL and ROC curves were calculated. Second, regression-based coefficients were used to develop a score predicting malignant AL. Finally, cut-offs were calculated and a diagnostic flow-chart able to distinguish malignant versus benign AL was defined. **Results:** 51 patients were enrolled (41F, 10M; mean age 61 years). Twenty-four (47%) had malignant AL (14 pheochromocytomas, 5 carcinomas, 5 others). The remaining 27 presented with lesions benign AL (22 adenoma, 2 haemangioma and 3 others). Norepinephrine, maximum lesion diameter, HU at the delayed phase (HU15min), relative and absolute washout, $AL-SUV_{max}$, $AL-SUV_{mean}$, ratio $AL-SUV_{max}/liver\ SUV_{max}$ ($R-SUV_{max}$) were associated with the presence of a malignant lesion (all $p < 0.05$). Regarding FDG-PET parameters, $R-SUV_{max}$ had the highest AUC (0.796) and a 1.5 cut-off showed a 75% sensitivity and a 75% specificity. A model including only $R-SUV_{max}$ and HU15min had an AUC of 0.893 and the following score was developed: "score = 40*($R-SUV_{max}$ - 1) + 1*HU15min". Excluding FDG-PET parameters, we calculated cut-offs of ceCT and HA parameters to discriminate malignant versus benign AL, finding 83% of malignant and 78% of benign lesions. Applying the $R-SUV_{max}$ cut-off of 1.5 to those remaining patients with uncertain diagnosis, we found an overall 96% sensitivity and 89% specificity for malignant AL. **Conclusion:** This study shows that combined morphological and metabolic parameters may predict the presence of malignant AL. An imaging-based score may be successfully applied to selected patients. Even more important is the availability of a reliable diagnostic flow-chart to stratify patients on the basis of malignancy risks, thus guiding undefined adrenal lesions to FDG-PET imaging. **References:** None

OP-579

Contribution of open mouth technique in F-18 FDG PET/CT imaging of patients with malignant lip neoplasm

G. Mutevelizade, C. Sezgin, E. Sayit, G. Gumuser; Celal Bayar University, Faculty of Medicine, Department of Nuclear Medicine, Manisa, TURKEY.

Aim/Introduction: F-18 FDG PET/CT has an important role for evaluating head and neck cancers. On the other hand, localization and size evaluation of this region can be rough due to the multitude of the anatomic structures and

physiologic uptakes. The aim of this study is to evaluate the contribution of open-mouth imaging technique at F-18 FDG PET/CT while staging malignant lip neoplasms.

Materials and Methods: Thirty-four patients (9 women, 25 men; mean age 70.9 ± 9.6 years) with histopathologically proven malignant lip neoplasm underwent F-18 FDG PET/CT (Philips, True Flight Select, USA) imaging for initial staging. Each patient imaged twice as whole-body F-18 FDG PET/CT with routine closed-mouth (CM) position; and open-mouth (OM) head and neck image, standardized with a special device. Open-mouth and CM images were evaluated by two nuclear medicine specialists blinded to each other. Lesion SUV max, localization, size and involvement of lymph nodes were evaluated. The data were compared to histopathological, clinical and radiological results **Results:** SUV max were calculated as 7.61 ± 6.4 and 7.57 ± 6.9 for CM and OM, respectively. There was no statistical significant difference between OM and CM SUV max. This revealed that openness or closure of the mouth did not affect SUVmax. Lesion localization was compared with clinical and radiological (MRI&CT) results and the localization was concordant at 50% of CM and 92% of OM images. Lesion size in F-18 FDG PET/CT was compared with histopathological findings and the size measurement was coherent at 47% and 79% for CM and OM images, respectively. Lesion size was also compared with MRI and it was consistent at 38% of CM and 74% of OM images. Regional lymph node metastasis were detected in 12 (35%) patient. It was observed that open-mouth acquisition did not contribute additionally in detecting the presence of regional lymph node metastasis. Statistical analysis was performed using SPSS 21.0 ($p < 0.05$ was considered as statistically significant).

Conclusion: We conclude that additional open-mouth head and neck imaging is useful and necessary for the accurate determination of the localization and size of the tumour, thus enhancing the value of PET/CT in staging, re-staging and response to the treatment of malignant lip neoplasms.

OP-580

Role of F-18 FDG PET/CT in Hemophagocytic Lymphohistocytosis (HLH)

T. T, S. Datta Gupta, S. Shamim, R. Kumar, C. Bal;
All India Institute Of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Hemophagocytic lymphohistocytosis (HLH) is an infrequent disorder seen primarily in paediatric age group, marked by persistent fever, splenomegaly with cytopenia, hypertriglyceridemia, and hypofibrinogenemia. Primary HLH may be managed by hematopoietic stem cell transplantation. However secondary HLH, usually associated with underlying infection, autoimmune diseases and malignancies, is managed as per its provoking cause. This study was performed to assess the role of F-18 FDG PET/CT in detection of underlying cause in secondary HLH.

Materials and Methods: We retrospectively analysed patients referred for FDG PET/CT with clinical suspicion of HLH. Clinical diagnosis was made using the HLH- 2004 criteria. Five out of 8 criteria were needed to be fulfilled for inclusion. Criteria included were fever, splenomegaly, cytopenia (Hb < 9.0 g/dl, platelets $< 100,000/\mu\text{l}$, and neutrophils $< 1,000/\mu\text{l}$), hypertriglyceridemia and/or hypofibrinogenemia (high triglycerides > 3.0 mmol/l or low fibrinogen < 150 mg/dl), low NK cell activity, hyperferritinemia (> 500 ng/ml), high sIL-2R ($> 2,400$ U/ml) and histological finding of hemophagocytosis. All referred patients underwent F18- FDG PET/CT study, which was reported independently by two experienced nuclear medicine physicians. Histopathological correlation was sought for PET positive lesions. **Results:** Seven patients (6 male, 1 female) with mean age of 18.45 years were included. All seven patients showed positive findings on PET/CT. FDG PET/CT revealed metabolically active lymphadenopathy, focal or diffuse splenic and marrow uptake in six (85%) of the seven included patients. One patient had FDG avid skin lesions and hepatomegaly with no splenic involvement. Five out of the seven patients underwent histopathological correlation. Out of these 5, biopsy of two revealed Hodgkin Lymphoma and one lupus disorder; 1 patient showed necrotising lymphadenitis on biopsy suggestive of autoimmune disorder, however serum antibody profile was negative; 1 case with focal marrow uptake was negative on bone marrow biopsy, (site of biopsy did not correlate to uptake); For the remaining two patients with PET positive lymphadenopathy histopathological correlation is awaited. Three out of five (60%) PET positive cases were true positives and two were false positive on biopsy. **Conclusion:** In conclusion, F-18 FDG PET/CT can be a useful tool in detecting the associated cause in cases of secondary HLH and thereby in guiding the management. Although a rare disease, studies with larger sample size may be appropriate to assess the accuracy of FDG PET/CT in HLH. **References:** None

OP-581**Non-conformist intracranial Ga-DOTATATE uptake**

C. Millo, A. Jha, K. Pacak;

NIH, Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Incidental intracranial SSTR-2 positive lesions have been reported in patients with neuroendocrine tumors, including Pheo/PGL, and commonly represent benign tumors such as meningiomas, pituitary tumors, both more commonly encountered in MEN1 patients, and hemangioblastomas seen in VHL patients. However, nefarious causes/lesions can also be detected, albeit rarely. The focus of our study was to highlight the rare cases of positive Ga-DOTATATE intracranial lesions, other than the benign ones comprised of the tumors mentioned above, that were found in our patient population. **Materials and Methods:** 1200 patients with neuroendocrine tumors, including familial genetic syndromes such as MEN1 and VHL, and Phe/PGL, underwent Ga-Dotatate PET/CT scanning between 11/2014 and 12/2019. Patients in which the abnormal intracranial uptake was due to known or MRI confirmed meningiomas, pituitary tumors, and hemangioblastomas, were excluded from the analysis. **Results:** 6 patients (0.5%) demonstrated abnormal intracranial uptake that was not explained by corresponding meningiomas, pituitary tumors, or hemangioblastomas, as verified by their clinical history and CT/MRI. One patient with history of familial midgut carcinoid presented with LLL mass c/w atypical carcinoid; the Ga-DOTATATE scan revealed a biopsy proven cerebellar lesion c/w NET. A second patient had history of cardiac PGL and developed brain lesions with evidence of SSTR-2 expression proven by biopsy to represent PGL. A third patient presented with biopsy proven brain PGL. A fourth patient had history of abdominal PGL and CBT and developed extensive intracranial uptake with involvement of the sinuses. A fifth patient had with history of abdominal PGL and CBT and presented with suspicious intracranial lesion that remained unelucidated. A sixth patient had known spinal cord PGL and demonstrated separate brain lesions with positive biopsy for PGL. **Conclusion:** These anecdotal cases depict a spectrum of Dotatate avid intracranial brain lesions beyond the more common benign tumors that are known to demonstrate SSTR-2. Though very rare, primary or metastatic NET and paragangliomas can involve the brain parenchyma and intracranial structures. Although not difficult to detect in the normally absent background intracranial Ga-DOTATATE uptake (with the exception of pituitary), the localization and extension of these abnormalities can be challenging and unexpected. Therefore, we recommend that Ga-DOTATATE studies include by default the entire head in their FOV followed by careful evaluation of intracranial activity. **References:** None

OP-582**Role of ¹⁸F-FDG PET/CT in detecting recurrent transitional cell carcinoma**

S. Shamim, P. Kaushik, J. Hussain, G. Arora, S. Datta Gupta, R. Kumar, C. Bal;

AIIMS, New Delhi, INDIA.

Aim/Introduction: There is paucity of literature on utility of ¹⁸F-FDG PET/CT in transitional cell carcinoma (TCC), possibly because the tracer is excreted in urine which makes scan interpretation difficult. Conventional imaging using cystoscopy, CT or MRI may be equivocal in detecting recurrence in presence of post-surgical changes, especially in upper urinary tract lesions. Hybrid PET/CT imaging and use of dual time point imaging with diuresis can overcome these problems. The present study was aimed at determining the role of ¹⁸F-FDG PET/CT in detecting recurrent TCC. **Materials and Methods:** Treated follow up cases of TCC (post-surgery and chemotherapy) who underwent FDG PET/CT for suspected recurrence, were retrospectively included in the study. Recurrence was suspected based on clinical features and/or conventional imaging. Whole body PET/CT scan was acquired on dedicated PET/CT scanner (Biograph mCT, Siemens, Germany and 710 Discovery, GE, USA) 45-60 minutes after injection of 10 mCi of FDG intravenously, following which 1mg/kg (maximum 40 mg) of furosemide was injected i.v. and a spot image with kidneys and bladder in field of view was acquired 110-120 minutes post-injection of FDG. All images were visually analyzed by two nuclear medicine physicians independently, who were blinded to each other's scan findings. **Results:** Twenty-nine patients of TCC underwent FDG PET/CT in our department since 2014, of which 12 patients (10 male and 2 female) with query of recurrence were included in this retrospective study. Mean age of the patients was 57.4±11.9 years. The primary site of TCC was kidney in 9, urinary bladder in 2 and ureter in 1 patient. FDG PET/CT was positive for recurrent disease in 10/12 (83%) patients and negative in 2 (17%) patients. Of the patients with recurrent disease, 2 patients had only local recurrence, 6 patients had recurrent metastatic disease while both local and metastatic recurrence was seen in 2 patients. The site of recurrent disease was lymph nodes in 4 patients, visceral disease in 4 patients and both in 2 patients. **Conclusion:** FDG PET/CT may be used for detection of local as well as metastatic recurrence in TCC particularly in patients with upper urinary tract TCC where cystoscopy is not feasible. Dual time point imaging with diuresis can help in avoiding pitfalls and artifacts due to urinary excretion of FDG. **References:** None

The value of cardiac sympathetic nervous system activity in predicting the effectiveness of radiofrequency ablation of atrial fibrillation

Y. Varlamova, K. Zavadovsky, I. Kisteneva, S. Sazonova, R. Batalov; Cardiology Research Institute, Tomsk NRC, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Atrial fibrillation (AF) is one of the widest spread forms of arrhythmia worldwide. To date, radiofrequency catheter ablation (RFCA) of AF is a valuable treatment option. So far there are no clear predictors of the effectiveness of AF ablation. Nowadays, the association of cardiac sympathetic nervous system and the development and maintenance of AF has been showed. However, the association between sympathetic innervation disturbances and AF RFCA effectiveness remains inconclusive. The aim of the study was to evaluate the prognostic significance of cardiac sympathetic activity, assessed by ^{123}I -MIBG scintigraphy, in AF RFCA efficacy. **Materials and Methods:** The study included 46 patients. All patients were divided into 2 groups: I group - AF patients (n=36), II group - sinus rhythm patients (n=10). All patients underwent ^{123}I -MIBG and $^{99\text{m}}\text{Tc}$ -MIBI scintigraphy (planar and SPECT) to evaluate the cardiac sympathetic activity and myocardial perfusion, respectively. Echocardiography was performed in all patients to assess the cardiac contractile function. The effectiveness of interventional treatment was assessed in one year by 24 hour Holter monitoring. **Results:** During a median follow-up of 12 ± 6 month, arrhythmia recurrence was observed in 15 patients. The univariate regression analysis showed that the left atrial diameter, ^{123}I -MIBG washout rate (WR), late ^{123}I -MIBG defect score and ^{123}I -MIBG/ $^{99\text{m}}\text{Tc}$ -MIBI mismatch score were predictors of AF recurrence. According to multivariate analysis only WR (odds ratio: 1.691, 95% confidence interval: 1.096-2.647, $p = 0.012$) and ^{123}I -MIBG/ $^{99\text{m}}\text{Tc}$ -MIBI mismatch score (odds ratio: 1.995, 95% confidence interval: 1.192-2.992, $p = 0.023$) were an independent predictors of AF RFCA effectiveness. The receiver operator characteristics curve (ROC) analysis indicated the potential diagnostic value of WR to predict recurrence of AF after RFCA with an

area under the curve of 0.996 ($P < 0.05$; sensitivity=98%, specificity=50%), and an optimum cut-off value of 21.5 %. ROC analysis gave an optimum cut-off value of 12 % for the ^{123}I -MIBG/ $^{99\text{m}}\text{Tc}$ -MIBI mismatch score with an area under the curve of 0.940 to predict of AF RFCA effectiveness ($p < 0.05$, sensitivity = 75%, specificity = 45%). **Conclusion:** To sum up, the prognosis of AF recurrence has a link with pre-ablation abnormalities of cardiac sympathetic innervation. **References:** None

OP-585

Relationship between heart rate response and cardiac innervation in patients with suspected or known coronary artery disease

C. Nappi¹, R. Assante¹, E. Zampella¹, V. Gaudieri¹, G. De Simini¹, A. Giordano¹, A. D'Antonio¹, W. Acampa¹, M. Petretta², A. Cuocolo¹; ¹Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY; ²Department of Translational Medical Sciences, University Federico II, Naples, ITALY.

Aim/Introduction: Chronotropic response to pharmacological stress test is blunted in patients with autonomic neuropathy. The relationship between heart rate (HR) changes during pharmacological stress test and cardiac autonomic dysfunction has not been fully investigated. We assessed the potential interplay between HR response (HRR) and myocardial innervation in patients with suspected or known coronary artery disease (CAD). **Materials and Methods:** We considered 71 consecutive patients with suspected or known CAD referred to pharmacological stress myocardial perfusion imaging (MPI) for the assessment of myocardial ischemia and to ^{123}I -metaiodobenzylguanidine (MIBG) imaging for the evaluation of cardiac innervation within one month from each other as part of their diagnostic work-up planned by the attending physician. HRR was calculated as the maximum percent change from baseline according to the formula: $(\text{peak HR} - \text{rest HR}) / \text{rest HR} \times 100$. ^{123}I -MIBG heart-to-mediastinum (H/M) ratio was calculated and a late H/M ratio < 1.6 was considered abnormal. **Results:** The majority of patients (56 out of 71, 79%) had known CAD while the remaining patients were evaluated due to primary dilated cardiomyopathy. No differences in demographic data and clinical characteristics were observed between patients with normal and abnormal H/M ratio. Similarly, hemodynamic data and MPI findings were comparable between the two groups, while left ventricular ejection fraction was significantly lower in patients with abnormal compared to those with normal H/M ratio ($34\pm 10\%$ vs. $40\pm 10\%$, $P < 0.05$). A significant response to stress test was observed in both categories; however, HRR was lower in patients with abnormal as compared to those with normal late H/M ratio (18 ± 9 vs. 26 ± 14 , $P < 0.05$). HRR progressively decreased with decreasing late H/M ratio tertiles (P for trend = 0.02). In particular, HRR mean value was 17 ± 10

in the low, 20 ± 12 in the middle, and 27 ± 16 in the high tertile. A significant correlation between HRR and H/M ratio ($r=0.28$, $P=0.03$) was also detectable. Finally, the addition of HRR to a model including age, diabetes, known CAD, left ventricular ejection fraction, and stress-induced ischemia added incremental value in predicting an abnormal late H/M ratio, increasing the global chi-square from 8.09 to 13.8 ($P=0.02$). **Conclusion:** In patients with suspected or known CAD undergoing pharmacological stress MPI and ^{123}I -MIBG cardiac imaging there was a significant relationship between HRR and late H/M ratio. HRR was an independent predictor of abnormal late H/M ratio, suggesting a strong interplay between cardiac response to stress test and cardiac innervation. **References:** None

OP-586

A novel method for regional innervation/perfusion mismatch assessed by cardiac ^{123}I -MIBG and rest $^{99\text{m}}\text{Tc}$ -tetrofosmin SPECT to predict arrhythmic events in ischemic heart failure

D. Verschure^{1,2}, E. Poel¹, A. F. Jacobson³, H. J. Verberne¹;
¹Amsterdam UMC, Amsterdam, NETHERLANDS, ²Zaans Medical Center, Zaandam, NETHERLANDS, ³Diagram Consulting, Kihei, HI, UNITED STATES OF AMERICA.

Aim/Introduction: Cardiac ^{123}I -MIBG SPECT imaging provides information on regional myocardial innervation. However, there is no consensus on how to use a, sometimes cumbersome assessed, 17-segment based score to assess prognosis. The present study examined whether a simpler regional scoring approach for evaluation of ^{123}I -MIBG SPECT combined with rest $^{99\text{m}}\text{Tc}$ -tetrofosmin SPECT myocardial perfusion imaging (MPI) could be used for the prediction of arrhythmic events (AEs) in patients with ischemic heart failure (HF). **Materials and Methods:** 502 ischemic HF subjects (NYHA II/III, LVEF $\leq 35\%$) of the ADMIRE-HF study cohort with complete cardiac ^{123}I -MIBG and rest $^{99\text{m}}\text{Tc}$ -tetrofosmin SPECT studies were enrolled. Both SPECT image sets were read together by 2 experienced nuclear imagers and scored by consensus. In addition to standard 17 segments scoring, the readers classified walls (i.e. anterior, lateral, inferior, septum and apex) as normal, matched defect of innervation and perfusion, mismatched (i.e., innervation defect larger than perfusion defect) or reverse mismatched (i.e., innervation defect smaller than perfusion defect). Cox proportional hazards ratios (HR) were used to determine if the visual segmental wall classification innervation/perfusion mismatch score, ^{123}I -MIBG summed defect scores (SDS), $^{99\text{m}}\text{Tc}$ -tetrofosmin SDS and innervation/perfusion mismatch SDS, LVEF, NYHA class, B-type natriuretic peptide (BNP) were associated with occurrence of AEs (i.e. sudden cardiac death, sustained VT, resuscitated cardiac arrest, appropriate ICD therapy). **Results:** At 2-year median follow-up, 52 subjects (10.4%) had AEs. Subjects with 1

or 2 mismatched walls were twice as likely to have AEs compared with subjects with either 0 or 3-5 mismatched walls (16.3% vs 8.3%, $p = 0.010$). Cox regression analyses showed that the combination of BNP and the presence of visual mismatch in 1-2 walls were independent predictors of AEs (HR 2.084 [1.109-3.914], $p = 0.001$) However, compared to the visual mismatch, the contribution of BNP is relatively small (i.e., HR 1.001 [1.000-1.001]). None of the other innervation, perfusion and mismatch scores using standard 17 segments were associated with AEs. **Conclusion:** In ischemic HF the highest risk of AEs occurs in subjects with intermediate levels of visual wall-level innervation/perfusion mismatches. Therefore, a simple visual wall-level based assessment of combined cardiac ^{123}I -MIBG and rest $^{99\text{m}}\text{Tc}$ -tetrofosmin SPECT can be used to differentiate those HF patients at higher AE risk from those with relatively low AE risk. **References:** None

OP-587

Low-dose dual-isotope by CZT camera: single imaging to assess cardiac function, myocardial perfusion and adrenergic innervation in heart failure

A. Giordano, G. De Simini, R. Assante, C. Nappi, A. D'Antonio, E. Zampella, V. Gaudieri, T. Mannarino, R. Green, V. Cantoni, P. Buongiorno, W. Acampa, A. Cuocolo;
 Department of advanced biomedical sciences, University Federico II of Naples, Naples, ITALY.

Aim/Introduction: We assessed the feasibility of a low-dose dual isotope $^{123}\text{I}/^{99\text{m}}\text{Tc}$ -acquisition protocol by a cadmium-zinc-telluride (CZT) dedicated camera for the simultaneous evaluation of left ventricular (LV) function, myocardial perfusion and adrenergic innervation in patients with heart failure (HF). **Materials and Methods:** A total of 36 patients (34 men, mean age 64 ± 9 years) with HF underwent simultaneous dual-isotope ^{123}I -metaiodobenzylguanidine (MIBG)/ $^{99\text{m}}\text{Tc}$ -sestamibi (74 MBq/185 MBq) cardiac gated CZT imaging with a single acquisition. Early and late heart to mediastinum ratio (H/M), washout rate (WR) and total defect score (TDS) were assessed from ^{123}I -MIBG images; while summed rest score (SRS) was computed from $^{99\text{m}}\text{Tc}$ -sestamibi images. Difference between innervation and perfusion were identified as innervation/perfusion mismatch (%). LV systolic function was considered reduced when ejection fraction (EF) was $<45\%$. **Results:** LVEF was normal in 13 (36%) patients and reduced in 23 (64%). Clinical characteristics were comparable in patients with normal and reduced LVEF. TDS ($r=0.51$, $P=0.001$) and SRS ($r=0.56$, $P<0.001$) resulted correlated with LVEF. A significant relation between early ($r=0.45$, $P=0.005$) and late ($r=0.50$, $P<0.005$) H/M ratio and LVEF and was also found. Patients with reduced LVEF compared to those with normal LVEF had higher SRS (15 ± 12 vs. 6 ± 8 , $P<0.05$), TDS (29 ± 15 vs. 19 ± 8 , $P<0.05$) and WR ($34 \pm 22\%$ vs. $16 \pm 34\%$, $P<0.05$) and

lower values of early (1.60 ± 0.3 vs 1.84 ± 0.3 , $P<0.05$) and late (1.50 ± 0.3 vs 1.9 ± 0.3 , $P<0.01$) H/M ratio. Conversely, myocardial mismatch was comparable in patients with normal and reduced LVEF ($19\pm 18\%$ vs. $18\pm 12\%$, $P=0.81$). Late H/M ratio resulted the only independent predictor of reduced LVEF ($P=0.05$). Although TDS correlated with SRS ($r=0.77$, $P<0.001$), ^{123}I -MIBG defect size was larger than perfusion defects (25 ± 14 vs. 12 ± 11 , $P<0.001$). WR was the only independent predictor of myocardial mismatch ($P<0.05$). **Conclusion:** In patients with HF, a low-dose dual isotope $^{123}\text{I}/^{99\text{m}}\text{Tc}$ with a single acquisition protocol using a CZT camera is clinically feasible and allows simultaneous evaluation of LV function, myocardial perfusion and adrenergic innervation. WR measurements provided by CZT camera could integrate the clinical value of innervation/perfusion assessment in heart failure patients. **References:** None

OP-588

The ability of ^{123}I -mIBG/ ^{199}Tl SPECT to predict appropriate ICD therapy in patients with ischemic heart failure

S. Sazonova, T. A. Atabekov, R. E. Batalov, J. N. Ilushenkova, Y. B. Lishmanov, S. V. Popov;
Cardiology Research Institute, Tomsk NRM, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Last years was shown the ability of ^{123}I -mIBG/perfusion cardiac scintigraphy to predict arrhythmic events in patient (pts) with heart failure (HF). However, the application of these methods as a predictor of appropriate ICD therapy in pts with HF after myocardial infarction (MI) remains questionable. **Aim.** To evaluate the ability of ^{123}I -mIBG and myocardial perfusion scintigraphy with ^{199}Tl to predict ICD-therapy in candidates for primary and secondary SCD prevention. **Materials and Methods:** The study included 80 pts ($63,7\pm 9.7$ years) with a MI (>3 month) and indications for ICD implantation for primary (1st group, $n=49$) and secondary prevention (2 group, $n=31$). All pts underwent cardiac scintigraphy with ^{123}I -mIBG and ^{199}Tl at 5 days before ICD implantation. ICD interrogation was performed at 6, 12, and 18 months. ^{123}I -MIBG (i.v.a. 300 MBq) planar and SPECT images were acquired at 15 minutes (early) and 4 hours (delayed). On planar images the heart/mediastinum ratios (H/Me, H/Md), washout rate (WR) were calculated. ^{199}Tl (i.v.a. 185 MBq) SPECT was performed according to the rest/4 h redistribution protocol. ^{123}I -MIBG and ^{199}Tl images were analyzed by a 17-segment model with a 5-point scoring. ^{123}I -MIBG scores (SMSe%, SMSd %), ^{199}Tl summed scores (SRS%, SDS%), trigger zone (TZ%) as SDS%-SMSd% were calculated. Both groups were subdivided according to the presence or absence of appropriate ICD therapy and compared by U-test. **Results:** During follow-up appropriate ICD-therapy (ATP or shocks) was registered

in 6 pts (12,2%) of the 1 group and in 11 pts (35%) of the 2 group. In the 1 group H/Me= $1,88\pm 0,56$, H/Md= $1,71\pm 0,042$, SMSe= $23,4\pm 10,07\%$, SMSd= $33,95\pm 16,11\%$, WR= $28,87\pm 21,14$; SRS= $17,46\pm 14,88$, SDS= $18,6\pm 16,23\%$, TZ= $15,0\pm 10,19\%$. In the 2 group H/Me= $1,97\pm 0,53$, H/Md= $1,9\pm 0,59$, SMSe= $22,61\pm 18,1\%$, SMSd= $24,6\pm 18,28\%$ ($p=0,028$), WR= $16,03\pm 8,26$; SRS= $17,87\pm 15,13\%$ ($p=0,69$), SDS= $15,94\pm 15,84\%$, TZ= $8,31\pm 7,39\%$. In the 1 group there were no statistical differences at scintigraphic parameters between subgroups of pts with and without appropriate ICD therapy. In the 2 group pts with appropriate ICD therapy had significantly larger SMSe ($40,1\pm 16,97\%$ vs $13,0\pm 9,59\%$, $p=0,00015$), SMSd ($42,18\pm 16,46\%$ vs $15,0\pm 10,44\%$, $p=0,00012$), WR ($20,09\pm 8,32$ vs $13,85\pm 7,51$, $p=0,049$), TZ ($12,44\pm 5,13\%$ vs $6,79\pm 8,17\%$, $p=0,025$), SRS ($31,4\pm 17,44\%$ vs $10,75\pm 7,69\%$, $p=0,0052$), SDS ($30,22\pm 20,3\%$ vs $9,4\pm 7,76\%$, $p=0,03$). **Conclusion:** Both ^{123}I -mIBG and ^{199}Tl SPECT demonstrated disability to predict appropriate ICD therapy in candidates for primary SCD prevention. The good relationship between size of denervated and/or hypoperfused myocardium and appropriate ICD therapy was shown in candidates for secondary SCD prevention. Probably the scar structure is more significant, than scar size in appearance of life-threatening arrhythmia **References:** None

Myocardial ^{123}I -Metaiodobenzylguanidine Scintigraphy in Patient with Heart Failure: a Gender Study

M. Conte¹, A. Di Rocco², C. De Angelis¹, V. Frantellizzi¹, A. Farcomeni³, G. De Vincentis¹;

¹Department of Radiological Sciences, Oncology and Anatomical Patology, "Sapienza" University of Rome, Rome, ITALY, ²Department of Public Health and Infectious Diseases, "Sapienza" University of Rome, Rome, ITALY, ³"Tor Vergata" University of Rome, Rome, ITALY.

Aim/Introduction: The aim of the study was to evaluate the prognostic significance differences of myocardial ^{123}I -metaiodobenzylguanidine (^{123}I -MIBG) scan between males and females in patients with heart failure (HF). **Materials and Methods:** Patients with HF prior to implantable cardioverter-defibrillator (ICD) implantation were consecutively enrolled. They underwent ^{123}I -mIBG scintigraphy using a dual-head gamma camera and a LEHR collimator. Planar anterior thoracic and Single Photon Emission Computed Tomography (SPECT) images were acquired at 15 and 240 minutes after tracer injection. Region of interest were manually drawn over the heart and the upper mediastinum and Early and late heart-to-mediastinum ratios (eHM, lHM) as well as myocardial washout rate (WR) were calculated. Early and late summed SPECT scores (ESS, LSS) were calculated. A statistical analysis was conducted taking into account age, body mass index

(BMI), males rate, comorbidities (diabetes, dyslipidemia, chronic renal failure, chronic obstructive pulmonary disease), smoke habits, administered treatment (ACE-inhibitors, α and β -blockers, potassium-sparing diuretics, calcium antagonists, sartans, amiodarone and digitalis), ESS, LSS, eHM, IHM, WR and ejection fraction. **Results:** 306 consecutive patients (247 males) were enrolled, 115 had arrhythmic events (AE). The median follow-up was of 85 months. In general population at univariate analysis ESS (HR= 1.023 CI95% 1.008-1.039; p=0.003) and LSS (HR=1.02 CI95% 1.005-1.035; p=0.009) resulted as risk factor in the prediction of AE. Moreover, eHM (HR= 0.326 CI95% 0.143-0.742; p=0.008) and IHM (HR=0.215 CI95% 0.094-1.002; p=0.001) resulted as protective factor in the prediction of AE, with AUC of 0.625 and 0.645 respectively. Gender analysis: in female no MIBG parameters gained statistical significance in the prediction of AE (p>0.05). Male group data results were similar to the total population, and also slightly better (eHM - AUC=0.677; IHM - AUC= 0.693). **Conclusion:** Our results indicated that MIBG represents a tool to predict AE in male patients: ESS and LSS are risk factors while eHM and IHM are protective factors. However, MIBG showed lower specificity and sensibility in long term analysis and in female predictive estimation. **References:** None

OP-590

Altered Electromechanical Coupling With Multisite Onset of Left Ventricle Mechanical Contraction Associated With Advanced Coronary Heart Disease

F. Ferrando-Castagnetto¹, M. Pedrera Cana², I. Vilacosta³, C. Real³, M. Ollarves Carrero², L. García Belaustegu², M. Olivan², R. Ricca-Mallada¹, M. Pérez Castejón², J. Carreras Delgado²;

¹Departamento de Cardiología - CCVU, Hospital de Clínicas, FM, UdelaR, Montevideo, URUGUAY, ²Servicio de Medicina Nuclear, Hospital Clínico San Carlos, Madrid, SPAIN, ³Instituto Cardiovascular, Hospital Clínico San Carlos, Madrid, SPAIN.

Aim/Introduction: Left ventricle (LV) mechanical dynamics have been poorly characterized in patients with ischemic heart disease not eligible for resynchronization therapy (CRT). Some experimental evidence suggests that, in certain patients with chronic coronary artery disease (CAD), there may be considerable LV mechanical dyssynchrony in the absence of severe systolic dysfunction or electrical dyssynchrony. We evaluated LV contractile dynamics in patients with advanced CAD. **Materials and Methods:** Phase histograms at rest were obtained in a sample of patients with known coronary artery disease (severe coronary malformation, old infarct, primary or delayed angioplasty and/or coronary bypass surgery) derived to 99mTc-MIBI gated-SPECT between July 2019 and March 2020. The site of onset of mechanical LV contraction (SOMC) was defined through SyncTool of Emory Cardiac Toolbox®, detecting those patients with “multisite” OMC, defined as the onset

in at least 3 of 17 segments. Peak amplitude (PA), phase standard deviation (PSD), and phase bandwidth (PBW) were compared with controls (n = 24). **Results:** We detected thirteen patients with multisite OMC and chronic coronary disease, 63 + 13 years old, 38% diabetic, LVEF = 39.8 + 13.6%, VTS = 112.4 + 64.9 ml, averaged summed rest score = 12.5 and summed difference score = 2.8. Indexes derived from phase analysis at rest showed values compatible with severe LV mechanical dyssynchrony (PA = 120.2 + 15.0, PSD = 50.3 + 18.1, PBW = 160.0 + 65.2 degrees, p <0.05 for all comparisons with controls). A multisite latest mechanical contraction was also detected in 4 of them (30.8%). **Conclusion:** Advanced CAD is associated with altered electromechanical coupling, characterized by multisite OMC, even in the absence of prolonged QRS duration. Prognostic and therapeutic implications of this mechanical substrate deserve to be evaluated in larger series that include CRT candidates with different underlying heart diseases. **References:** None

OP-591

Left Ventricular Diastolic Asynchrony Combined with Left Ventricular Ejection Fraction Decline Based on Gated Myocardial Perfusion Imaging Can Early Predict Cardiotoxicity Caused by Anthracyclines

J. Wang, Y. Lin, W. Gu, C. Qiu, R. Niu, Y. Wang;

The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: To explore the value of quantitative parameters of gated myocardial perfusion imaging (GMPI) in early prediction of anthracycline treat - related cardiotoxicity (ATRC). **Materials and Methods:** Fifty-eight patients with newly diagnosed diffuse large B-cell lymphoma (DLBCL) were enrolled. All patients were administered 6 cycles of R-CHOP chemotherapy. Rest GMPI was performed before and after anthracycline chemotherapy. Myocardial perfusion abnormal extent (Extent), Left ventricular ejection fraction (LVEF), end diastolic and systolic volumes (EDV and ESV), peak filling rate (PFR), left ventricular systolic and diastolic synchronization parameters such as phase standard deviation (SD), phase histogram bandwidth (BW) were calculated at automatically using the ECToolbox program. ATRC was defined as symptomatic heart failure; cardiac death, arrhythmia, or infarction; a decrease in LVEF of >15% from baseline; or a decrease in LVEF of >10% to <50%. Univariate logistic regressions were performed first. Factors with p values <0.20 in the univariate model were included in multivariate models. Receiver-operating characteristic (ROC) curves were used to assess the performance of linear predictors of risk for ATRC. **Results:** ATRC occurred in 14 of 58 patients. There were no statistically significant differences between ATRC group and Non-ATRC group in terms of gender, age, BMI, hypertension, diabetes, hyperlipidemia

(all $P > 0.05$). Compared with before chemotherapy, the value of QTc interval of electrocardiogram, LVEF, PFR, $SD_{systolic}$, $BW_{systolic}$, $SD_{diastolic}$, $BW_{diastolic}$ were significantly changed after chemotherapy (all $P < 0.05$). The $\Delta QTc, \Delta LVEF, \Delta PFR, \Delta SD_{systolic}, \Delta SD_{diastolic}$ were separately calculated as the difference of the indicators before and after chemotherapy. The multivariate logistic regressions revealed both $\Delta LVEF$ (OR: 0.846; 95% CI: 0.739 to 0.969; $P = 0.016$) and $\Delta SD_{diastolic}$ (OR: 1.186; 95% CI: 1.040 to 1.353; $P = 0.011$) as significant predictors of ATRC. ROC analysis revealed the AUC of $\Delta LVEF$ and $\Delta SD_{diastolic}$ in predicting ATRC were 0.774, 0.827 separately (all $P < 0.001$), while the AUC of $\Delta SD_{diastolic}$ combined with $\Delta LVEF$ in predicting ATRC was 0.869 ($P < 0.001$), which higher than single $\Delta LVEF$ and single $\Delta SD_{diastolic}$, its diagnostic sensitivity and specificity were 92.9% and 65.9%. **Conclusion:** Left ventricular diastolic asynchrony and LVEF decline post-anthracycline were both independent predictors of ATRC, the combination of $\Delta LVEF$ and $\Delta SD_{diastolic}$ have a good efficacy for early prediction of ATRC in DLBCL patients. **References:** None

OP-592

The diagnostic accuracy of cardiac I-123-mIBG scintigraphy as a biomarker for mild cognitive impairment with Lewy bodies

G. Roberts^{1,2}, R. Durcan¹, P. C. Donaghy¹, S. Barker¹, S. Lawley¹, C. A. Hamilton¹, J. Ciafone¹, G. Petrides², K. Howe², N. Barnett¹, M. Firbank¹, J. P. Taylor¹, J. O'Brien³, A. J. Thomas¹;

¹Newcastle University, Newcastle upon Tyne, UNITED KINGDOM, ²Newcastle upon Tyne Hospitals, Newcastle upon Tyne, UNITED KINGDOM, ³University of Cambridge, Cambridge, UNITED KINGDOM.

Aim/Introduction: Cardiac mIBG scintigraphy (cardiac mIBG) is recommended as a biomarker in the 2020 research criteria for mild cognitive impairment with Lewy bodies (MCI-LB) [1]. Prospective studies assessing the accuracy of mIBG for the detection of MCI-LB are required. **Objective:** To examine the diagnostic accuracy of cardiac mIBG for differentiating probable MCI-LB from MCI due to Alzheimer's disease (MCI-AD). **Materials and Methods:** We conducted a prospective cohort study into the accuracy of cardiac mIBG in the diagnosis of MCI-LB. Ninety-five people over 60 years of age with MCI were recruited. MCI-LB was diagnosed in individuals with two or more core features (fluctuating cognition, visual hallucinations, REM sleep behaviour disorder, parkinsonism) or one core feature with abnormal dopaminergic imaging. MCI due to probable Alzheimer's disease (MCI-AD) was diagnosed in individuals with no core features of Lewy body disease and who met the Alzheimer's Association criteria [2]. Individuals with just one core feature or abnormal dopaminergic imaging only were excluded due to lack of certainty as to whether their MCI could be attributed to Lewy body disease. All recruits

were administered 111 MBq ($\pm 10\%$) mIBG and scanned 4 hours later. Anterior planar images were processed to obtain the heart-to-mediastinum ratio (HMR). Thirty-two age-matched controls without cognitive impairment were used to set a cardiac mIBG diagnostic threshold two standard deviations below mean age-matched control heart-to-mediastinum ratio. **Results:** Thirty-seven patients were diagnosed with MCI-LB, of which 22 had an abnormal MIBG scan, resulting in a sensitivity of 59% (95% CI: 42-75%). Forty-three patients were diagnosed with MCI-AD, of which 38 had a normal scan, resulting in a specificity of 88% (95% CI: 75-96%). The overall accuracy was 75% (95% CI: 64-84%). The positive likelihood ratio was 5.1 and negative likelihood ratio 0.46. **Conclusion:** At the MCI stage, over half of patients with probable Lewy body disease already have positive cardiac MIBG scans. Combined with high specificity, this means cardiac MIBG is a useful biomarker even at the MCI stage (likelihood ratio 5.1). **References:** 1. McKeith, I., et al., Research criteria for the diagnosis of prodromal dementia with Lewy bodies. *Neurology*, 2020. 2. OP-593

Predictive value of the cardiac sympathetic innervation and contractile function in cardiac resynchronization therapy

A. Mishkina, K. Zavadovsky, V. Saushkin, D. Lebedev, Y. Lishmanov;

Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: To evaluate the predictive value of the cardiac sympathetic activity and contractility, assessed by radionuclide methods, in the prediction of cardiac resynchronization therapy (CRT) response. **Materials and Methods:** This study included 38 heart failure (HF) patients with ischemic (n=16) and non-ischemic (n=22) etiology. Before CRT all patients underwent ¹²³I-metaiodobenzylguanidine (¹²³I-MIBG) imaging for cardiac sympathetic activity evaluating. The following indexes were estimated: early and delayed heart to mediastinum ratio (eH/M and dH/M), summed MIBG Score (eSMS and dSMS). All patients underwent gated myocardial perfusion scintigraphy with assessments of LV dyssynchrony indexes: standard deviation (SD) and histogram bandwidth (HBW). Additionally, all patients underwent gated-blood-pool-SPECT with both ventricles ejection fraction (EF) and stroke volume (SV) assessment. **Results:** One year after CRT patients were divided into two groups: responders (n=26) and non-responders (n=12). The response was defined as LV_ESV decreased greater than or equal to 15% or

LV_EF increase greater than or equal to 5%. The following differences in the preoperative scintigraphic parameters between responders and non-responders were found: eH/M (2.16 and 1.74; $p < 0.05$), dH/M (1.94 and 1.53; $p < 0.05$), dSMS (13 and 16.5; $p < 0.05$), SD (101.9 and 141.8ms; $p < 0.05$). According to logistic regression analysis eH/M (OR=1.25 per 0.1 unit increase; 95% CI 1.054-1.49; $p < 0.05$), dH/M (OR=1.43 per 0.1 unit increase; 95% CI 1.09-1.87; $p < 0.05$), dSMS (OR=0.91; 95% CI 0.84-0.99; $p < 0.05$), SD (OR=0.97; 95% CI 0.95-0.98; $p < 0.05$) were related to CRT response. In patients with ischemic HF SD (OR=1.55; 95% CI 1.09-2.2; $p < 0.05$) and HBW (OR=1.13; 95% CI 1.02-1.24; $p < 0.05$), and right ventricle (RV) EF (OR=1.11; 95% CI 1.001-1.23; $p < 0.05$), RV_SV (OR=1.07; 95% CI 1.003-1.138; $p < 0.05$) were predictors of CRT response. In non-ischemic HF patients dH/M (OR=1.47 per 0.1 unit increase; 95% CI 1.08-2; $p < 0.05$), SD (OR=0.83; 95% CI 0.73-0.95; $p < 0.05$), HBW (OR=0.96; 95% CI 0.93-0.99; $p < 0.05$) showed the predictive value in terms of CRT response. **Conclusion:** ^{123}I -MIBG scintigraphy and gated myocardial perfusion scintigraphy can be used as additional methods for predicting the effectiveness of CRT. In ischemic HF patients preoperative values of LV dyssynchrony and RV contractility were independent predictors of response to CRT. In non-ischemic HF patients cardiac sympathetic activity, as well as LV dyssynchrony can be used as prognostic criteria for a positive response to CRT. **References:** None

The role of nuclear medicine imaging with ^{18}F -FDG PET/CT, combined ^{111}In -WBC/ $^{99\text{m}}\text{Tc}$ -Nanocoll and $^{99\text{m}}\text{Tc}$ -HDP SPECT/CT in evaluation of patients with chronic problem after TKA or THA in a prospective study

R. Aleksyniene¹, V. Iyer², H. C. Bertelsen¹, M. Frost¹, V. Khalid³, H. C. Schönheyder⁴, L. H. Larsen⁴, P. T. Nielsen³, A. Kappel⁵, T. R. Thomsen⁵, J. Lorenzen⁶, I. Ørsted⁷, O. Simonsen³, P. L. Jordal⁶, S. Rasmussen³, PRIS Study Group;

¹Department of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, ²Department of Nuclear Medicine, Uppsala University Hospital, Uppsala, SWEDEN, ³Department of Orthopaedic Surgery, Aalborg University Hospital, Aalborg, DENMARK, ⁴Department of Clinical Microbiology, Aalborg University Hospital, Aalborg, DENMARK, ⁵Center for Microbial Communities, Aalborg University, Aalborg East, Life Science Division, The Danish Technology Institute, Aarhus, DENMARK, ⁶Life Science Division, The Danish Technology

Institute, Aarhus, DENMARK, ⁷Department of Infectious Disease, Aalborg University Hospital, Aalborg, DENMARK.

Aim/Introduction: The aim was to assess the diagnostic value of nuclear imaging with ^{18}F -FDG PET/CT, combined ^{111}In -WBC/ $^{99\text{m}}\text{Tc}$ -Nanocoll and $^{99\text{m}}\text{Tc}$ -HDP SPECT/CT for patients with chronic problem related to knee or hip prosthesis (TKA or THA) scheduled by the structured multidisciplinary algorithm within the prospective study. **Materials and Methods:** The study was a part of a prospective study conducted in Denmark from December 2011 to January 2014 within the framework of an innovation consortium (Danish acronym PRIS). Fifty five patients (26 women and 29 men, mean age 64 years) with persisting pain and/or a mechanical problem but without clinical or radiological signs for aseptic loosening or prosthetic joint infection (PJI) (29 knee and 26 hip) underwent imaging with $^{99\text{m}}\text{Tc}$ -HDP SPECT/CT, combined ^{111}In -labeled WBC/ $^{99\text{m}}\text{Tc}$ -Nanocoll bone marrow SPECT/CT, and ^{18}F -FDG PET/CT. The combined imaging report in conjunction with the clinical data were evaluated at multidisciplinary conferences and guided patient management. The final diagnosis of PJI infection and/or loosening was based on the intraoperative findings and microbiological culture results and the clinical follow-up 2-3 years after inclusion. **Results:** 23 patients (42%) underwent percutaneous biopsies/ joint aspirates or revision surgery after imaging and the final diagnosis was obtained by microbiological culturing. 20 patients (38%) were scheduled for clinical follow-up due to negative all three scans in 6 patients. 14 patients with no suggestive periprosthetic infection or loosening on both ^{18}F -FDG PET/CT and ^{111}In -labeled WBC/ $^{99\text{m}}\text{Tc}$ -Nanocoll bone marrow SPECT/CT. Remaining patients with findings suggestive for PJI or aseptic loosening were scheduled for clinical follow-up due to other reasons (severe comorbidity, mild symptoms). Clinical follow-up (median follow-up 438 days) was performed on all 55 patients. 11 patients excluded from final statistical analysis (4 patients due missing leucocyte/bone marrow imaging and 7 patients due to equivocal clinical follow-up results). The diagnostic performance of ^{111}In -labeled WBC/ $^{99\text{m}}\text{Tc}$ -Nanocoll bone marrow SPECT/CT for PJI showed sensitivity of 100% (CI 0.74-1.00), specificity 97% (CI 0.82-1.00), PPV 92% (CI 0.64-1.00), NPN 100% (0.88 - 1.00) and accuracy 98% (CI 0.88-1.00), for PET/CT -the sensitivity 100% (CI 0.74-1.00), specificity 76% (CI 0.56-0.90), PPV 63% (CI 0.38-0.84), NPN 100% (0.85 - 1.00) and accuracy 83% (CI 0.68-0.93). **Conclusion:** In a standardized prospectively scheduled patient group the results showed highly specific performance of combined ^{111}In -WBC/ $^{99\text{m}}\text{Tc}$ -Nanocoll SPECT/CT in confirming chronic PJI after TKA or THA. ^{18}F -FDG PET/CT has an appropriate accuracy but the utility of use in the diagnostic algorithm of suspected PJI needs further evidence. **References:** None

EPS-104**The Use of a Novel Semiquantitative Parameter in the Three-phase Bone Scan to Predict the Results of ^{99m}Tc-HMPAO-labeled Leukocyte Scintigraphy in Patients with Suspected Septic Loosening of Unilateral Knee Prosthesis**

N. Quartuccio¹, L. Sturiale¹, M. Siracusa², A. Arnone¹, R. Laudicella², M. T. Arnone¹, P. Alongi³, G. L. Mauro⁴, L. Camarda⁵, M. D'Arienzo⁵, R. Sciortino⁶, S. Baldari², G. Arnone¹;

¹Nuclear Medicine Unit, A.R.N.A.S. Ospedali Civico, Di Cristina e Benfratelli, Palermo, ITALY, ²Department of Biomedical and Dental Sciences and of Morpho-functional Imaging, Nuclear Medicine Unit, University of Messina, Messina, ITALY, ³Nuclear Medicine Unit, Fondazione Istituto G. Giglio, Cefalù, ITALY, ⁴Rehabilitation Unit, Paolo Giaccone Hospital, Palermo, ITALY, ⁵Department of Orthopaedic Surgery (DICHIRONS), University of Palermo, Palermo, ITALY, ⁶Department of Orthopaedic Surgery, Ospedale Civico ARNAS, Palermo, ITALY.

Aim/Introduction: The evaluation of the three-phase bone scan in patients with possible loosening of knee prosthesis is based on the assessment of asymmetry of counts in the different phases of the exam between the prothesized and the healthy knee. Scintigraphy with autologous leucocytes is the imaging technique of choice to discriminate between aseptic and septic loosening. Nevertheless, it is a more complicated, costly and longer exam. Our aim was to assess different semiquantitative parameters in three-phase bone scan, including a novel parameter named perfusion-to-blood pool ratio (P/BP ratio) for the prediction of the results of autologous leukocyte scintigraphy. **Materials and Methods:** 30 patients with unilateral knee arthroplasty were evaluated by three-phase bone scan (after at least 1 year from arthroplasty) and ^{99m}Tc-HMPAO-labeled leucocytes scintigraphy (within an interval of 2 months from the three-phase bone scan). In three-phase bone scan, a region of interest (ROI) was drawn in the perfusion and blood-pool phase images, including the prosthetic region and using an isocontour with threshold of 40% of the maximum pixel activity within the ROI. A mirror ROIs were placed on the healthy knee. Perfusion (Pr) and Blood Pool (BPr) ratios were calculated by dividing the total counts in the ROI including the prosthetic region for the total counts in the ROI including the healthy knee; P/BP ratio was obtained using the formula $\{[(Pr/BPr) \times 100] - 100\}$. ROC curves were created in order to determine the optimal cutoff value for each semiquantitative parameter to predict the positivity of the autologous leukocyte scintigraphy. **Results:** Autologous leukocyte scintigraphy revealed 13 cases suggestive for septic loosening and 17 negative cases. Positive cases presented values of Pr, BPr and P/BP ratio above the optimal cutoff values, which resulted 1.91 for Pr (sensitivity = 100%, specificity = 58.8%), 1.5 for BPr (sensitivity = 92.3%, specificity = 41.18%) and 25% for P/BP ratio (sensitivity = 100%, specificity = 76.47%). Corresponding areas under

the curve for the Pr, BPr and P/BP ratio were 0.72, 0.67 and 0.82. **Conclusion:** P/BP ratio appears the semiquantitative parameter with the highest predictive capability and may reinforce the clinical suspicion of septic loosening in patients with unilateral knee prosthesis. These results warrant studies in larger patient populations; we will evaluate whether the use of P/BP ratio may anticipate differential diagnosis between aseptic and septic loosening and have an impact on clinical decision making. **References:** None

EPS-105**White blood cells scintigraphy as an alternative to the arthrocentesis in suspected periprosthetic knee infection**

E. Noriega-Álvarez, A. M. García Vicente, V. M. Poblete García, M. E. Bellón Guardia, F. J. Pena Pardo, M. P. Talavera Rubio, B. González García, E. Casillas Sagrado, Á. M. Soriano Castrejón; University Hospital of Ciudad Real, Ciudad Real, SPAIN.

Aim/Introduction: To analyse the diagnostic accuracy of ^{99m}Tc-HMPAO-labeled white blood cells scintigraphy (WBCS) to consider it as a reliable alternative to avoid arthrocentesis in patients with suspected periprosthetic knee infections (PKI). **Materials and Methods:** This retrospective study included 24 patients (13 women, mean age 68 years) with suspected PKI undergoing a WBCS and an arthrocentesis between 2017 and 2019. In WBCS a time decay-corrected acquisition was performed, obtaining serial planar images at 30 minutes, 3 hours and 8 hours after injection, although in some patients the third planar image (at 8 hours) could not be obtained. WBCS were visually classified as: "negative for infection" if no uptake was seen in planar images or when the uptake was decreasing over time, or "positive for infection" when at least one focus of abnormal uptake increased its intensity or extension from 3 to 8 hours. Subsequently, WBCS results were compared with final diagnosis. The final diagnosis was based on the results of the arthrocentesis. Then, sensitivity, specificity, accuracy, and positive and negative predictive values of WBCS were determined, as well as Kappa index and ROC curve. **Results:** The final diagnosis showed PKI in 13 patients and it was ruled out in 11. On the other hand, WBCS was positive for infection in 10 patients and negative in 14 (3 false negative, though these patients did not undergo the late image at 8 hours, very useful to differentiate infection from inflammation as recommended by the EANM guidelines¹)(table 1). The values of sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy were 76.9%; 100%; 100%; 78.6% and 87.5%, respectively. Comparing final diagnosis with WBCS a substantial Kappa agreement of 0.75 (p < 0.01), and an area under the ROC curve of 0.885 (p < 0.01) were obtained. **Conclusion:** The high specificity, positive predictive value, and diagnostic accuracy of WBCS denote its value as a non-invasive technique to confirm PKI, representing

a reliable alternative to arthrocentesis. Nevertheless, prospective studies with a larger number of patients are required. **References:** 1-Signore A, Sconfienza LM, Borens O, Glaudemans AWJM, Cassar-Pullicino V, Trampuz A, et al. One-year follow-up with ^{18}F -FDG PET/CT of large vessel vasculitis treated with tocilizumab

I. Martínez-Rodríguez¹, D. Prieto-Peña², R. Quirce¹, J. Jiménez-Bonilla¹, M. de Arcocha-Torres¹, A. Sánchez-Salmón¹, N. Martínez-Amador¹, G. Molina-Mendoza¹, O. Cuenca-Vera¹, J. Andrés-Pacheco¹, Á. Gutiérrez-González¹, S. Ruiz Llama¹, F. J. Gómez-de la Fuente¹, M. Calderón-Goerke², R. Blanco², M. A. González-Gay², I. Banzo¹;

¹Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN, ²Rheumatology Service. Marqués de Valdecilla University Hospital. IDIVAL, Santander, SPAIN.

Aim/Introduction: Large vessel vasculitis (LVV) treatment is based on corticosteroids, although sometimes other immunosuppressive drugs, like methotrexate, are necessary due to frequent relapses after decreasing prednisone dose. In recent years, new biological therapies, such as tocilizumab (TCZ), have been incorporated into the therapeutic arsenal with good initial results. Our aim was to evaluate the usefulness of ^{18}F -FDG PET/CT (PET/CT) in the one-year follow-up of patients with LVV treated with TCZ. **Materials and Methods:** An observational study was carried out including 23 patients (19 women, 66 ± 11 years) with a diagnosis of LVV and an initial positive PET/CT scan. In all the patients a follow-up PET/CT scan was performed at ≤ 1 year after the onset of TCZ. PET/CT scans were obtained 180' after intravenous injection of 7 MBq/Kg of ^{18}F -FDG. PET/CT images were assessed both visually and semiquantitatively. For the visual analysis ^{18}F -FDG uptake (graded from 0-3 in comparison to liver uptake) was evaluated in 5 vascular territories: supraaortic trunks (SAT), thoracic aorta (TA), abdominal aorta (AA), iliac arteries (IA) and femorotibial arteries (FTA). A total vascular score (from 0-15) was also calculated. For the semiquantitative analysis a target to background ratio (TBR: SUVmax thoracic aorta wall/ SUVmax vascular background) was calculated. **Results:** In the visual analysis, the overall total vascular score decreased from 4.87 ± 2.85 to 3.36 ± 1.56 ($p = 0.0065$). Per patient, the score decreased in 69.6% of them, did not change in 17.4% and increased in 13%. When we considered the different vascular territories, the percentage of patients with ^{18}F -FDG uptake grade 2-3 decreased on PET/CT follow-up from 26.1% to 4.4% in SAT, from 91.3% to 65.2% in TA, from 17.4%

to 0% in AA, from 8.7% to 0% in IA and from 17.4% to 8.7% in FTA. Overall, in the semiquantitative analysis the TBR decreased significantly from 1.73 ± 0.58 to 1.48 ± 0.26 ($p = 0.0025$). Per patient, the TBR decreased in 18/23 patients (78.3%) and increased in 5/23 (21.7%). Furthermore, a decrease in the TBR below 1.34 (cut-off level established in a control population) was observed in 7/23 patients (30.4%). **Conclusion:** Visual and semiquantitative analysis of PET/CT images showed a significant decrease of ^{18}F -FDG vascular uptake at one-year follow-up of patients with LVV under TCZ therapy. A decrease of TBR below the cut-off level established in controls was observed in one third of the patients. **References:** None

EPS-107

Correlation of clinical and biochemical parameters with ^{18}F -FDG PET/CT in patients with large vessel vasculitis under biological therapy with tocilizumab

I. Martínez-Rodríguez¹, D. Prieto-Peña², R. Quirce¹, J. Jiménez-Bonilla¹, M. de Arcocha-Torres¹, A. Sánchez-Salmón¹, N. Martínez-Amador¹, G. Molina-Mendoza¹, O. Cuenca-Vera¹, J. Andrés-Pacheco¹, Á. Gutiérrez-González¹, S. Ruiz Llama¹, F. J. Gómez-de la Fuente¹, M. Calderón-Goerke², R. Blanco², M. A. González-Gay², I. Banzo¹;

¹Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN, ²Rheumatology Service. Marqués de Valdecilla University Hospital. IDIVAL, Santander, SPAIN.

Aim/Introduction: The recent incorporation of biological therapies such as tocilizumab (TCZ) to the therapeutic strategy of large vessel vasculitis (LVV) has been a notable advance. The classic inflammatory parameters, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), are ineffective in the follow-up of the patients since they normalize rapidly. Our aim was to study if there is a correlation between different clinical and biochemical parameters and ^{18}F -FDG PET/CT (PET/CT) findings in the follow-up of patients with LVV treated with TCZ. **Materials and Methods:** We included 23 patients (19 women) with a diagnosis of LVV and positive initial PET/CT scan treated with TCZ due to steroid-refractory LVV, relapse or atypical polymyalgic syndrome. Clinical outcome (complete response / partial response / no response), ESR, CRP, and initial and follow-up PET/CT results at ≤ 1 year from the start of TCZ (mean: 10.34 ± 3.13 months) were evaluated. PET/CT scans were obtained 180' after intravenous injection of 7 MBq/Kg of ^{18}F -FDG. PET/CT images were analyzed visually (total vascular score of 5 territories) and semiquantitatively (TBR: SUVmax thoracic aorta wall/ SUVmax vascular background). **Results:** Of the 23 patients included, 19 (82.6%) had a clinical complete response and 4 (17.4%) had a partial response. The TBR decreased significantly in patients with complete response (1.75 ± 0.63 vs. 1.49 ± 0.28 ; $p = 0.0126$) and there was no

difference in patients with partial response (1.63 ± 0.18 vs. 1.46 ± 0.16 ; $p = \text{ns}$). The total vascular score established by PET/CT showed similar behavior to the TBR, decreasing in patients with complete response (4.95 ± 3.06 vs. 3.00 ± 1.73 ; $p = 0.0038$) and showing no significant differences in those patients with partial response (4.50 ± 1.73 vs. 4.25 ± 0.96 ; $p = \text{ns}$). ESR and CRP decreased in patients with complete response (ESR: 31.42 ± 26.03 vs. 2.42 ± 1.12 mm/1h; CRP: 1.54 ± 1.64 vs. 0.13 ± 0.07 mg/dL; $p < 0.001$). These parameters also decreased in patients with partial response (ESR: 27.0 ± 41.61 vs. 2.75 ± 0.96 mm/1h; CRP: 1.23 ± 1.27 vs. 0.1 ± 0.0 mg/dL), although the differences were not significant. No correlation was observed between inflammatory parameters and the TBR. **Conclusion:** ^{18}F -FDG PET/CT demonstrated its utility for assessing inflammatory vascular activity in relation to clinical outcome in patients with LVV treated with TCZ. No correlation was observed between PET/CT findings and biochemical inflammatory parameters. These promising results should be confirmed in a larger population. **References:** None

EPS-108

Chasing Infection: Is There An Specific ^{18}F -FDG Pattern To Accurately Differentiate Septic From Aseptic Inflammation In Aortic Root/Ascending Aorta Graft Replacement?

B. Rodriguez-Alfonso, D. Martinez-Lopez, L. Canales-Rodriguez, A. Forteza-Gil, A. Ramos-Martinez, R. Jimeno-Pernett, A. Sanfiel Delgado, M. Mitjavila-Casanovas; Hospital Universitario Puerta De Hierro, Majadahonda, SPAIN.

Aim/Introduction: Infective endocarditis in patient with graft replacement of the aortic root and ascending aorta is infrequent (0,2%/patient/year) but life-threatening. Accurate and prompt diagnosis is challenging. Imaging test contribute to the assessment of infection. The use of ^{18}F -FDG-PET/CT has been previously reported in these patients. Nevertheless, the lack of uniform interpretation criteria and misleading diagnosis due to inflammatory changes limit its use, especially the first year after surgery. The aim of this study was to detect a "normal" pattern of ^{18}F -FDG distribution along the graft during the first year after surgery in non-infected subjects. **Materials and Methods:** Prospectively designed study including patients with aortic root or ascending aorta replacement undergoing serial PET/CT at 3, 6 and 12 months after surgery. CRP and blood cultures were obtained the day of each PET/CT study. Patients with clinical or analytical suspicion of infection were excluded. Myocardial suppression protocol was applied. Selective thoracic images were acquired 60 minutes after the injection of 180MBq of ^{18}F -FDG. Studies were visually and semiquantitatively assessed regarding the pattern of radiotracer distribution along the graft (homogeneous/heterogenous) and the intensity of uptaking areas (SUVmax,

SUVratio). Fluid collections or other significative findings were also determined. **Results:** Eighteen patients were included. Significant ^{18}F -FDG uptake along the graft was detected in all the studies with a mean SUVmax 4.79 (SD 1.2), 4.28 (SD 0,85) and 4.29 (SD 0.94) at 3, 6 and 12 months respectively. Heterogenous distribution along the graft was noticed in 55% of the studies at 3 months, 44% at 6 months and 72% at 12 months. Six patients (33%) showed retrosternal fluid collections that persisted throughout the year, with progressive growth in one case. An unsuspected stage I sarcoidosis was depicted in one patient. **Conclusion:** Cautious interpretation should be made in patients with aortic root or ascending aorta replacement undergoing PET/CT for suspicion of infective endocarditis because significant inflammatory uptake persists the first year after surgery. Uptake level in postsurgical inflammation overlap to those reported in literature in septic inflammation¹. Heterogeneous pattern in non-infected patients is highly depicted and thus it should not be considered as a specific criteria for infection. **References:** 1.Daniel García-Arribas, Isidre Vilacosta, Aida Ortega-Candil, Cristina Rodríguez-Rey, Carmen Olmos, María Jesús Pérez-Castejón, et al. Usefulness of positron emission tomography/ computed tomography in patients with valve-tube graft infection. Heart. 2018; 104 (17): 1447-54.

EPS-109

^{18}F -FDG-PET/CT in the Diagnosis of Infective Endocarditis in Patient with Electronic Cardiac Device and Fever of Unknown Origin and/or Bacteriemia

S. Guzmán Ortiz, B. Rodríguez Alfonso, A. Ramos-Martinez, M. Cobo Marcos, S. Pérez Quirós, M. Mitjavila Casanovas; University Hospital Puerta de Hierro Majadahonda, Madrid, SPAIN.

Aim/Introduction: To asses diagnosis performance of ^{18}F -FDG-PET/CT for the detection of infective endocarditis (IE) in patients with electronic cardiac device (ECD) presenting fever of unknown origin and/or positive blood cultures. **Materials and Methods:** We retrospectively analysed all PET/CT studies conducted in our hospital from 01/2018 to 01/2020 in patients with ECD and fever of unknown origin (FUO) and/or bacteraemia to rule out IE. Patients with sing or symptoms of pocket-generator infection were excluded. Results of both imaging tests (Ecocardiography and PET/CT) were compared with final diagnosis to asses sensitivity, specificity and positive and negative predictive values (PPV, NPV). Duke criteria obtain by the conventional approach (Duke-1) and after the addition of PET/CT (Duke-2) were compared to final-Duke criteria to asses the better correlation. For the final diagnosis, culture of explanted devices or consensual decision of the multidisciplinary endocarditis team and a follow-up period not inferior to 4,86 weeks were considered as gold-standar (GS). **Results:** Twenty-two patients were included. Fever was the only

symptom in 4, positive blood culture in 3 and 15 presented both. All patients had echocardiography previous to PET/CT (82% transoesophageal echocardiography). According to GS, IE was established in 5 patients (25%) and discarded in 17 (75%). Just 1 patient underwent device explantation and culture, demonstrating *S. aureus* IE. Both, sensitivity and specificity were higher for PET/CT compared to echocardiography (0.66 vs 0.33 and 0.87 vs 0.75 respectively). When considering results of both imaging studies, sensitivity reach 1 but specificity decreased to 0.62. Duke-1 was concordant to final-Duke classification in 5 patients (23%), 2 definite-IE and 3 rejected-IE, whereas Duke-2 was concordant in 8 patients (36%), the 5 patients with definite-IE and 3 rejected-IE. In the possible-IE group according to Duke-1 (14 patients), the addition of PET/CT correctly re-classified 3 definite-IE but it also misclassified 3 rejected-IE as definite-IE. **Conclusion:** Patients with ECD and FUO and/or bacteraemia are a particular subgroup in which PET/CT shows moderate sensitivity and high specificity in the detection of IE, improving the low-moderate yield of echocardiography. Duke criteria performed poorly even after adding PET/CT results showing a low concordance with final-Duke. **References:** None

EPS-110

Visual Vascular Score with 2-[¹⁸F]FDG: validation on a control sample

R. Ferreira, M. R. Victor, S. Carmona, A. I. Santos;
Hospital Garcia de Orta, Almada, PORTUGAL.

Aim/Introduction: To assess interobserver agreement and validate a visual vascular score (Eur J Nucl Med Mol Imaging.2018;45:1250-1269) of 2-[¹⁸F]FDG physiological arterial uptake, in a possible control group for suspected large vessel vasculitis. **Materials and Methods:** Retrospective analysis of 2-[¹⁸F]FDG PET/CT oncological scans from an occasional sample of patients 50 or more years' old, without suspicion of inflammatory disease, characterizing age, gender, known risk factors for atherosclerosis, blood glucose level and activity administered. To obtain a total vascular score, all PET/CT scans were attributed a visual vascular score to 7 arterial compartments (carotid, subclavian, axillary, thoracic aorta, abdominal aorta, iliac and femoral) by 3 observers with different years of practice: 1 over 10 (obs1), 1 about 3 (obs2) and 1 less than 1 (obs3). Statistical analysis was performed using IBM SPSS Statistics. **Results:** A total of 51 scans from 51 patients were evaluated, the most common diagnosis being lung cancer (n=21;41%). Fever of unknown origin, infection and hepatic lesions were exclusion criteria. The mean age was 69[*sd*=9.4;min=50;max=90] years' old and 32/51(63%) patients were male. Thirty-two (63%) had arterial hypertension, 18(35%) dyslipidaemia, 13(25%) diabetes, 21(41%) history of smoking, 5(10%) ischemic heart disease and 6(12%) peripheral arterial

disease. Blood glucose levels prior to the acquisition had a median value of 102[P25:92;P75:116] mg/dL and the 2-[¹⁸F]FDG administered activity had a mean value of 247[*sd*=67;min=102;max=398] MBq. The vascular score for each compartment was assumed as the concordant classification between 2 out of 3 observers, 3 out of 3, or the score attributed by the most experienced observer in one case of total disagreement. Total score was 0 in 30(59%) patients, 1 in 9(18%), 2 in 3(6%), 3 in 5(10%), 4 in 3(6%) and 5 in 1(2%). Kappa index showed moderate agreement for the: subclavian territory- obs1/obs2 (k=0.563;p=0.001), obs1/obs3 (k=0.505;p=0.004), obs2/obs3 (k=0.491,p=0.009); axillary territory- obs1/obs3 (k=0.506;p=0.002); thoracic aorta- obs1/obs2 (k=0.489;p<0.001); abdominal aorta- obs1/obs2 (k=0.510,p<0.001); and femoral territory- obs1/obs2 (k=0.527,p<0.001). **Conclusion:** All patients were classified as having a total vascular visual score ≤5, translating a relatively homogeneous sample. The majority of the arterial territories were scored as 0/1 and none was scored as 3, and so this sample might be considered as a control group when evaluating the presence of vasculitis. However, the interobserver agreement was weak and should also be evaluated in a pathological sample. This classification might also need a learning curve and/or could benefit from a semiquantitative analysis. **References:** None

EPS-111

FDG-PET imaging of gastrointestinal Graft-versus-Host disease

W. Roll¹, G. Evers², R. Strotmann¹, J. Albring², B. Noto¹, M. Weckesser¹, M. Stelljes², M. Schäfers¹;

¹Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY, ²Department of Medicine A, Hematology, Oncology and Pulmonary Medicine, University Hospital Münster, Münster, GERMANY.

Aim/Introduction: Following Allogeneic stem cell transplantation (alloSCT), a potentially curative treatment for many refractory and high-risk hematologic malignancies, intestinal Graft-versus-Host disease (GvHD) is a frequent complication, associated with a significant morbidity and mortality. As previously shown, FDG-PET can be used for diagnostic purposes and might have a prognostic value for patients suffering from intestinal GvHD. The aim of this retrospective analysis was to further elaborate the value of FDG-PET in a larger patient cohort with intestinal GvHD. **Materials and Methods:** Between 06/2011 and 02/2019, 101 patients with suspected acute intestinal GvHD underwent FDG-PET examination. Complete clinical and FDG-PET data sets were reviewed for presence of intestinal inflammation. 74 of the 101 patients with clinically and/or histologically proven intestinal GvHD and signs of inflammation in FDG-PET were analyzed in detail. Quantitative PET parameters, as well as clinical data, were compared between patients

with fast and slow / no response to immunosuppressive treatment. **Results:** 18F-FDG-PET detected intestinal GvHD with a sensitivity and specificity of 93.0% (95% CI: 84.9 - 97.1) and 73.3% (95% CI: 44.8 - 91.1), respectively. Patients with subsequent rapid relief of GvHD symptoms had significantly higher standard uptake values for SUVmax (mean 13.5, 95% CI: 10.7 - 16.4) and SUV peak levels (mean 9.2, 95% CI: 7.3 - 11.1) compared to patients with slow or no response to immunosuppressive therapy (mean SUVmax: 7.7; 95% CI: 7.0 - 8.4; mean SUVpeak: 5.4, 95% CI: 4.9 - 5.8; p .005). **Conclusion:** This retrospective analysis indicates that 18F-FDG-PET detects acute intestinal GvHD with good sensitivity and specificity. Of further interest, our results suggest potential significance of FDG-PET in predicting treatment response following immunosuppressive therapy. Before implementation into clinics prospective studies are needed to corroborate our results. **References:** None

Simple radiosynthesis of ^{68}Ga -desferrioxamine B ($^{68}\text{GaDFO}$) for infection imaging

A. Darwesh, R. Wellman, V. Abbate, M. S. Cooper, R. Hider, M. Morais, S. Y. A. Terry, M. T. M. Ma, P. J. Blower;
King's College London, London, UNITED KINGDOM.

Aim/Introduction: Endovascular stent graft infections are difficult to diagnose.¹A PET radiotracer that is taken up selectively by microorganisms could provide more specific detection than currently used [^{18}F]FDG. The Fe^{3+} complex of DFO, a siderophore, is taken up by bacteria, making its isostructural ^{68}Ga complex applicable for imaging infection.² DFO is a clinically approved drug³, hence its ^{68}Ga complex has a low regulatory barrier to clinical translation. Here, we report a GMP method for $^{68}\text{GaDFO}$ preparation, its bacterial binding in vitro, and its in vivo pharmacokinetics in healthy mice. **Materials and Methods:** $^{68}\text{GaDFO}$ was radiolabelled by mixing aqueous DFO (20 μl), aqueous solution of sodium acetate (3.6 M) (20/30 μl), and ^{68}Ga chloride (200 μl). The mixture was diluted with water to 1 ml then incubated for 10 min at room temperature. The radiochemical purity was assessed by TLC and HPLC. $^{nat}\text{GaDFO}$ was added to $^{68}\text{GaDFO}$ and analysed by LC-MS. Stability in human serum was measured by RP-HPLC after 60-min incubation at 37 $^{\circ}$ C. $^{68}\text{GaDFO}$ uptake in *E. coli* was studied in vitro and compared to ^{68}Ga ferrichrome-C, enterobactin, and siderophore-free ^{68}Ga . Mice were injected intravenously with $^{68}\text{GaDFO}$ and PET/CT scanned for 60 min. Mice were sacrificed at 60 min, and organs were counted in a gamma-counter **Results:** $^{68}\text{GaDFO}$ was labelled with high radiochemical purity ($\geq 95\%$) as measured by TLC and HPLC. $^{68}\text{GaDFO}$ demonstrated no binding to serum proteins at any time point by RP-HPLC. All ^{68}Ga labelled siderophores showed higher *E. coli* uptake than siderophore free ^{68}Ga , with ^{68}Ga ferrichrome-C showing the highest uptake. $^{68}\text{GaDFO}$ exhibited rapid renal

excretion and low blood retention. Ex vivo biodistribution at 60 min showed most of the activity resided in urine **Conclusion:** $^{68}\text{GaDFO}$ radiolabelling with GMP graded reagents gave a product with high radiochemical purity identified as a 1:1 complex of Ga^{3+} with DFO. The complex showed specific uptake in *E. coli*. $^{68}\text{GaDFO}$ did not release ^{68}Ga to serum proteins, indicating high stability of the compound in serum. $^{68}\text{GaDFO}$ is rapidly cleared with no significant retention in any organ except kidneys. In vivo biodistribution of $^{68}\text{GaDFO}$ on infected animal models is now planned **References:** 1. J. C. Marc Elieson, T. Mixon, Case Reports, 2012, 39, 884-889. 2. W. Rabsch and G. Winkelmann, Biol. Met., 1991, 4, 244-250. 3. M. Naser, S. Mehrnoosh, E. Hassan, N. Hajar, S. Mehdi, S. Mohsen, G. Mehdi, P. Hoda and A. Mehdi, Int. J. Hematol. stem cell Res., 2016, 10, 239-247.

FDG-PET/CT is clinically valuable in the majority of patients referred from Emergency Department with unclarified systemic inflammation

S. Hess^{1,2}, R. Horvat³;

¹Dept. of Radiology and Nuclear Medicine, Hospital South West Jutland, University Hospital of Southern, Esbjerg, DENMARK,

²Department of Regional Health Research, University of Southern Denmark, Odense, DENMARK, ³Dept. of Radiology and Nuclear Medicine, Hospital South West Jutland, University Hospital of Southern Denmark, Esbjerg, DENMARK.

Aim/Introduction: FDG-PET/CT is increasingly used to assess infection and inflammation, not only in well-defined clinical entities, but also in heterogeneous populations from Emergency Departments (ED) with unclarified systemic inflammation. It remains controversial when to introduce FDG-PET/CT, but some advocate introduction early in the course of admission. We retrospectively assessed the clinical value of all FDG-PET/CT performed in ED-patients with suspected or unclarified inflammation of unknown origin. **Materials and Methods:** All patients referred to FDG-PET/CT from the ED during 2019 for unclarified inflammation, unresolved infection or bacteremia, or fever of unknown origin were included. Medical records were comprehensively reviewed for baseline characteristics, results of FDG-PET/CT and clinical conclusions at discharge, which constituted the reference standard. **Results:** Forty-four consecutive patients were included (52% males, mean age 70 years [22-92]) and divided into three groups according to results of PET/CT. Group 1 (n=22/44, 50%): Directly helpful results, i.e. true positive diagnoses [pneumonia (n=5), abscess (n=4), spondylodiscitis (n=3), catheter-related infection (n=2), novel cancers (n=2), progressive known cancer (n=1), giant-cell arteritis (n=1), or endocarditis (n=1)], or patients with established infections but poor treatment response where PET/CT ruled-out suspected additional occult infectious foci. Group 2 (n=10/44, 23%): Potentially

helpful, i.e. focal findings ruled out with negative PET/CT scans, no complications, and a discharge diagnosis of non-specific, self-limiting infection. Group 3 (n=12/44, 26%): Not helpful, non-specific findings and discharge diagnoses other than simple, self-limiting infections. Of note, in half of these cases, the final diagnoses are not usually detectable by PET, i.e. urinary tract infection (n=3), native-valve endocarditis (n=2), and erysipelas outside the scan area (n=1). Baseline characteristics were similar in the three groups 1-3, e.g. mean body temperature (i.e. 37.8 C, 37.6 C, and 37.5 C, respectively) and C-reactive protein (i.e. 154 mg/L, 152 mg/L, and 167 mg/L, respectively). Bacteremia was present in 17 patients; most in group 1 (n=10) compared to group 2 (n=2), and group 3 (n=5), with comparable fractions in groups 1 and 3 (i.e. 46% and 47%, respectively), but lower in group 2 (20%). **Conclusion:** FDG-PET/CT is clinically helpful in establishing a diagnosis in the majority of patients with unclarified or unresolved inflammation in a heterogenic ED-population, i.e. 50-73% (group 1 or group 1+2) depending on how "helpful" is defined. Patients' basic baseline characteristics are not useful for discriminating patients with useful or not useful FDG-PET/CT. Further studies on optimal patient selection in prospective settings are highly desirable. **References:** None

EPS-114

Contribution of ^{18}F -FDG-PET/CT in the diagnosis of patients with fever of unknown origin

S. Georga¹, P. Exadaktylou¹, I. Petrou¹, D. Katsampoukas¹, E. Moraliadis¹, K. Arvaniti², G. Giataganas³, G. Arsos¹;

¹3rd Department of Nuclear Medicine, Aristotle University Medical School, Papageorgiou Hospital, Thessaloniki, GREECE,

²ICU and Antimicrobial Stewardship Unit, Papageorgiou Hospital, Thessaloniki, GREECE, ³Department of Radiology, Papageorgiou Hospital, Thessaloniki, GREECE.

Aim/Introduction: Conventional laboratory and imaging investigation despite being time-consuming and costly, are often inconclusive in revealing the underlying cause of fever of unknown origin (FUO). ^{18}F -fluorodeoxyglucose (^{18}F -FDG) accumulates in malignant lesions as well as at sites of active infection or inflammation, the three major causes of FUO, thus making ^{18}F -FDG-PET/CT a useful tool for approximation of the underlying cause of FUO, especially when potential diagnostic clues are missing. The aim of the study was to assess the diagnostic contribution of ^{18}F -FDG-PET/CT in a small, representative series of FUO patients of a tertiary hospital. **Materials and Methods:** We retrospectively reviewed whole-body ^{18}F -FDG-PET/CT scans performed in 50 consecutive, non-immunocompromised, adult patients referred to our department for further FUO investigation. ^{18}F -FDG-PET/CT scans were considered positive for active disease if any focus of increased ^{18}F -FDG uptake other than physiological uptake was observed. Scans showing

normal ^{18}F -FDG distribution throughout the body and no hypermetabolic foci, were considered negative for active disease. Positive and negative ^{18}F -FDG-PET/CT scans were compared to the final diagnosis based on histopathological and microbiological findings, generally acceptable clinical criteria or a minimum of 6 months of clinical follow-up. ^{18}F -FDG-PET/CT scan was considered contributory to the diagnosis when detected the underlying cause of FUO or correctly suggested the most appropriate site for a biopsy leading to an accurate diagnosis. **Results:** Final diagnosis was established in 39/50 (78%) of the patients. The underlying cause of FUO was malignancy in 8 (16%), infection in 20 (40%), noninfectious inflammatory diseases in 11 (22%), while fever remained unexplained in 11/50 (22%) of the patients. ^{18}F -FDG-PET/CT scan was positive for active disease in 42/50 (84%) of patients and was negative for active disease in 8/50 (16%) of patients. There were 36 TP, 6 FP, 6 TN and 2 FN results. Accordingly, the sensitivity, specificity, accuracy, positive predictive value and negative predictive value of ^{18}F -FDG-PET/CT for active disease detection in patients with FUO were 94.7%, 50.0%, 84.0%, 85.7%, and 75.0%, respectively. ^{18}F -FDG-PET/CT scan was considered clinically helpful and contributory to the diagnosis in 35/50 (70%) of patients. **Conclusion:** ^{18}F -FDG-PET/CT is a valuable diagnostic modality in the evaluation of patients with FUO, substantially contributing in our study to the diagnosis in 70% of patients, by either identifying the underlying cause of FUO or correctly targeting suspect lesions for further evaluation. Earlier application of ^{18}F -FDG-PET/CT in FUO investigation, could be cost-effective by means of shortening the diagnostic workup period. **References:** None

EPS-115

The role of ^{18}F FDG-PET/CT in the diagnostic work-up of fever of unknown origin (FUO) and inflammation of unknown origin (IUO)

M. Allocca, T. Tagliente, D. Malandrino, A. Berni, M. Di Paolantonio, A. Martini, C. Olianti, P. Saletti, L. Poggesi, R. Sciagrà; University of Florence, Florence, ITALY.

Aim/Introduction: Fever of unknown origin (FUO) and inflammation of unknown origin (IUO) are diagnostically challenging conditions. ^{18}F FDG PET/CT is a sensitive diagnostic technique that may improve diagnosis. The aim of this study was to assess the problem-solving value of ^{18}F FDG-PET/CT in FUO/IUO, taking into account the following diagnostic sub-categories: infections, non-infectious inflammatory disease (NIID), neoplasm, miscellaneous causes, no diagnosis. **Materials and Methods:** 50 patients aged 18-86, admitted to Internal Medicine Unit for FUO/IUO from January 2016 to December 2019, and who underwent ^{18}F FDG-PET/CT vertex-pelvis scan, were retrospectively evaluated. On ^{18}F FDG-PET/CT images lesion SUVmax and SUVpeak, SUVmax and a Deauville-

like score for the evaluation of spleen and bone-marrow uptake were assessed. Besides, clinically and laboratory parameters useful to final diagnosis were examined. **Results:** No significant differences in main vital parameters and laboratory values were found in FUO vs. IUO, except for body temperature, according to definition (mean±sd in FUO= 38.4°C±0.4 vs. IUO= 37.4°C±0.3; $p<0.001$). Diagnosis was established in 45 patients: 18 neoplasms (36%), 13 NIIDs (26%), 12 infections (24%), 2 miscellanies (4%). In 5 patients, who had spontaneous regression of symptoms, no abnormalities were found. ^{18}F FDG-PET/CT played a decisive role in 25/45 cases (55%), identifying possible, not previously detected causes. PCR was found as the best predictors of ^{18}F FDG-PET/CT diagnostic usefulness ($p=0.005$) and in particular for PCR>40mg/L (Wilks' $\Lambda=0.078$; $p=0.006$; accuracy=75%). In our sample, lesion SUVmax and SUVpeak resulted significantly higher ($p<0.001$) in neoplasms vs other diagnostic sub-categories (mean±sd: 12.64±7.68 vs 4.50±2.20 for lesion SUVmax; 9.97±6.36 vs 3.63±1.70 for lesion SUVpeak). The qualitative assessment of bone marrow metabolism (Deauville-like score) showed an uptake \geq liver in 50% of NIID cases, while in 23% only of the infection group. However, no significant difference ($p=0.09$) in marrow SUVmax values was found between NIID and infection groups (mean±sd: 3.54±1.00 vs 2.94±0.63, respectively). **Conclusion:** The study demonstrated a determinant diagnostic role of ^{18}F FDG-PET/CT in more than a half of FUO/IUO patients, with a possible relationship with higher PCR values. The observation of a trend for bone marrow uptake to be higher in NIID vs infections is intriguing and should be further expanded. **References:** Schönau V, et al. The value of ^{18}F -FDG-PET/CT in identifying the cause of fever of unknown origin (FUO) and inflammation of unknown origin (IUO): data from a prospective study; *Ann Rheum Dis* 2018;77:70-77. doi:10.1136/annrheumdis-2017-211687

Does FDG-PET contribute to patients diagnosed with Primary and Secondary Hypophysitis?

S. Asa¹, Ö. Korkmaz², M. Beytur¹, R. Uslu Beşli¹, P. Kadioğlu², M. Sağer¹, K. Sönmezoğlu¹;

¹Istanbul University-Cerrahpaşa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TURKEY, ²Istanbul University-Cerrahpaşa Faculty of Medicine, Department of Internal Medicine, Endocrinology Department, Istanbul, TURKEY.

Aim/Introduction: Hypophysitis is a rare inflammatory disease of the pituitary gland that mostly mimics the pituitary masses. It is divided into two groups as primary and secondary. It is crucial to make the correct differential diagnosis in these patients. In this study, we aimed to examine the contribution of FDG PET imaging in determining the underlying inflammatory etiology in patients diagnosed with hypophysitis. **Materials and**

Methods: In our retrospective study, 11 patients were sent to FDG PET imaging was performed with PET / CT and PET / MR systems. In patients with focal activity involvement, the presence of pituitary stalk involvement with the parenchyma, or the proximity of the lesion to the optical resection was evaluated. Also, SUV maximum and SUV mean values were calculated from the lesion areas determined visually. The Mann-Whitney U test was used for comparisons.

Results: The patient group was 7 male and 4 women. Pathological focal activity involvement was detected in 3 of 8 patients diagnosed with primary hypophysitis, while PET was negative in 5 patients. PET was positive in all 3 patients diagnosed with secondary hypophysitis. Non-pituitary findings related to other involvement of secondary disease in PET were also detected in 2 of the patients. In PET, only one patient with involvement in the pituitary was operated due to visual impairment and pressure findings, and diagnosed as germinoma and was accepted as SH. The diagnosis of the other two SH patients was IgG4 related disease and Erdheim Chester disease. There was a significant difference between the SUV parameters and the SUV values of the control group in a total of 6 patients with focal activity involvement in PET. found ($p = 0$). Besides, SUV values (median SUVmax: 4.94; median SUVmean: 3.11) showed a significant difference from the control group in patients diagnosed as hypophysitis clinically-radiologically whether or not focal lesions were selected ($p = 0.001$). **Conclusion:** Despite the limitation of the resolution, it may be possible to determine the inflammatory reaction in the pituitary by PET imaging. The differential diagnosis becomes easier when the FDG-positive lesions of the underlying disease other than pituitary are detected in secondary hypophysitis cases. The evaluation of the biological information provided by FDG using PET / MR in conjunction with the morphological detail provided by MR may have an essential contribution to the management of patients with pituitary disease **References:** None

EPS-117

COVID-19 related findings assessed by dual reporting in our series of ^{18}F -FDG PET/CT studies performed over the coronavirus pandemic

J. Garcia, S. Ortiz, A. Compte, P. Bassa, S. Mourello, M. Soler, M. Buxeda, T. Blanch, E. Valls, E. Riera; CETIR ASCIRES Grupo biomédico, Barcelona, SPAIN.

Aim/Introduction: To assess incidence in radiological and metabolic findings due to COVID-19 in our oncology patients referred for an ^{18}F -FDG PET/CT study, and reported by a Nuclear Medicine physician and a Radiologist over the coronavirus pandemic. **Materials and Methods:** From January 15th through April 15th 2020, a total of 877 ^{18}F -FDG PET/CT procedures were performed in oncology patients. All patients were symptom-free at the time of the PET/CT

procedure, especially with no fever or respiratory distress. Each patient fasted for > 6 hours before imaging. After ensuring that blood glucose was < 160 mg/dL, 0.125 mCi/kg ^{18}F -FDG were administered i.v. 1 hour before image acquisition. Imaging was performed with PET/CT scanner (Gemini.Philip) equipped with LSO crystals and 16-slice CT. A CT scan in maximum inspiration (120kV, 25 mAs, axial slice thickness 2.5 mm) was first acquired followed by a second CT with same parameters but patient breathing normally, for attenuation correction of PET images. A whole-body PET imaging was then taken from the base of the skull to the upper-thigh (3 min/bed). Images were visually inspected by experienced Nuclear Medicine and Radiologist specialists jointly. Inspiratory CT was assessed according to the CORADS classification by the Dutch Radiological Society. SUVmax values were also calculated in lung involvement. **Results:** Out of 877 studies performed, 784 (89.4%) did not show lung involvement (CORADS 1). Ninety-three studies (10.6%) showed lung disease on CT as follows: 5.9% CORADS 2 (52 cases), 1.6% CORADS.3 (14 cases), 2.5% CORADS.4 (22 cases), 0.6% CORADS.5 (5 cases). Therefore CT detected in 27 cases (3.1%) a high/very high likelihood of COVID-19 lung disease. There were only 2 cases with mediastinal lymphadenopathy, rated CORADS 2. In 23 patients (44.2%) with low probability of COVID-19 (CORADS.2), abnormal lung ^{18}F -FDG uptake was detected. However, none of the cases with intermediate/high/very high probability of COVID-19 (CORADS.3–4–5) showed abnormal ^{18}F -FDG uptake. **Conclusion:** Dual specialist interpretation of ^{18}F -FDG PET/CT studies allowed detection of lung involvement consistent with COVID-19 according to CORADS classification. Uptake of ^{18}F -FDG limited only to low probability cases of lung involvement (CORADS.1), due to inflammatory/infectious disease. Lack of abnormal ^{18}F -FDG uptake seen in all intermediate/high/very high probability (CORADS.3–4–5) cases may be due to an early phase of the disease, since no symptoms were reported. Further studies are warranted to assess the predictive value of ^{18}F -FDG uptake in the remaining clinical stages of the lung disease. **References:** EJNMIM. doi:10.1007/s00259-020-04767-1. EJNMIM. doi:10.1007/s00259-020-04762-6. EJNMIM. doi:10.1007/s00259-020-04734-w.

EPS-118

^{18}F -fluorodeoxyglucose (FDG) PET/CT findings in patients with CT lung abnormalities suggestive of COVID-19 infection

C. Aveline, Q. Pouliot, M. Gauthé, L. Turpin, K. Kerrou, M. Calzada, V. Gaura-Schmidt, B. Sgard, J. Zhang, J. Talbot, F. Montravers; Hôpital Tenon, Paris, FRANCE.

Aim/Introduction: In relation with the Covid-19 outbreak in the Paris area, we determined the incidence of lung lesions on CT suspicious for Covid-19 pneumonia in patients

referred to FDG PET/CT and the FDG uptake by those. We also aimed to evaluate the proportion of those patients finally diagnosed with SARS-CoV-2 infection. **Materials and Methods:** We retrospectively reviewed the FDG PET/CTs of patients referred to our nuclear medicine department during the COVID-19 pandemic outbreak in Paris, France. We searched for typical lung findings on CT suggestive of COVID-19 pneumonia (bilateral subpleural ground glass opacities and/or consolidations in multiple segments). If this pattern was observed, we determined the FDG uptake by the pulmonary lesions and collected the medical data of the patient, in order to determine the aetiology: SARS-CoV-2 related pneumonia or other causes. **Results:** 617 patients were referred for FDG PET/CT between March 1st and April 30th 2020, mainly for initial assessment or follow-up of malignancies; 31 showed pulmonary lesions on CT (without contrast medium injection) which were compatible with COVID-19 pneumonia (5%). All lesions showed an increased FDG uptake (mean SUVmax 3.44, median 2.8, range 1.1–10.9). In 7 of them (23% of patients with CT lung abnormalities and overall about 1 % of patients) referred for cancer imaging, this FDG PET/CT pattern was confirmed to be due to Covid-19 pneumonia (diagnosis based on highly evocative clinical symptoms and/or positive RT-PCR for SARS-CoV-2). Three of these 7 patients were asymptomatic at the time of FDG PET/CT but became symptomatic about 10 days later; the Covid-19 infection was already known for the 4 other patients. In 4/7 patients, bilateral mediastinal nodes took-up FDG (mean SUVmax 3.87). The 24 other patients (77%) had a different final aetiological diagnosis: other viral or bacterial infections, consequences of a recent bronchoalveolar lavage, and known pulmonary lesions of autoimmune diseases. There was no difference in FDG uptake by lung lesions between Covid-19 patients and others (mean, median [range] SUVmax 3.13, 1.7 [1.1–6.4] vs. 3.53, 2.85 [1.2–10.9] respectively, $p=0.71$). **Conclusion:** In our area with relatively high prevalence of Covid-19, about 1 in 4 patients showing evocative pulmonary CT patterns on FDG PET/CT was considered to be infected by this virus. The FDG uptake by parenchymal lesions was usually moderately increased, and may also be observed in bilateral mediastinal nodes. Moreover, FDG PET/CT identified some patients in the early phase of the Covid-19 infection, before symptoms onset. **References:** None

EPS-119

Incidental Findings Suggestive of COVID-19 Pneumonia in Asymptomatic Patients Derived to ^{18}F -FDGPET/CT. Preliminary Results Obtained in a Reference Single Center During the Pandemia in Spain

A. Blanes¹, C. G. Wafie Corie¹, R. Valhondo Rama¹, L. García Beláustegui¹, M. N. Cabrera Martín¹, C. Rodríguez Rey¹, R. Couto Caro¹, A. Ortega Candil¹, M. García García-Esquinas¹, F. Ferrando-Castagnetto², J. L. Carreras Delgado¹;

¹Hospital Clinico San Carlos, Madrid, SPAIN, ²Hospital de Clínicas Dr. Manuel Quintela, Facultad de Medicina, Universidad de la República, Montevideo, URUGUAY.

Aim/Introduction: The objective of the study is to evaluate the prevalence of incidental findings suggestive of COVID-19 pneumonia in a sample of patients referred for a ¹⁸F-FDG PET/CT study, asymptomatic for inflammatory lung disease, in a period corresponding to a high rate of contagion from COVID-19 in Hospital Clínico San Carlos (Madrid, Spain). We aim to contrast these findings with their real-time reverse polymerase chain reaction (rRT-PCR) result and to describe radiological and metabolic findings of pneumonia. **Materials and Methods:** Consecutive patients with whole-body (WB) ¹⁸F-FDG PET/CT from February 20th to April 30th 2020. Intravenous contrast-enhanced CT was always used except contraindications. The CO-RADS criteria (1-6) was applied to classify the probability of COVID-19 pneumonia on chest CT and the maximum standardized uptake value (SUVmax) was evaluated to measure metabolic behavior of the lungs. We compared these radiological and metabolic findings with rRT-PCR result (gold standard). All patients were carefully interrogated about coronavirus-like symptoms prior to PET/CT acquisition and all of them were asymptomatic. All the studies were acquired on a Biograph 6 True Point PET/CT (Siemens, Germany) following European Association of Nuclear Medicine Guidelines. **Results:** We identified 46 asymptomatic patients with incidental findings suggestive of COVID-19 pneumonia for a total of 507 WB ¹⁸F-FDG PET/CT studies, what it means a percentage of 9.1%. The mean age was 66.4 years. 54.3% (25/46) of the patients were men. Among the reasons for the request, 76.1% (35/46) were oncological and 23.9% (11/46) non-oncological. On 14 patients (30.4%) rRT-PCR for COVID-19 were performed consequently PET/CT findings, being positive for 64.3% (9/14). The remaining 69.6% (32/46) of the patients had no rRT-PCR for COVID-19 reports. The mean SUVmax of the lung glass opacities and/or consolidations were measured, obtaining 6.2±3.7, 5.5±2.5 and 4.3±2.5 for positive, negative and non-performed rPCR, respectively. **Conclusion:** ¹⁸F-FDG PET/CT may detect incidental finding COVID-19 pneumonia in asymptomatic patients in regions with high SARS-CoV-2 prevalence. Although suspicion of COVID-19 pneumonia shows FDG uptake in most cases of our sample, the additional diagnostic value of pulmonary metabolic activity should be defined in larger series of patients. Nuclear Medicine workers need to be aware of the possibility of contact with patients infected even if they are asymptomatic and should be prepared accordingly. **References:** None

Investigation into the Impact Manufacturers have upon Syringe Residues in Different Volumes of Radiopharmaceuticals

T. Stephens;

University Hospitals Birmingham, Birmingham, UNITED KINGDOM.

Aim/Introduction: Diagnostic Reference Levels (DRL) when using Tc DMSA were noted to be reduced at imaging and later found to be due to syringe residue. These residues had measured at a 60-70% of the original dose in some instances and the issue appeared to be random when using 3ml and 5ml syringes with this particular radioisotope. An investigation was carried out to determine which syringes caused high residue and correlate a factor for the increase. As there was an initial question whether the time the dose spent in the syringe pre-injection or the time post kit manufacture was a contributing factor, this was also examined. **Materials and Methods:** The method involved testing every 3ml and 5ml syringe available within the department. Two separate doses were drawn up in each syringe and measured. One dose was left to incubate at room temperature for one hour before being emptied and the other emptied 5-10 minutes post dispensing. After being re-measured each syringe was washed out with saline to see the effect on its residue. This whole method was repeated twice, the second was to assess the shelf life and its effect on the residue. **Results:** It was found that two syringe manufacturers left a residue of 4-5% of the original dose. Four syringe types had 30-50% residue and two syringes had 70-80% residue remaining. The washout with the saline was deemed ineffective as each washout would remove <0.5% of the residue. It was concluded that certain manufacturers had packaging that looked very similar which explained how the residue amounts seemed to randomly occur. **Conclusion:** The outcome of this study has highlighted that patient doses have been affected by high residual activity in certain syringes leading to the increased risk of undiagnostic studies being carried out. Further work involving investigation of syringe residue with other

radiopharmaceuticals, syringe manufacturer and syringe volume is already under way to ensure DRLs are met thus providing a consistent and standardised service. Important for other centres to make sure that they are measuring their residues post injection and working out exact dose administered **References:** None

OP-611

Two Deep Inspirations - Friend or Foe?

J. Terzic, M. Rode Pedersen, S. Monrad Laugesen, B. Hoyer Mathiasen;
Department of Nuclear Medicine, Hospital Lillebaelt, Vejle, DENMARK.

Aim/Introduction: Patients at our department are instructed to take two deep inspirations prior to FDG-PET/CT scan. The purpose of this procedure is to ensure well ventilated and expanded lungs, thus eliminating or reducing the occurrence of atelectasis. However, as this procedure is not, to our knowledge, applied at other departments, we wanted to investigate its actual effects. The aim of this study was to evaluate, if there was any significant differences in the prevalence of atelectasis between a control group and a trial group. **Materials and Methods:** A total of 179 patients, who underwent FDG-PET/CT, at our department during March 2020, were included in the study. By using two identical scanners, patients were randomized daily to either the control or the trial group. The control group were instructed to take two deep inspirations prior to scan, and the trial group were not. Scans were performed at low dose (ref. mAs 40, kV 120) and dose modulated using CARE Dose 4D. Nuclear physicians evaluated the image quality to determine whether atelectasis was present for each patient. Furthermore, atelectasis diagnosis was separated into a set of four pre-defined categories; Subsegmental atelectasis, Segmental atelectasis (dependent on other pathologies), Gravity dependent atelectasis or Uncertain. To ensure the quality of the study, physicians were blinded in regards to which group patients belonged to. **Results:** After randomization of patients, there were 75 in the control group and 104 in the trial group. 60% of patients in the control group was not presented with any type of atelectasis, compared to 50% of patients in the trial group ($p=0.185$). The prevalence of subsegmental atelectasis was identical in the control and trial group, (17.3%), while segmental atelectasis was present in 9.3% of the control group and 11.5% of the trial group ($p=0.637$). The prevalence of gravity dependent atelectasis in the control and trial group was 10.7% and 17.3%, respectively ($p=0.213$). Although differences between the control and trial groups were observed, none of these were statistically significant. Furthermore, instructing patients to take two deep inspirations would in several cases induce severe cough, potentially causing motion artefacts. **Conclusion:**

Our study did not find any significant differences in the prevalence of atelectasis between patients who were instructed to take two deep inspirations prior to a FDG-PET/CT scan and patients who did not receive instructions. This does not emphasize the use of deep inspirations prior to low dose FDG-PET/CT. **References:** None

OP-612

Evaluation of data-driven gating for ^{68}Ga -DOTATOC PET-CT in patients with neuroendocrine tumors

J. Sigfridsson¹, H. Romelin¹, E. Lindström^{2,3}, S. Kvernby^{2,3}, I. Velikyan^{1,3}, A. Sundin^{1,3}, M. Lubberink^{1,3};

¹PET Centre, Uppsala University Hospital, Uppsala, SWEDEN,

²Medical Physics, Uppsala University Hospital, Uppsala,

SWEDEN, ³Radiology & Nuclear Medicine, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: In PET imaging, respiratory motion can severely impair image quality, especially in tissues near the diaphragm, and consequently may lead to poorer lesion detection, delineation and quantitation. Respiratory gating has been available for many years. Previously available gating techniques involve separate devices and are hard to implement in routine clinical practice, respiratory gating has therefore often not been utilized to its full extent. Data-driven gating (DDG), based on detection of respiratory signal using principal component analysis of dynamic sinogram data, would allow for routine implementation of respiratory gating. To date, DDG has only been validated for FDG-PET. The aim of the present work was to assess the effectivity of respiratory signal detection in DDG and its effect on standardized uptake values (SUV) for ^{68}Ga -DOTATOC. **Materials and Methods:** Fifteen patients underwent a whole-body PET-CT scan 1 h after injection of 1.5 MBq/kg body weight of ^{68}Ga -DOTATOC on a General Electric Discovery MI 4-ring PET-Scanner, with 2 min acquisition per bed position. MotionFree (GE-Healthcare), a principal component analysis based respiratory DDG software, was applied prospectively and the scan time per bed position was doubled for beds where a respiratory motion signal was detected in the raw data. Quiescent period gated images, containing 50 % of the doubled scan time data, were reconstructed with Q. Static software (GE Healthcare). All images were reconstructed using TOF-OSEM (3 iterations, 16 subsets) with resolution recovery. SUV_{max} measurements on ^{68}Ga -DOTATOC positive lesions ($n=22$) without and with DDG were compared. Also, the effectiveness of the detection of respiratory signal was evaluated retrospectively. **Results:** Using the same threshold value for respiratory motion detection as recommended by the manufacturer for FDG ($r = 15$), motion was detected on mean 2.2 bed positions per scan. DDG resulted in a mean 16% increase in SUV_{max} ($p = 0.0001$). **Conclusion:** Using the same threshold as for FDG, respiration signals were detected in considerably more bed positions than

previously reported for FDG (mean 2.2 versus 1.2), likely due to the higher image contrast for ^{68}Ga -DOTATOC than for FDG. DDG yielded significantly higher SUV_{max} values as compared to non-gated images. **References:** None

OP-613

Predictive value of multiparametric PET/MR in patients with head and neck squamous cell carcinoma treated with chemoradiotherapy

A. Kedves^{1,2,3}, M. Emri², K. Fabian¹, D. Sipos^{1,2,3}, O. Freihat³, J. Tollar¹, Z. Cselik⁴, G. Bajzik², I. Repa², A. Kovacs¹, Z. Toth^{3,5};

¹Department of Medical Imaging, Faculty of Health Sciences, University of Pecs, Kaposvar, HUNGARY, ²Dr. Jozsef Baka Diagnostic, Radiation Oncology, Research and Teaching Center, Kaposvar, HUNGARY, ³Doctoral School of Health Sciences, University of Pecs, Pecs, HUNGARY, ⁴Oncoradiology, Csolnoky Ferenc County Hospital, Veszprem, HUNGARY, ⁵MEDICOPUS Healthcare Provider and Public Nonprofit Ltd., Somogy County Moritz Kaposi Teaching Hospital, Kaposvar, HUNGARY.

Aim/Introduction: The aim of the study was to evaluate the predictive value of the pretreatment, simultaneously acquired PET/MR based metabolic, and diffusion parameters of head and neck squamous cell carcinoma treated with chemoradiotherapy (CRT). **Materials and Methods:** Retrospective evaluation was performed using pretreatment and post CRT PET/MR image datasets of 68 histologically proven head and neck cancer patients. PET SUV_{max} , SUL_{peak} , MTV and TLG parameters and MR ADC_{mean} values were calculated using pretreatment imaging data. Therapeutic response was evaluated using posttreatment scans, two patient subgroups were created according to the presence or absence of viable tumor. For statistical analysis, Spearman's correlation and Wilcoxon's test were used. **Results:** After completing the CRT, a viable residual tumor was detected in 36/68 (53%) cases, while 32/68 (47%) patients showed complete remission. Significant correlation was not found between the pretreatment ADC_{mean} parameter and the therapeutic success ($p = 0.88$). The PET parameters, SUV_{max} and SUL_{peak} , MTV, and TLG were statistically significantly different between the two patient subgroups ($p = 0.032$, $p = 0.01$, $p < 0.0001$, $p = 0.0004$). **Conclusion:** Our preliminary result suggests that MR ADC_{mean} data originating from pretreatment PET/MR is not useful for therapeutic response prediction, while the evaluated PET parameters (SUV_{max} , SUL_{peak} , MTV, and TLG) seems to be more promising for that purpose, thus their inclusion to risk stratification may also be of additional value. **References:**

OP-614

Comprehensive Review of Zr-89 Immuno-PET in Emerging Clinical Use: What the Technologist Needs to Know

A. Scott¹, M. Morris²;

¹Advanced Molecular Imaging and Therapy, LLC, Glen Burnie, MD, UNITED STATES OF AMERICA, ²Advanced Molecular Imaging and Therapy, Glen Burnie, MD, UNITED STATES OF AMERICA.

Aim/Introduction: The modern paradigm of medical oncology therapy is personalized treatment planning based on molecular and genomic characteristics. Molecular histopathology is a current standard of care for guiding therapy regimens. Emergence of Zr-89 immuno-PET agents introduces the opportunity for an evolution to in vivo, whole-tumor, whole-body molecular diagnostics. The half-life of Zr-89 (78.41 hours) allows for various types of immuno-PET tracers, with different characteristics. Technologists need to understand the washout characteristics of types of immuno-PET tracers and their safety considerations, as well as radiation safety considerations related to Zr-89 emission properties (approximately 23% positron and 77% gamma at 909 keV). **Materials and Methods:** Comprehensive literature review using pubmed with the search term "Zr AND 89 AND immuno AND PET" was performed. Review articles were excluded. Remaining resulting articles were included and evaluated for molecular tracer utilized, administration technique, imaging technique, and patient safety considerations from the nuclear medicine technologist's perspective. **Results:** There were 107 articles identified meeting the search criteria. There were 11 review articles identified and excluded leaving 96 articles for evaluation. Articles were categorized by those describing studies in human subjects, by specific Zr-89 immuno-PET tracer, and by physical, technical, and safety aspects for human use. Specific aspects of each Zr-89 Immuno-PET agent in current human use were assessed and detailed from the technologist's perspective. **Conclusion:** Zr-89 immuno-PET is an important emerging area of molecular imaging in oncology, yet the technologist community still has limited exposure to this diverse category of radiotracer in humans in everyday clinical practice. This comprehensive review is intended to provide a single source of information for technologists to better understand Zr-89 immuno-PET agents and their practical considerations related to image quality and safety at the point of care. **References:** 107 Literature articles meetings search criteria can be provided as a supplemental upon request.

OP-615

Clinical Usefulness of $^{99\text{m}}\text{Tc}$ -DMSA SPECT/CT in Evaluating Focal Defects in Transplanted Kidneys

B. Ferreira, A. Parthipun;
Royal Free London, NHS Foundation Trust,
London, UNITED KINGDOM.

Aim/Introduction: There are several imaging modalities at our disposal in order to aid the diagnosis of complications in transplanted kidneys (e.g. ultrasonography, magnetic

resonance imaging, Computed Tomography or Scintigraphic Renogram studies with ^{99m}Tc -MAG3). ^{99m}Tc -DMSA studies are often used to identify focal parenchymal defects, the presence of which alters the clinical management. Although ^{99m}Tc -DMSA SPECT studies improve accuracy of identifying defects compared to planar scintigraphy, it still remains non-specific and cannot differentiate between multiple causes of defects. The aim of this study is to evaluate whether adding anatomical correlation through the execution of simultaneously acquired SPECT and CT studies can improve on the lack of specificity of performing a simple SPECT study. **Materials and Methods:** 26 transplanted kidney ^{99m}Tc -DMSA SPECT/CT cases, from January 2019 until January 2020 were reviewed by a Nuclear Medicine Consultant. Images were reconstructed using a Hermes' Hybrid Viewer™. SPECT images were analysed and areas with defect/reduced radiopharmaceutical uptake were identified; these findings were respectively compared with the co-registered non-contrast CT images. **Results:** Of 26 kidneys reviewed, 2 were normal on both modalities, and 2 had diffuse parenchymal disease on SPECT with no focal defects nor CT abnormality. From the remaining 21 kidneys, there were 41 focal defects on ^{99m}Tc -DMSA SPECT: 25 of the SPECT defects had corresponding CT defects, 1 (2.4%) corresponded to foetal lobulation, 1 (2.4%) to a renal mass, 4 (10%) to cysts and 19 (46%) were linked to parenchymal scars. There were 16 (39%) defects on SPECT which were unmatched on CT, suggesting focal nephritis. **Conclusion:** The combination of non-contrast CT images adds value to ^{99m}Tc -DMSA SPECT studies. This technique allows the identification of space occupying lesions or masses that can cause focal uptake defects observed in SPECT studies, and differentiate them from 'normal' findings such as cysts or anatomical variants (e.g. foetal lobulation). Furthermore, it also differentiates scarring (indicated by the presence of cortical thinning on CT) from focal nephritis (unmatched SPECT defects), with its respective impact on therapeutic management. **References:** 1) H. Serum Creatinine Measurement as a Predictor for Single Sample GFR using [^{99m}Tc]Tc-DTPA

A. Matos, C. Findlay, G. Hilland, S. Small;

Department of Nuclear Medicine, Gartnavel General Hospital, NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM.

Aim/Introduction: The purpose of this study was to compare slope intercept (SI) glomerular filtration rate (GFR) and the single sample (SS) GFR measurements to aid confidence in transitioning to a SS-GFR method. We also wished to assess at the validity of using estimated GFR (eGFR) as a single sample time predictor. **Materials and Methods:** Using 4-sample SI-GFR measurements, the equivalent SS-GFR was calculated using the single sample time point identified in the BNMS guidelines⁽¹⁾. The patient's most recent eGFR measurement was used to identify which of the 4 blood samples would be the SS equivalent. eGFR was calculated using the Chronic Kidney Disease Epidemiology Collaboration Creatinine 2009 equation. **Results:** One hundred and forty-two [^{99m}Tc]Tc-DTPA SI-GFR patients were retrospectively reviewed with an average eGFR of 92.2 ± 25.4 mL/min/1.73m². The average SI-GFR and SS-GFRs were 85.4 ± 24.3 and 85.4 ± 23.2 mL/min/1.73m² respectively. Time between eGFR and measure GFR (mGFR) was 19.1 ± 39.8 days. Using t-Test: Paired Two Sample for Means, recommended SS times across all eGFRs values demonstrated no statistically significance between SI-GFR and SS-GFR ($p=0.81$, $N=142$) with an absolute average difference between the SI-GFR and SS-GFR of 1.95 ± 1.7 mL/min/1.73m². Using the non-parametric Wilcoxon Signed Rank test to analyse subgroups, investigation revealed that there were no statistically significant differences between the SI-GFR and SS-GFR for eGFRs >100 mL/min/1.73m² ($p=0.05$, $N=58$) and eGFRs 70-100 mL/min/1.73m² ($p=0.09$, $N=58$). However, there were statistically significant differences for eGFRs between 25-70 mL/min/1.73m² ($p<0.00$, $N=24$). **Conclusion:** Preliminary findings using eGFR to determine SS times for [^{99m}Tc]Tc-DTPA mGFRs showed that SS-GFRs taken at 2 hours (eGFRs >100 mL/min/1.73m²) and 3 hours (eGFRs 70-100 mL/min/1.73m²) correlate with SI-GFRs. However, results from this group of patients demonstrated that SS-GFRs taken at 4 and 6 hours (eGFRs 25-70 mL/min/1.73m²) were different from the SI-GFR measurement. This could indicate that low eGFRs are a bad predictor for SS-GFR times, but further work is needed to develop on the results of this group. It will also be valuable to investigate if there is improved accordance between the two methods if a recent eGFR measurement is available to assist the SS-GFR time identification. Finally, the clinical significance of any discrepancies between SS and SI GFRs will also be of relevance during this transition period. **References:** (1) Burniston, M. (2018). Improved Comfort and Image Quality When Using Purpose-Built Support For Hand and Wrist SPECT/CT In Supine Position

A. Leite, M. Humphrys, B. Walker, M. Jessop;

Brighton and Sussex University Hospitals NHS

Trust, Brighton, UNITED KINGDOM.

Aim/Introduction: Current methods of upper extremity positioning and immobilisation, such as the ‘superman position’, can be very difficult for patients to tolerate (especially if they have poor mobility) with increased risk of movement while performing a SPECT/CT scan. This project aimed to minimize patient movement and improve patient comfort when performing SPECT/CT of wrist and hands. In addition, the improved positioning was aimed at producing higher quality images. **Materials and Methods:** A new support was created allowing the patient to lie in the supine position with arms raised above the head. A purpose-built extension was built to work in combination with an existing support, which then allowed immobilization of hands and wrist. Attached to this new support made from perspex, were hand and wrist orthotic devices (splints) made out of plastic with hook and loop fasteners. In addition, disposable bandages were used to immobilise the elbows. The hands were centred in the CT field of view (FOV). During image processing, when creating fused SPECT/CT images, the support and table were cropped. A maximum intensity projection (MIP) was created using settings C=1500 W=2000. **Results:** Initially, a number of trial acquisitions were performed to ensure that the hands would be correctly centred in the FOV, to avoid image distortion of the CT. To facilitate this, a standard bed height was set in the imaging protocol. The support was used with two patients. Both patients gave good feedback about the support. The patients commented that staying still in the ‘superman position’ would be extremely painful in their specific circumstances, as one had a shoulder injury while the other had a hernia and reflux. The use of the bandages on the elbows gave more support to the patient which ensured the elbows remained still throughout the scan, without the arms relaxing downwards. Improved positioning allowed for better image interpretation. Cropping the table and support produced improved image aesthetics. The MIP reconstructed at the settings used, produced an image with a transparent appearance which allowed good visualisation of functional abnormality and localization, especially when rotating the image. **Conclusion:** This immobilization device has allowed patients to lie in the supine position for hand and wrist SPECT/CT. This has successfully minimized patient movement and improved patient comfort, while improving image quality. **References:** None

Somatostatin Receptor-Based Imaging with ^{99m}Tc -EDDA/HYNIC-TOC: Departmental Protocol Update to Include Whole Body SPECT-CT

R. Martins, L. Aloj, I. Harper;

Addenbrooke's Hospital, CUH, Cambridge, UNITED KINGDOM.

Aim/Introduction: Neuroendocrine tumours (NETs) can vary in histology and biological behaviour, which results in various responses to therapy. Determining these factors through different diagnostic tools helps develop specific therapy adjustments for each patient. As part of the diagnosis and follow-up, somatostatin receptors’ (STTR) imaging plays an essential role in both differentiating NETs and staging the disease progression. Alongside computed tomography (CT), magnetic resonance imaging (MRI) and positron emission tomography (PET), Nuclear Medicine (NM) STTR scintigraphies with ^{111}In -Diethylene Triamine Pentaacetic Acid -Octreotide (^{111}In -DTPA-Octreotide) or with ^{99m}Tc -HYNIC-[D-Phe1, Tyr³-Octreotide] Trifluoroacetate (^{99m}Tc -EDDA/HYNIC-TOC) are performed in the first instance to locate and assess NETs, as well as to predict eventual therapy response. (Maxwell and Howe, 2015) (Tsoli et al, 2019) The purpose of this study is to analyse imaging data collected from ^{99m}Tc -EDDA/HYNIC-TOC scans in order to update current scanning protocols within the Department of Nuclear Medicine (DNM). **Materials and Methods:** The DNM has recently moved from using ^{111}In -DTPA-Octreotide to ^{99m}Tc -EDDA/HYNIC-TOC. Both tracers’ cost-effectiveness was briefly compared in terms of radiotracer availability, image quality and patient compliance. Images of 19 ^{99m}Tc -EDDA/HYNIC-TOC scans in patients with NETs were also reviewed by main reporting consultant in order to update existing scanning protocols. **Results:** Despite being more expensive, patient compliance and management have improved with the use of ^{99m}Tc -EDDA/HYNIC-TOC, for the scan is performed only during the course of one day. ^{99m}Tc -EDDA/HYNIC-TOC scans provide better image quality and overall tracer distribution due to its pharmacokinetic properties when compared to ^{111}In -DTPA-Octreotide. From the imaging data analysis, consultants found no evidence to suggest whole body (WB) images provided information not visible on the SPECT-CT performed 3 to 4 hours post-injection, where the contrast between lesions and background is better. **Conclusion:** Scanning protocols with ^{99m}Tc -HYNIC-TOC can be updated to only perform neck to pelvis SPECT-CT at 3 to 4 hours post-injection, without the need of a late WB scan. This protocol change maximizes clinical information obtained and overall image quality, which can prove very useful in diagnosing and staging NETs whenever higher resolution imaging through PET-CT is not immediately available to patients. **References:** Maxwell, J.E and Howe, J.R., 2015. 3D Anthropomorphic Phantom Facilitates Accurate Dosimetry for Head and Neck Radiopharmaceutical Therapy Trials

D. Adam, J. Grudzinski, B. Cox, I. R. Marsh, T. Bradshaw, P. Hill, P. Harari, B. P. Bednarz;

University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Accurate and personalized dosimetry is important for combined external beam radiotherapy and radiopharmaceutical therapy (RPT) treatment regimens in which a cumulative target tumor dose is delivered. The accuracy of RPT dosimetry is limited by uncertainties related to quantitative nuclear medicine scans (i.e. PET, SPECT). Measurements to quantify recovery coefficients (RC), a form of partial volume corrections (PVC), are often taken with nuclear medicine phantoms with idealized geometries and activity distributions which address the size but not the shape of a structure. A 3D printed anthropomorphic phantom with replaceable, patient-specific, 3D printed inserts facilitates a way to standardize activity quantification for more accurate, personalized RPT dosimetry. This work details the construction of a 3D printed head and neck phantom and the dosimetric impact of RCs derived from the phantom are studied using a Monte Carlo (MC) RPT dose calculation platform [1]. **Materials and Methods:** The phantom is based upon open-access CT data provided by the Radiation Therapy Oncology Group (RTOG) 0522 study [2]. The main chamber, a fused thyroid gland void, and removeable parotid and tumor voids were 3D printed using stereolithography (SL) out of a photopolymer resin. The skull, spine, and lacrimal gland voids were 3D printed using SL out of a photopolymer resin mimicking bone material. RCs were calculated for the phantom that was filled with an Iodine-131 solution and imaged using SPECT/CT (120 projections, 60s/projection). The phantom was imaged after injecting the ~20ml tumor insert with 6.99 $\mu\text{Ci/ml}$ and the main phantom with 0.71 $\mu\text{Ci/ml}$ (9.88:1 insert/background ratio). Jaszczak phantom hot sphere measurements were also conducted to compare to the anthropomorphic phantom. **Results:** A RC of 0.47 was calculated for the tumor region. The impact of RC was compared against a ground truth MC scenario in which uniform activity concentrations were assigned to the tumor and main chamber. In comparison to the ground truth, the mean dose to the tumor was underestimated by 57%

and 9% before and after applying the RC, respectively. **Conclusion:** This work highlights the importance of accurate RC calculations for PVC of SPECT-based Iodine-131 RPT dosimetry and offers a method to integrate patient-specific SPECT PVC into dosimetry workflows. Future work will include 3D printing multiple phantom inserts based on patient-specific contours and characterizing the PVCs and resultant dosimetry. **References:** [1] Besemer, A, et al. Making a copy of conventional anthropomorphic phantom section by 3D printing

S. Stuchebrov¹, A. Bulavskaya¹, Y. Cherepennikov¹, A. Grigorieva¹, I. Miloichikova^{1,2}, E. Gargioni³;

¹Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION,

²Cancer research institute of Tomsk national research medical center of the Russian academy of sciences, Tomsk, RUSSIAN FEDERATION, ³University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY.

Aim/Introduction: Currently, along with rising radiation exposure in single radiotherapy sessions and growing complexity of dose planning, rigorous verification using phantoms, which simulate patients' anatomy taking into account properties of different tissues and organs, is also required. For this purpose, conventional anthropomorphic phantoms simulating certain organs and bone tissues, made of different tissue equivalent materials are used. Authors propose making of anthropomorphic phantoms by the means of 3D-printing. The aim of this study is to design and produce a copy of conventional anthropomorphic phantom section using proposed approach, and compare its tomography data with default data. **Materials and Methods:** Authors obtained computed tomography (CT) images of the Alderson Radiation Therapy male phantom using Siemens Somatom Definition AS CT-scanner at the University Medical Center Hamburg-Eppendorf. These data were used to develop a 3D model of the eighth phantom section (neck area), simulating larynx, bone marrow, muscle and bone. The model is designed using Slicer and Meshmixer software. CT-indices of different volumes were used to choose suitable materials and printing parameters. The phantom section is made using 3D printer Prusa i3 Multi Material 2.0. The phantom thicknesses equals to 1 inch. After that, CT-imaging of the printed section was performed, and CT-images of the printed and default phantom sections were compared in order to check the geometry and the matching of CT-indices. **Results:** The result of this study proves the possibility to produce an anthropomorphic phantom by 3D-printing. Comparison of CT-images shows that 3D-printing allows making an object on the base of its DICOM data with 1 mm accuracy throughout the whole

volume that is comparable to CT-tomography data accuracy. The difference of CT-indices for each printed volume is less than 5%. The value of CT-indices for default and printed sections equals to: 980 (default) and 940 (printed) for larynx; 30 (default) and 15 (printed) for bone marrow; 15 (default) and 17 (printed) for muscle; 400 (default) and 380 (printed) for bone. The results match within the variation of CT-indices in conventional clinical CT-images of corresponding tissues of real patients. **Conclusion:** In this study, we demonstrate the possibility to make an anthropomorphic phantom by 3D printing with reproducing shapes and CT-indices of a conventional phantom. Considered approach allows making of inserts for a conventional phantom with unique geometry corresponding to clinical verification tasks for radiotherapy plan. This work is supported by the Russian Science Foundation, project No. 19-79-10014. **References:** None

The dosimetric impact of deformable image registration on multi-timepoint internal dosimetry studies

I. Marsh, J. J. Grudzinski, R. Hernandez, M. M. Turek, D. M. Vail, Z. S. Morris, J. P. Weichert, B. P. Bednarz;
University of Wisconsin-Madison, Madison,
WI, UNITED STATES OF AMERICA.

Aim/Introduction: Accurate voxel-based personalized dosimetry for targeted radionuclide therapy relies on the temporal coregistration of serial PET/CT or SPECT/CT images. In regions where uptake varies both spatially and temporally, coregistration can have a significant impact. This work investigates the impact of incorporating locoregional affine and deformable image registration (DIR) in the calculation of 3D internal dose distributions. **Materials and Methods:** Five companion canine patients presenting with widespread metastatic disease were administered $^{86}\text{Y-NM600}$ and scanned via PET/CT at 2, 24, and 48 h post-injection. Tumor and normal tissue volumes were contoured at each timepoint and absorbed dose rate (ADR) distributions from $^{90}\text{Y-NM600}$ were estimated using a Geant4-based Monte Carlo internal dosimetry platform. Absorbed dose distributions were generated using either whole-body or locoregional CT-CT affine coregistration (WAC or LAC, respectively) prior to applying demons-based DIR. The 48 h PET/CT, corresponding to peak differential tumor uptake, served as the reference to which all other timepoints were registered. CT-CT image transformations were applied to the corresponding ADR distribution and voxel-level absorbed dose was integrated within each region of interest. **Results:** The Sørensen-Dice index measured overlap of locoregionally registered tumor ($n = 11$) and liver ($n = 5$) volumes was $17 \pm 29\%$ and $5 \pm 6\%$ higher than that achieved using the whole-body approach, respectively. The incorporation of DIR further improved

temporal coregistration by an average of 6% for tumor volumes and 18% for liver volumes when compared to LAC. Differences in reported D90 for tumor DVHs ranged from -19.7 to 3.0% for WAC vs LAC+DIR and -2.2 to 1.7% for LAC vs LAC+DIR. In the liver these differences ranged from -9.5 to 4.1% and -9.2 to 3.3%, respectively. **Conclusion:** This work shows that the approach used for temporal coregistration will have a meaningful impact on multi-timepoint personalized dosimetry calculations. Incorporating DIR can improve coregistration of tumor and normal tissue volumes across an imaging series and potentially lead to more accurate internal dose distributions. **References:** None

Aim/Introduction: The availability of software solutions is instrumental in the development of clinical dosimetry. Both academic and commercial solutions are available, each with advantages and drawbacks. In this work, we present a free, open source software, based on 3D-Slicer designed to perform patient-specific dosimetry. **Materials and Methods:** 3D Slicer is an open source software platform for medical imaging, image processing, and three-dimensional visualisation. Its modules already include tools suitable for dosimetry, such as: Dicom import, 3D image display, registration and segmentation. We developed additional features needed for patient-specific dosimetry: • Handling (import and co-register) multiple time-points Dicom images from PET/CT or SPECT/CT reconstructed images • Specific module for calibrations/corrections (sensitivity, contrast recovery and dead-time) • Fitting and integration

time-related events (activity and absorbed dose rates) • Calculating absorbed doses via local energy deposition or convolution, in both homogeneous and heterogeneous media (including density correction). • Generating Monte Carlo input files for absorbed dose calculation. OpenDose3D is able to report cumulated activity and residence times, absorbed dose rates, mean absorbed doses with uncertainties. The validation of this tool covered: sanity checks of its interface and dosimetry calculations following different scenarios. **Results:** Absorbed dose kernels for convolution in homogeneous or heterogeneous media were implemented for several radionuclides, and, depending on the user's requirements, more can be added. Thanks to the scripting capabilities of 3D Slicer, all calculation steps of the dosimetry process can be automated (except the VOI/organ segmentation). Conversely, the modular nature of the tool allows the saving and retrieval of intermediary steps within the process. The OpenDose3D module is fully functional and currently being tested on several clinical datasets including sequential PET (90Y-labelled glass microspheres for transarterial radioembolization - TARE) and SPECT/CT (¹³¹I for thyroid cancer remnant ablation and ¹⁷⁷Lu-DOTATATE for peptide receptor radionuclide therapy). Preliminary results for TARE cases, using local energy deposition, indicate good agreement with direct Monte Carlo simulations performed with GAMOS. **Conclusion:** We developed a 3D Slicer scripted module to perform patient-specific dosimetry for molecular radiotherapy. The module has been developed collaboratively in order to establish mechanisms through which it can continue to evolve with the clinical need. Users can engage directly in the development, and provide new functionality with addition and support. Being part of the OpenDose collaboration¹, the whole project is publicly available/accessible. **References:** ¹Chauvin et al. 2020 jnumed.119.240366

An International Multi-Center Investigation on the Accuracy of Radionuclide Calibrators for Theranostics in Nuclear Medicine

C. Saldarriaga Vargas^{1,2}, M. Bauwens³, I. N. A. Pooters³, S. Pommé⁴, S. M. B. Peters⁵, M. Segbers⁶, W. Jentzen⁷, A. Vogg⁸, F. H. P. van Velden⁹, S. L. Meyer Viol¹⁰, M. Gotthard⁵, F. M. Mottaghy^{3,8}, J. E. Wildberger³, P. Covens², R. Wierts³;

¹Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM, ²Vrije Universiteit Brussel, Jette, BELGIUM, ³Maastricht University Medical Center, Maastricht, NETHERLANDS, ⁴European Commission Joint Research Centre (JRC), Geel, BELGIUM, ⁵Radboudumc, Nijmegen, NETHERLANDS, ⁶Erasmus MC, Rotterdam, NETHERLANDS, ⁷University of Duisburg-Essen, Essen, GERMANY, ⁸University Hospital RWTH Aachen University, Aachen, GERMANY, ⁹Leiden University Medical Center, Leiden, NETHERLANDS, ¹⁰University Medical Center Utrecht, Utrecht, NETHERLANDS.

Aim/Introduction: Personalized molecular radiotherapy based on theranostics requires accurate quantification of the amount of radiopharmaceutical activity administered to patients both in diagnostic and therapeutic applications. This international multi-center study aims to investigate the clinical measurement accuracy of radionuclide calibrators for 7 radionuclides used in theranostics: ^{99m}Tc, ¹¹¹In, ¹²³I, ¹²⁴I, ¹³¹I, ¹⁷⁷Lu and ⁹⁰Y. **Materials and Methods:** In total, 32 radionuclide calibrators from 8 hospitals located in the Netherlands, Belgium and Germany were tested. For each radionuclide, a set of four samples comprising two clinical containers (10-mL glass vial and 3-mL syringe) with two filling volumes were measured. The reference value of each sample was determined using two secondary standard ionization chambers of certified radioactivity calibration centers (Belgian Nuclear Research Centre SCK CEN and Joint Research Centre Geel). The deviation in measured activity with respect to the reference value was determined for each radionuclide and each measurement geometry. In addition, the combined systematic deviation of activity measurements in a theranostic setting was evaluated for 5 clinically-relevant theranostic pairs: ¹³¹I/¹²³I, ¹³¹I/¹²⁴I, ¹⁷⁷Lu/¹¹¹In, ⁹⁰Y/^{99m}Tc and ⁹⁰Y/¹¹¹In. **Results:** For ^{99m}Tc, ¹³¹I, and ¹⁷⁷Lu, a small minority of measurements were not within ±5% range from the reference activity (percentage of measurements not within range: ^{99m}Tc: 6%, ¹³¹I: 14%, ¹⁷⁷Lu: 24%) and almost none were outside ±10% range. However, for ¹¹¹In, ¹²³I, ¹²⁴I and ⁹⁰Y more than half of all measurements were not accurate within ±5% range (¹¹¹In: 51%, ¹²³I: 83%, ¹²⁴I: 63%, ⁹⁰Y: 61%) and not all were within ±10% margin (¹¹¹In: 22%, ¹²³I: 35%, ¹²⁴I: 15%, ⁹⁰Y: 25%). A large variability in measurement accuracy is observed between radionuclide calibrator systems, type of sample container (vial vs syringe), and source-geometry calibration/correction settings used. Consequently, we observed large combined deviations (percentage deviation >10%) for the investigated theranostic pairs, in particular for ⁹⁰Y/¹¹¹In, ¹³¹I/¹²³I and ⁹⁰Y/^{99m}Tc. **Conclusion:** Our study shows that substantial over- or under-estimation of therapeutic tissue doses are likely to occur in a theranostic setting when radionuclide calibrators are used with factory-set calibration factors. These findings underline the importance of thorough validation of radionuclide calibrator systems for each clinically-relevant radionuclide and sample geometry. **References:** None

OP-624

A correlation study between clinical outcome and absorbed dose to organs at risk and lesions for patients with High-Risk Neuroblastoma administered with high-activity therapy of ¹³¹I-mIBG

B. Cassano¹, M. Pizzoferrero², S. Valeri³, S. Donatiello¹, C. Polito^{1,4}, D. Ciucci^{1,3}, F. Martire^{1,3}, A. Castellano⁵, C. Altini², M. C. Garganese², V. Cannatà¹;

¹IRCCS Bambino Gesù Children's Hospital, Medical Physics

Unit, Rome, ITALY, ²IRCCS Bambino Gesù Children's Hospital, Nuclear Medicine Unit/Imaging Department, Rome, ITALY, ³Tor Vergata Postgraduate School of Medical Physics, Rome, ITALY, ⁴Sapienza University of Rome, Postgraduate School of Medical Physics, Rome, ITALY, ⁵IRCCS Bambino Gesù Children's Hospital, Oncoemathology Unit, Rome, ITALY.

Aim/Introduction: The administration of high-activity of ¹³¹I-metaiodobenzylguanidine (¹³¹I-mIBG) is a gold standard for treating patients affected by relapsed/refractory metastatic high-risk neuroblastoma (HR-NBL). One of the most promising strategies is the tandem high-activity therapy, which consists of two administrations of ¹³¹I-mIBG separated by 15 days. The aim of this study was to report the absorbed dose to WB, red marrow (RM) and tumours in order to correlate them with clinical outcome of the patients.

Materials and Methods: 20 patients (10 boys and 10 girls, age range [3;20] years) affected by relapsed-refractory HR-NBL and treated with tandem high activity therapy were enrolled. The first administration was weight-based (444 MBq/kg) [6.6;17.5] GBq, while the second one was dosimetry-based, achieving 4 Gy to WB. Data collection for the assessment of absorbed dose to WB and RM (D_{WB} and D_{RM}) was performed taking measurement in a time window [0.5;144] hours after the administration, according to the MIRD and EANM guidelines. The WB dose-rate has been measured with an external probe placed at 2 meters distance while a well counter was used to measure the blood activity. Lesion dosimetry (D_{Lesion}) was performed on 13 patients following the conjugated view method acquiring five static images in a time window [2;144] h for a total of 13 lesions evaluated. The response was classified in Progression and Stable Disease (PD and SD), Partial and Complete Response (PR and CR) according to semiquantitative assessment based on SIOPEN-mIBG score system. **Results:** The cumulative D_{WB} , D_{RM} and D_{Lesion} ranged from [2.5; 4.8], [0.7; 2.4] and [13;464] Gy. A linear correlation between the absorbed dose to WB and RM were obtained with a correlation coefficient equals to $R^2=0.97$. After ¹³¹I-mIBG therapy, combined with chemotherapy, patient 3, 4, 7 and 6 showed CR, PR, SD and PD respectively. A correlation between the clinical outcome and the absorbed dose to lesion was obtained with a threshold at 80 Gy. **Conclusion:** The dosimetric approach was necessary to perform a patient-specific treatment both to administer the maximum tolerable activity to the patients and to evaluate the efficacy of the therapy. The absorbed dose to lesion ranged in a very wide interval and could be a predictor of the outcome of the treatment. Tandem high-activity therapy, in combination with chemotherapy treatment, was well tolerated and effective in patients with HR-NBL. Benefits were observed in the treatment of relapse/progression, improving survival rates without severe toxicities. **References:** None

Aim/Introduction: Treatment of differentiated thyroid cancer with radioiodine has been performed for almost 80 years. Nevertheless, controversies remain over the related radiation risks and the optimal treatment regimen for individual patients. Large-scale prospective multi-centre studies are essential to resolve these controversies. Multi-national multi-centre clinical studies will allow sufficient patient recruitment to achieve the statistical significance required to address these issues. Optimisation and standardisation of data acquisition and processing are essential to ensure quantitative imaging so that patient-specific dosimetry may be compared between centres. We report here on the set-up of a European network of centres able to perform standardised quantitative imaging of radioiodine within the EU consortium MEDIRAD. **Materials and Methods:** Four SPECT/CT systems and one SPECT system at four European centres were characterised with respect to their system volume sensitivity, recovery coefficients and dead-time to enable quantitative imaging of patients administered with radioiodine for the treatment of thyroid cancer. A site set-up protocol was developed that complied with varying local and national interpretation of radiation protection guidance and laws. Furthermore, image acquisition protocols were developed that allowed for flexible imaging schedules based on local requirements and availability of equipment to allow a wide range of centres to be included in the studies. Reconstructions were performed locally using Flash3D and Volumetrix MI, respectively, with OSEM (4 iterations, 10 subsets), CT (SPECT/CT) and Chang (SPECT) attenuation correction and triple-energy window scatter correction with no post-reconstruction filtering. **Results:** System volume sensitivities of three 3/8" Siemens Intevo SPECT/CT systems were found to be in the range from 62 to 74 cps/MBq. A 5/8" GE Discovery 670 SPECT/CT was found to have a sensitivity of 92.2 cps/MBq. Lastly, a Siemens Symbia S SPECT system was found to have a sensitivity of 55.6 cps/MBq. Recovery coefficients measured on the Siemens Intevo systems agreed within the uncertainties

on all systems. **Conclusion:** This network has been set-up to support a series of clinical studies to determine accurately absorbed doses for thyroid cancer patients treated with radioiodine. Results from the site set-up indicate that global calibration parameters for similar set-ups (camera and reconstruction) may be used for an extension of the imaging network. Standardisation of the imaging and dosimetry protocol, however, was found to be challenging due to local differences in ethical approval, radiation protection and availability of equipment. **References:** None

Aim/Introduction: The aim of the UK-based multi-centre clinical trial SELIMETRY (EudraCT No 2015-002269-47) is to investigate the potential use of the MEK 1/2 inhibitor, Selumetinib (AZD6244, ARRY-142886), to re-sensitise patients with iodine refractory differentiated thyroid cancer to radioiodine therapy. Lesion biokinetic analysis is performed both for the pre-treatment ^{123}I -Nal and for the subsequent ^{131}I -Nal therapy. The aim of this study was to evaluate the potential for the ^{123}I -Nal study to predict the biokinetics following the therapeutic administration.

Materials and Methods: Pre-treatment dosimetry involved up to five SPECT/CT scans at 5, 24, 30, 48 and 72 hours after a 370 MBq ^{123}I -Nal administration following four weeks of Selumetinib therapy. Four post-therapy SPECT/CT scans were performed at 24, 48, 72 and 144 hours

following radioiodine therapy with 5.5 GBq of ^{131}I -Nal. rhTSH stimulation was used before ^{123}I -Nal scans and ^{131}I -Nal therapy. The SPECT scans were quantified using system calibration factors [1]. Activity retention in lesions was determined from large VOIs placed on the SPECT scans to include spill-out due to the partial-volume effect. Activity in the large VOIs was corrected for background activity. Lesions were outlined on the CT scans by a trained radiologist to obtain lesion volumes. Absorbed doses were calculated using the MIRD formalism. Uncertainties in the absorbed doses were estimated using recent EANM guidance. Pearson product-moment correlation coefficients were computed to assess relationships between results from pre-treatment and post-therapy dosimetry. **Results:** Preliminary results obtained for 10 lesions (lesion size range: 0.4 - 42.3 ml), in 3 patients treated as part of the clinical trial suggest a strong, positive correlation between predicted activity retention at 24 hours from the pre-treatment dosimetry and measured activity retention post-therapy ($r=0.98$, $n=10$, $p<0.001$). Predicted and measured activity retention at 24 hours after administration agreed in the majority of cases (8/10) within the associated uncertainties. Furthermore, a strong, positive correlation between predicted and measured effective half-lives of activity retention in lesions assuming a single exponential decay was found ($r=0.96$, $n=10$, $p<0.001$). **Conclusion:** Preliminary results suggest that the lesion biokinetics of pre-treatment ^{123}I -Nal are applicable to subsequent ^{131}I -Nal therapy of advanced thyroid cancer. This will potentially allow for a more personalised approach in the treatment of patients with metastatic thyroid cancer based on patient-specific dosimetry. **References:** [1] Gregory RA et al. OP-627

Absorbed dose estimation of thyroid residues, salivary glands and distal metastases after ^{131}I therapy using SPECT/CT with scatter, dead time and partial volume correction

M. Abuqbeidah, M. Demir, S. Sager, N. Yeyin, K. Sonmezoglu; Istanbul University, Istanbul, TURKEY.

Aim/Introduction: It was aimed to calculate the absorbed dose of salivary glands, thyroid residues and distal metastases after ^{131}I therapy with resolving the quantification degrading factors. **Materials and Methods:** IEC body phantom was filled by 1983.2 MBq ^{131}I followed by 20 SPECT/CT scans. Recovery coefficients were calculated for 26.51, 11.49, 5.57, 2.57, and 0.52 cm³ spheres. Triple energy window (6%) was used for scatter correction and special equations were derived for dead time correction. 31 patients (73 ± 16 kg, 46 ± 17 years) were scanned (1 bed) involving salivary glands and lungs at

6, 24, and 168 hours following administration of 5069 ± 1924 MBq¹³¹I. CT images were used to draw the salivary glands ROIs, while the thyroid residues (n=22) and the distal lesions (n=10) were delineated by 30% iso-contour owing to its superior accuracy over 40 and 50% iso-contour. The absorbed doses were calculated using IDAC-Dose 2.1 for salivary glands, and sphere model for thyroid residues and lesions. **Results:** The mean residence time of single parotid gland (n = 31) and single submandibular gland (n=25) was 8.6 ± 11.2 and 3.1 ± 2.2 minutes, respectively. While that was 3.52 ± 4.54 h for thyroid residues and 0.31 ± 0.34 h for the distal lesions. The range of the salivary glands uptake (%) at 6 h was 0.27–1.67 and 0.03–0.99 at 24 h, while thyroid residues uptake ranged from 0.06 to 10.9 at 2 h, and it was 0.04–18.3 at 24 h. The parotid glands dose was 0.46 ± 0.47 Gy/GBq, and the submandibular glands dose was 0.16 ± 0.10 Gy/GBq. The total salivary glands (n = 26) mean dose was 0.41 (0.21–1.11) Gy/GBq, whereas 78 (0.5–400) Gy/GBq was found as thyroid residues dose, and 2 (0.8–15) Gy/GBq for the distal lesions. 100% of the distal lesions and 30% of the thyroid residues received dose ≤ 70 Gy. **Conclusion:** The salivary glands doses were comparable with few studies conducted with ¹³¹I tracer that verifies the accuracy of the present methodology. Also, salivary glands uptake might largely affect the thyroid uptake during the first hours when using the thyroid probe for uptake measurement, while this impact decreases at 24 h due to the activity clearance. The salivary glands failure may occur after total administration of 54.5 GBq ¹³¹I with respect to 60 Gy tolerated dose and 1.1 Gy/GBq. The resultant low dose of the lesions emphasizes the importance of dosimetry based therapy to deliver effective and successive absorbed dose. **References:** None

OP-628

Optimization of a dual-energy quantitative computed tomography (DEQCT) method to quantify the mineral bone volume fraction (MBVF) for bone marrow dosimetry in molecular radiotherapy

M. Salas Ramirez, J. Tran-Gia, M. Lassmann;

Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY.

Aim/Introduction: The quantification of the absorbed dose to active bone marrow is essential for determining the risk of marrow toxicity in patients undergoing molecular radiotherapy. The development of parameterized computational models of bone marrow for calculating patient-specific radionuclide S-values requires the implementation of imaging methods for quantifying the mineral bone volume fraction (MBVF). This study aims to optimize a phantom-independent dual-energy quantitative computed tomography (PI-DEQCT) method (without external calibration standards) for a SPECT/CT system to enable the calculation of MBVF for bone

marrow dosimetry in molecular radiotherapy. **Materials and Methods:** First, a previously implemented PI-DEQCT method (validated in a Siemens Healthineers Symbia Intevo Bold (SPECT)/CT system [1]) was optimized (improvement: inclusion of soft tissue-equivalent materials in the beam hardening correction). Subsequently, the MBVF was measured in a phantom simulating the vertebral geometry (European Spine Phantom, ESP) using the non-optimized and optimized PI-DEQCT method. Then, the MBVF in the spongiosa region of the head and neck of two femoral bones from an adult boar was measured using the optimized PI-DEQCT method. The two bone samples were located in a plastic box without dispersion material and imaged with a dual-energy CT acquisition protocol. For comparison, four external standards (water and three water-pHEMA mixtures, each with a different MBVF (0.03, 0.07, and 0.10)) were attached to the box to enable a phantom-dependent MBVF quantification (PD-DEQCT) method [2]. Lastly, the effective atomic number (Z_{eff}) and the effective density (ρ_{eff}) of the analyzed volume were obtained using the PI-DEQCT method and compared with the values provided by a commercially available tool for DECT systems (syngo. CT DE Rho/Z, Siemens Healthineers). **Results:** As previously reported, the BMVF quantification errors in the ESP with the non-optimized method ranged between 5.4% and 31.7% [1], while for the new optimized method, it ranged between -12.1% and -3.3%. The errors between the MBVF quantification with PI-DEQCT and PD-DEQCT in the boar bones were -1.84% (bone 1) and 2.48% (bone 2). Lastly, the $\rho_{\text{eff}}/Z_{\text{eff}}$ values showed a good agreement between PI-DEQCT and the Rho/Z tool (relative errors 5.23%/3.2% [bone 1] and 6.7%/2.46% [bone 2]). **Conclusion:** The good agreement between both DEQCT methods provides evidence for the feasibility of a phantom-independent MBVF quantification using the presented PI-DEQCT method with a commercial hybrid (SPECT)/CT system. Moreover, PI-DEQCT enables a good characterization of the spongiosa region based on the obtained $\rho_{\text{eff}}/Z_{\text{eff}}$ values. **References:** [1] Salas-Ramirez et al., PhysMedBiol 2019;64(20). OP-629

Implementation of SPECT auto-contouring detector motion in GATE Monte Carlo simulation for ¹⁷⁷Lu and ¹³¹I Molecular Radiotherapy (MRT) dosimetry

G. Kayal^{1,2}, M. Chauvin¹, E. Mora-Ramirez³, L. Struelens², M. Bardiès¹;

¹CRCT, INSERM, Toulouse, FRANCE, ²SCK CEN, Belgian Nuclear Research Centre, Mol, BELGIUM, ³Universidad de Costa Rica, Escuela de Física, CECANUM, San José, COSTA RICA.

Aim/Introduction: Monte Carlo (MC) modeling of SPECT imaging systems provides unique insight to evaluate quantitative imaging procedures in Molecular Radiotherapy

(MRT) dosimetry. The modeling of time dependent phenomena, including detector movement allows the simulation of more realistic acquisition conditions. To date, SPECT modeling in GATE cannot account for body contour acquisitions where detector heads move as close as possible to the patient resulting in a non-circular orbit (NCO), which improves image resolution and uniformity. In this work we developed and validated NCO - step and shoot acquisition mode for use in GATE SPECT modeling.

Materials and Methods: We modelled ^{177}Lu SPECT experimental acquisitions performed on a Siemens Symbia T2 dual headed gamma camera with MELP collimator. SPECT projections were obtained for cylindrical (with 2 organ inserts) and elliptical (with 4 organ inserts) phantoms¹, using a matrix size of 128 x 128, 60 projections per head, acquisition time of 20 and 30 seconds per projection and total activity of 303.4 MBq and 1190.3 MBq for the 2-organ and 4-organ phantom respectively. A GATE (v8.2) model implementing NCO acquisitions was designed and validated based on the experimental settings. Additionally, ^{131}I and ^{177}Lu circular orbit (CO) and NCO SPECT projections were simulated using the 4-organ phantom model for the same Siemens Symbia T2 gamma camera, with MELP (for ^{177}Lu) and HE (for ^{131}I) collimator and the same acquisition parameters to highlight the relevance of NCO modeling.

Results: Simulation time for 2-organ (3.6×10^{11} primaries) and 4-organ (2.1×10^{12} primaries) phantoms were 5h and 9.5h respectively using the regional HPC centre CALMIP. Simulated images were compared with experimental images and were found to be in good agreement with a high similarity of 94% using structural similarity index (SSIM) and a relative difference of less than 5% from profiles. Simulated images for ^{177}Lu and ^{131}I were compared between circular and body contouring motion (using both SSIM and profiles). The maximum difference in the counts between the two gamma camera motions CO and NCO (taking into account all the projections) was less than 1% for ^{177}Lu and up to 10.6% for ^{131}I . This difference arises from the higher septal penetration of ^{131}I compared to ^{177}Lu . **Conclusion:** We developed and validated NCO acquisition modes for GATE SPECT modeling. This implementation is recommended for all NCO acquisitions and essential in the case of radionuclides with high septal penetration such as ^{131}I .

OP-630

Generation of realistic SPECT/CT images for ^{177}Lu dosimetry in Molecular Radiotherapy (MRT) based on Monte Carlo simulation with GATE

G. Kayal^{1,2}, M. Chauvin¹, A. Vergara-Gil¹, N. Clayton¹, L. Struelens², M. Bardiès¹;

¹CRCT, INSERM, Toulouse, FRANCE, ²SCK CEN, Belgian Nuclear Research Centre, Mol, BELGIUM.

Aim/Introduction: Patient-specific dosimetry in MRT relies on quantitative imaging, pharmacokinetic assessment and absorbed dose calculation. The DosiTest¹ project was initiated to evaluate the uncertainties associated with each step of the clinical dosimetry pathway, via a virtual multicentric intercomparison based on Monte Carlo modeling. The first phase of the project considered only planar imaging². This work presents the generation of 'virtual' clinical SPECT/CT datasets based on GATE Monte Carlo modelling, which can subsequently be integrated in commercial image workstations as if they were real patient datasets.

Materials and Methods: Our study considered a therapy cycle of 6.85 GBq ^{177}Lu -labelled DOTATATE derived from an IAEA-CRP project (E23005) on "Dosimetry in Radiopharmaceutical therapy for personalised patient treatment". Patient images were obtained from a GE Infinia gamma camera with MEGP collimator. A patient model was generated by segmenting and labelling volumes of interest on the patient CT image and modeled SPECT projections (matrix size of 128 X 128 with 15 seconds per projection and energy window of 208 keV \pm 20%) were generated based on experimental time points at 1h, 4h, 24h, 48h and 96h. Next, these simulated projections were integrated in the SPECT/CT DICOM envelopes from the patient, allowing the integration of the modelled projections into a commercial workstation. Simulated projections were validated against real SPECT projections for similarity using the SSIM (Structural Similarity Index Metric) index. Finally, images were reconstructed using a standard reconstruction algorithm (5 iterations, 16 subsets OSEM reconstruction and CT-based attenuation correction). **Results:** Simulated images produced with GATE were very close to experimental images with SSIM indices ranging from 85 % to 90 % among the different time points. Image reconstruction of the simulated projections were performed on a HERMES workstation. Simulation of SPECT projections with realistic activities in a therapeutic context took 11.5 hours to compute using 3560 CPU cores at the regional HPC centre CALMIP (instead of 5.4 years with a single CPU), thus making it feasible to perform multicentric virtual intercomparison with simulated SPECT images. **Conclusion:** These results demonstrate that GATE can be used for realistic simulation of ^{177}Lu SPECT/CT acquisitions. Now, the modelled datasets will be circulated to clinical departments, in order to allow them to benchmark their clinical dosimetry procedure on a common reference dataset, so as to further assess the uncertainties in the entire dosimetric chain. **References:** 1 Garcia et al. 2015 Med Phys 42(12):6885-94. 2 Costa et al. 2017 Physica Medica 42:292-7.

Multicentre External Validation of a Prediction Nomogram for 68Ga-PSMA-11 PET/CT in different Clinical Settings of PSA Failure, after Radical Treatment for Prostate Cancer

F. Ceci¹, L. Bianchi^{2,3}, P. Castellucci⁴, C. Artigas⁵, J. Leite⁶, P. Corona⁷, A. Farolfi⁴, Q. A. Shagera⁵, R. Moreira⁶, C. González⁷, D. Deandreis¹, S. Fanti^{4,3};

¹Nuclear Medicine, Department of Medical Sciences, University of Turin, Turin, ITALY, ²Department of Urology, S.Orsola-Malpighi University Hospital, Bologna, ITALY, ³Department of Specialistic, Diagnostic and Experimental Medicine, University of Bologna, Bologna, ITALY, ⁴Nuclear Medicine, S.Orsola-Malpighi University Hospital, Bologna, ITALY, ⁵Department of Nuclear Medicine, Institut Jules Bordet, Université Libre de Bruxelles, Bruxelles, BELGIUM, ⁶PET/CT Center, DASA - Diagnósticos da América, Rio de Janeiro, BRAZIL, ⁷Fundación Centro Diagnóstico Nuclear (FCDN), Buenos Aires, ARGENTINA.

Aim/Introduction: A clinical nomogram has been recently developed to predict 68Ga-PSMA-11-PET/CT positivity in different clinical setting of PSA failure, after radical therapy in prostate cancer (PCa) [1]. Since its implementation in clinical practice is still limited by lack of a formal external validation, we aimed to validate this tool in a large multicentre cohort.

Materials and Methods: We retrospectively included 1515 PCa patients with confirmed PSA failure after radical therapy (surgery n=1428; radiotherapy n=87), from five high-volume PET-centres (University of Bologna n=682; DASA-Rio de Janeiro n=295; Bruxelles-Bordet n=255; University of Turin n=223; FCDN-Buenos Aires n=60). All patients had complete clinical/pathologic/laboratory information. The external cohort was stratified according to clinical setting categories as defined in the original population: a) Group-1: first-time biochemical recurrence (BCR), n=668; Group-2: BCR after salvage therapy, n=506; Group-3: biochemical persistence (BCP) after radical prostatectomy, n=202; Group-4: advanced stage PCa before second-line systemic therapies, n=139. 68Ga-PSMA-11-PET/CT detection rate in the overall population and in each sub-group was assessed. A multivariable logistic regression model was produced to assess the predictors of positive scan. Third, the performance characteristics of the model were assessed by quantifying the predictive accuracy, according to model calibration and Yuden's index was used to find the best nomogram's cut-off. Finally, decision curve analysis (DCA) was implemented to quantify the nomogram's clinical value. **Results:** In the external cohort, the overall detection rate was 54.6% vs. 51.2% in the original population. PET/CT detection rates in different clinical setting were: Group-1 43.4% vs. 40.3%; Group-2: 58.1% vs- 54.0%; Group-3 60.4% vs. 60.5%; Group-4 88.2% vs. 86%. In the multivariate analysis, ISUP grade ($p=0.004$), PSA ($p<0.001$), PSA doubling time ($p<0.001$) and clinical setting ($p<0.001$) were independent predictors of positive scan. The predictive accuracy of the nomogram was optimal and comparable to the original model (82.6% vs. 82.3%). The calibration plot indicated ideal concordance between actual and predicted probability of positive 68Ga-PSMA-11-PET/CT. In DCA, the nomogram revealed clinical net benefit when the threshold probabilities of positive scan was >10%. **Conclusion:** The original nomogram exhibited excellent characteristics on multicentre external validation. Given its optimal accuracy, this prediction nomogram might be an easy tool to help clinicians in the decision-making process of recurrent PCa and to reduce the incidence of false-negative scan. **References:** Ceci F, et al. Prediction nomogram for 68Ga PSMA-11 PET/CT in different clinical settings of PSA failure after radical treatment for prostate cancer. Eur J Nucl Med Mol Imaging. 2020;47(1):136-146.

OP-636

A phase II, open-label single-arm study to assess safety, clinical utility of disease burden assessments with 68Ga-

PSMA-11 PET/CT in localizing recurrent prostate cancer

M. Piert¹, M. Abghari-Gerst², M. Rodnick², J. Hearn², J. S. Montgomery², A. Alva², Z. Reichert², D. Spratt², P. J. H. Scott²;

¹University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA, ²University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: While PET/CT with the prostate-specific membrane antigen (PSMA) ligand 68Ga-PSMA-11 is widely used at the time of biochemically recurrent (BCR) prostate cancer, prospective and quantitative data of the utility and disease burden from the United States are still scarce.

Materials and Methods: In this registered trial, 671 patients with BCR after radical prostatectomy (RP) (n=275, 41%), definitive radiation therapy (RT) (n=167, 25%), or RP with post-operative RT (PORT) (n=229, 34%) underwent 68Ga-PSMA-11 PET/CT. Presence of prostate cancer was assessed qualitatively and quantitatively using a user-assisted semi-automatic segmentation routine on a per-patient and per-region base. Lesions were validated by histopathologic analysis and a composite reference standard including follow-up imaging and prostate-specific antigen (PSA) response criteria in absence of systemic treatment. Study endpoints were the detection rate, positive predictive value (PPV), PSMA-positive disease burden, and safety. **Results:** 68Ga-PSMA-11 PET/CT localized prostate cancer sites in 567 of 671 (84.5%) of patients. The overall detection rate increased with PSA levels (ng/mL): 59% for <0.5 (n=102), 77% for 0.5 to <1.0 (n=87), 87% for 1.0 to <2.0 (n=113), 90% for 2.0 to <5.0 (n=142), and 94% for ≥5.0 (n=227, p<0.001). On a per-patient basis, PPV was 0.88 (95% CI, 0.81-0.92) by histopathologic validation (n=59) and 0.93 (95% CI, 0.91-0.95) by the composite reference standard (n=243). In patients with positive scans, the number of identified lesions, the whole-body PSMA tumor volume (PSMA-TV) and whole-body total lesion PSMA (TL-PSMA, normalized by body weight or lean body mass) correlated positively with the PSA level, while no correlation was found with the PSA doubling time or Gleason score at diagnosis. The detected PSMA-TV and TL-PSMA significantly (p<0.001) increased with escalation of interval treatment (from surveillance, over PORT, to ADT). Based on the scan results the intended therapeutic management (at 1-month) changed in 74% of cases (n=461), while actual management changes at 12-months were noted in 77% of cases (n=353). Heart rate and blood pressure reading were stable before and after 68Ga-PSMA-11 administration, and no serious adverse events associated with 68Ga-PSMA-11 administration were observed. **Conclusion:** 68Ga-PSMA-11 PET/CT is safe, has an excellent detection rate and PVP in BCR prostate cancer and has high impact on therapeutic decision making.

OP-637**Patterns of failure on ⁶⁸Ga-PSMA-11 PET/CT after radical prostatectomy (RP), radiotherapy (RT), and RP with post-operative RT (RP-PORT)**

M. Rodnick, M. Abghari-Gerst, J. W. D. Hearn, J. S. Montgomery, A. Alva, Z. Reichert, D. E. Spratt, T. D. Johnson, P. J. H. Scott, M. Piert;

The University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: Conventional imaging has demonstrated different failure patterns based on initial treatment of prostate cancer. Such information is helpful to inform adaptation and optimization of treatment techniques. Given the improved sensitivity and specificity of PSMA-ligands, we performed a propensity matched analysis of the relapse patterns after definitive treatment (RP, RT, or RP-PORT).

Materials and Methods: Within a registered prospective single-center trial investigating the diagnostic performance of ⁶⁸Ga-PSMA-11 PET/CT, 592 subjects received approx. 300 MBq ⁶⁸Ga-PSMA-11 PET/CT, 60 min. p.i. Patient and disease characteristics, treatment details and PSMA-scan results (total PSMA-positive tumor volume, identified disease location [local (prostate/prostate bed/seminal vesicles), pelvic nodal, soft tissue (including extra-pelvic nodal), and/or bone] were recorded. Propensity score matching on age, PSA at initial treatment, Gleason grade group, types of interval treatments, time-interval between definitive treatment to scan, and PSMA-positive tumor burden was performed, followed by logistic regression analysis on propensity score matched cases to determine the multiple comparison corrected odds ratio (OR). **Results:** Five hundred of 592 scans resulted positive for recurrent prostate cancer [(194 RP, 130 RT, and 176 RP-PORT; age: 69.5,70(68.9-70.1) years. The PSA (ng/mL) at time of scan was 4.5,1.5(3.3-5.8) for RP, 10.7,5.5(8.2-13.2) for RT, and 4.9,2.0(3.7-6.1) for RP-PORT (mean/median (95%CI)]. In matched cohorts, the odds of local recurrence after RT were significantly higher than following RP (OR 8.0 (98.75%CI 3.8-16.8; n=267) and RP-PORT (OR 18.8 (98.75%CI 7.7-45.8, n=288; p<0.001). Conversely, the odds for nodal recurrence in the pelvis were significantly higher after RP compared to RT (OR 2.3 (98.75%CI 1.2-4.4) and RP-PORT (OR 3.3 (98.75%CI 1.8-6.7; p<0.001). Compared to RT, the odds for distant metastatic disease in bone was higher after RP (OR 2.6 (98.75%CI 1.1-5.9) and RP-PORT (OR 2.3 (98.75%CI 1.0-5.3; p<0.001). Significant differences were absent for any comparison regarding soft tissue metastases. **Conclusion:** This study evaluated only patients who experienced treatment failure and therefore this analysis cannot quantify the overall probability of recurrence across treatment modalities, especially given lack of randomization. Nevertheless, among patients with positive scans, different patterns of failure were observed based on the initial treatment, with a higher rate of local recurrence after RT, and higher rates of nodal and osseous

metastases after RP. These findings may inform treatment techniques and warrant further investigation. **References:** None

OP-638

Recurrence patterns after radical prostatectomy, definitive radiation therapy and salvage radiation therapy with ^{68}Ga -PSMA-11 PET/CT in non-metastatic castrate sensitive prostate cancer patients: a single center post-hoc retrospective analysis

W. Armstrong, P. Thin, R. Alano, K. Nguyen, K. Booker, J. Gartmann, V. Lok, S. Lira, I. Sonnie, N. G. Nickols, A. U. Kishan, J. Czernin, J. Calais;
University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: 20 to 50% of prostate cancer (PCa) patients undergoing radical prostatectomy (RP) or definitive radiation therapy (dRT) will experience disease recurrence. However, anatomical recurrence patterns may differ depending on the therapeutic approaches. The aim of this post-hoc retrospective analysis was to investigate if the relapse pattern as assessed by ^{68}Ga -PSMA-11 PET/CT was different depending on the type of local pelvic therapy (RP, dRT, salvage RT (SRT), pelvic lymph node dissection (PLND), pelvic lymph node RT (PLNRT)) in patients with non-metastatic castrate sensitive (nmCS) recurrent disease after primary definitive therapy. **Materials and Methods:** Patients who underwent a ^{68}Ga -PSMA-11 PET/CT for nmCS PCa recurrent disease after primary definitive therapy were screened from a database of 4 prospective studies (NCT02940262, NCT03515577, NCT04050215, NCT03582774). Patients who underwent primary staging ($n = 95$), without definitive therapy ($n = 68$), with known metastatic disease (M1) ($n = 68$) or with castrate resistant (CR) disease ($n = 291$) were excluded. We examined the relationship between recurrence patterns as assessed by ^{68}Ga -PSMA-11 PET/CT (PROMISE criteria) and prior local treatments: i) RP, ii) dRT, iii) RP + SRT. **Results:** 787 patients were included in the analysis. Positive scan rates were 60%, 94% and 75% in RP, dRT and RP + SRT populations, respectively. Median pre-scan PSA levels were 0.50 (0.02–72.5) ng/ml, 4.4 (0.1–202) ng/ml, and 1.07 (0.04–33) ng/ml for patients who underwent RP ($n = 464$), dRT ($n = 109$) and post-RP SRT ($n = 214$). Median time to first recurrence was 27.7 after RP and 54.6 months after dRT ($p = < 0.0001$). Patients who underwent RP had lower local recurrence (LR) pattern (T+) rates by PSMA PET than those with dRT (99/464; 21% vs 69/109; 63%; $p = < 0.0001$). Nodal metastasis (N1) positivity rate was similar between RP and dRT (179/464; 39% vs 43/109; 39%; $p = 0.87$). Extrapelvic metastasis (M1) positivity rate was lower for RP than dRT (93/464; 20% vs 51/109; 47%; $p = < 0.0001$). Median time from post-RP SRT to second recurrence was 22.3 months. In patients who had

a second recurrence after RP and SRT the positivity rate of LR (T+), N1 disease and M1 disease by PSMA PET/CT was 12% (24/214), 46% (99/214) and 44% (95/214). **Conclusion:** In this cohort of patients with nmCS PCa recurrent disease after primary definitive therapy, the anatomic patterns of failure assessed by PSMA PET differ based on prior local and systemic treatments. **References:** None

OP-639

Performance of ^{68}Ga -PSMA-11 PET/CT in patients with recurrent prostate cancer. A multi-centre evaluation of 2533 patients

A. Afshar-Oromieh¹, M. Livorsi da Cunha², J. Wagner², U. Haberkorn³, W. Weber⁴, M. Eiber⁴, T. Holland-Letz⁵, I. Rauscher⁴;
¹Department of Nuclear Medicine, University Hospital of Bern, University of Bern, Bern, SWITZERLAND, ²Department of Nuclear Medicine, Hospital Israelita Albert-Einstein, Sao Paulo, BRAZIL, ³Department of Nuclear Medicine, Heidelberg University Hospital, Heidelberg, GERMANY, ⁴Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY, ⁵Department of Biostatistics, German Cancer Research Center, Heidelberg, GERMANY.

Aim/Introduction: To evaluate the performance of ^{68}Ga -PSMA-11 PET/CT in the diagnosis of recurrent prostate cancer (PCa) in a large patient's cohort. **Materials and Methods:** The initial database included 6758 patients scanned with ^{68}Ga -PSMA-11 PET/CT at 1h p.i. in the departments of nuclear medicine of Heidelberg (Germany), Technical University of Munich (Germany) and Albert-Einstein Hospital of São Paulo (Brazil). Of these patients, those with untreated Primary PCa, undergoing androgen-deprivation therapy, referred for PSMA-Endoradiotherapy and those previously treated with chemotherapy or exclusively external beam radiation therapy were excluded from the analysis, giving a total of 2533 included patients. Potential influences of different factors such as PSA-level, PSA-doubling-time (PSA_{DT}), PSA-velocity (PSA_{Vel}), Gleason Score (GSC, including the separate analysis of 7a and 7b), age and amount of injected tracer were evaluated in a multivariate analysis. **Results:** The rate of pathological PET/CT-scans was 43% for PSA less than 0.2 ng/ml, 58% for PSA between 0.2 and 0.5ng/ml, 72% for PSA between 0.5 and 1.0ng/ml and increased to a maximum of 93% for PSA bigger than 10ng/ml. A pathologic PET/CT was significantly ($p = 0.001$) associated with PSA level and higher GSC. Amount of injected tracer, age, PSA-DT and PSA-Vel were not associated with a higher probability of a positive PET/CT. **Conclusion:** ^{68}Ga -PSMA-11 PET/CT conducted at 1h p.i. demonstrated its high performance in the largest patient cohort yet analysed. Tumour detection showed a clear association with higher PSA and higher GSC. No association was found between a pathological ^{68}Ga -PSMA-11 PET/CT and age, amount of injected tracer, PSA_{DT} or PSA_{Vel} . **References:** None

OP-640**Early BCR: in which patients is it worth performing a further PSMA scan?**

A. Paccagnella¹, A. Farolfi¹, G. Ricci², P. Castellucci¹, F. Mattana¹, L. Muraglia¹, S. Fanti¹;

¹Department of Nuclear Medicine, Policlinico S.Orsola, University of Bologna, Bologna, ITALY, ²Department of Nuclear Medicine, M. Bufalini Hospital, Cesena, ITALY.

Aim/Introduction: to identify potential factors able to predict 68Ga-PSMA-11 PET/CT (PSMA-PET) positivity after a previous negative PSMA-PET performed in patients with early biochemical recurrence (BCR). **Materials and Methods:** from March 2016 to March 2020 we retrospectively reviewed patients with the following inclusion criteria: 1) diagnosis of prostate cancer treated with radical prostatectomy; 2) BCR defined by PSA measurement \geq 0.2 ng/mL; 3) a negative PSMA-PET during early phases of BCR (PET1); 4) a subsequent PSMA-PET (PET2) within 20 months; 5) no treatment between PET1 and PET2, with exception of hormonal therapy (HT). Imaging dataset was evaluated by two independent experienced readers and in case of disagreement by the opinion of a third reader. We considered: PSA values at the time of the scans, PSA_{dt}, PSA_{vel}, Δ PSA and Δ time between PET1 and PET2. Mann-Whitney U test and Chi-Square test were used to compare the distribution of patients' characteristics across PET2 results. Regression analyses were employed to determine predictors of a positive PET2; ROC curves were calculated. **Results:** 431 patients had a negative PSMA-PET during early phases of BCR, 73/431 (17%) patients met all the inclusion criteria. 32/73 (44%) were T3a or greater, 14/73 (19%) were N1, 31/73 (42%) had a G₅ \geq 8. Mean-PSA1 was 0.88 ng/ml (median 0.5; range 0.2-9.5); mean-PSA2 was 2.5 ng/ml (median 1.13; range 0.23-43.8); mean- Δ time was 8.5 months (2-20); mean- Δ PSA was 1.65 ng/ml; mean-PSA_{dt} was 14.1 months; mean-PSA_{vel} was 2.2 ng/ml/years. 13/73 (18%) patients were on HT at the time of PET2. PET2 was positive in 29/73 (40%); 21/29 (72%) had loco-regional disease and 8/29 (28%) had distant metastasis. Δ PSA, PSA_{dt}, PSA_{vel} and HT were associated with a positive PET2 (all $p < 0.05$). On univariate regression analysis PSA_{dt} and being on HT were predictors of a positive PET2, but on multivariate only PSA_{dt} was significant (OR 0.9, CI95% 0,886-0,998, $p = 0,044$). PSA_{dt} had an AUC of 0.69 and a 7.3 months cut-off showed a 69% sensitivity and a 70% specificity. PET2 was positive in 13/45 (29%) patients with PSA_{dt} $>$ 7 months and in 16/28 (57%) patients with PSA_{dt} \leq 7. **Conclusion:** this study shows that PSA kinetics and being on HT during PET2 are predictors of a positive PSMA-PET after a first negative in patients with early BCR. A cut off PSA_{dt} of 7 months could be used to improve the selection of patients for a second scan, reducing the number of negative scans and increasing detection rate. **References:** None

OP-641**68Ga-PSMA PET/CT prospective study in prostate cancer occult recurrence patients: diagnostic performance, impact on therapeutic decision-making and long-term benefits**

C. Rousseau¹, L. Ferrer¹, M. Le Thiec², V. Fleury², M. Frindel², D. Rusu², B. Maucherat², A. Rauscher², P. Baumgartner², A. Morel², N. Varmenot¹, L. Champion¹, F. Kraeber-Bodéré¹;

University, CNRS, Inserm, CRCINA, F-44000, Nantes, FRANCE,

²ICO René Gauducheau, F-44000, St Herblain, FRANCE.

Aim/Introduction: The aim of this prospective study was to investigate the impact of 68Ga-PSMA-11 PET/CT on management of prostate cancer patients with occult biochemical recurrence (OBR). **Materials and Methods:** 130 hormone-naïve OBR (PSA from 0.05 to 1.5 ng/mL) patients were enrolled in the study (NCT03443609), whose design was described previously in preliminary results report¹. PSMA detection rates were determined and correlated to various clinical variables using univariate and multivariable analyses (Cox regression analysis). **Results:** After pre-screening, 13 patients were excluded due to positive pelvic mpMRI (9 pts) or bone scan (4 pts). The median time from radical prostatectomy +/- radiotherapy to OBR was 5.2 y [0.2-17.1]. Ninety-two among the 130 patients (70.8%) had a positive PSMA PET/CT. One hundred eighty-four lesions were detected, 97/184 in lymph nodes (52.7%), 47/184 in bone (25.5%), 34/184 into prostate bed (18.5%) and 6/184 (3.3%) in peritoneal nodules. PSMA detection rates were 59.6 %, 73.9 % and 81.1% for patients with PSA value ranging from 0.05 to 0.29, 0.3 to 0.59 and 0.6 to 1.59 ng/ml respectively. Univariate analysis revealed PSA value before PSMA, PSA doubling time and PSA velocity as potential predictive factors for positive 68Ga-PSMA PET/CT ($p = 0.008$ to 10^{-4}). In multivariate analysis, only PSA velocity was identified as significant independent predictor of positive 68Ga-PSMA PET (adjusted odd of 4.35 - 95%CI: [1.79-10.58], $p = 0.001$). Thanks to PSMA PET/CT, therapeutic management changed in 71/130 patients (54.6%). Take the example of 33 patients, previously treated by surgery and bed prostate radiotherapy, who would have a surveillance due to low PSA increase: 23 of them (70%) were able to have stereotactic radiotherapy on PSMA positive areas. For 5/23 (21.7%) and 12/23 (52.2%) of them, a decrease of more than 90% or 50% of PSA level after treatment was observed respectively. Considered all the cohort, a major impact on PSA value was observed with a decrease of more than 90% or 50% of PSA level from few weeks after treatment in 34/130 (28.4%) and 62/130 (47.7%) respectively. This continues for 46/130 patients (35.5%) who were still in biochemical complete remission, after PSMA based treatment with a median follow-up of 23.4 months [14.5-30.5]. **Conclusion:** Results showed, in more than half of patients, a major impact of PSMA PET/CT on treatment

management allowing them to benefit very early from focal PSMA based therapy with a long-term biochemical complete response for 35.5% of them. **References:** Rousseau C et al., doi: 10.1002/pros.23869.

OP-642

Forced diuresis with furosemide increases diagnostic certainty in the assessment of local recurrence in prostate cancer patients with biochemical recurrence referred for [⁶⁸Ga]Ga-PSMA-11-PET/CT compared to patients without preparation

C. Uprimny, S. Bayerschmidt, A. S. Kroiss, H. Sviriydenka, G. di Santo, B. Nilica, S. Rauch, E. von Guggenberg, C. Decristoforo, I. J. Virgolini;
Medical University of Innsbruck, Innsbruck, AUSTRIA.

Aim/Introduction: On [⁶⁸Ga]Ga-PSMA-11-PET/CT tracer accumulation in the bladder is reduced with furosemide. The purpose of the study was (a) to evaluate whether forced diuresis with furosemide has the potential to increase diagnostic certainty in the assessment of local recurrence (LR) in prostate cancer patients with biochemical recurrence in comparison with patients without preparation and (b) whether furosemide has an influence on biodistribution and uptake of [⁶⁸Ga]Ga-PSMA-11 in organs with physiologic tracer accumulation. **Materials and Methods:** two groups with 140 prostate cancer patients each, referred for [⁶⁸Ga]Ga-PSMA-11-PET/CT because of biochemical recurrence after primary were compared: group one (median PSA: 1.39 ng/ml) receiving no preparation prior to imaging, whereas patients in group two (median PSA: 0.87 ng/ml) were injected with 20 mg furosemide shortly after tracer injection. Evaluation of presence of LR was performed visually. In addition intensity of tracer accumulation in lesions suspicious of LR and in organs with physiologic tracer uptake was assessed using maximum standardized uptake value (SUV_{max}). **Results:** Lesions with pathologic tracer uptake judged as LR were found in 26 cases of group one (18.6%), compared with 39 cases in group two (27.9%), showing a median SUV_{max} of 9.3 (range: 3.9–37.0) and 8.0 (range: 3.2–52.7), respectively. In 21 cases of group one an equivocal finding was present (21%), compared with 17 cases in group two (12.1%). No LR was detected in 93 cases of group one (66.4%) and in 84 cases of group two (60%). Findings between both groups differed statistically significantly. Median SUV_{max} values of organs and tissues with physiologic uptake of [⁶⁸Ga]Ga-PSMA-11 in group one and two were: liver (10.3 vs 10.2), spleen (11.6 vs 12.1), parotid gland (19.7 vs 19.7), lacrimal gland (8.5 vs 10.2), small bowel (16.2 vs 17.0), bone (1.6 vs 1.7), vascular activity (2.2 vs 2.4), kidney (55.8 vs 55.7) and bladder (62.4 vs 9.7). Apart from bladder activity no statistically significant difference between the two groups was found. **Conclusion:** Forced diuresis with 20 mg furosemide increases detection rate of local

recurrence in patients with biochemical recurrence referred for [⁶⁸Ga]Ga-PSMA-11-PET/CT in comparison with patients without preparation. Apart from a significant reduction in bladder activity injection of furosemide shortly after tracer administration did not influence intensity of tracer uptake in organs with physiologic tracer accumulation. **References:** None

OP-643

The influence of digital PET/CT on diagnostic certainty and interrater reliability in ⁶⁸Ga-PSMA-11 PET/CT for recurrent prostate cancer

I. Alberts, J. Hünemann, C. Sachpekidis, C. Mingels, V. Fech, K. Bohn, A. Rominger, A. Afhsar-Oromieh;
Institut für Nuklearmedizin, Bern, SWITZERLAND.

Aim/Introduction: To evaluate the influence of digital PET/CT on diagnostic certainty, sensitivity and inter-rater reliability. **Materials and Methods:** This retrospective study compared two cohorts of patients who underwent ⁶⁸Ga-PSMA-11 PET/CT on a digital PET/CT (dPET/CT) (n=82) or an analogue scanner (aPET/CT) (n=82) for recurrent prostate cancer (PC). Both cohorts were matched for clinical parameters. Four physicians (consultant nuclear medicine physician, two experienced residents and a junior resident) read each scan independently and were blinded to clinical details and each other's results. Lesions were rated according to PSMA-RADS criteria. The number of equivocal and pathological lesions as well as the frequency of discrepant findings and the interrater reliability for the two scanners were compared. **Results:** Overall dPET/CT detected greater numbers of all lesion types compared to aPET/CT (benign p<0.001, equivocal p=0.005, pathological p=0.05155). Likewise, a significantly higher patient-based sensitivity (number of scans rated by all four readers as pathological) was observed for dPET/CT (84% vs. 58%, p<0.05). The higher number of lesions detected resulted in a higher false discovery rate (proportion of non-pathological lesions as a total of all lesions detected) for dPET/CT compared to aPET/CT (60.7% vs 56.4%, p=0.008), but not at the cost of increased diagnostic uncertainty (equivocal lesions for dPET/CT 11.6% vs aPET/CT 12.6%. p=0.4). No significantly increased rate of discrepant scans (where one or more readers differed in opinion as to whether the scan is pathological) was observed for dPET/CT compared to aPET/CT (20% vs. 16% respectively, p=0.18). However, interrater reliability was slightly lower for dPET/CT (PET/CT Krippendorff's $\alpha=0.72$ substantial agreement,) compared to aPET/CT ($\alpha=0.82$ almost perfect agreement). Interrater reliability did not improve with reader experience and did not correlate with the number of, or discrepancies in, the finding of equivocal lesions. **Conclusion:** Our results demonstrate a higher rate of detection for pathological lesions and higher patient based sensitivity for dPET/CT compared with aPET/CT, in

keeping with the known improved sensitivity and tumour-to-background ratio in dPET/CT. This improved sensitivity was coupled with slightly improved diagnostic certainty, with a lower rate of equivocal results. The higher sensitivity, however, was at the cost of higher false detection rates and lower interrater agreement, although interrater agreement showed no relationship with diagnostic uncertainty.

OP-644

The value of early dynamic imaging in ⁶⁸Ga-PSMA PET/CT in prostate cancer patients with biochemical recurrence

S. Castro, G. Ferreira, L. Violante, J. Teixeira, I. Sampaio Lucena, H. Duarte;

Portuguese Institute of Oncology - Porto, Porto, PORTUGAL.

Aim/Introduction: ⁶⁸Ga-PSMA urinary bladder accumulation may hinder locoregional prostate cancer (PC) lesion detection. The aim of this study is to determinate if an early ⁶⁸Ga-PSMA-PET/CT acquisition may improve PSMA-avid lesion detection in patients with biochemical recurrence. **Materials and Methods:** Retrospective study of 148 patients with PC biochemical relapse (after prostatectomy/radiotherapy), referred for ⁶⁸Ga-PSMA-PET/CT scan between 01/01/2018 and 30/06/2018 (mean age 71 ±7.8 years; median prostate specific antigen: 3.5 [IQR 7.0] ng/mL; median Gleason score 7). Early dynamic pelvic ⁶⁸Ga-PSMA-PET/CT scans were acquired immediately after tracer injection during 10 minutes, and whole-body ⁶⁸Ga-PSMA-PET/CT scans were acquired 42-79 (mean 60.9 ±8.9) minutes after tracer injection (median activity 108.2MBq). Images were reviewed by two Nuclear Medicine physicians and suspicious lesions for PC were noted. Quantitative uptake (SUVmax) of PC lesions and background tissue (gluteus muscle, left external iliac artery and bladder) was evaluated in both sets of images and compared using Intraclass Correlation Coefficient (ICC), Wilcoxon matched-pair signed-rank test and Bland-Altman analysis. **Results:** A total of 114 patients presented PC lesions (detection rate: 77%) and 149 lesions were analyzed: 43 within the prostate gland/prostatic fossa, 101 lymph node and 5 bone metastasis. There was a strong correlation between initial and late images' quantitative uptake in total (ICC 0.943 [p<0.001]), prostate (ICC 0.864 [p<0.001]), lymph node (ICC 0.949 [p<0.001]) and bone lesions (ICC 0.846 [p=0.056]). No significant difference was found in the quantitative uptake of total, lymph node and bone lesions across the two measured time points, while prostate lesions exhibited only slightly higher tracer uptake on late images (median SUVmax 9.10 [IQR 7.30] initial vs 10.13 [IQR 11.70] late, mean bias -2.34 ±5.42, p<0.001). On the other hand, bladder activity was much higher on late images (median SUVmax 1.83 [IQR 2.50] initial vs 47.40 [IQR 52.00] late, mean bias -54.82 ±46.18, p<0.001), hindering PC lesions detection in 4 cases, which

were only visible in early images and later confirmed with a post-diuretic acquisition. Muscle and vascular activity was higher in early images (median SUVmax 1.70 [IQR 0.70] and 5.72 [IQR 2.00] initial vs 0.73 [IQR 0.30] and 1.53 [IQR 0.50] late, p<0.01). **Conclusion:** Early dynamic ⁶⁸Ga-PSMA-PET/CT imaging showed comparable lesion uptake to late whole-body imaging, while bladder activity was significantly higher at later time points. Performing an additional early acquisition provides a window of opportunity to identify lesions with low background activity and may improve the detection rate of pelvic lesions in PC patients. **References:** None.

OP-645

Is there any clinical-pathological variable able to predict a true positive ⁶⁸Ga-PSMA PET/CT result?

J. Bastidas, F. Grisanti, J. J. Rosales, A. Bronte, A. Erhard, B. Miñana, C. Guitierrez, J. Perez Gracia, J. A. Richter, M. Rodriguez; Clinica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: To define clinical-pathological variables that allow to predict the positivity of ⁶⁸Ga-prostate-specific membrane antigen (PSMA) PET/CT for detecting relapse of treated prostate cancer (PCa). **Materials and Methods:** Inclusion criteria was: Patients with biochemical recurrence (BQR) in whom PSMA findings should be confirmed by 1) histopathological study; 2) Prostate-specific agent (PSA) response after salvage therapy (radiotherapy or surgery); 3) other image methods. Clinical and pathological variables were also collected. Patients were stratified into three different clinical scenarios: persisting detectable PSA after radical prostatectomy (Group-1), first-time BQR after curative intent treatment (Group-2), and BQR after salvage therapy (Group-3). By definition, negative PSMA results were considered False Negative (FN). The association between variables was assessed using univariate and multivariate Cox regression analysis. For categorical variables, Chi-square was used, and for continuous variables, Mann-Whitney test was used. Values are expressed as mean (±standard deviation) or median (P25-P75). **Results:** Sixty-eight patients were retrospectively studied. The PSA at PSMA study was 2.5 (±6.6) ng/ml, the PSA-doubling time was 8.5 (±10.2) months and the PSA-velocity was 0.17 (±0.37) ng/ml/month. The Gleason score was ≤7 in 45/68 (66%). Eleven patients (18%) were under androgen-deprivation therapy. The True Positive (TP) rate was 70,5% (48/68) confirmed by a histopathological study in 4 patients, PSA response after salvage therapy in 28 and by other image methods in 16. The FN were 20/68 (29,4%). No clinical-pathological variables were found to be significantly correlated with a TP PSMA result. However, when patients were studied by clinical scenarios, to belong to Groups 1 (n=13) and 2 (n=14) multiplied by 5 (OR = 5, 95% CI: 1.64-15.29, p = 0.005) the probability of having an FN result. Moreover, Group 3 (n=41)

FN patients had lower values than TP patients for: PSA 1.08 (0.95–1.76) vs. 1.63 (0.89–2.9) $p > 0.5$; PSA-doubling time 10.67 (3.36–16.17) vs. 4.09 (1.9–8.6) $p > 0.5$ and PSA-velocity 0.03 (0.015–0.08) vs. 0.08 (0.04–0.18) $p = 0.1$. **Conclusion:** In this study, no clinical-pathological variable was found to predict a true positive PSMA result. Nevertheless, differences were found between clinical scenarios. With patients who have persisting detectable PSA after radical prostatectomy or patients with first-time BQR after curative intent treatment, have a five times greater probability of an FN result. Interestingly, patients with an FN result in the group with BQR after rescue therapy had lower values of PSA, PSA_{dt} at PSMA, being almost statistically significant for PSA velocity.

Pathological lesions are at risk to be missed in linear colour scales in ⁶⁸Ga-PSMA-11 PET/CT

C. Mingels¹, C. Sachpekidis^{1,2}, J. Hünermund¹, K. P. Bohn¹, V. Fech¹, A. Rominger¹, A. Afshar-Oromieh¹, I. Alberts¹;

¹Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,

²Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY.

Aim/Introduction: Despite being a primarily visual speciality, the optimal colour scale for viewing fused images in PET/CT has been inadequately investigated. The aim of this study was to evaluate the influence of linear and non-linear colour scales in ⁶⁸Ga-PSMA-11 PET/CT for recurrent prostate cancer. **Materials and Methods:** A retrospective evaluation of 50 consecutive patients undergoing PET/CT for recurrent prostate cancer with ⁶⁸Ga-PSMA-11 was performed. Three separate readers (one consultant and two experienced residents) read all scans in randomised order and were blinded to clinical details and each other's analyses. Each scan was read first using the non-linear "PET-rainbow" look-up table, re-randomised and then read in the linear "hot-metal new" look-up table. Readers were blinded to the maximum intensity projection and stand-alone PET images. They were asked to rate all lesions using only the fusion PET/CT for each colour look-up table. Lesions were classified with a three-point scale (benign, pathological and equivocal). The average number of pathological lesions per patient (paired t-test) and inter-rater reliability (Fleiss' κ) were compared for each colour scale. Lesions were validated by composite follow-up of histology, radiology and laboratory parameters. **Results:** A greater number of lesions per patient ($p = 0.002$) rated as pathological were reported by all three readers in the "PET-rainbow" scale (mean 2.98 ± 2.47) compared to the "hot-metal new" scale (mean 2.63 ± 2.45). On a per patient basis, a total of 40 scans (80%) were rated as pathological in "PET-rainbow" and 37 (74%) in "hot-metal new" respectively. Clinical follow up was available for 30

patients, confirming 27/30 true positive scans for "PET-rainbow", 25/30 true positive scans for "hot-metal new", and two false negative scans in "hot-metal new". Both colour scales correctly identified one true negative patient. Follow-up identified no false positive scans for either scale. However, inter-rater reliability was slightly higher for "hot-metal new" (Fleiss' κ : 0.64) compared to "PET-rainbow" (κ : 0.58). **Conclusion:** A linear colour scale like "hot-metal new" demonstrated lower patient-based sensitivity, and incorrectly identified two patients as having negative scans (false negatives at follow-up). Conversely, the non-linear colour scale "PET-rainbow" showed superior sensitivity and positive predictive value, albeit with a slightly lower inter-rater agreement. The differences between the two colour-scales find explanation in the physical properties of the tracers and colour scales. Our results suggest that use of PET-rainbow is better suited to imaging with ⁶⁸Ga-PSMA-11 PET/CT and should be implemented for clinical routine use as well as for clinical studies. **References:** None

Fully-automatic data-driven motion correction improves the diagnostic performance of myocardial perfusion imaging with CZT cameras

C. Ko^{1,2}, K. Ko¹, R. Yen¹, C. Chen²;

¹National Taiwan University Hospital, Taipei, TAIWAN, ²Biomedical Engineering, National Taiwan University, Taipei, TAIWAN.

Aim/Introduction: Myocardial perfusion imaging (MPI) sometimes suffered from motion artifacts. The motion artifacts can cause image blurring and may degrade the diagnostic accuracy. Data-driven motion correction can be performed on list-mode enabled CZT cameras, and this may reduce the artifacts. We have developed a fully-automatic motion correction algorithm (NoMo software) with the aid of deep-learning technique. This study aimed to evaluate the effects of this algorithm on the diagnostic performance of coronary artery disease (CAD). **Materials and Methods:** We unselectively recruited 9469 consecutive subjects referred for routine treadmill-exercise MPI between June 2011 and Dec 2017. Among them, 1115 subjects with subsequent coronary angiography within 180 days were analyzed.

The images were automatically segmented and rotated with the aid of a trained deep-learning model for further analysis. The emitted photon events were binned into five respiratory gates and were reconstructed into motion-corrected images. The original and corrected images were independently scored on the AHA 17-segment model with manual verification. Summed scores were used to predict obstructive CAD ($\geq 70\%$ stenosis). Receiver operating characteristics (ROC) analysis was used to evaluate the diagnostic performance. A p-value of less than 0.05 was considered significant. **Results:** The heart excused more in post-stress images than in redistribution images (10.0 ± 3.9 mm vs. 7.6 ± 3.1 mm, $p < 0.01$). ROC analysis showed significantly increased area under curve (AUC) for corrected images in prediction of CAD (0.796 vs 0.741, $p < 0.01$). Vessel-based analysis also showed significantly increased AUC (LAD: 0.750 vs. 0.696, LCX: 0.754 vs. 0.716, RCA: 0.729 vs. 0.672, all $p < 0.01$). One-third of the falsely positive studies can be avoided with motion correction. **Conclusion:** The diagnostic performance of MPI can be improved with fully automatic motion correction. This technique can reduce significant amount of falsely positive studies. **References:** None

Evaluation Of Coronary Flow Reserve By A New Method Using Routine Myocardial SPECT And Comparison To Dynamic SPECT With The Same Patients For Both Methods

L. Philippe¹, M. Bailly², Y. El Yaagoubi¹, C. Prunier-Aesch¹;

¹Medecine Nucleaire Tourangelle, Chambray-les-Tours, FRANCE,

²Médecine Nucléaire - CHR Orléans, Orléans - La Source, FRANCE.

Aim/Introduction: Coronary Reserve assessment in Nuclear Medicine is usually performed using the “Dynamic SPECT” method with a CZT gamma-camera. We evaluate a new method, previously described (EANM 2019), without first-pass, using the short axis slices of a routine ^{99m}Tc-Tetrofosmin SPECT, providing an estimation of the Coronary Flow Reserve (CFR) by means of a Coronary Reserve Index (CRI). Counts ratio (myocardial Stress/Rest) represents the CRI, after adjustments with 5 corrective factors. In order to validate the CRI method, we compare results obtained with both methods (Dynamic SPECT and routine SPECT). **Materials and Methods:** Patients referred for dynamic Myocardial Perfusion Image (MPI) between November 2018 and March 2020 with Invasive Coronary Angiography (ICA) performed within 3 months were included. SPECT data were acquired on a CZT-based pinhole cardiac camera using Stress / Rest one-day Tc-^{99m}-tetrofosmin protocol. Kinetic analysis was done with Corridor 4DM™ software using a 1-tissue-compartment model and converted to MBF using a previously determined extraction fraction correction. Furthermore, we applied the new CRI method, to the data

SPECT of a series of 25 patients who previously underwent a Dynamic SPECT. Unlike Dynamic SPECT, CRI method can be applied subsequently to the SPECT acquisition, or can be linked to the standard SPECT processing. Comparison of the 2 methods (“Dynamic” and CRI) concern the diagnosis of CAD: according to ICA, 15 patients had significant CAD: 3 patients had 3-vessels disease, 8 patients 2-vessels disease, and 4 patients one-vessel disease. A coronary stenosis was considered as significant over 30%. **Results:** For “Dynamic” SPECT method, the cut-off value Normal vs CAD, was 2.0. Among the 25 patients, this method induced 14 true positives, 7 true negatives, 1 false negative, and 3 false positives (probably related to microvascular alteration), giving 93% Sensitivity - 70% Specificity - 82% Positive Predictive Value - 88% Negative Predictive Value. 21/25 patients are well classified, and the ROC AUC = 0.78. For the CRI method, we observe 15 true positives, 7 true negatives, 0 false negative, and 3 false positives (different of “Dynamic” SPECT), giving 100% Sensitivity - 70.0% Specificity - 83% Positive Predictive Value - 100% Negative Predictive Value. 22/25 patients are well classified, and the ROC AUC = 0.78. **Conclusion:** The diagnostic value of both methods are good and quite similar. Results show that maybe, these methods don't evaluate exactly the same physiological process (epicardial CFR \pm micro-circulation). **References:** None

OP-650

The evaluation of myocardial blood flow and coronary flow reserve in myocardial infarction with non-obstructive coronary arteries patients

K. Zavadovsky, A. Mochula, A. Maltseva, D. Vorobyeva, M. Gulya, V. Shipulin, V. Ryabov;

Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: To elucidate the severity of myocardial perfusion, myocardial blood flow (MBF) and myocardial flow reserve (MFR) impairment in patients with myocardial infarction with non-obstructive coronary arteries (MINOCA) in comparison to those with MI with obstructive coronary artery disease (MICAD) and non-obstructive stable coronary artery disease (CAD). **Materials and Methods:** The study group comprised 40 patients (29 men, age 62.9 ± 10.7 years) who underwent ECG and invasive coronary angiography (ICA). Based on ICA results three groups were created: 1. MINOCA (n=11); 2. MICAD (n=17); 3. Control group - stable CAD with non-obstructive coronary arteries (n=12). A total of 12/17 (71%) MICAD patients underwent PCI with stenting; in 2/12 cases two arteries were revascularized. The first and the second groups of patients underwent Creatine phosphokinase-MB (CPK-MB) and Troponin I (TnI) assessment at admission and after 24 hours. In 7-10 days all patients underwent myocardial perfusion CZT

gamma-camera with the assessment of standard indices of myocardial perfusion (SSS, SRS, SDS) and quantitative parameters: rest MBF (rMBF), stress MBF (sMBF) and MFR. **Results:** After 24 hours cardiospecific biomarkers levels in MINOCA group were significantly ($p < 0.05$) lower compared to MICAD group patients: CPK-MB 21.5 (IQR 13.7;45.0) vs. 94.4 (53.1;217.0) U/L; Tnl 0.5 (0.1;3.3) vs. 9.8 (2.0;23.0) ng/ml. Standard myocardial perfusion indices differed significantly ($p < 0.05$) among all three groups (except SDS between the first and second groups): MINOCA: SSS 5.0 (3.0;6.0), SDS 2.0 (1.0;3.0); MICAD: SSS 9.0 (5.0;13.0), SDS 3.0 (2.0;5.0); control group: SSS 1.5 (0.5;2.0), SDS 0.0 (0.0;2.0). However, sMBF and MFR differed significantly in all three groups of patients: MINOCA: sMBF 1.2 (0.8;1.7) ml/min/g, MFR 2.0 (1.2;2.4); MICAD: sMBF 0.7 (0.6;1.0) ml/min/g, MFR 1.2 (1.1;1.5); control group: sMBF 2.2 (2.1;2.3) ml/min/g, MFR 2.6 (2.5;2.8). In 7/11 (64%) of MINOCA patients the value of sMBF was ≤ 1.5 ml/min/g. In the MICAD group 16/17 (94%) had sMBF ≤ 1.5 ml/min/g and all control group patients had sMBF > 1.5 ml/min/g. In 4/11 (36%) of MINOCA patients MFR values were less than 2; in MICAD group MFR < 2 was observed in 15/17 (88%) patients. **Conclusion:** MINOCA patients are heterogeneous in terms of myocardial perfusion, MBF and MFR impairment. Despite the absence of obstructive coronary artery lesion, myocardial perfusion and blood flow assessed semiquantitatively and quantitatively are impaired more severely in MINOCA group, compared to stable CAD patients. This study was supported by the Russian Federation President Grant MK-1347.2020.7. **References:** None

Determinants of myocardial perfusion reserve assessed by dynamic stress $^{201}\text{Tl}/\text{rest}^{99\text{mTc}}\text{-tetrofosmin}$ single photon emission computed tomography in patients with diabetes mellitus and stable coronary artery disease

J. Choi, E. Shin, M. Oh, S. Chae, C. Lee, D. Moon;

Asan Medical Center, Seoul, KOREA, REPUBLIC OF

Aim/Introduction: Quantification of myocardial perfusion reserve (MPR) provides predictive information on cardiovascular outcome. We aimed to identify determinants of myocardial flow reserve in patients with type 2 diabetes mellitus and stable coronary artery disease. **Materials and Methods:** We conducted a prospective study to enroll consecutive patients who were aged 19 years or older, and had type 2 diabetes mellitus and stable coronary artery disease. All patients underwent dynamic stress $^{201}\text{Tl}/\text{rest}^{99\text{mTc}}\text{-tetrofosmin}$ single photon emission computed tomography (SPECT) using a dedicated multiple pinhole camera with cadmium-zinc-telluride detectors. **Results:** Between July 2017 and September 2019, we included 277 patients for analysis. There were 236 men, and 41 women. The median age was 65 [interquartile range (IQR), 59-71]. The median global MPR was 2.4 [1.9-3.0]. Characteristics

of patients that showed a significantly lower MPR were advanced age of more than 70 years ($n=74$, 2.2 [1.8-2.6] vs. 2.4 [2.0-3.0], $P=0.034$), smoking history ($n=63$, 2.2 [1.8-2.4] vs. 2.5 [2.0-3.1], $P=0.0004$), hyperlipidemia ($n=85$, 2.2 [1.9-2.6] vs. 2.5 [1.9-3.1], $P=0.021$), hypertension ($n=204$, 2.3 [1.9-2.8] vs. 2.6 [2.0-3.2], $P=0.013$), and abnormal summed stress score of myocardial perfusion scan ($n=136$, 2.2 [1.7-2.7] vs. 2.5 [2.1-3.1], $P < 0.0001$). Body mass index of 30 or higher, prior history of myocardial infarction or coronary intervention, and left ventricular dysfunction were not associated with global MPR ($P > 0.1$). Multivariate linear regression analysis showed that age of more than 70 years ($P=0.0098$), smoking history ($P=0.0012$), hypertension ($P=0.013$), and abnormal summed stress score of myocardial perfusion scan ($P=0.0011$) were independent determinants of MPR. **Conclusion:** Advanced age and cardiovascular risk factors are determinants of MPR assessed by dynamic stress $^{201}\text{Tl}/\text{rest}^{99\text{mTc}}\text{-tetrofosmin}$ SPECT in patients with type 2 diabetes and stable coronary artery disease. **References:** None

OP-652

Comparison of dynamic SPECT Myocardial Blood Flow and Flow Reserve with regadenoson and dipyridamole

M. Bailly¹, Q. Brana¹, F. Thibault¹, M. Courtehoux², G. Metrard¹, D. Angoulvant², M. Ribeiro²;

¹CHR Orléans, Orleans, FRANCE, ²CHRU Tours, Tours, FRANCE.

Aim/Introduction: Regadenoson is a recent selective A2A adenosine receptor agonist. It is currently unclear if the absolute stress flow increase differs between pharmacological stress agents. We compared dipyridamole and regadenoson Myocardial Blood Flow (MBF) and Myocardial Flow Reserve (MFR) values obtained with dynamic Cadmium Zinc Telluride (CZT) SPECT Myocardial Perfusion Imaging (MPI), to evaluate if they could induce the same level of hyperemia. **Materials and Methods:** Patients referred for dynamic MPI for Coronary Artery Disease (CAD) screening between November 2018 and March 2020 were retrospectively analyzed. SPECT data were acquired on a CZT camera, using 1-day stress/rest $^{99\text{mTc}}\text{-tetrofosmin}$ dynamic protocol. All analysis was performed using Corridor 4DM. To rule out confounding factors, patients with prior cardiac disease, ischemia or infarction and diabetes were excluded in a sub-group analysis. The remaining patients were matched for clinical characteristics (age, gender, BMI, cardiovascular risk factors) and compared in terms of stress MBF and MFR. **Results:** 162 patients stressed with dipyridamole were compared with 66 patients stressed with regadenoson. Global MFR wasn't different between regadenoson and dipyridamole groups (2.46 ± 0.87 vs. 2.64 ± 1.02 respectively for dipyridamole and regadenoson, $p=0.36$) but stress MBF was higher in regadenoson group (1.71 ± 0.73 vs. 1.44 ± 0.55 ml/min/g respectively for regadenoson and dipyridamole, $p < 0.05$). When potential pathological patients were

excluded, two groups of 41 patients comparable in terms of age, gender, BMI, resting left ventricular ejection fraction, cardiac risk factors and cardiovascular treatments at the time of evaluation ($p=0.2$ at least) were analyzed. Mean global MFR wasn't different between the two groups: 2.62 ± 0.77 and 2.46 ± 0.76 respectively for dipyridamole and regadenoson ($p=0.88$). Stress MBF wasn't significantly different between dipyridamole (1.57 ± 0.56 ml/min/g) and regadenoson patients (1.61 ± 0.62 ml/min/g) ($p=0.88$). **Conclusion:** Regadenoson showed higher stress MBF values in our global results, but dipyridamole and regadenoson induced equivalent hyperemia with similar global stress MBF and MFR when confounding factors were ruled out. These results should be confirmed on a large, prospective and randomized study. **References:** None

Quantification of Myocardial Flow Reserve using Dynamic CZT camera in Symptomatic Patients with Multiple Vessels Disease

D. Agostini¹, G. Liu², A. Manrique¹, H. Shi²;

¹Department of Nuclear Medicine, CHU Caen Normandy, Caen, FRANCE, ²Department of Nuclear Medicine, Zhongshan Hospital Fudan University, Shanghai, CHINA.

Aim/Introduction: Quantification of myocardial flow reserve (MFR) by CZT has previously demonstrated diagnostic value in patients with stable CAD in comparison with PET and FFR (Agostini D et al 2018). We appraised the feasibility of myocardial blood flow (MBF), MFR and LVEF estimation using dynamic CZT camera in symptomatic patients with multiple vessels disease (MVD). **Materials and Methods:** 52 patients (42M, 10F; 60 ± 12 yrs) with chest pain and/or dyspnea underwent dynamic CZT and angiography within a 3 month timeframe. A stenosis was considered obstructive if greater than 50%. All pts had MVD. All pts underwent one-day dynamic rest (296 ± 29 MBq)/regadenoson stress (865 ± 95 MBq) myocardial perfusion imaging by ^{99m}Tc-sestamibi CZT SPECT to measure MBF and LVEF. For SPECT, reconstructed frames were automatically segmented to extract the vascular input function and the LV uptake curve. A net retention model was used to estimate global uptake values, and then MBF was derived using Leppo correction. MFR was defined as the ratio of stress MBF over rest MBF using a commercially available software (4DM, Invia, Ann Arbor, MI). **Results:** We divided pts into 2 groups: G1 with normal stress LVEF >50%, n=43; and G2 with LVEF <50%; n=9. Stress MBF in G1 was significantly higher (2.35 ± 0.86) than in G2 (1.38 ± 0.62 ml/min/g; $P=0.0006$). Rest MBF was identical in G1 (0.96 ± 0.29) and in G2 (0.81 ± 0.22 ml/min/g; $P=ns$). MFR in G1 was significantly higher (2.59 ± 1.04) than in G2 (1.66 ± 0.42 ; $P<0.0001$). Stress MBF and MFR correlated well with stress LVEF ($r=0.54$; $r=0.45$; $P=0.0008$). No gender variation was observed for MBF and MFR. **Conclusion:**

Stress MBF and MFR data using dynamic ^{99m}Tc-sestamibi CZT were decreased in pts with LV dysfunction and appeared to correlate well with stress LVEF in pts with MVD. **References:** Agostini D et al. Eur J Nucl Med Mol Imaging. 2018;45(7):1079-1090

OP-654

The detection of multivessel coronary artery disease: the value of SPECT CZT myocardial blood flow and coronary flow reserve assessment

K. Zavadovsky¹, A. Mochula¹, A. Maltseva¹, A. Baev¹, S. Andreev¹, R. Liga², A. Gimelli³;

¹Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION, ²Università di Pisa, Pisa, ITALY, ³Fondazione Toscana/CNR Gabriele Monasterio, Pisa, ITALY.

Aim/Introduction: The recent Cadmium-Zinc-Telluride (CZT) camera for myocardial perfusion scintigraphy allows evaluating absolute myocardial blood flow (MBF) and coronary flow reserve (CFR), possibly increasing the accuracy in detecting of multivessel coronary artery disease (CAD). The aim of this study is to evaluate the accuracy of stress MBF and CFR quantitation performed by myocardial perfusion scintigraphy for the detection of multivessel CAD.

Materials and Methods: Fifty-two patients with suspected or known CAD were enrolled in the study. All patients underwent CZT MPS, with the evaluation of MBF and CFR, followed by invasive coronary angiography. According to MPS and coronary angiography results, patients were divided into three groups. 1) non-obstructive CAD and normal MPS scan (control group) (n=7), 2) one vessel disease (1VD) (n=16), with significant coronary stenosis ($\geq 70\%$) in one major epicardial coronary artery, 3) multivessel disease (MVD) group (n=29), with two or more major epicardial coronary arteries with ($\geq 70\%$) stenoses or with $\geq 50\%$ LMA stenosis. **Results:** Absolute MBF and CFR were significantly reduced in patients with MVD as compared to those with 1VD [0.93 (IQR 0.76; 1.39) vs 1.94 (1.37; 2.21) ml/min/g, $p=0.00012$] and [1.4 (IQR 1.02; 1.85) vs 2.3 (1.8; 2.67), $p=0.0004$], respectively. The Syntax score correlated with global stress MBF ($\rho=-0.64$; $p<0.0001$) and CFR ($\rho=-0.53$; $p=0.0003$). ROC analysis showed higher sensitivity and specificity for stress MBF (85.2% and 81%), and CFR (88.9% and 80%) compared with semiquantitative MPS stress evaluation (69% and 69%). Multivariate regression analysis showed that only stress MBF [OR (95% CI) 0.59 (0.42-0.82); $p<0.0003$] was an independent predictor of MVD. **Conclusion:** The use of absolute myocardial blood flow analysis with the CZT camera may identify high risk patients, such as those with multivessel disease. This approach could be used in clinical practice, increasing the accuracy in the evaluation of patients with known or suspected coronary artery disease. **References:** None

OP-655**Assessment Of Coronary Flow Reserve By Routine Tetrofosmin SPECT, Without First Pass: Comparison With Invasive Coronary Angiography And With Visual Calcium Score**

L. Philippe, Y. El Yaagoubi, C. Prunier-Aesch;

Medecine Nucleaire Tourangelle, Chambray-les-Tours, FRANCE.

Aim/Introduction: Coronary Flow Reserve (CFR) assessed by SPECT is not always in agreement with the evaluation of the % stenosis. At least two reasons can explain these discrepancies: Invasive Coronary Angiography (ICA) provides an anatomic approach, while SPECT gives a functional evaluation. Secondly, pathologies other than CAD can affect the CFR: dyslipidemia, HBP, diabetes, myocardial hypertrophy, ... We evaluate CFR by routine 99mTc-tetrofosmin-SPECT to assess the CAD severity, ICA nevertheless being the "gold" standard for CAD diagnosis. **Materials and Methods:** CFR is evaluated by computation using a 5 steps correction of the myocardial Stress/Rest counts-ratio as described previously, with slight algorithm improvement mainly related to the mathematical fit of the extraction curve (exponential model instead of polynomial fit) and to the more accurate time data directly obtained from the gamma-camera acquisition data. The 5 steps processing produces a Coronary Reserve Index (CRI) which was calculated in a series of 101 patients addressed to our institution for routine myocardial stress and rest perfusion SPECT. Among these patients, 56 patients underwent also ICA, 50 patients had visual estimation of the Calcium Score (vCS) and 5 patients, both vCS and ICA. vCS was performed using a 3 grades scale: normal (0), low to intermediate (1), important to severe (2). This evaluation was performed by means of the low dose CT used for attenuation correction (not sufficient for a quantitative score). We used only non-attenuation corrected short-axis SPECT slices for CRI computation. **Results:** The 56 ICA indicated, for an optimal discrimination between normal and CAD patients, a 3.0 CRI cut-off. Using this value, we observe 92% Sensitivity, 75% Specificity, 98% Positive Predictive value, and 43% Negative Predictive Value. The area under the ROC curve is 0.73. The comparison of the CRI and the 50 vCS shows a decrease of CRI when the vCS worsens: (mean CRI \pm 1 SD) Grade 0: 3.28 \pm 1.29 Grade 1: 3.00 \pm 1.25 Grade 2: 2.62 \pm 1.44. The differences are not significant, mainly due to the small number of patients in each group. **Conclusion:** CFR assessment by means of a CRI computed at the end of the routine 99mTc-tetrofosmin-SPECT is of value for CAD diagnosis. This assessment can be performed automatically for each patient, without additional time, and without additional injected dose activity. The CRI information, associated to the vCS improves the efficiency and reliability of the SPECT report. **References:** None

OP-656**Stunned Myocardium is Associated with Low Myocardial Flow Reserve using Dynamic CZT camera in Symptomatic Patients with Multiple Vessels Disease**D. Agostini¹, G. Liu², A. Manrique¹, H. Shi²;¹Department of Nuclear Medicine, CHU Caen Normandy,Caen, FRANCE, ²Department of Nuclear Medicine,

Zhongshan Hospital Fudan University, Shanghai, CHINA.

Aim/Introduction: Stunned myocardium is defined as a post-ischemic drop of LVEF >5% compared to rest conditions. We aimed to determine the myocardial blood flow (MBF) and flow reserve (MFR) using CZT camera in patients with multiple vessels disease (MVD) and stunned myocardium. **Materials and Methods:** 52 symptomatic patients (42M, 10F; 60 \pm 12 yrs) with chest pain and/or dyspnea and angiographically proven MVD underwent dynamic CZT and angiography within a 3 month timeframe. A stenosis was considered obstructive if greater than 50%. All pts underwent one-day dynamic rest (296 \pm 29 MBq)/regadenoson stress (865 \pm 95 MBq) myocardial perfusion imaging by ^{99m}Tc-sestamibi CZT SPECT to measure MBF and LVEF at both stress and rest. For SPECT, reconstructed frames were automatically segmented to extract the vascular input function and the LV uptake curve. A net retention model was used to estimate global uptake values, and then MBF was derived using Leppo correction. MFR was defined as the ratio of stress MBF over rest MBF using a commercially available software (4DM, Invia, Ann Arbor, MI). **Results:** We divided pts into 2 groups: G1 with a post stress reduction of LVEF >5%, n=14; and G2 without reduction of LVEF; n=38. Stress MBF was identical in G1 (1.91 \pm 0.98) and in G2 (2.28 \pm 0.62 ml/min/g; P= ns). Rest MBF was identical in G1 (0.93 \pm 0.29) and in G2 (0.95 \pm 0.29 ml/min/g; P= ns). However, MFR in G1 was significantly lower (1.93 \pm 0.55) than in G2 (2.61 \pm 1.1; P=0.005). No gender variation was observed for MBF and MFR. **Conclusion:** Stunned myocardium is associated with a low MFR using dynamic 99mTc-sestamibi CZT in symptomatic pts with MVD. **References:** None

OP-657**Long-term prognostic value of gated SPECT after acute myocardial infarction and primary percutaneous coronary intervention**

A. D'Antonio, E. Zampella, R. Assante, V. Gaudieri, C. Nappi, T.

Mannarino, G. De Simini, A. Giordano, V. Cantoni, R. Green, P.

Buongiorno, W. Acampa, A. Cuocolo;

Department of Advanced Biomedical Sciences,

University "Federico II" of Naples, Naples, ITALY.

Aim/Introduction: We evaluated whether changes in myocardial perfusion after acute myocardial infarction (AMI) and primary percutaneous coronary intervention (PCI) predict cardiac events at long-term follow-up. **Materials and**

Methods: We enrolled 112 patients referred to stress-rest gated SPECT myocardial perfusion imaging (MPI) at 1 month (baseline) and 6 months (control) after an AMI treated with primary PCI. Summed stress (SSS), summed rest (SRS), summed difference scores and left ventricular (LV) ejection fraction (EF) were obtained. MPI was considered worsened or improved according to $\geq 5\%$ change from baseline to control. End-diastolic (EDV) and end-systolic (ESV) volumes were measured and expressed as indexes (I). Remodeling was defined as an increase in LVEDVI $\geq 20\%$ from baseline to control. Patient follow-up was obtained and occurrence of cardiac death, MI and unstable angina requiring revascularization were considered as events. **Results:** During follow-up (86 \pm 38 months), 21 events occurred (19% cumulative event rate). Patients with events compared to those without at baseline had lower stress (43 \pm 11% vs. 48 \pm 10%, $p < 0.05$) and rest (42 \pm 10% vs. 48 \pm 10%, $p < 0.05$) EF, and higher stress (38 \pm 16 ml/m² vs. 30 \pm 14 ml/m², $p < 0.05$) and rest (38 \pm 17 ml/m² vs. 30 \pm 14 ml/m², $p < 0.05$) ESVI. At control, patients with events had higher stress ESVI (44 \pm 26 ml/m² vs. 29 \pm 14 ml/m², $p < 0.01$) and rest ESVI (41 \pm 20 ml/m² vs. 29 \pm 16 ml/m², $p < 0.01$) and lower rest EF (44 \pm 11% vs. 50 \pm 11%, $p < 0.01$), stress EF (44 \pm 11% vs. 51 \pm 11%, $p < 0.05$), rest EDVI (69 \pm 24 ml/m² vs. 54 \pm 18 ml/m², $p < 0.01$). Myocardial perfusion status worsened in 17 (15%) patients, improved in 43 (38%), and unchanged in 52 (46%). Annual event rate (AER) was higher (7%) in patients with worsening compared to both those with improvement (1%) and unchanged (2%) SSS (both $p < 0.001$). Resting remodeling was found in 13 (12%) patients. AER was higher in patients with remodeling compared to those without (9% vs. 1%, $p < 0.001$). At multivariate Cox analysis, SSS worsening ($p < 0.01$) and rest remodeling ($p < 0.001$), resulted independent predictors of events. At Kaplan-Meier analysis, event-free survival was lower in both patients with remodeling and SSS worsening (p for trend < 0.001). **Conclusion:** After AMI and primary PCI, worsening of SSS and cardiac remodeling are related to higher risk of cardiac events at long-term follow-up. Serial MPI is useful to improve risk stratification at long-term follow-up in patients after AMI and primary PCI. **References:** None

Complementary diagnostic value of PSMA PET and MR radiomics for prostate cancer staging

E. Solari¹, A. Gafita¹, D. Visvikis², W. Weber¹, M. Eiber¹, M. Hatt², S. G. Nekolla¹;

¹Nuklearmedizinische Klinik, Klinikum rechts der Isar, München, GERMANY, ²LaTIM, INSERM, Univ. Brest, Brest, FRANCE.

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-targeted positron emission tomography (PET) and magnetic resonance imaging (MRI) are the main imaging techniques for prostate cancer (PC) diagnosis. We previously showed that PSMA PET radiomics can predict Gleason scores. We investigated here the potential additive value of MR images (T1w, T2w, ADC maps) for PC staging.

Materials and Methods: Simultaneous PSMA PET/MR studies for primary staging of PC from a single scanner were retrospectively included. Gleason score (GS) was obtained in histopathology after radical prostatectomy. The entire prostate was manually segmented in PET and MR (T1w, T2w, ADC maps) images. Image biomarker standardization initiative (IBSI)-compliant handcrafted features (first order intensity, shape, texture) with fixed bin widths (8-128 discrete values) were extracted from both PET and MR prostate volumes. The train and validation scheme was stratified 5-fold cross-validation, balancing the training data with SMOTE. Between 1 and 20 features were extracted through recursive feature elimination (RFE). A radial-basis support vector machine (SVM) model with hyperparameter tuning was trained for the classification of GS by groups (≤ 7 , 8, ≥ 9). The performance (balanced accuracy, specificity and sensitivity) of the best classifiers on the validation data is reported as mean and standard deviation over the 5 folds.

Results: 130 patients were included in the analysis. 64% (83) of the patients exhibited a GS of 7, 21% (27) a GS of 8 and 15% (20) a GS of 9. The 5-fold averaged balanced accuracy of radiomics from T2w images (77.8 \pm 7.6%) was superior to that of PET (73.7 \pm 8.6%), ADC (71.3 \pm 12.0%) and T1w (73.2 \pm 12.3%). Combined PET+T2w radiomics accuracy (acc. 80.0 \pm 6.2%), sensitivities (GS \leq 7: 86.3%, GS=8: 70.6%, GS \geq 9: 78.0%) and specificities (GS \leq 7: 74.0%, GS=8: 90.5%, GS \geq 9: 92%) were superior to other combinations, including T2w-only radiomics (acc.: 77.8%; sens.: 78.7%, 75.0%, 72.2%; spec.: 84.2%, 82.3%, 85.9%). The combination of PET and all three MR image types did not improve the results from PET+T2w. **Conclusion:** Despite the unbalanced dataset, an accurate prediction of GS was achieved. The combined information gathered from PET and MR radiomics features slightly improved performance compared to PET-only and MR-only. The combination of PET and T2w images produced the best results. **References:** *This project is funded by the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 764458

OP-660**Complementarity of PET and MR radiomic features for the characterization of lung cancers**

F. Orlhac¹, M. Lacroix^{1,2}, I. Buvat¹, J. Bernaudin³, C. Nioche¹, M. Soussan^{1,4}, P. Brillet², F. Frouin¹;

¹Institut Curie, Inserm, U1288 LITO, Orsay, FRANCE, ²AP-HP, Hôpital Avicenne, Service de radiologie, Bobigny, FRANCE, ³Université Paris 13, Inserm, UMR 1272 Hypoxie et Poumon, Bobigny, FRANCE, ⁴AP-HP, Hôpital Avicenne, Service de médecine nucléaire, Bobigny, FRANCE.

Aim/Introduction: To study the complementarity of radiomic features extracted from PET and MR images of lung cancer patients for the development of radiomic signatures distinguishing between adenocarcinoma and other histological types. **Materials and Methods:** A prospective cohort of N=52 patients with an advanced lung cancer was studied. All patients underwent a pretreatment 18F-FDG PET scan and a T2-weighted MR at 3 Teslas. The tumor lesion was segmented with an adaptive threshold in the PET images. The MR images were preprocessed using a bias field correction and a normalization of voxel intensities with fat as a reference region [1], before lesion segmentation based on an intensity threshold manually set for each patient. Radiomic features were computed in 3D for PET images (48 features) and in 2.5D for MR images (44 features corresponding to the median value over all slices of each patient) with LIFEx [2]. A screening procedure based on leave-one-out cross-validation was used to identify radiomic models able to distinguish between adenocarcinoma and other lesion subtypes. The procedure involved: 1) selection of all features with a p-value of univariate Wilcoxon test lower than 0.005, 0.01, 0.05 or 0.10 for (N-1) learning patients, 2) based on these features, selection of only one feature among correlated features using a Pearson correlation cut-off varying from 0.95 to 0.50, 3) building of a radiomic signature using the linear discriminant analysis, 4) test of the model on the Nth patient. The performance was evaluated using the Youden Index (sensitivity+specificity-1). **Results:** 32 lesions were adenocarcinomas and 20 were another subtype. The screening procedure consistently demonstrated the best classification performance after strong univariate selection of features (p<0.01 in Wilcoxon test). Focusing on this selection setting, Youden Index was no greater than 0.33 for PET features, between 0.24 and 0.46 for MR features and between 0.30 and 0.54 when combining PET and MR features. In each case, the best performance was obtained with a small number of features: 1 feature for PET-only models, between 2 and 6 for MR-only models, and between 3 and 5 for PET-MR based models. **Conclusion:** Lung cancer subtypes can be better distinguished when combining a small number of PET and MR radiomic features than with many PET or many MR features separately, highlighting the

potential contribution of MR on top of PET for characterizing lung lesions. **References:** [1] Lacroix et al. Front Oncol 2020. [2] Nioche et al. Cancer Res 2018.

OP-661**Radiomics and FDG PET/CT in cervical cancer: a single centre experience**

F. Mattana¹, A. Farina¹, S. Telo¹, N. Fraccascia¹, G. M. Lima², S. Strolin³, E. Loi³, E. De Crescenzo⁴, A. M. Perrone⁴, P. De Iaco⁴, L. Strigari³, C. Nanni¹, S. Fanti¹;

¹Department of Nuclear Medicine, S.Orsola-Malpighi University Hospital, Bologna, ITALY, ²Department of Nuclear Medicine, Modena University Hospital, Modena, ITALY, ³Medical Physics Unit, S.Orsola-Malpighi University Hospital, Bologna, ITALY, ⁴Department of Obstetrics and Gynecology, S.Orsola-Malpighi University Hospital, Bologna, ITALY.

Aim/Introduction: To investigate the prognostic value of baseline 18F-FDG-PET/CT analysing the correlation between its radiomic variables (RV) with progression-free survival (PFS) and overall survival (OS) rates in patients with locally advanced cervical cancer (LACC) treated with concomitant-chemoradiation-therapy (CCRT). **Materials and Methods:** In our single center retrospective study, we have selected LACC patients treated with CCRT, who underwent baseline 18F-FDG-PET/CT from August 2007 to October 2017, performed using hybrid PET/CT scanners, according to EANM guidelines. Metabolic tumor volumes (MTV, i.e. volume of interest consisting of all spatially connected voxels within a fixed threshold of 40% of the SUVmax) was calculated following the TNM criteria: primary tumour, local/distant pathologic lymph nodes and metastasis were segmented using PET-edge tool included in the MIM software. RV extraction was performed with PyRadiomics version 2.0.1. A total of 99 RV were extracted from each region of interest and for each modality (PET or CT) and PFS and OS were calculated. The correlation between RV, OS and PFS was analyzed by both the univariate and multivariate analyses (UVA and MVA, respectively) using the Kaplan-Meier method and long-rank tests. **Results:** According to our inclusion criteria, we enrolled 114 patients. Patients characteristic were: median age: 61 (range 28-94); lesion histotypes: 90 squamous cell carcinomas, 16 adenocarcinomas and 7 of other histotypes; FIGO class: F2=1, F3=3, F4=77, F5=9, F6=13, F7=11 patients. At the UVA, assuming a cutoff of p<0.10, 25 RV and SUVmax were significantly associated with OS rates. Higher-CT-Difference-Entropy (p=0.019), CT-Difference-Average (p=0.048), CT-Zone-Entropy (p=0.044), PET-Small-Dependence-High-Gray-Level-Emphasis (p=0.003), PET-Small-Dependence-Emphasis (p=0.0061), PET-Small-Area-Emphasis (p=0.006) and Lower-PET-Large-Dependence-Low-Gray-Level-Emphasis (p=0.006), CT-Contrast (p=0.0218), PET-Large-Dependence-High-

Gray-Level-Emphasis ($p=0.0198$) and SUVmax ($p=0.028$) resulted as significant prognostic factors ($p=0.0091$) and were significantly associated with higher OS rates. Of note, lower p -values were registered using parameters extracted from PET than CT images. A prognostic nomogram was developed using the most significative values to assign the OS probability at 60 months after baseline PET/CT (Concordance indexes=0.68). **Conclusion:** Despite our small cohort of patients, this preliminary study revealed that various RV, in particular CT-Contrast and PET-Large-Dependence-High-Gray-Level-Emphasis, are significantly associated with OS rates in patients with LACC treated with CRT. Further analyses are ongoing to validate this data in a larger population, which may help for stratifying the patient's pre-therapy risk. The prognostic nomogram, if validate with prospective study, could be introduced in LACC management and easily used in the clinical practice. **References:** None

OP-662

Relationship between histopathological parameters and ^{18}F -FDG PET radiomic features in breast cancer patients

F. Görtan, N. Coskun, N. C. M. Güldali;

Turkish Ministry of Health, Ankara City Hospital,

Department of Nuclear Medicine, Ankara, TURKEY.

Aim/Introduction: The aim of this study is to evaluate the relationship between histopathological parameters and textural radiomic features of ^{18}F -FDG PET images in patients with breast cancer. **Materials and Methods:** Forty-three patients with histopathologically proven breast cancer who were referred to our department for pretreatment ^{18}F -FDG PET-CT scan were retrospectively enrolled in this study. Histopathological parameters including tumor type, histologic grade, estrogen and progesterone receptor status, Ki67 index and HER2 (Human Epidermal Growth Factor) status were derived from pathology specimens. ^{18}F -FDG PET/CT images were acquired from vertex to midhigh 60 minutes after i.v. injection of 6 MBq/kg ^{18}F -FDG at 2 minutes per bed position. SUV based parameters, as well as histogram, shape and textural radiomic features were extracted from PET images using a medical image analysis software. **Results:** Analysis between hormone receptor status and imaging features revealed statistically higher SUVmax ($p=0.016$; $p=0.005$), SUVmean ($p=0.020$; $p=0.005$), Histogram Entropy ($p=0.005$; $p=0.019$), GLCM Entropy ($p=0.001$; $p=0.014$), GLRLM HGRE ($p=0.023$; $p=0.040$), GLRLM SRHGE ($p=0.015$; $p=0.002$) and GLZLM HGZE ($p=0.017$; $p=0.002$) values in estrogen receptor negative and progesterone receptor negative patients respectively. Patients with higher Ki67 index demonstrated statistically higher SUVmax ($p=0.033$), SUVmean ($p=0.042$), Histogram Entropy ($p=0.008$), GLCM Entropy ($p=0.002$), GLRLM SRE ($p=0.015$), GLRLM RP ($p=0.026$), but lower

GLCM Homogeneity ($p=0.014$), GLRLM LRE ($p=0.014$), GLRLM LGRE ($p=0.000$), GLRLM SRLGE ($p=0.000$), GLRLM LRLGE ($s=0.003$), NGLDM Coarseness ($p=0.006$), GLZLM LZGE ($p=0.044$), GLZLM LGZE ($p=0.000$), GLZLM SZLGE ($p=0.001$), GLZLM LZLGE ($p=0.011$) values. Triple negative patients had statistically higher SUVmax ($p=0.004$), SUVmean ($p=0.004$), Histogram Entropy ($p=0.004$), GLCM Entropy ($p=0.001$), GLRLM Dissimilarity ($p=0.022$), GLRLM HGRE ($p=0.003$), GLRLM SRHGE ($p=0.001$), GLZLM HGZE ($p=0.002$), GLZLM SZHGE ($p=0.008$), GLZLM ZP ($p=0.042$) but lower GLCM Homogeneity ($p=0.037$) values. **Conclusion:** Our study results indicate that radiomic features of ^{18}F -FDG PET images of pretreatment breast cancer patients, consistent with estrogen, progesterone and HER2 receptor negativity as well as high Ki67 index values, contain inherent intratumoral heterogeneity. These may correlate with poor therapy response or high frequency of relapses during the course of the disease. Although higher SUVmax values generally correlates well with aggressiveness of the disease, revealing heterogeneous nature of the tumor at the beginning of treatment process will make clinicians to choose more aggressive treatment procedures for these patients. **References:** None

OP-663

Preliminary comparative results between FES and FDG in ER+ metastatic breast cancer: a radiomic approach

L. Ferrer^{1,2}, B. Maucherat¹, T. Carlier^{2,3}, F. Kraeber-Bodéré^{1,2,3}, C. Rousseau^{1,2};

¹ICO René Gauducheau, St Herblain cedex, FRANCE,

²University of Nantes, CNRS, INSERM CRCINA, Nantes,

FRANCE, ³University hospital, Nantes, FRANCE.

Aim/Introduction: 16α - ^{18}F -Fluoro- 17β -Oestradiol (FES) PET-imaging provides a non-invasive, in vivo measurement of the ligand binding function of estrogen-receptor (ER) in situ of metastatic breast cancer. We conducted a multicentric study (NCT03442504) to predict the value of FES PET at patient level, before a second hormonotherapy based on FDG response obtained at follow up. The aim of this work is to explore the correlation between FDG and FES PET examinations performed few days apart using radiomics features. **Materials and Methods:** Two FDG and FES PET examinations were performed for 20 patients from march 2017 to november 2019. The 5 most intense lesions visible in both PET images were delineated with DOSISOFT software (v.3.1.1.20L). We used all the software's algorithms to delineate each lesion for both examination. Thanks to a label majoritary voting approach [1], we created a unique mask from each lesion from which selected radiomics features were extracted [Table 1] using pyradiomics library (v.3.0). This selection was arbitrarily based on our previously work [2] related to radiomics reproducibility in multicentric trials. FES and FDG images were normalized in

SUV and resampled with a $0.4 \times 0.4 \times 0.2$ cm³ pixel size using BSpline algorithm. Gray value histograms were discretized with a fixed 0.5 SUV bin size. We only considered for this analysis volumes greater than 64 voxels (2 cm³). Statistical analysis were conducted with scipy stats module (v.1.3.1). **Results:** Among 96 delineated lesions, only 43 paired lesions remained after applying the 64 voxels cut-off. Hence, 4 patients did not exhibit FES-FDG any paired lesions. Spearman correlation and regression slopes are presented in table 1. Among all compared features, no correlation was observed except than a weak one for coarseness ($\rho=0.5$, $p=0.002$) in neighbourhood grey tone difference matrices. This suggests that higher values are observed in FES than in FDG respective volume, implying that textures tends to be more locally uniform in former than in latter volume. **Conclusion:** In ER+ metastatic breast cancer, intra-tumoral textural properties extracted from correlated FES and FDG volumes seem to be different. These preliminary findings should be confirmed and this work should be extended to assert whether both FES and FDG intra-tumoral properties assessed using handcrafted radiomics are related to patient outcomes. **References:** 1. Identifying a reliable radiomic signature from scarce data: illustration for 18F-FDOPA PET images in glioblastoma patients

F. Orlhac^{1,2}, A. Rollet³, I. Buvat¹, J. Darcourt^{3,4}, V. Bourg⁵, C. Nioche¹, C. Bouveyron⁶, N. Ayache², O. Humbert^{3,4};

¹Institut Curie, Inserm, U1288 LITO, Orsay, FRANCE, ²Université Côte d'Azur, Inria, Epione, Sophia-Antipolis, FRANCE,

³Université Côte d'Azur, Centre Antoine Lacassagne, Service

de Médecine Nucléaire, Nice, FRANCE, ⁴Université Côte d'Azur, CEA, TIRO, Nice, FRANCE, ⁵Université Côte d'Azur,

CHU Pasteur 2, Service de Neurologie, Nice, FRANCE,

⁶Université Côte d'Azur, Inria, MAASAI, Nice, FRANCE.

Aim/Introduction: The design and validation of a reliable radiomic signature is challenging when few patients are available because the disease is rare, the imaging protocol is specific and/or the classes are unbalanced. In this context, we propose an approach to identify a signature and estimate its reliability. **Materials and Methods:** 84 patients with a clinical and MRI suspicion of recurrent glioblastoma were retrospectively included. Each patient underwent a 18F-FDOPA PET-CT scan. For each patient, the suspicious lesion was segmented and 49 radiomic features were calculated using LIFEx [1]. Our goal was to distinguish between tumor recurrence and radiation-induced necrosis as confirmed on pathological data, or on a 3-month clinical/

imaging follow-up. A screening procedure was developed to identify a signature using leave-one-out (LOO) cross-validation. The procedure involved: 1) selection of all features with a p-value of univariate Wilcoxon test lower than alpha varying from 0.005 to 0.10 for (N-1) learning patients, 2) based on these features, selection of only one feature among correlated features using a Pearson correlation cut-off R varying from 0.95 to 0.50, 3) building of a radiomic signature involving the resulting features using a linear discriminant analysis, 4) test of the model on the Nth patient, 5) characterization of the model performance using the Youden Index ($Y = \text{sensitivity} + \text{specificity} - 1$). The final model selection was based on the consistency of Y values as a function of alpha and R, on the consistency of selected features between the different models, and favored models involving a low number of features. To test the reliability of the selected signature, we repeated the process by excluding one patient using a jackknife procedure (ie, 84 LOO of 83 patients each). We compared the results with those obtained with the same alpha and R when randomly assigning a label to each patient (sham task). **Results:** 61 patients had tumor recurrence and 23 had radiation necrosis. Visual interpretation yielded Y equal to 0.35 (Lizarraga scale, Se=100%, Sp=35%). Using LOO, 10/28 radiomic models had $Y > 0.35$. The largest Y ($Y = 0.49$, Se=62%, Sp=87%) were obtained with 4 features on average, reflecting the volume, sphericity and heterogeneity (GLCM_Correlation, GLCM_Contrast) of the lesion uptake. Using the jackknife procedure, Y was 0.47 ± 0.06 (range: [0.32;0.56]), significantly higher (Wilcoxon $p < 0.05$) than for the sham task ($Y = 0.06 \pm 0.18$, range: [-0.52;0.47]). **Conclusion:** The proposed systematic screening procedure enabled the identification of a parsimonious radiomic signature from scarce data. **References:** [1] Nioche et al. Textural features combined with static and dynamic parameters of 18F-FDopa PET imaging for the non-invasive prediction of the IDH mutation status in glioma

T. Zaragori^{1,2}, J. Oster¹, M. B. Chawki², B. Chen^{1,3}, V. Roch², L. Taillandier^{4,5}, G. Karcher², L. Imbert^{2,1}, A. Verger^{2,1};

Nancy CRAN, CNRS UMR 7039, Vandoeuvre-lès-Nancy, FRANCE.

Aim/Introduction: The IDH mutation is a key-factor of favorable prognosis in patients with glioma. 18F-FDopa PET imaging, currently recommended in glioma assessment,

has shown good performances by combining static and dynamic parameters for the non-invasive prediction of this mutation. The aim of this study was to evaluate whether textural features extracted from the ^{18}F -FDopa PET images can further enhance the performances of this prediction over static and dynamic parameters. **Materials and Methods:** Seventy-five patients having undergone a ^{18}F -FDopa PET scan with dynamic acquisitions for glioma assessment at initial diagnosis were retrospectively included. Seven conventional static parameters (S) and one-hundred-twenty-seven textural features (T) were extracted from 10-to-30 min post-injection static images as well as two conventional dynamic parameters (D) from the 30-min duration dynamic acquisitions. Features were extracted from gliomas metabolic volume segmented with Nestle's method. Four models were trained to predict the patient's IDH mutation status with respectively S, S+D, S+T and S+D+T features. These models were based on a SVM classifier with a linear kernel, and an automated selection of the 10 best metafeatures. The latter were first built by combining highly correlated normalized features using a hierarchical clustering approach. These 10 best metafeatures were then selected according to the Wilcoxon score ranking obtained during 100 bootstrap iterations. A nested cross-validation with 1000 bootstrap iterations of outer loop results was performed for each model and performances were expressed through an AUC score using the neuropathological result as a reference. **Results:** The S+T model achieved better results than the S model (AUC of 0.652 (95% Confidence Interval): [0.614;0.691] vs 0.567[0.517;0.618]) but with lower performances as compared to the S+D model (AUC of 0.755[0.718;0.788]). Moreover, results were not improved when adding textural features to the S+D model (AUC of 0.734[0.697;0.767] for the S+D+T model), highlighting the fact that most of the information is provided by dynamic parameters. **Conclusion:** The integration of textural features improves the prediction of the IDH mutation status of ^{18}F -FDopa PET imaging in patients with glioma only if compared to a model based on conventional static parameters. The inclusion of dynamical parameters yields the best performances, strengthening the case for integrating them into clinical routine. **References:** 1. University of Technology, Delft, NETHERLANDS, ⁴Radboud

University Medical Center, Nijmegen, NETHERLANDS.

Aim/Introduction: Central necrosis (CN) often occurs as a result of hypoxia and glucose deprivation, caused when fast tumour growth and oxygen consumption are left unmatched by sufficient blood supply. CN manifests itself predominantly in aggressive cancers and is associated with poor prognosis. It can be detected by [^{18}F]FDG PET as an often central region with little to no tracer uptake. Currently, radiomics does not provide guidelines whether or not to include CN during volume of interest (VOI) delineation. Isocontour methods inherently exclude CN. In some studies, these CN-subvolumes are added manually, but this is not always reported. The aim of this study was to assess how CN influences PET radiomic analysis. **Materials and Methods:** Two cohorts of patients visually selected for showing CN on the [^{18}F]FDG PET/CT scan were included retrospectively: patients with pheochromocytomas and paragangliomas (PPGL, n=24) and patients with non-small cell lung carcinomas (NSCLC, n=12). VOIs were delineated using a 50% isocontour method based on the peak standardized uptake value or a fuzzy locally adaptive Bayesian method for the PPGL and NSCLC cohort, respectively ($\text{VOI}_{\text{vital-tumour}}$). In addition, VOIs were generated by manually adding the volumes of CN to the delineations ($\text{VOI}_{\text{gross-tumour}}$). The necrotic tumour fraction was determined by: $\text{NTF} = 1 - \text{VOI}_{\text{vital-tumour}} / \text{VOI}_{\text{gross-tumour}}$. From each of these 72 VOIs, 90 radiomic features were extracted. Per cohort, differences in radiomic features between delineation with and without CN were assessed using a paired T-test with Benjamini-Hochberg correction for multiple testing. **Results:** Median NTFs were 0.27 and 0.11 for the PPGL and NSCLC cohort, respectively (range 0.01-0.78 and 0.03-0.60, non-different for both cohorts, p=0.280). At least 46% of the features were significantly different between either $\text{VOI}_{\text{vital-tumour}}$ and $\text{VOI}_{\text{gross-tumour}}$ (46% and 50% (p=0.551) for the PPGL and NSCLC cohort, respectively), where first order features (n=18) were affected the most (61% and 56% (p=0.735) for the PPGL and NSCLC cohort, respectively), shape features (n=13) the least (23% for both cohorts (p=1.000) and texture features (n=59) 46% and 54% (p=0.357), respectively. **Conclusion:** In both tumour types, almost 50% of features were affected, demonstrating that the impact of whether or not to include CN in the VOI on the radiomic analysis is significant. Until preference of delineation method, including the choice to add or leave out CN, has been investigated, radiomic studies should report whether or not CN was included in the VOI. **References:** None

OP-667**A Phantom Study to Evaluate the Stability of PET Images Radiomic Features with Time of Acquisition**E. Alsyed¹, R. Smith², L. Bartley², C. Marshall², E. Spezi¹;¹Cardiff University, Cardiff, UNITED KINGDOM, ²Wales Research & Diagnostic PET Imaging Centre, Cardiff, UNITED KINGDOM.

Aim/Introduction: The term radiomics refers to a method of extracting quantitative features from radiographic medical images, some of which cannot be seen by the human eye. In recent years, there has been an increasing interest in utilising radiomic features extracted from positron emission tomography (PET) images which may serve as biomarkers to monitor cancer prognosis and treatments. One major issue effecting confidence in adopting radiomic features as key prognostic indicators clinically is their stability under varying PET image acquisition parameters. The main goal of this phantom study is to assess the stability of PET image radiomic features with varying time duration before image acquisition. **Materials and Methods:** Artificially constructed tumour inserts using an array of radioactivity filled syringes were used to model four tumours with varying degrees of heterogeneity. The inserts were placed into a cylindrical uniform water filled phantom and imaged using a GE690 PET/CT for 80 minutes. Images were re-binned into 4x20 minutes PET scans. Region of interests (ROI) were segmented (cylindrical delineation) in the first configuration and copied to all other configurations. SPAARC [1] was utilised to extract 78 3D-radiomic features for each tumour volume at each time point. The Coefficient of Variation (COV) was calculated for each feature to analyse its stability with imaging time. Stabilities were categorized into four groups including stable ($COV \leq 5\%$), moderately stable ($5\% < COV \leq 10\%$), poorly stable ($10\% < COV \leq 20\%$) and unstable ($COV > 20\%$) were assessed [2]. **Results:** More than 32(41%) features showed stability ($COV \leq 5\%$) for all four configurations. Eleven (14%) and seven (9%) features exhibited instability ($COV > 20\%$) for homogeneous shapes 1 and 3, respectively. Eleven (14%) and thirteen (16%) features showed instability ($COV > 20\%$) for inhomogeneous shapes 2 and 4, respectively. Twenty-three (29%), Six(7%), nine(11%) and three (4%) features showed poor stability ($10\% < COV \leq 20\%$) for configuration 1,2,3 and 4, respectively. **Conclusion:** PET image radiomics features may be affected by varying acquisition time. Further clinical studies are needed to evaluate the stability of PET images radiomic features over different acquisition time. Radiomic features with high (unstable) COV should be omitted in radiomic studies. **References:** [1] P.Whybra, C.Parkinson, K. Foley, J. Staffurth and E. OP-668**A transfer learning approach to facilitate ComBat-based harmonization of multicentre radiomic features in new datasets**M. Hatt¹, F. Lucia^{2,1}, I. Masson³, A. Mervoyer³, C. Reinhold⁴, P. Robin⁵, J. Alfieri⁶, C. Rousseau⁷, O. Pradier^{2,1}, U. Schick^{2,1}, D. Visvikis¹, R. Da-ano¹;¹INSERM, LaTIM, UMR 1101, Brest, FRANCE, ²CHU Brest, radiotherapy department, Brest, FRANCE, ³Department of Radiation Oncology, Institut de cancérologie de l'Ouest René-Gauducheau, Saint-Herblain, FRANCE, ⁴Department of Radiology, McGill University Health Centre, Montreal, QC, CANADA, ⁵CHU Brest, Department of Nuclear Medicine, Brest, FRANCE, ⁶Department of Radiation Oncology, McGill University Health Centre, Montreal, QC, CANADA, ⁷Department of Nuclear Medicine, Institut de cancérologie de l'Ouest René-Gauducheau, Saint-Herblain, FRANCE.

Aim/Introduction: In order to demonstrate the clinical potential value of radiomics, multi-center studies are needed. They are challenging, as the variability in scanner manufacturers and models, acquisition protocols and reconstruction settings hamper the ability to pool radiomic features for modeling. ComBat is a harmonization method able to eliminate such "center-effect", however it suffers from limitations when dealing with new, unseen data (i.e., patients and/or centers not included in the initial harmonization). Our objective was to develop a novel method based on transfer learning (TL) in order to facilitate the use of ComBat in that context. **Materials and Methods:** The TL-based ComBat implements three steps: i) save the parametric empirical estimates obtained in the initial data harmonization on the available data, ii) use the initial estimates in step 1 to calculate the new adjusted batch effect estimators and iii) calculate the final adjusted data using the estimators obtained in step 2. It was evaluated on a dataset of radiomic features extracted from PET and MRI images of 197 patients with cervical cancer from 3 centers, with the task of predicting local failure (LF) using 3 different machine learning methods (support vector machine (SVM) and random forest (RF), both with embedded feature selection, as well as logistic regression (LR) combined with least absolute shrinkage and selection operator). Two experiments were carried out: 1) stratified random sampling was used to split the data from 3 centers into training (n=140 with 51 LF) and testing (n=57 with 16 LF) sets. In the TL case, all patients from the testing set were set aside and not used in the initial harmonization. 2) Brest and McGill (n=147 with 52 LF) were used as the training set, whereas Nantes (n=50 with 15 LF) was the testing set. In

the TL case, all patients from Nantes were set aside in the initial harmonization. **Results:** In both experiments, the TL approach led to models with accuracy very close to the reference (all data available for harmonization), across all three ML methods. In most cases the resulting performance was exactly the same, the accuracy values being within 1 to 3 points (e.g., RF accuracy of 0.90 with TL vs. 0.93 using all data). **Conclusion:** The proposed approach was successful in applying the previously determined harmonization transform to the radiomic features values of new patients, in both configurations of new patients from a known center or a new center. **References:** None

Traumatic Brain Injury Induced Amyloid Plaque Scintigraphy

A. Datta¹, G. Mann^{1,2}, A. Kaul¹, M. Thirumala², A. Mishra¹; ¹Institute of Nuclear Medicine and Allied Sciences, Delhi, INDIA, ²University of Delhi, Delhi, INDIA.

Aim/Introduction: Epidemiological evidence implicates formation of diffused amyloid plaques after incident of Traumatic Brain Injury as a risk factor for developing associated neurodegenerative disorders. Early detection of these plaques consequently remains vital for better regulation of these diseases. Considering this, we developed

a cost-effective, homodimeric chalcone scaffold-based SPECT radiotracer which specifically binds detrimental A β ₁₋₄₂ plaques. The bifunctional chelating agent, pentapa-en-NH₂ was explored for the development of SPECT agent. We hypothesise the developed bivalent homodimeric molecule to display enhanced binding affinity and blood brain barrier penetration. **Materials and Methods:** The bifunctional chelator was synthesised through a series of steps in high purity and further conjugated to the chalcone derivative using bivalent approach. The molecule was conjugated to ^{99m}Tc and further used for pre-clinical studies. A repetitive mild TBI mouse model was developed and uptake of tracer was studied. **Results:** The molecular docking studies reported multiple binding of tracer at the recognition sites of A β fibrils with a significantly high binding score (-12.64) as compared to known A β ligands. Bischalcone derivative, 6,6'-(((2-(bis(2-(4-((E)-3-(4-(dimethylamino)phenyl)acryloyl)phenoxy)ethyl)amino)ethyl)azanediyl)bis(methylene))dipicolinic acid, (Ch)₂pa was synthesized in 95% yield with high purity. Radiolabelling was carried out with ^{99m}Tc under mild conditions with 95.4% efficiency and 103-124 MBq μ mol⁻¹ specific activity. In vitro binding assay with A β ₁₋₄₂ aggregates displayed high binding affinity of (Ch)₂pa. The fluorescent data displayed absorption/emission at 410/540 nm and exhibited blue shift with 10-fold increase in emission intensity on binding with A β aggregates. Blood kinetics performed on normal rabbit displayed fast clearance (t_{1/2}(F) = 32 \pm 0.04 min; t_{1/2}(S) = 3h 55min \pm 0.03 min). A repetitive mild TBI mice model was established and ex vivo staining of TBI mice model brain sections with (Ch)₂pa showed specific binding of complex to amyloid plaques. In vivo scintigraphy displayed two-fold increase of radioligand concentration in TBI model as compared to sham mice owing to higher amyloid burden in TBI model. Ex vivo biodistribution analysis demonstrated high blood brain barrier penetration in TBI model mice with brain uptake of 5.24 \pm 0.31% ID g⁻¹ at 2 min p.i. and 3-fold higher than brain uptake in sham mice. **Conclusion:** These preliminary studies reveal the enhanced amyloid binding affinity by bivalent approach and offers a new perspective in ^{99m}Tc probes for β -amyloid imaging. The study also highlights the increased amyloid burden in traumatic brain injury cases and provides a novel approach for prognosis and ultimately better regulation of TBI induced dementia. **References:** None

Does gadolinium deposition in the brain affect to F18-FDG brain uptake?

R. Sanchez Jurado¹, E. Blanco Perez²;

¹ERESA, Valencia, SPAIN, ²Alzira's Hospital, Valencia, SPAIN.

Aim/Introduction: Gadolinium-based contrast agents have revolutionized MRI and diagnostic medicine. They have allowed us to detect diseases that would otherwise be

extremely difficult to diagnose. However, new publications affirm that minute traces of gadolinium are often retained in the brain tissue of patient years after undergoing an MRI. The purpose of this study was to determine whether repeated administrations of gadolinium in brain MRI studies would affect the uptake of 18F-FDG in brain PET-CT. **Materials and Methods:** More than three thousand patients from two different hospitals, those who underwent both contrast-enhanced MR (CE MR) of the brain and F18-FDG brain PET/CT from January 2009 to January 2019 were identified. The SUVmax was measured in the globus pallidus (GP), thalamus (T), dentate nucleus (DN), pons (P), substantia nigra (SN) and red nucleus (RN) on the PET/CT scanners in patients which had 3-12 successive CE MR brain studies. The SUVmax of the corresponding areas in the control group of patients that had not undergone previous CE MR was also measured. **Results:** Seventeen patients (mean age \pm SD, 52 ± 12 y; 11 men and 6 women) finally were included in the subject group, which were divided in two groups: Group A 'elderly' (mean age \pm SD, $59 \pm 5,8$ y; 9 men and 3 women) and Group B 'early' (mean age \pm SD, $36 \pm 4,8$ y; 2 men and 3 women). Seventeen patients were included in the control group and they were divided in Group C 'elderly' (mean age \pm SD, $56 \pm 5,1$ y; 7 men and 5 women) and Group D 'early' (mean age \pm SD, $32 \pm 5,1$ y; 4 men and 1 women). The median DN, GP, T and P SUVmax were significantly lower in the subject group than in the control group. However, SN and RN were significantly higher in the subject group than in the control group. **Conclusion:** The median SUVmax in the DN, GP, T and P were 6%, 54%, 48% and 44% lower, respectively, in the Group A respect to Group C; and 16%, 19%, 4% and 12%, respectively, in the Group B respect to Group D. Highlight the results obtained in SN and RN that were 6% and 10% higher, respectively, in the Group A to Group C; and 16% and 24% higher, respectively, in the Group B to Group D. **References:** None

OP-688

Preliminary Results of Developing a Planar Camera for Building an Open-type Brain-PET scanner

H. Liang, H. Wu, C. Cheng, C. Lin;

INER (Institute of Nuclear Energy Research), Taoyuan, TAIWAN.

Aim/Introduction: A project of developing a planar PET scanner for brain function imaging was raised. In our current design, two planar cameras are arranged in a sliding scan scheme. Due to camera sliding, it is required the proposed camera to have whole imaging area successive. However, due to Anger logic not able dealing with inter-detector information, missing rows/columns of crystals in the cross-over regions in a crystal 2D map was observed. Therefore, it is necessary to build a position decoding algorithm capable of solving crossover problems, to make our camera have a whole successive imaging area. **Materials and Methods:**

The proposed planar PET camera is composed of 9 imaging detectors, connecting with a plate of 2-mm-thick window. Each detector is composed of a scintillation layer (31 \times 31, 1.5-mm-pixel-LYSO-crystal array), a photonic layer (144-pixels SiPM), and a readout circuit (1:12 weighting). Instead of Anger logic, the ratios of the 4 acquired weighted signals, i.e. $x+/x-$ and $y+/y-$, from each detector are applied to decode the event positions. Due to the pre-designed weights in the readout, a position mapping curve vs. weighted signal ratios (i.e. $x+/x-$ and $y+/y-$) is built. Such curve is applied for position decoding of event signals to realize event positions. When the signal ratios approaching two ends of the mapping curve (i.e. 12.004 and 0.0833), it indicates that the incident events occurred in crossover region crystals. Thus, position correction calculations by using neighbor detector signals are applied for such events. In such position decoding algorithm (weighted signal ratio driven), it is expected to recover the event counts of the crossover region crystals. **Results:** From a crystal 2D map obtained by Anger logic, it is observed that 2 rows/columns of crystals are missing in the cross-over regions, and thus makes a countable crystal array of 29 \times 29 for each detector. With applying the proposed position decoding calculation to the same experimental data, it is observed that the lost 2 rows/columns of crystals are recovered, and thus makes the countable crystal array to be 30 \times 30. It implies that our new position decoding calculations work for making the camera imaging area successive. **Conclusion:** In this study, a set of position decoding calculations is built, and its effectiveness is proved. However, the crystals in the peripheral edges are still missing. The following efforts will be put on searching a similar way of position decoding calculations to recover the edge rows/columns. **References:** None

Start of a new Cardiac PET service with Rb-82 in a UK based hospital: operational management of patients pathway

G. Testanera, L. Menezes, L. Price, M. Burniston, R. Gregory, C. Copland;

Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Coronary Arterial Disease (CAD) is the disease responsible for most deaths in UK and consequently Myocardial Perfusion Scintigraphy (MPS) is one of the most common examinations performed in Nuclear Medicine (NM). In our hospital, the MPS output was an average of 1650 MPS scans a year divided across 4 sites. To improve our service, In 2018 we started a project to introduce cardiac PET-CT with Rb-82 which provides diagnostic information

on CAD competitive with Cardiac CT, with less radiation dose to the patient. The project included switching 50% of MPS scans from conventional NM to Cardiac PET-CT. This new procedure allows rest and stress images of the heart to be achieved in one short appointment of 30 minutes and radiotracer Rb-82 is produced internally from a Sr-82/Rb-82 generator enabling the service to be more operationally flexible. **Materials and Methods:** The PET-CT service is equipped with a GE-Discovery 710 PET system with a 128 slice CT enabling for a diagnostic CT for calcium scoring. To set up the service we required a cart for Rb-82 infusion, Sr-82/Rb-82 generator, adenosine infusion pump, 3 lead ECG and dedicated training for technologist, physics and nursing staff. Corridor 4DM, a suite for cardiac post processing was installed to support reporting on the Hermes Medical platform. **Results:** The service started in November 2019 with 10 patients a week and in 2 months the number of scans performed reached 24 a week, consisting of about 45% of overall MPS scans, very near to the original plan of 50% conversion. The triage was actioned prioritising clinical appropriateness over operational reasons. Oncology scan capacity was preserved with a mobile PET-CT support installed. Only 1 minor adverse event was observed and patients feedback showed improved satisfaction. Cardiac PET proved also to be much more suitable during the pandemic, since only one appointment was needed. **Conclusion:** Rb-82 Cardiac PET-CT proved to be a game changer in CAD patient pathway¹, improving diagnostic accuracy, patient experience and reducing radiation dose by 80%. The service requires a massive amount of effort from the PET team and a very careful triaging of patients, to ensure appropriateness of scans and to preserve oncology patient slots when limited resources are available in the PET service. It also proved to be safer for patients in the unexpected pandemic event. **References:** ¹ Jaarsma et al. *J Am Coll Cardiol.* 2012 May 8;59(19):1719-28.

OP-691

Assessment of the effect of fasting on stomach interference on Rubidium-82 PET-CT MPI

G. Testanera, B. Ribeiro, R. Gregory, M. Costa, S. Ferreira, S. Townrow, A. Simeonova, C. Copland, L. Price, M. Burniston, L. Menezes;
Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Rubidium-82 chloride (⁸²Rb) PET/CT has revolutionised how myocardial perfusion imaging (MPI) is performed. This method allows MPI within a 30 minute appointment and is more accurate than the equivalent nuclear medicine techniques. However ⁸²Rb PET/CT images can suffer from interference from stomach and liver activity. This study aims to determine whether implementing a protocol that instructs the patient to fast for 6 hours prior to their appointment reduces the interference from sub-

diaphragmatic activity. **Materials and Methods:** The level of stomach interference was assessed for rest and stress PET/CT MPI images sets, for one group of 59 patients that had fasted for 6 hours and a separate group of 59 patients that had not been instructed to fast. Images were viewed using Corridor 4DM with a 10 step colour map. This map allows the viewer to identify areas that are less than 40%; 40-60%; 60-70%; and >70% of the maximum image count. The interference was therefore scored based on the level of counts in the region between the myocardium and gastric wall, as absent (1) if <40%, mild (2) if 40-60%, moderate (3) if 60-70% and severe (4) if >70% of the maximum. These areas had to cover at least 4 slices with 20% angular coverage. All 236 images were scored by an experienced technologist, physicist and nuclear medicine cardiologist. The median of the 3 scores for each image were compared between the image sets for each protocol, the statistical significance of the results was assessed using a Mann-Whitney U-test. **Results:** Demographics for both patient groups were similar (average BMI 28.8±8.13 kg/m² and 28.97±5.66 kg/m², age 63.54±12.28 years and 66.77±10.76 years for 6 hour fasted and unfasted groups respectively). For the rest studies, there was a statistically significant difference between the two patient groups, with interference scores higher in the non-fast patients (1.93±1.06 and 1.48±0.73 for no fast and 6 hour fast patients respectively, p=0.036). For the stress studies the average interference scores were also higher for the non-fast compared to the 6hr fast patients (1.79±0.95 and 1.52±10.78 respectively, p=0.13). **Conclusion:** The level of interference from sub-diaphragmatic activity was on average significantly lower in the rest images when the patients were asked to fast for 6-hours prior to their appointment; this provides support for the ASNC/SNMMI guidelines. **References:** Dilsizian et al. ASNC imaging guidelines/SNMMI procedure standard for positron emission tomography (PET) nuclear cardiology procedures. *J Nucl Cardiol.* 2016;23(5):1187-1226.

OP-693

The investigation of automated region growing method for the detection of heart to streamline calculation of ²⁰¹Tl-MUI at stress in patients

K. Nishimoto¹, S. Tomiguchi², F. Sakamoto², S. Shiraishi³, Y. Kawamata³;

¹Graduate School of Health Science Kumamoto University, Kumamoto, JAPAN, ²Faculty of Life Sciences Kumamoto University, Kumamoto, JAPAN, ³Kumamoto University Hospital, Kumamoto, JAPAN.

Aim/Introduction: Quantitative index such as ²⁰¹Tl Myocardial Uptake at stress (MUI) is useful for the diagnosis of coronary arterial disease (CAD) on stress ²⁰¹Tl single photon emission computed tomography-myocardial perfusion imaging (²⁰¹Tl-SPECT-MPI). However, it is necessary to

extract the left ventricular contour for calculation of the left ventricular myocardial counts. The aim of this study was to evaluate the feasibility of automated program for extracting the left ventricular myocardium (LVM) by comparing number of voxels in LVM estimated with the automated program and that obtained with manually extracting LVM on stress ^{201}Tl SPECT-MPI using a CZT camera (NM530c; GE). **Materials and Methods:** The automatic program for extracting LVM based on region growing method was developed. We obtained the number of voxels in LVM by using this program and manually set ROI on LVM, respectively. Three different radioactivity in myocardium of phantom images (74, 37, 18.5 kBq/ml) and normal 95 patients (SSS=0) performed stress ^{201}Tl SPECT-MPI were enrolled. We evaluated the concordance of the number of voxels in LVM obtained by two methods with Jaccard similarity coefficient. **Results:** Jaccard similarity coefficient in all cases of phantom images and 94 patients of 95 clinical images showed equal 1. **Conclusion:** The developed automatic program for extracting LVM is feasible to use in patients with normal myocardial perfusion. **References:** None

OP-694

Evaluation of extent and severity of myocardial perfusion defects: quantitative [perfusion SCOREs] and qualitative [segments] analysis

A. Ghilardi¹, G. Medolago²;

¹ASST-PG23, Bergamo, ITALY, ²Humanitas Gavazzeni, Bergamo, ITALY.

Aim/Introduction: Determination of amount of ischemia/scar or viable myocardium is essential for patient management. It is important to report amount of ischemic/scarred/viable myocardium, by qualitative analysis [#segments hypoperfused] or quantitatively [#SCOREs], anyway as a percentage of left ventricle, taking into account that ESC recommends that patients with stable angina or silent ischemia with proven large area of ischemia (10-12%) should receive revascularization. We Evaluated variability/differences of assessing extent of reversible/fixed perfusion defects obtained by qualitative and quantitative analysis, to better determine extent and severity of hypoperfused myocardium for clinical decision making **Materials and Methods:** All patients with known/suspected coronary artery disease underwent stress exercise/rest single day protocol using $\text{Tc}^{99\text{m}}$ -Sestamibi as radiopharmaceutical. Gated_SPECT was performed using double-head Siemens_Symbia_S equipped with LEHR collimators; short-and-long (sagittal-horizontal)-axis oblique slices were obtained by reorienting transaxial image data using iterative filtering and displayed with different pixel thickness and colour grading windows to better visualize ischemic/scar/viable myocardium. Gated_SPECT images were interpreted based on a 17-segment model. Qualitative analysis

categorized images either normal or ischemic/necrotic/viable [0-4 score]. Quantitative perfusion and functional parameters were derived fully automatically using commercially available software program [Cedars-Sinai QPS and QGS]. **Results:** Comparing qualitative slices imaging [hypoperfused #segments] and quantitative data [#SCOREs] diagnostic mismatch was frequently found. #SCOREs value is objective/operator_independent, easily repeatable and mostly a powerful prognostic tool. However it may not fit absolute segmental myocardial uptake of $\text{Tc}^{99\text{m}}$ -Sestamibi, referring to commercial normal [albeit validated] database. Furthermore even if #SCOREs can be converted to percent of total myocardium (% myocardium) involved with ischemic/fixed defects [by dividing the summed scores by 68, the maximum potential score (4*17), and multiplying by 100], it doesn't often correlate to segmental hypoperfused defect size. Qualitative analysis allows to assess hypoperfused defect size in terms of extent: #segments, severity: "0-4 score [normal, moderate, severe, absent uptake]" and percentage of hypoperfused myocardium [by multiplying 6% [100%/17segments] by #segmental defects] differentiating small [6%], moderate [12%], large [18%] and viable/not viable defects **Conclusion:** Both qualitative and quantitative analysis are needed for accurate evaluation of myocardial perfusion defects size for patient management. In our experience qualitative analysis showed to be more convenient/suitable to assess accurately, promptly ischemic/scarred/viable myocardium for clinical decision making, using a more standardize model **References:** Germano G, Kavanagh P, Waechter P, Areeda J, Sharir T, Lewin H, Berman D. A new automatic approach to myocardial perfusion SPECT quantitation. J Nucl Med 1998 (abstract); 39(5):62P.

OP-695

Introduction to COVID-19 Pandemic

L. Camoni; Università & Spedali Civili di Brescia, Brescia, ITALY

OP-696

Ventilation scintigraphy: is it really safe now with COVID-19 pandemic?

S. Mendes, I. Ferreira, J. Isidoro, G. Costa, P. Soeiro, J. P. Lima; Hospitais da Universidade de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Ventilation-perfusion scintigraphy in the emergency setting is essential for some patients. However, with the COVID-19 pandemic and most infected patient beings asymptomatic, ventilation procedure became particularly challenging due to the generation of extremely small carbon aerosols (0.005-0.2 μm). Nuclear medicine technicians may therefore be at higher risk of COVID-19. The aim of these work was to assess the risk of infection and thereby implement additional procedure safety standards if necessary. **Materials and Methods:** Ventilation

simulation with Thecnegas generator and phantom able to perform inspiration and exhale was performed. Technicians individual equipment used for protection was head cover, face protection, mask N95, gown and foot protection. Millenium VH gamma camera without collimators was used to measure the activity in individual equipment, technician lung, walls, the floor and the Thecnegas generator. All the data was corrected for the background and for decay. **Results:** Gown had the higher particles contamination (17KBq). Relative to gown the head cover had 5% (0.9 KBq), face protection 3% (0.5 KBq), mask N95 9% (1.5 KBq), foot protection 6% (1.0 KBq). The personal uniform was evaluated and the pants had 5% (0.8 KBq) and the shirt had 1% (0.2 KBq). The total contamination of the components of the room had a medium of contamination of 0.9 KBq (min. 0.004 KBq; máx. 5.5 KBq). The lungs and the face radioactive contamination after the removal of all the protection equipment, even without a shower, were lower than the detection sensitive of the gamma camera. **Conclusion:** These preliminary results suggest that protective individual equipment reduce the probability of particle lung aspiration by the technicians, aspect very important when we perform this procedure in a patient infected with the corona virus. **References:** None

OP-697

Management of COVID-19 pandemic in Nuclear Medicine Departments: a contribute for the Portuguese community

P. Costa, J. Lemos, D. Vieira, N. Arantes;
Nuclear Medicine Department, School of Health,
Politécnico do Porto, Porto, PORTUGAL.

Aim/Introduction: Considering the infection with the new Coronavirus (SARS-CoV-2), which may evolve into CoronaVirus Disease 2019 (COVID-19), and the pandemic that is active, standards, guidelines and recommendations have been issued by diverse entities at the governmental, professional and scientific levels. During this pandemic, it is mandatory that the operation of Nuclear Medicine (NM) Departments will be conditioned restricted and internal protocols and practices adjusted accordingly. NM Departments integrated in hospital institutions are included in their contingency plans, generally, and currently operate under the contingency regulations in place, who report to the best available evidence. It was conducted a literature review that aims to aggregate international recommendations and to document practices for the management of the COVID-19 pandemic in NM Departments. The pertinence relies in a possible lack of practical information reporting to the specific context of NM, as well as lack of time to do the careful research of the best available evidence. This work aims to describe the gathered information, and share the process of research, revision,

and dissemination amongst the Portuguese community of NM Departments and the feedback obtained. **Materials and Methods:** An informal literature review was conducted in scientific databases, but also in other sources of information such as scientific and/or professional entities involved in the NM field, concerning scientific articles, clinical studies or other reports or guidelines that are relevant for the operation or management of NM Departments. Results were disseminated among Portuguese NM community and feedback was obtained via e-mail and social media. **Results:** A total of 13 references were found and reviewed by the authors, leading to the compilation of a document divided in these topics: i) General measures for infection prevention and control; ii) Management of staff and work routines; iii) Management of scheduled procedures and future appointments; iv) Measures for patients and accompanying persons; and v) Special care in the interpretation of NM examinations. Feedback obtained will be compiled and shared, but preliminary evaluation resulted in an overall positive acceptance of the document and the recognition of the efforts conducted given the lack of specific and direct indications for NM Departments. **Conclusion:** The current pandemic of COVID-19 has brought some necessities and challenges to the reality of NM that will remain relevant in the near future, at least, thus being very important to adapt and adjust the management and operation of NM Departments always based on scientific evidence available. **References:** None

Search for the optimal bis-iminobiotin for the pretargeting strategy using a mutated low immunogenic streptavidin

K. Washiyama¹, T. Tatsumi², S. Zhao¹, A. Sugiyama², M. Aoki¹, K. Yamatsugu², N. Ukon¹, K. Nishijima¹, S. Shimoyama¹, C. Tan¹, T. Joho¹, N. Oriuchi¹, M. Kanai², K. Takahashi¹, T. Kodama²;
¹Fukushima Medical University, Fukushima, JAPAN,
²The University of Tokyo, Tokyo, JAPAN.

Aim/Introduction: By separating the role of an antibody and a radioligand, the pretargeting strategy has been expected to increase the therapeutic effect of radioimmunotherapy.

We have developed a pretargeting system using a mutated low immunogenic streptavidin denoted as Cupid, which can fuse to scFV mAb, and a bis-iminobiotin compound denoted Psyche that specifically binds to Cupid [1]. The purpose of this study was to explore the relationships between the molecular structure of a series of Psyches, binding stabilities to Cupid, and pharmacokinetics of ^{211}At -labeled Psyches in mice in order to identify the optimal candidates for pretargeting radionuclide therapy. **Materials and Methods:** We synthesized several trimethylstannylated bis-iminobiotins called Psyche-B, -J, -N, and -P, and evaluated its affinity to Cupid using surface plasmon resonance (SPR). ^{211}At was manufactured in our facility and isolated through dry distillation. ^{211}At was labeled to Psyches and purified as no-carrier-added products using RP-HPLC. For the stability evaluation, ^{211}At -Psyches were incubated with PBS and serum for 24 hours. For the biodistribution studies, a series of ^{211}At -Psyches were administered to CEA-expressing xenograft mice with and without a 100 pmol of anti-CEA scFv-Cupid. The interval between ^{211}At -Psyches and anti-CEA scFv-Cupid administration was set 24 h. **Results:** SPR results showed that all Psyches have a high affinity to Cupid, especially Psyche-B has $K_D=5.1\text{E}^{-11}$ M. The logD values of ^{211}At -Psyches differed depending on their structure, eg. ^{211}At -Psyche-P (0.37), ^{211}At -Psyche-J (-1.26). All ^{211}At -Psyches showed high stability in PBS. However, while ^{211}At -Psyche-N and -P are relatively stable in plasma, ^{211}At -Psyche-B dissociated in serum within 1 hour. The biodistribution of all ^{211}At -Psyches in mice without Cupid showed the same trends; the blood clearance was fast, showing $<1\%$ ID/g at 6 hours after administration. However, the biodistribution of all ^{211}At -Psyches when 100 pmol of Cupid was administered 24 hours before showed different patterns for each compound. ^{211}At -Psyche-P showed almost the same pharmacokinetics with and without Cupid. In contrast, ^{211}At -Psyche-J and B showed increased uptake in the tumor up to the experimental period (24h). Despite being unstable in plasma, ^{211}At -Psyche-B have reached 16.3 ± 4.1 %ID/g at 24 hours after administration. **Conclusion:** Although ^{211}At -Psyche-B showed serum instability ex vivo, the high affinity of Psyche-B to cupid compensates the tumor uptake and its accumulation increased over time in vivo. Based on the encouraging results, we will evaluate ^{211}At -Psyche-B as a promising candidate for further pretargeting optimization. **References:** [1] Sugiyama et al., Proc. Jpn. Acad. Ser. B 95:602, 2019

Design and evaluation of lactosaminated cetuximabs as a clearing agent for antibody-based PNA-mediated pretargeting

M. Altai^{1,2}, A. Vorobyeva¹, A. Myrhammar³, K. Westerlund³, S. Yoneoka⁴, T. Tsukahara⁴, A. Eriksson-Karlström³, A. Orlova⁵, V. Tolmachev¹;

¹Immunology, Genetics and Pathology, Uppsala, SWEDEN, ²Division of Oncology and Pathology, Department of Clinical Sciences, Lund, SWEDEN, ³Department of Protein Science, KTH, Stockholm, SWEDEN, ⁴Laboratory for Advanced Nuclear Energy, Tokyo, JAPAN, ⁵Department of Medicinal Chemistry, Uppsala, SWEDEN.

Aim/Introduction: Pretargeting is a promising strategy allowing for the rational use of long circulating, monoclonal antibodies (mAbs) in therapy. We developed a pretargeting approach based on hybridization between peptide nucleic acids (PNAs). The anti-HER2 mAb trastuzumab (T) was coupled to the HP1 PNA-probe (T-ZHP1) and injected first. Forty-eight hours later, a complementary radiolabeled HP2 PNA-secondary probe was injected. Pretargeting resulted in 2-fold increase in tumor-to-blood radioactivity uptake ratio compared to direct targeting using trastuzumab. Here, we extend further on this strategy by developing a clearing agent (CA) aimed at chasing the primary T-ZHP1 in vivo to clear it faster from the circulation prior to the injection of the secondary radiolabeled-HP2 probe. **Materials and Methods:** We designed a CA based on the mAb cetuximab, site-specifically conjugated to a PNA HP2 probe recognizing T-ZHP1 using a photoactivatable Fc-binding Z domain. Thereafter, the CA was galactosylated to improve hepatic clearance through binding to asialoglycoprotein receptors. Binding interaction of ^{125}I -radiolabeled CA (cetuximab-galact₃₅-ZHP2) with primary-T-ZHP1 was evaluated using cell dishes coated with T-ZHP1. The influence of galactosylation and conjugation of PNA-modified Z-domain on cetuximab biodistribution was evaluated in normal mice injected with [^{125}I]-radiolabeled CA and the controls cetuximab, cetuximab-ZHP2 or cetuximab-galactose. The blood clearance of primary T-ZHP1 radiolabeled with [^{131}I], with and without CA administration (6h post-T-ZHP1 injection) was also evaluated in normal mice. Blood samples from mice (1 h post-CA injection) were collected and analyzed using size-exclusion chromatography. **Results:** Cetuximab was efficiently photoconjugated with Z-HP2. Lactosamination resulted in an average of 35 lactose units per cetuximab molecule. Binding of [^{125}I]-CA to T-ZHP1-coated dishes was 1.5-4-fold ($p<0.05$) higher than to controls, were an excess of the complementary-PNA, HP2, was added to T-ZHP1 before the addition of [^{125}I]-CA or when no T-ZHP1 was added. Results from the biodistribution study demonstrated that the CA cleared from the blood to the liver more rapidly than the parental cetuximab in as early as 1 h p.i. Injection of the CA 6 h p.i. of the primary T-ZHP1 resulted in a modest but significant ($p<0.05$) increase in clearance of T-ZHP1 from the blood, compared to T-ZHP1 alone (8.5 ± 1.8 vs. 6.0 ± 0.4 %ID/g). Analysis of blood-borne radioactivity demonstrated that $90.8\pm 1.8\%$ of the total serum-associated radioactivity post-[^{131}I]-T-ZHP1 administration followed by injection of the CA, is still in high molecular weight form i.e. intact

T-ZHP1. **Conclusion:** The obtained results provide an initial proof-of-principle and efforts to further optimize the CA are ongoing. **References:** None

Comparative evaluation of novel ¹⁷⁷Lu-labeled PNA conjugates for affibody mediated PNA-based pretargeting

M. Oroujeni¹, A. Vorobyeva^{1,2}, Y. Liu¹, T. Xu¹, H. Tano³, L. Vasconcelos³, K. Westerlund³, A. Karlström³, A. Orlova^{4,2}, V. Tolmachev^{1,2};

¹Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, ²Research Centrum for Oncotheranostics, Research School of Chemistry and Applied Biomedical Sciences, Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, ³Department of Protein Science, School of Engineering Sciences in Chemistry, Biotechnology and Health, KTH Royal Institute of Technology, Stockholm, SWEDEN, ⁴Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Affibody molecules are engineered scaffold proteins, which demonstrated excellent imaging of HER2 expression in breast cancer metastases using SPECT and PET. Radiometal-labelled affibody molecules show high renal uptake, which prevented the use of them in targeted therapy. Earlier, we have demonstrated that affibody-mediated peptide nucleic acid (PNA)-based pretargeting provides low kidney uptake and significantly extends survival of mice bearing HER2-expressing xenografts without renal toxicity. The aim of this study was to evaluate the targeting properties of three novel secondary DOTA-conjugated pretargeting agents, HP16, HP17 and HP18, and compare them directly with the properties of the first generation secondary probe, HP2. **Materials and Methods:** The primary probe was created by the coupling of a novel HP15 recognition tag to the HER2-binding ZHER2:342 affibody molecule. Radiolabelling of secondary probes with ¹⁷⁷Lu was performed at 95 °C for 60 min. In vitro stability of ¹⁷⁷Lu-labels was tested by a challenge with a 500-fold molar excess of EDTA. In vitro specificity of pretargeting was tested and cellular processing was evaluated using HER2-expressing SKOV3 and BT474 cell lines. Biodistribution was measured in Balb/c nu/nu mice bearing SKOV3 xenografts. The radiolabelled secondary probes were injected 16 h after injection of the primary probe. The distribution of activity was measured at 4 and 144 h after injection of the radiolabelled secondary agent. In vivo specificity of pretargeting was tested by injection of ¹⁷⁷Lu-secondary agent without preinjection of primary agent. **Results:** Radiolabelling with ¹⁷⁷Lu resulted in high yield and over 95% radiochemical purity. All labels were stable under the EDTA challenge. In vitro pretargeting specificity test showed that binding of the ¹⁷⁷Lu-secondary agent to cells was mediated

by PNA-PNA hybridization. Cellular processing revealed high cellular retention over time and slow internalization rate. With a preinjection of the primary probe, the tumour uptake of all secondary probes at 4 h was in the range of 19–24%ID/g. Without primary probe preinjection, the tumour uptake was 0.08–0.12%ID/g. Uptake in normal tissues (except kidneys) was negligible, several hundreds fold lower than in tumours. The renal uptake ranged from 6±1%ID/g for HP16 to 12±1%ID/g for HP18 at 4 h pi. The ratios of areas under the curve for tumour and kidneys was 3.8, 2.9, 1.9 and 2.0 for HP16, HP17, HP18 and HP2, respectively. This indicates that ¹⁷⁷Lu-HP16 would provide the most favourable dosimetry. **Conclusion:** This study showed that HP16 is the best variant among all secondary agents. **References:** None

Tetrazine-functionalized clearing agent to increase contrast in antibody imaging

E. Schlein¹, J. Rokka¹, T. Gustavsson¹, J. Eriksson^{2,3}, S. Syvänen¹, D. Sehlin¹;

¹Department of Public Health and Caring Sciences, Uppsala University, Uppsala, SWEDEN, ²PET Centre, Uppsala University Hospital, Uppsala, SWEDEN, ³Department of Medical Chemistry, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Antibodies, engineered to enter the brain, can reach concentrations up to 80-fold higher than unmodified antibodies, similar to those observed with small, lipophilic radioligands [1]. Due to the long biological half-life of a radiolabelled antibody, imaging of brain targets with antibody-based ligands must be performed several days after injection. To overcome this problem we used clearing agents (CA), which induce accelerated peripheral clearance immediately after administration [2, 3]. Here, we aimed to combine antibody-based imaging with a CA to allow imaging shortly after administration of an amyloid-β (Aβ) antibody. **Materials and Methods:** The Aβ antibody RmAb158 [4] and its bispecific, brain penetrating variant RmAb158-scFv8D3 [1] were modified with mannose for direct increased clearance or with trans-Cyclooctene (TCO) for induced clearance. The mannose modified [¹²⁵I]antibody was studied in wildtype mice using ex vivo biodistribution 24h after injection. Transgenic (tg-ArcSwe [5], Aβ pathology model) and wildtype mice were administered with [¹²⁵I] RmAb158-TCO and SPECT/CT scanned 3 days later. Immediately after, CA was administered and additional SPECT/CT scans were taken after 1 h and 1 day post CA injection. The tetrazine-functionalised CA reacts quickly with the TCO-modified antibody (inverse electron-demand Diels-Adler reaction) to induce radioligand clearance from blood. Blood was sampled at defined time points after antibody injection for analysis. The perfused brain tissue was cryosectioned for subsequent ex vivo autoradiography analysis. **Results:** Both strategies cleared efficiently, with

a decrease of up to 90% of RmAb158. The bispecific RmAb158-scFv8D3 could not be cleared from the blood, likely due to its binding to blood cells. Hence we used RmAb158 for imaging, in combination with the tetrazine-functionalized CA, which was more efficient and has the advantage of inducible clearance. [¹²⁵I]RmAb158 SPECT/CT images obtained 3 days after antibody injection showed immediate liver accumulation upon CA administration, which substantially reduced antibody concentration in blood (Fig. 1). Contrast of the brain derived signal increased after 1 h CA administration and further improved after 24 h (Fig. 2). **Conclusion:** Results indicate that the method works as intended and that the use of clearing agents may be a promising strategy for antibody-based imaging in combination with more short-lived radionuclides. **References:** 1. Evaluation of therapeutic effect of the targeted alpha therapy using Cupid-²¹¹At-labeled Psyche-B pretargeting system in a human gastric cancer cell xenograft

S. Zhao¹, A. Sugiyama², N. Ukon¹, S. Shimoyama¹, T. Tatsumi², M. Aoki¹, F. Gao¹, K. Yamatsugu², K. Nishijima¹, T. Joho¹, N. Oriuchi¹, K. Takahashi¹, M. Kanai², T. Kodama², K. Washiyama¹;
¹Fukushima Medical University, Fukushima, JAPAN,
²The University of Tokyo, Tokyo, JAPAN.

Aim/Introduction: Targeted alpha therapy using astatine-211 (²¹¹At) is one of the most promising anticancer therapies. Recently, we have developed a novel Cupid-Psyche pretargeting system [Cupid, a mutated low-immunogenicity streptavidin; Psyche, a modified bis-biotin with specific affinity to Cupid. Single-chain variable fragment (scFv) antibodies against various cancer cell surface antigens can be fused with Cupid, which specifically marks malignant cells (Ref. 1)]. In this study, we evaluated the therapeutic effect of the anti-carcinoembryonic antigen (CEA) scFv-Cupid and ²¹¹At-labeled Psyche-B (²¹¹At-Psyche-B) pretargeting system on high-level CEA-expressing xenograft mice. **Materials and Methods:** A CEA high-level expressing human gastric cancer cell xenograft (MKN-45) was established in nude mice. In the biodistribution study, the mice were intravenously injected with 100 pmol of anti-CEA scFv-Cupid antibodies. After 24 h, they were injected with 250 kBq of ²¹¹At-Psyche-B (n=3 in each group). Blood, organs, and tumor tissues were collected, weighed, and measured for radioactivity using a gamma counter. In the treatment study, the mice were assigned to a control group and three treatment groups (n=5, in each group), and received 100 pmol of anti-CEA scFv-Cupid antibodies. Twenty-four hours

after the injection, the mice in the treatment groups were injected with a single dose of ²¹¹At-Psyche-B (0.37, 1.11, and 1.85 MBq or vehicle solvent). The tumor volumes were measured three times per week for 26 days. To determine safety, we also measured the body weight three times per week. **Results:** The accumulation levels of ²¹¹At-Psyche-B in the tumor significantly increased over time. There were no significant differences in tumor volume among the four groups at the initial treatment time. After 26 days, the tumor volume significantly increased in the control group (347.0 ± 101.6 to 1837.5 ± 430.7 mm³, P<0.01). In contrast, the tumor volume dose-dependently suppressed over time in the groups treated with 0.37, 1.11 and 1.85 MBq of ²¹¹At-Psyche-B. There were no significant differences in body weight among the four groups at the initial treatment time and 26 days after the treatment despite the transient body weight loss observed in the groups treated with ²¹¹At-Psyche-B. **Conclusion:** A high accumulation level of ²¹¹At-Psyche-B was observed in the CEA high-expression tumor, and the tumor volume was suppressed dose-dependently by the Cupid-²¹¹At-Psyche-B treatment. Therefore, the CEA scFv-Cupid and ²¹¹At-labeled Psyche-B pretargeting system might be an effective targeted treatment for cancers expressing CEA. **References:** 1. OP-704

Successful Pretargeting Approach for Peptide Receptor Radionuclide Therapy of GRPR-positive Prostate Cancer

M. Verhoeven, M. Handula, K. Chen, M. de Jong, Y. Seimbille, S. U. Dalm;
 Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: The gastrin-releasing peptide receptor (GRPR) is overexpressed on prostate cancer and is therefore a suitable target for imaging and therapy using high-affinity GRPR-targeting radioligands. Unfortunately, studies have revealed that it is not only the tumor that will show high radiotracer uptake; the tracer also accumulates in the GRPR-expressing pancreas. However, the radiotracer clears relatively fast from this healthy organ while tumor radioactivity retains much better. This study aims to overcome pancreatic irradiation and herewith associated side effects when GRPR-targeting radioligands are applied for cancer treatment by applying a pretargeting strategy based on the inverse electron demand Diels-Alder click reaction. **Materials and Methods:** A panel of 6 vectors with structures containing the binding domain of the GRPR antagonist NeoB coupled to trans-cyclooctene with various linkers and spacer lengths were synthesized. The IC₅₀ values were determined with a competition binding assay on PC3 prostate cancer cells. Cells were incubated with 0.5 mL of 1 nM [¹¹¹In]In-NeoB (50MBq/nmol) +/- increasing concentrations (10⁻¹²-10⁻⁶ M) of the unlabeled

vectors. Membrane-bound fractions and internalized fractions of 4 DOTA-containing vectors were identified via an internalization assay in which PC3 cells were exposed to 0.5 mL of 1 nM indium-111 radiolabeled vectors (50MBq/nmol) +/- 1 μ M unlabeled NeoB. To verify the click reaction between vector and [¹¹¹In]In-Tz-PEG₁₁-DOTA (effector) both were added in a 1:1 ratio in PBS. After incubation, the mixture containing the collected click product was verified using HPLC and mass spectrometry. Additionally, a pilot in vivo study was performed in PC3 xenografted Balb/c nu/nu mice. Animals were first injected with 600 pmol vector and 4 h later with ~20 MBq/600 pmol effector. One hour after the second injection SPECT/CT imaging was performed. **Results:** The IC₅₀ value of all vectors was in the 0.1-0.37 nM range. For the 4 DOTA-containing vectors, the membrane-bound fraction of 53.2-64.4% was higher than the internalized fraction (35.6-46.8%). In vitro, all vectors underwent a click reaction with the effector. The SPECT/CT images showed a clearly detectable signal in the tumor indicating an in vivo click reaction. **Conclusion:** Our findings provide evidence that a pretargeting approach is feasible for GRPR-mediated radionuclide therapy. All vectors have shown to be promising candidates as they possess high GRPR binding affinities and binding to the effector was successful. The results of the pilot in vivo study are encouraging. Further research is needed for optimization of conditions for future in vivo imaging and therapy studies. **References:** None

The “click” chemistry approach as in vivo pre-targeting strategy for microspheres and bacteria

M. M. Welling¹, N. Duzzenko^{1,2}, D. M. van Willigen¹, T. Buckle¹, D. D. D. Rietbergen^{1,3}, M. Roestenberg², F. W. B. van Leeuwen¹;

¹Interventional Molecular Imaging, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS,

²Department of Parasitology and Department of Infectious Diseases, Leiden University Medical Center, Leiden, NETHERLANDS,

³Section of Nuclear Medicine, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS.

Aim/Introduction: Pre-targeting is a proven strategy for in vivo delivery of a diagnostic or therapeutic payloads. The pre-targeting concept can be realized through various conjugation strategies, one of which is copper-free “click” reactions, which have shown in vivo potential for imaging and radionuclide therapy. This conjugation strategy, however, has not yet been explored in combination with microspheres or unicellular organisms. Hence, we aimed to evaluate the in vivo efficacy of strain-promoted azide-alkyne cycloaddition (SPAAC) “click” reactions in the hepatic delivery of a payload. **Materials and Methods:** MAA microspheres (diameter 10-90 μ m) were functionalized with a biorthogonal Cy5 fluorophore bearing an azide functionality (N₃) to generate MAA-Cy5-N₃. *S. aureus*

(diameter ~ 1 μ m) were functionalized with ^{99m}Tc-UBI₂₉₋₄₁-Cy5-N₃ to generate *S. aureus*-UBI₂₉₋₄₁-Cy5-N₃. In situ and in vitro “click” conjugation was studied over time using a radioactivity assay and fluorescence microscopy. To validate the pre-targeting strategy in vivo, both entities, radiolabeled with ^{99m}Tc, were locally delivered in the microvasculature of the liver. Secondary targeting was realized following reaction with intravenously administered indium-111-radiolabeled diethylenetriaminepentaacetic acid-dibenzocyclooctyne (¹¹¹In-DTPA-DBCO). Imaging of ¹¹¹In-DTPA-DBCO in mice without MAA deposits or mice infected with non-functionalized *S. aureus* served as controls. **Results:** In vitro data confirmed effective “click” reactions on both the MAA particles and the bacterial membrane. SPECT imaging and %ID/g biodistribution studies revealed significantly ($p < 0.05$) increased accumulation of ¹¹¹In-DTPA-DBCO at the sites where MAA-Cy5-N₃ (7.5±1.5%ID/g vs 3.5±0.5%ID/g in control mice) and *S. aureus*-UBI₂₉₋₄₁-Cy5-N₃ (9.3±1.3%ID/g vs. 6.0±0.5%ID/g in control mice) accumulated. Ex vivo fluorescence imaging confirmed the presence of either functionalized MAA or *S. aureus* in excised spleens and livers of mice. **Conclusion:** Copper-free “click” chemistry between a DBCO moiety and Cy5-N₃-functionalized microspheres or bacterial entities in the liver could be used to realize in vivo pre-targeting. Thereby demonstrating that this generic concept can serve both theragnostic radioembolization strategies and bacterial colonization applications. **References:** Welling et al. ACS Infect. First clinical experiences with an innovative Gamma-probe to guide parathyroid radio-guided surgery: Navigator and Lock-on-target functions of the Gonioprobe

V. Frantellizzi, M. S. De Feo, S. Sollaku, R. Falconi, R. Pani, M. Bononi, J. Lazri, A. Matto, G. De Vincentis; Sapienza University of Rome, Rome, ITALY.

Aim/Introduction: Minimally invasive radio-guided parathyroidectomy (MIRP) represents a validated surgical

approach in patients with primary hyperparathyroidism (PHPT) caused by single adenomas. To date, little attention has been paid to how the physical characteristics of gamma-probes may impact on intraoperative detection of abnormal tissue with increased uptake of ^{99m}Tc -sestamibi. The aim of this analysis was testing an innovative gamma-probe prototype, the Gonioprobe, in selected patients with parathyroid adenomas particularly difficult to identify due to anatomy modifications from previous neck surgery or concomitant thyroid goiter **Materials and Methods:** In the fall of 2019 three patients were submitted to MIRP with Gonioprobe in our center. The Gonioprobe performs the dual function of Navigator and Lock-on-target thanks to its 5 scintillating independent crystals. This innovative prototype was used to both detect abnormal parathyroid tissue during intervention, and to ensure no radioactivity in surgical bed after adenoma removal. All patients were administered a very low activity of ^{99m}Tc -sestamibi (111 MBq) 2 hours before intervention. Parathyroid hormone (PTH) assay and frozen biopsy were performed to confirm the successful excision of the adenoma. The intraoperative nerve monitoring system was used to protect the recurrent laryngeal nerve (RLN) from injuries **Results:** Thanks to its characteristics, our newly developed prototype allowed the immediate guidance of surgeon's hand towards the target with extreme precision and high spatial resolution, showing in-vivo target to background ratio higher than 1.5 in all cases, specifically 1.81 for case 1 and 1.57 and 1.89 for case 2 and 3 respectively. After the removal of the adenomas, high radioactivity levels in ex-vivo tissues and no residual radioactivity in surgical bed were detected, with the "Twenty percent rule" satisfied in all cases. A decrease of more than 50% of PTH levels was observed 10 minutes after the removal of the adenomas and frozen section analysis confirmed parathyroid tissue in all the excision materials. No RLN damage was registered. The mean operative time from the incision to the complete removal was 20 minutes. The postoperative course was uneventful for all patients who were discharged on the third postoperative day **Conclusion:** The intraoperative use of the Gonioprobe for MIRP allowed the accurate removal of parathyroid adenomas even in case of previous neck surgery or thyroid nodular disease and offered a significant advantage by reducing surgical time, radiation exposure to surgical staff, postoperative complications, as well as hospitalization and costs **References:** None

³Università degli studi di Roma Sapienza, Rome, ITALY.

Aim/Introduction: Recently, a flexible design of DROP-IN gamma-probe was introduced for robot-assisted radioguided surgery, exploiting traditional low-energy SPECT-isotopes. This study explores the use of a novel DROP-IN beta-particle (DROP-IN) detection probe to support the implementation of the large number of PET-tracers available during robot-assisted tumor-receptor-targeted resections, together with beta-RGS intrinsic advantages **Materials and Methods:** Following engineering of the DROP-IN probe, robotic implementation was investigated using ex-vivo surgical specimens. Seven prostate cancer patients with PSMA-PET positive tumors received an intraoperative injection of ~70 MBq ^{68}Ga -PSMA-11, followed by prostatectomy and extended pelvic lymph node dissection. **Results:** The probe was able to identify the position of the tumor in the prostate specimens: S/B was > 5 when pathology confirmed that the tumor was located <1 mm below the specimen surface. PSMA-PET positive lymph nodes, as found in two patients, could be identified with the DROP-IN probe (S/B>3). **Conclusion:** This ex vivo study underlines the potential to use a DROP-IN probe for intraoperative tumor identification on the prostate surface and confirmation of PSMA-PET positive lymph nodes. In vivo tests are now on schedule to further validate this technique. **References:** None

and Management, The University of Tokyo, Tokyo, JAPAN.

Aim/Introduction: FDG-PET is one of the effective nuclear examinations to diagnose various cancers and identify lymph node (LN) metastasis preoperatively. However, it's too difficult to locate each metastatic LN during surgery. This difficulty usually leads to unnecessary node removal, in which impairment of neighboring nerves would be inevitable, resulting in a deterioration of a patient's quality of life. To overcome this problem, we developed an intraoperative PET imaging system. **Materials and Methods:** This system consists of an external detector array (49 pixels of 10mm x 10mm x 20mm, GAGG)(SiPM) connected to a patient's surgical bed and a movable detector probe (4

layers of 12 pixels of 2mm x 2mm x 3mm, GAGG)(SiPM) which is small enough to be inserted into peritoneal cavity along with a laparoscope tracked by an optical tracking system. In this proof-of-concept study, we imaged the ^{22}Na point source (290kBq) and FDG (0.6MBq/2mL) with/without the low concentration FDG background. PET scan was performed by swinging the movable detector at the speed of a few millimeters per second for 2 mins at the distance of about 2 cm above from the activity source. The image is reconstructed using a modified filtered back projection algorithm. **Results:** Our developed system reconstructed images of a ^{22}Na point source with 3 mm spatial resolution. And we could succeed in imaging FDG in a 2min-scan. It was confirmed that the accumulation could be imaged even in an environment with a low concentration of FDG in the background. Even if the probe was not fixed, the spatial resolution equivalent to that of the conventional fixed PET was obtained by integrating the position information. **Conclusion:** We could develop the intraoperative PET imaging system with a movable detector probe tracked by an optical tracking system. This system has potential to achieve the limited operations. **References:** None

Preliminary study of the feasibility of Cerenkov luminescence imaging in metastasectomy

E. Ciarrocchi¹, S. Saponaro¹, F. Bartoli², A. G. Cataldi², S. Vitali², P. A. Erba², N. Belcari¹;

¹University of Pisa, Department of Physics, Pisa, ITALY,

²University of Pisa and Azienda Ospedaliero Universitaria Pisana, Department of Translational Research and of New Surgical and Medical Technologies, Pisa, ITALY.

Aim/Introduction: Cerenkov luminescence imaging (CLI) is an imaging modality to detect distributions of radiopharmaceuticals that can allow intra-operative visualization of surgical margins and immediate surgery refinement. We are planning a pilot clinical study to evaluate its impact on pulmonary and hepatic metastasectomy, using ^{18}F -FDG and ^{68}Ga -DOTATOC. We are currently optimizing the clinical protocol regarding patient inclusion criteria, activity to inject, maximum allowed delay for imaging and radiation monitoring. **Materials and Methods:** To optimize the clinical protocol, we are performing a preliminary study, featuring, on one side, an analysis of patient PET/CT data (n=45) to determine typical uptake, lesion dimension, resection margins; on the other, an in-vitro study to determine the detection limits for ^{18}F and ^{68}Ga in animal tissue specimens as a function of the depth in tissue, using signal-to-noise ratio (SNR) as metrics. ^{18}F -FDG and ^{68}Ga -HCl were either diluted in distilled water inside Petri dishes or uniformly distributed in agar-based solid phantoms and placed under animal liver slabs. Acquisitions were performed with acceptable exposure times (no longer

than five minutes) and spatial resolution (0.9375 mm/pixel). We have also acquired images with 550- and 800- nm short-pass filters to try estimating the source depth. We plan to repeat the same in-vitro measurements with animal lung specimens. **Results:** PET/CT data indicate tumor uptakes that vary from 4-11 kBq/cc at the time of CLI, assumed to be approximately 5 hours post-injection. So far, we have obtained the following in-vitro results: 1) the light yield of ^{68}Ga is 15 (22) times that of ^{18}F in agar (Petri); 2) when imaged in air, a certain amount of activity in a given volume produces in the agar phantoms a signal that is 2.3 (1.6) times that in a Petri for ^{68}Ga (^{18}F); 3) the average attenuation length of our animal liver specimens is ~1.5 mm; 4) the detection limits with SNR=2 for ^{68}Ga in a Petri dish are 0.93 kBq/cc in air, and 2.7 kBq/cc at a depth of 2.5 mm in liver. The detection limits for agar, for other depths and for ^{18}F agree well with the conversion factors given by 1)-3). **Conclusion:** The fact that clinical uptakes are larger than the detection limits we measured is promising, because it suggests that intra-operative Cerenkov luminescence imaging in the liver is likely to be feasible. **References:** None

Cerenkov Luminescence Imaging in prostate cancer: unraveling of the basal halo

J. olde Heuvel¹, H. G. van der Poel¹, E. M. Bekers¹, M. P. M. Stokkel¹, C. H. Slump², B. J. de Wit-van der Veen¹;

¹Netherlands Cancer Institute, Amsterdam, NETHERLANDS,

²University of Twente, Enschede, NETHERLANDS.

Aim/Introduction: Positive surgical margins (PSM) are found in up to 38% of patients after radical prostatectomy. Cerenkov Luminescence Imaging (CLI) is a novel imaging technology that could be used for intra-operative margin assessment after injection of ^{68}Ga -PSMA [1]. In this ongoing clinical trial an area of increased signal intensity, referred to as halo, was visible on all images of the prostate base, despite the fact that the tumor was not located there in 6/13 patients. Since this basal halo might hamper visualization of PSMs, the study aim is to unravel its origin. **Materials and Methods:** The study was approved by local ethics committee and all patients signed informed consent. All CLI images were acquired at 150s, 8x8 binning, with and without 550nm shortpass filter and corrected for decay. Possible sources for the halo that were assessed are; 1) urine contamination and 2) chemiluminescence. First, two prostates of patients injected with ~100MBq ^{68}Ga -PSMA are imaged before and after rinsing it with sodium chloride. Subsequently, prostates of three patients who underwent surgery without ^{68}Ga -PSMA injection were imaged to assess signal intensities in non-radioactive specimens. The signal half-life, influence of a 550nm short-pass filter and 6µm thick scintillator sheet on the intensity of the halo signal were investigated. **Results:** Rinsing a radioactive prostate

did not reduce the signal both visually and quantitatively, suggesting the halo is not caused by urine contamination. The basal halo was also observed in non-radioactive specimens. The use of the 550nm short pass filter reduced this signal with 85%. The half-life of the basal halo was on average 50 ± 12 min. A scintillator sheet reduced the image intensity by 50% of its original signal, in both non-filtered and filtered setting. **Conclusion:** The basal halo is not caused by urine contamination, and importantly, is also visible in non-radioactive specimens. It is hypothesized that the halo is produced by chemiluminescence from radical oxygen species [2], generated by use of diathermia at the base to separate bladder from the prostate. The half-life of this diathermia halo and ^{68}Ga -Cerenkov signal is similar (50 vs. 68 min), so it remains difficult to distinguish the two. **References:** 1. olde Heuvel J, de Wit-van der Veen BJ, van der Poel HG, et al. ^{68}Ga -PSMA Cerenkov luminescence imaging in primary prostate cancer: first-in-man series. *Eur. Aim/Introduction: The introduction of a small and tethered DROP-IN gamma probe helped facilitate precision radioguided surgery in the robotic workflow by enhancing the manoeuvrability of the detection modality [1,2,3]. In addition to radioguidance, fluorescence guidance is increasingly being implemented during robotic surgery, in particular angiography and lymphatic mapping with indocyanine green (ICG). Next to issues in manoeuvrability of the fluorescence laparoscope, fluorescence imaging may limit the surgical logistics: during laparoscopic surgery its overall depiction of the patient anatomy (e.g. bleedings) has proven inferior to white light imaging. Hence implementation of fluorescence imaging requires a surgeon to pause the resection, interrupting the surgical workflow. In addition, this means fluorescent tracers are not detected

during the actual resection under white light. To this end, we developed and investigated click-on fluorescence detectors that convert robotic surgical instruments into fluorescence imaging devices (so-called SmartForceps), detecting fluorescence tracers in the tissues grasped during every stage of the surgical procedure. **Materials and Methods:** A tailored fibre-based fluorescence detector for ICG was engineered so that it could be clicked-on to traditional instruments of the surgical robot. Translational performance evaluation was performed using: 1) phantoms; 2) during robotic surgery in pigs (n=5), evaluating angiography and lymph node localisation; and 3) on surgical specimens from clinical sentinel node procedures that made use of the hybrid tracer ICG- ^{99m}Tc -nanocolloid (n= 2; prostate cancer). **Results:** The instruments, including detectors, could be introduced through standard 12 mm trocars. After insertion in the abdomen, the detectors did not interfere with the instruments grasping ability or manoeuvrability. Only in fluorescent samples, as confirmed with fluorescence imaging, fluorescent counts were detected using the SmartForceps. Porcine surgery demonstrated grasping of tissue allowed for the identification of blood vessels (bladder, bowel and kidney) and pelvic lymph nodes. During ex vivo evaluation with human prostate cancer related lymph nodes, the SmartForceps could distinguish sentinel nodes from non-sentinel nodes, as confirmed by fluorescence imaging and gamma probe detection. **Conclusion:** This study successfully introduces a click-on fluorescence-based sensing module for robotic surgical instruments, turning regular forceps into SmartForceps. This technology allows fluorescence sensing during white light resections. In addition, it opens the way for bio-sensing applications, where the surgical instruments can be used to characterise the molecular aspects of tissues. **References:** [1] M.N. van Oosterom et al., *AJNM*, 2016; [2] P. Imaging Cancer Immunology: Magnetic Particle Imaging of Immunotherapy

J. Mansfield¹, G. Ren¹, M. Gerosa², J. Gaudet¹, N. Carvou¹, Y. Zhang², P. Goodwill¹, M. Wintermark²;

¹Magnetic Insight, Alameda, CA, UNITED STATES OF AMERICA, ²Stanford University, Palo Alto, CA, UNITED STATES OF AMERICA.

Aim/Introduction: The rapid growth of immuno-oncology research has fueled a need to evaluate the location, quantity, and phenotype of immune cells. Tumour-associated macrophages (TAMs) play a pivotal role in cancer immunotherapy. However, current methods for qualitative and quantitative measurements of TAM accumulation are insufficient. Magnetic Particle Imaging (MPI) is a novel tomographic molecular imaging technique

used to non-invasively track cells labeled with magnetic nanoparticles. MPI provides sensitive (≤ 50 attomole nanoparticle detection limit), depth-independent, 3D quantitative data and imagery (>3 logs linear dynamic range) about nanoparticle biodistribution in longitudinal studies. Phagocytotic cells, such as macrophages, become labeled with the nanoparticles in situ following intravenous injection. **Materials and Methods:** A murine breast tumour model was established by injecting 3×10^5 4T1 cells into the 5th mammary fat pad of 8–10-week-old female Balb/c mice. Immunotherapy treatment was with a CD47 mAb (200 μ g \times 5 days). Two groups were used: a CD47-treated group and an untreated control group. All mice were injected with an iron-oxide MPI tracer (Synomag PEG 50, Micromod GMBH, 5 mg/kg) and then 3D images were acquired on MPI and MRI (T2-weighted multi-slice, multi-echo sequences). Images were acquired at 1, 3, and 7 days after tracer injection. MPI and MRI images were co-registered and quantitated. Tumour, liver, spleen, and draining lymph nodes were harvested, imaged, fixed, and stained with Perls Prussian blue for analysis of iron content. **Results:** This preliminary study suggests that TAM accumulation increases following CD47 mAb treatment. All mice showed an accumulation of tracer in the tumor and liver following injection and signal was predominately detected in the expanding margins of the tumour. There was an increased tracer accumulation at the tumour site for the treated group compared to the control on days 1 and 3 following injection, but not on day 7 ($p = 0.002$, 0.243 and 0.075, respectively). **Conclusion:** MPI provides valuable quantitative and spatial distribution information for preclinical models. In combination with existing FDG-PET techniques for increased glucose consumption, in situ tagging of phagocytic cells with magnetic tracers and MPI could significantly improve the specificity of inflammation detection. This would enable researchers to monitor the efficacy of immunotherapies with the sensitivity, specificity and quantitation they require. **References:** None

3D Compton Imaging: A new modality for nuclear medicine at 511 KeV and above

A. Iltis¹, G. Zeufack¹, M. Lopez¹, H. Snoussi², L. Zimmer^{3,4}, N. Costes³, C. Bouillot³, Z. Hmissi¹, F. Lavenne³, J. Redoute³;

¹Damavan Imaging, Rosieres pres Troyes, FRANCE,

²Université de Technologie de Troyes (UTT), Troyes,

FRANCE, ³CERMEP-Imagerie du vivant, Bron, FRANCE,

⁴INSERM, CNRS, Université de Lyon, Lyon, FRANCE.

Aim/Introduction: So far, the main imaging modalities for nuclear medicine are PET and SPECT scanners. Both modalities require a large number of views or many LOR to reconstruct a tomographic image of a patient. To populate all those views in a reasonable time, a large activity above 100 MBq must be injected to the patient. Besides for

both modalities each detector element (Septa or pair of coincidence detector) has a limited field of view below 10°. Compton imaging offers wide FOV (90° \times 90°) and requires no collimation. 2D Compton imaging has been proposed as an alternative to SPECT, but Compton imaging doesn't work well at the low energies of SPECT tracers (140 KeV).

Materials and Methods: We have developed a hand-held Compton camera based on temporal imaging and CeBr₃ monolithic scintillator plates for nuclear industry. This camera has the following characteristics: 1) A 90 \times 90° Field of view with small equipment allowing to study large animals (monkeys, horses-) 2) 3D imaging with 3–4 views only 3) Injection of a dose to the patient an order of magnitude lower than standard. Typically we would need less than 10 MBq for a human body. 4) Reasonable spatial resolution below 1 cm³ for human torso, probably below 0,1 cm³ for brain. 5) Using well known isotopes as those used for PET imaging 6) But we could also use also radiotherapy isotopes having significant emissions above 400 KeV (¹³¹I, ¹⁷⁷Lu, ²¹¹At ...). 7) Digital photon counting allowing quantification with a good signal/noise **Results:** With this camera we have obtained first views of a mouse injected with Fluorine 18. We have obtained both 2D images from a single view and tomographic 3D image by using 3 views at right angle to the object, using only a 0,6 MBq dose and 5 minutes exposures. The results presented here are very preliminary and the images obtained are in no way optimized, but they are very promising. **Conclusion:** 3D Compton imaging appears as a promising new imaging modality in complement to SPECT and PET as it allows: It seems possible with this technology to obtain tomographic 3D images with a voxel size below 1 cm³ in human patients with an injected dose an order of magnitude below standard practice in PET and with a portable equipment **References:** T Zafarifety et al. Concordance of PD-L1 status between image-guided percutaneous biopsies and matched surgical specimen in non-small cell lung cancer

L. Zhao, H. Chen, Y. Zhuang, Q. Lin; the First Affiliated Hospital of Xiamen University, Xiamen, CHINA.

Aim/Introduction: Determining PD-L1 expression status could help select patients with non-small cell lung cancer (NSCLC) who will optimally benefit from anti-PD-1/PD-L1 immunotherapy. Currently, PD-L1 testing is mainly performed on biopsy samples because of diagnosis at the advanced stage. However, the inevitable intra-tumor heterogeneity would markedly affect the results of PD-L1 status investigations. As such, the concordance of PD-L1 status between biopsy samples and matched resected specimens varied across previous studies [1, 2]. This study aimed to evaluate the concordance of PD-L1 expression between image-guided percutaneous biopsies and matched surgical specimens. **Materials and Methods:** We evaluated 157 patients diagnosed with operable NSCLC on both surgical tissue sections and matched lung biopsies retrospectively. The patients underwent either regular computed tomography (CT)-guided biopsy (n=82) or ¹⁸F-FDG positron emission tomography (PET)/CT-guided biopsy (n=75). The diagnostic success rates of CT- and ¹⁸F-FDG PET/CT-guided biopsy were scored. The concordance between surgical specimens and lung biopsies for PD-L1 TPS was evaluated using Cohen's kappa (κ) coefficient. **Results:** The diagnostic success rates of CT- and ¹⁸F-FDG PET/CT-guided biopsy were 82.9% (68/82) and 93.3% (70/75), respectively. Immunohistochemical expression of PD-L1 was evaluated in both surgical resected specimens and matched biopsies in the eligible 138 patients. The concordance rate of PD-L1 expression between surgical tissue sections and matched biopsies was fairly high at 83.3% (115/138), and the κ value was 0.73 (95% CI: 0.63–0.83, P < 0.001). The concordance rate was higher

for tissue sections from ¹⁸F-FDG PET/CT-guided biopsy than for tissue sections from CT-guided biopsy (88.6% [62/70, κ value: 0.81] vs 77.9% [53/68, κ value: 0.66]). **Conclusion:** PD-L1 TPS was strongly concordant between surgical specimens and matched lung biopsies. Thus, routine evaluation of PD-L1 expression in diagnostic percutaneous biopsies could be reliable for identifying patients who will benefit from anti-PD-1/PD-L1 immunotherapy. Moreover, our result showed ¹⁸F-FDG PET/CT-guided biopsy has higher diagnostic success rate and concordance compare with CT-guided biopsy. **References:** 1. OP-719

Differentiation of the histopathological types of solitary pulmonary nodules with ¹⁸F-FDG PET/CT radiomic using machine-learning methods

Y. Zhou, R. Tian; West China Hospital, Chengdu, CHINA.

Aim/Introduction: Our study assessed the ability of ¹⁸F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) radiomics features combined with a large panel of machine-learning methods to differentiate primary lung cancer from metastatic lung cancer and squamous cell carcinoma from adenocarcinoma, and secondly to identify optimal machine-learning methods. **Materials and Methods:** 775 patients pathologically diagnosed as primary or metastatic lung lesions were retrospectively studied. Radiomics features were extracted from semiautomatically segmented PET and CT images using the LIFEx package. Five feature selection methods and nine machine learning classifiers were used to establish the differentiate models. The patient cohort was randomly divided into a training and a validation group and the robustness of the procedure was tested by ten-fold cross validation. The areas under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity were calculated to evaluate the discriminative ability of these models. **Results:** Forty-five differentiate models were established based on radiomics features from PET and CT images. Most of the classifiers represented feasible ability in differentiation, with AUC more than 0.8 when combined with suitable selection method. In the differentiation of primary lung cancer and metastatic lung cancer, for models based on PET

images, the combination of GBDT and AdaBoost classifier represented the highest AUC of 0.98 in the validation group, while the combination of Xgboost and GBDT classifier represented the highest AUC of 0.863 in the validation group for models based on CT images. In the differentiation of squamous cell carcinoma and adenocarcinoma, for models based on PET images, the combination of GBDT and GBDT classifier represented the highest AUC of 0.917 in the validation group, while the combination of GBDT and LDA classifier represented the highest AUC of 0.853 in the validation group for models based on CT images. Most of the DT-based models were overfitting, suggesting that this classifier was not suitable for application. **Conclusion:** Radiomics features extracted from ^{18}F -FDG PET and CT images are efficient to differentiate primary lung cancer from metastatic lung cancer and squamous cell carcinoma from adenocarcinoma using machine-learning methods. **References:** None

OP-720

Comparison of Metabolic and Morphological Response Criteria for Early Prediction of Response and Survival in NSCLC Patients Treated with Checkpoint Inhibitors

A. Castello, S. Rossi, L. Toschi, E. Lopci;

Humanitas Clinical and Research Hospital, Rozzano (MI), ITALY.

Aim/Introduction: Immunotherapy with immune checkpoint inhibitors (ICI) has positively changed the history of several malignant tumors. In parallel, new challenges have been arisen in the evaluation of treatment response due to their peculiar anticancer effect. In the current study we aim to compare different response criteria, both morphological and metabolic, for assessing response and outcome in patients with advanced non-small-cell lung cancer (NSCLC) treated with ICI. **Materials and Methods:** Overall, 52 patients with advanced NSCLC candidate to ICI were prospectively evaluated. Inclusion criteria comprised whole body contrast-enhanced CT and ^{18}F -FDG PET/CT at baseline and at the first response evaluation after 3 or 4 cycles of ICI. Response assessment by CT was performed according to RECIST 1.1 and iRECIST criteria, whereas metabolic response on PET was computed by EORTC, PERCIST, imPERCIST, and PERCIMT criteria. The concordance among the different tumor response criteria and the performance of each criterion to predict PFS and OS were calculated. **Results:** Inclusion criteria were fulfilled in 35 out of 52 patients. We observed a low agreement between iRECIST and imPERCIST ($\kappa=0.174$) with discordant response in 14 patients ($p=0.005$), fair agreement between iRECIST and EORTC ($\kappa=0.360$), and PERCIST ($\kappa=0.404$), and moderate for PERCIMT ($\kappa=0.484$). Moreover, we found a moderate agreement between EORTC and imPERCIST ($\kappa=0.446$) with discordant response in 21 patients ($p<0.001$), particularly regarding stable metabolic disease and progressive metabolic disease groups. All criteria

were significantly associated with PFS, while only PERCIMT and imPERCIST were associated with OS. Of note, in patients classified as immune stable disease (iSD), imPERCIST well differentiated those with longer PFS ($p<0.001$) and OS ($p=0.001$). In the multivariate analysis, performance status (HR=0.278, $p=0.015$), iRECIST (HR=3.799, $p=0.026$), and imPERCIST (HR=4.064, $p=0.014$) were predictive factors for PFS, while only performance status (HR=0.327, $p=0.035$) and imPERCIST (HR= 3.247, $p=0.007$) were predictive for OS. **Conclusion:** At the first evaluation during treatment with ICI, imPERCIST criteria correctly evaluate treatment response and appear able to predict survival. Moreover, in patients with iSD on CT, imPERCIST was able to discriminate those with longer survival. This advantage might allow for earlier therapy modification based on the metabolic response. **References:** The Italian Association for Research on Cancer (AIRC - Associazione Italiana per la Ricerca sul Cancro) is acknowledged for the support on research with the grant nr. 18923.

OP-721

Analysis of the Association between SUV index in ^{18}F -FDG PET/CT Imaging and Malignant Risk of Ground-Glass nodules: A Retrospective Cohort Study

R. Niu, X. Shao, X. Shao, J. Wang, M. Xu, Y. Wang;

The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: To explore the association between the SUV index (GGN SUVmax / liver SUVmean) in ^{18}F -FDG PET / CT imaging and the malignant risk of ground-glass nodules (GGNs). **Materials and Methods:** A retrospective analysis of 166 patients with GGN who underwent PET/CT from January 2012 to October 2019 was performed. There were 113 males and 53 females, aged (60.8 ± 9.1) years. 192 GGNs were confirmed by postoperative pathology, 22 in the benign group, and 170 in the adenocarcinoma group. The clinical and imaging data of all patients were collected and analyzed. The patients were grouped based on SUV index tertiles, and the differences of clinical and imaging parameters among groups were compared with analysis of ANOVA or Kruskal-Wallis test. Univariate logistic regression method was used to analyze the influencing factors of malignant GGN. Multivariate logistic regression and stratified analysis were used to correct for confounding factors. Generalized additive model was used to test the nonlinear relationship between the SUV index and the malignant risk of GGN. **Results:** The percentages of malignant GGN from Tertile 1 to Tertile 3 were 89.1%, 95.3%, and 81.2%, respectively. After adjusting for the potential confounding factors, we found that the malignancy risk of GGN significantly decreased as the SUV index increased (OR, 0.245; 95% CI, 0.119–0.504; $P<0.001$), and the increase of SUV index was significantly correlated with the reduction of malignant risk (OR, 0.099;

95% CI, 0.025–0.394; $P = 0.001$), especially between Tertile 3 and Tertile 1 (OR, 0.064; 95% CI, 0.012–0.356; $P = 0.002$). Curve fitting showed that the SUV index was linearly and negatively correlated with the malignant risk of GGN, and the correlation was not affected by age, GGN number, type, shape, vacuolar signs, and CTR levels, indicating that SUV index had no significant interaction with these factors (P for interaction range: 0.187–1.000). **Conclusion:** The SUV index is an independent correlation factor for GGN malignant risk, and these two factors are linearly and negatively correlated. The understanding of this correlation will help to improve the accuracy of PET/CT in GGN diagnosis. **References:** None

OP-722

Prediction of mutational status in lung cancer using PET radiomics

M. Berraho¹, O. Tankyevych^{1,2}, G. Tachon³, M. Hatt², D. Visvikis², C. Cheze le Rest^{1,2};

¹Nuclear medicine, CHU de Poitiers, Poitiers, FRANCE,

²LaTIM, INSERM, UMR1101, Brest, FRANCE, ³Cancer biology, CHU Poitiers, Poitiers, FRANCE.

Aim/Introduction: Nowadays, precise characterization of lung adenocarcinoma at the genetic level is a fundamental requirement for personalized therapy. The present work aims at evaluating radio-genomic associations of quantitative parameters derived from initial 18FDG PET/CT in lung adenocarcinoma. The study was retrospectively designed to assess feasibility of mutational status identification using pretreatment PET image derived parameters. **Materials and Methods:** 487 patients with pulmonary adenocarcinoma were included in this retrospective study. All patients underwent 18FDG PET/CT for initial staging and EGFR, KRAS, BRAF mutational status and PDL1 expression, ALK translocation and ROS1 fusion were assessed. All primary tumors were identified (volume larger than 4 cm³) on PET images and were automatically segmented using the FLAB algorithm, and radiomics parameters were derived. The association between PET parameters and biological characteristics were evaluated. **Results:** A total of 120 features were extracted from each PET image. Routinely used SUVmax had no efficient predictive value for any of the biological studied characteristics. In univariate and multivariate analysis, several PET parameters were associated with EGFR, PDL1, ROS1 and BRAF status, with individual AUC reaching 0.86. The best performing parameters were different depending on the studied gene. Textural parameters did better than any volume related ones. No parameter managed to predict efficiently KRAS and ALK translocation (AUC < 0.65). **Conclusion:** Our results confirm that PET radiomics could help detect lung adenocarcinoma harboring EGFR, BRAF mutation, ROS fusion, and PDL1 expression. PET radiomics could be a powerful approach to identify specific molecular subgroups of pulmonary

carcinoma and should be considered to guide patient management. **References:** None

PERCIST-derived metabolic volume response predicts overall and progression-free survival in patients with malignant pleural mesothelioma treated with Pembrolizumab

J. Ferdinandus, F. Barbato, M. Chodyla, W. P. Fendler, L. Kessler, M. Metzzenmacher, F. Krefting, T. Hager, K. Herrmann, D. C. Christoph; University Hospital Essen, Essen, GERMANY.

Aim/Introduction: Despite promising response rates in phase 1b and 2 clinical trials, immune checkpoint inhibition (ICI) with pembrolizumab for the treatment of malignant pleural mesothelioma (MPM) did not result in survival benefit in the PROMISE-meso trial compared to 2nd-line chemotherapy. Due to lack of validated imaging response criteria, responder-subgroups with potential survival benefit have not yet been identified. Here, we assess the predictive value of PET metabolic response in patients undergoing four cycles of high-dose pembrolizumab (10 mg/kg, d₁, q2w) considering the KEYNOTE-028 trial procedure for chemotherapy-resistant malignant pleural or peritoneal mesothelioma. **Materials and Methods:** RECIST v1.1, mRECIST, PERCIST (using SULpeak, MTV and TLG) response assessment criteria were used separately to categorize responders in CT and PET imaging studies. Progression-free survival (PFS) and overall Survival (OS) of responders were compared to non-responders using Kaplan-Meier methods and log-rank comparisons. Fishers-exact testing was used to compare PD-L1e expression status of responders vs. non-responders. **Results:** Twenty-seven patients had [¹⁸F]-FDG-PET/CT imaging at baseline and after four cycles of pembrolizumab. Response rates were 7%, 7%, 30%, 30% and 33% based on RECIST v1.1, mRECIST, PERCIST, MTV and TLG response criteria, respectively. Regarding PFS, only MTV and TLG response groups showed a significant different survival ($p < 0.01$, respectively). Regarding OS, only a reduction of MTV $\geq 30\%$ predicted prolonged survival ($p < 0.01$). PD-L1 expression could not be associated with response rates or survival. **Conclusion:** PERCIST-derived metabolic volume response predicts survival in pretreated patients with malignant mesothelioma receiving high-dose pembrolizumab. These results warrant inclusion of PET response assessment in future clinical trials and routine practice. **References:** None

OP-724

Interobserver reliability in the quantitative assessment of [^{99m}Tc]-labeled anti-Programmed Death-Ligand 1 (PD-L1) SPECT/CT in non-small cell lung cancer

D. Hughes¹, G. Chand¹, H. Ting², V. Warbey¹, V. Goh¹, G. Cook¹;

¹Department of Cancer Imaging, School of Biomedical Sciences

and Engineering, King's College London, London, UNITED KINGDOM, ²Department of Research and Development, NanoMab Technology Limited, Shanghai, CHINA.

Aim/Introduction: Checkpoint inhibition using directed antibody therapy (e.g. anti-programmed death-1 antibody) has become a standard of care in the management of non-small cell lung cancer (NSCLC). [^{99m}Tc]-labeled anti-PDL1 single-domain antibody single-photon emission computed tomography (SPECT) has been shown to demonstrate tumour to blood pool ratios that correlate with tumoural PD-L1 expression. In this study, we assessed whether this quantitative assessment demonstrated interobserver reliability. **Materials and Methods:** Using 1 and 2h post-injection [^{99m}Tc]sdAb-PD-L1 SPECT scans in 21 patients with NSCLC, three independent observers applied a manual technique for measurement of ROI_{max} of primary tumour, metastatic lesions and normal tissue references to determine PD-L1 expression. A two-way random effects model was applied to estimate the intraclass correlation coefficient (ICC) of single measurements and tumour (T) ROI_{max} to blood pool (BP) ROI_{max} ratio using SPSS. **Results:** Manual ROI_{max} scoring of primary tumour (0.95 confidence interval, 0.90-0.97), lung (0.99-1.0) and nodal (0.95-0.98) metastases all demonstrated an ICC of >0.9. Blood pool ROI_{max} score ICC was 0.9 (0.84-0.94) with a T:BP ICC of 0.83 (0.73-0.90). The ICC for normal lung tissue was 0.84 (0.75-0.90), however, applying an anatomically defined rule-based approach to scoring demonstrated a trend toward improved reliability (ICC 0.89; 0.82-0.93). **Conclusion:** Measurement of PD-L1 expression using [^{99m}Tc]-labeled anti-PD-L1 SPECT of primary tumour, lung and nodal metastases is achievable with excellent interobserver reliability. In addition, T:BP previously shown to correlate with tumoural PD-L1 expression demonstrated good interobserver reliability. **References:** None

OP-725

Role of texture parameters derived from baseline 18F-FDG PET/CT as prognostic markers in non-small cell lung cancer (NSCLC) patients undergoing platinum-based chemotherapy

A. Sharma, A. K. Pandey, C. Bal, R. Kumar;

All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: To prospectively evaluate the role of texture parameters evaluated from baseline 18F-FDG PET/CT in prediction of overall survival (OS) in biopsy proven NSCLC patients who were planned to undergo platinum-based chemotherapy. **Materials and Methods:** Forty five patients (36 male, 9 female) with biopsy proven NSCLC (22 adenocarcinoma, 17 Squamous cell carcinoma and 6 NSCLC NOS) and mean age 55.22±10.370 years were enrolled in the study. Each patient underwent a baseline whole body 18F-FDG PET/CT scan on Biograph mCT 64 slice

after 60 minutes of injecting 5.18-7.77 MBq/kg of 18F-FDG intravenously. For texture analysis, the displayed PET/CT images with maximum tumor diameter were exported in JPEG format and analysis was performed using R version 3.4.3. Ten Intensity Histogram based first order and 21 GLCM based second order texture features (16 bins, zero degree direction, 1 pixel distance) were evaluated. SUV and MTV based parameters were also evaluated. Cut-off values for all significant parameters (p < 0.05) were calculated using ROC analysis. Univariate Survival analysis was performed in which survival patterns were compared by log rank method and presented using Kaplan-Meier curves. Multivariate analysis was performed and hazard ratios (HRs) were evaluated by Cox regression model. **Results:** Median follow up time of 45 patients was 9 months (range: 1 - 27 months) during which 27 patients died. In univariate survival analysis, 6 first order texture parameters i.e. entropy, skewness, uniformity, mean, median and RMS were found to be significantly associated with OS with cut-off values 3.37, -0.803, 0.130, 10.26, 12.50, 11.49 and HRs 4.908 (p=0.004), 4.006 (p=0.002), 2.649 (p=0.018), 3.573 (p=0.003), 3.153 (p=0.009), 2.685 (p=0.019), respectively. Among the second order parameters, mean, auto-correlation, energy, entropy, inverse variance, maximum probability, sum average, sum entropy, sum variance were significantly associated with OS with cut-off values 10.45, 131.70, 0.0725, 3.561, 0.3603, 0.211, 22.51, 4.164 and HRs 3.573 (p=0.003), 2.685 (p=0.019), 2.965 (p=0.015), 2.349 (p=0.038), 2.213 (p=0.048), 3.749 (p=0.003), 2.845 (p=0.018), 2.834 (p=0.014), respectively. Among the clinical parameters, only ECOG was significantly associated with OS (HR 2.839, p = 0.01). In multivariate cox regression analysis skewness was found to be the independent predictor of OS with HR 4.006 (p=0.002). None of the SUV and tumor volume based parameters were significantly associated with OS. **Conclusion:** Texture parameters evaluated from baseline 18F-FDG PET/CT performed better than routinely used metabolic parameters and can be used as reliable prognostic markers of OS in NSCLC. **References:** None

OP-726

Value of 18F-FDG PET/CT-Based Radiomics Model to Distinguish the Growth Patterns of Early Invasive Lung Adenocarcinoma Manifesting as Ground-Glass Opacity Nodules

X. Shao, R. Niu, X. Shao, Y. Wang;

the Third Affiliated Hospital of Soochow

University, Changzhou, CHINA.

Aim/Introduction: The growth pattern of invasive lung adenocarcinoma (IAC) manifesting as ground-glass opacity nodules (GGNs), is divided into lepidic, acinar, papillary, micropapillary, and solid predominant. The use of predominant growth patterns not only helps to classify IAC into subtypes but also serves as a prognostic

indicator independent of the clinical stage. Among the first three most common growth patterns, the prognosis of acinar or papillary types is worse than lepidic. The confirmation of the IAC growth pattern before surgery is essential for the risk stratification of GGN and personalized treatment. This study aimed to establish and validate the PET/CT-based radiomics model and use it to predict the intermediate-high risk growth patterns in early invasive adenocarcinoma (IAC). **Materials and Methods:** Eighty-two ground-glass nodules (GGNs) from 80 patients with stage IA who underwent a preoperative ^{18}F -FDG PET/CT scan and histopathological examination were included in this study. Texture analysis software was used to extract 52 PET and 49 CT radiomics features. The least absolute shrinkage and selection operator (LASSO) algorithm was used to select radiomics features and develop radiomics signatures. We used the receiver operating characteristics curve (ROC) to compare the predictive performance of conventional CT parameters, radiomics signatures, and the combination of these two. Also, a nomogram based on conventional CT indicators and radiomics signature score (rad-score) were developed. **Results:** GGNs were divided into lepidic group ($n = 17$) and acinar-papillary group ($n = 65$). Seven radiomics features were selected to calculate the rad-score (Rad-score = $-1.58597 \times \text{GLRLM_LRE} + 0.00207 \times \text{GLZLM_LZE} + 0.00058 \times \text{GLZLM_LZLGE} - 0.00012 \times \text{GLZLM_LZHGE} + 0.21479 \times \text{GLZLM_ZLNU} + 3.05551 \times \text{GLZLM_ZP} - 0.00138 \times \text{HUMax}$), and the area under the curve (AUC) of rad-score was 0.819, which was not significantly different as attenuation value of the ground-glass opacity component on CT (CT_{GGO}) (0.686). When rad-score was combined with CT_{GGO} (joint model, Logit (P) = $9.91059 + 0.00854 \times \text{CT}_{\text{GGO}} + 1.82346 \times \text{rad-score}$), the AUC increased to 0.846 (95% CI [0.741–0.951]), which was significantly higher than CT_{GGO} ($P = 0.007$). Furthermore, the decision curve analysis of the three models also showed higher clinical value for the joint model. **Conclusion:** PET/CT-based radiomics model showed good performance in predicting intermediate-high risk growth patterns in early IAC, providing useful methods for risk stratification, clinical management, and personalized treatment. **References:** None

18F fluorodeoxyglucose PET/CT Radiomic signature for prediction of lung cancer histology and outcome

E. Giovannini¹, L. Florimonte², M. Cuzzocrea², M. Castellani², L. Dellavedova³, E. Borsò¹, G. Giovacchini¹, C. Aschele⁴, A. Ciarmiello¹;
¹Nuclear Medicine U.O. - Sant'Andrea Hospital, La Spezia, ITALY, ²Fondazione IRCCS Ca' Granda- Ospedale Maggiore Policlinico, Milan, ITALY, ³ASST Ovest Milanese, Milan, ITALY, ⁴Oncology OU- Sant'Andrea Hospital, La Spezia, ITALY.

Aim/Introduction: Textural feature analysis, also known as part of radiomics, is an emerging field in quantitative

medical imaging analysis, allowing to extract higher dimensional features from grey level distribution of image that are unrecognizable by visual inspection. Preliminary data suggest that radiomics may be used for histological features classification or prognostic evaluation. This study was aimed to evaluate deep learning radiomic approach as a non invasive tool for classification of tumor histology and outcome in lung cancer patients. **Materials and Methods:** 85 patients with lung cancer (58 male, 27 female), mean age 70 ± 10 years underwent PET/CT with FDG at initial staging. For data analysis, patients were grouped according to diagnosis in early stage ($n=46$) and metastatic stage ($n=39$). A total of 43 radiomics features and SUVmax were extracted from PET/CT for each primary tumor lesion. Receiver operating characteristic curve (AUC) was used to reduce the high dimensionality of radiomic features selecting for subsequent analysis only those exceeding the value of 0.6. The textural features survived to this cut-off were grouped in all possible combination and tested for the accuracy to discriminate among patient's group. The 632+ bootstrap method was used to assess the discrimination performance of each feature subset in terms of AUC. Comparison between textural features and SUVmax for group classification was explored. Statistical analysis was performed with Chi-Square test. Analysis was implemented under Matlab 2019b using Deep Learning Toolbox. **Results:** Twenty-four of 43 textural features showed an AUC value of >0.6 . The combination with the best diagnostic performance included the following 7 textural features: (GLCM_Contrast, GLSZM_SZE, GLSZM_LZE, GLSZM_ZSN, GLSZM_ZP, GLSZM_LZHGE, NGTDM_Coarseness) which emerged as being more useful to distinguish between groups, compared to the SUVmax (AUC: 0.77 vs. 0.69, $P < 0.001$). In comparison with SUVmax, radiomic model significantly improved the prediction of tumor histology ($\text{Chi}^2=25.2$ vs. 2.4; $P > 0.00001$ vs. $P=0.12$) and disease progression rate ($\text{chi}^2=5.9$ vs. 4.8; $P=0.01$ vs. $P=0.02$). **Conclusion:** Radiomic modeling is a promising approach for prediction of lung cancer histology and outcome. Although this technique deserves validation on larger population it may support clinical decision strategy with complementary information. **References:** None

OP-728

A novel model for predicting the invasiveness of early lung adenocarcinoma by combining ^{18}F -FDG PET and HRCT

X. Shao, X. Shao, R. Niu, M. Xu, Y. Wang;
 The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: To establish a novel model for predicting and validating the invasiveness of early lung adenocarcinoma by ^{18}F -FDG PET combined with HRCT. **Materials and Methods:** 149 patients with early stage lung

adenocarcinoma who underwent preoperative PET/CT and HRCT examination in our hospital from October 2011 to October 2019 were enrolled. 457 ground-glass nodules (GGN) were detected by PET/CT, 37.2% (170/457) of GGNs were surgically removed. In order to establish a new prediction model and verify its accuracy, we randomly divided the 170 GGNs resected into a modeling group (89) and a verification group (81), the two groups were divided into pre-invasive/minimally invasive adenocarcinoma (MIA) subgroup and invasive adenocarcinoma (IAC) subgroup according to pathological subtypes. The stepAIC (Akaike Information Criterion) method was used to build the PET/CT model, respectively. Receiver operating characteristic (ROC) curve analysis was used to compare the diagnostic efficacy of different models. **Results:** In the modeling group, the proportion of mixed GGNs, irregular shape, lobulation sign, bronchiectasis/distortion/truncation sign, D_{GGN} , D_{Solid} , CTR, CT_{GGO} , and SUV index in the IAC subgroup were significantly higher than those in the pre-invasive/MIA subgroup, the difference was statistically significant (all $P < 0.05$). Among the quantitative parameters of PET/CT (D_{GGN} , D_{Solid} , CTR, CT_{GGO} , SUV_{index}), the SUV_{index} had the best diagnostic efficacy (AUC = 0.854). Use the stepAIC method to build a multi-factor model: $\text{logit}(P) = 2.56455 + 0.00592 \times CT_{GGO} + 3.55028 \times SUV_{index}$. In the modeling group, the efficacy of the model in predicting early lung adenocarcinoma invasion was AUC = 0.854, and the sensitivity, specificity, and accuracy were 0.737, 0.923, and 0.764. In the validation group, the model predicted the early lung adenocarcinoma invasion: the efficacy was AUC = 0.802, and the sensitivity, specificity, and accuracy are 0.970, 0.643, and 0.914. The model has similar prediction performance in the modeling group and the validation group, and has good robustness. **Conclusion:** The novel model based on the combination of FDG PET and HRCT parameters has a good predictive value for early lung adenocarcinoma invasiveness and can effectively avoid misdiagnosis and missed diagnosis of IAC. **References:** None

OP-729

PD-L1 expression correlation with metabolic parameters of ^{18}F -FDG PET/CT and clinicopathological characteristics in non-small cell lung cancer

L. Jiang;

Shanghai Pulmonary Hospital, Shanghai, CHINA.

Aim/Introduction: Immunotherapy targeting programmed cell death-ligand 1 (PD-L1) has shown promising results in non-small cell lung cancer (NSCLC) patients. Exploring PD-L1 expression could help to select NSCLC candidates for immunotherapy. ^{18}F -FDG PET/CT could provide phenotypic information of malignant tumors. Thus, this study investigated PD-L1 expression correlation with metabolic parameters of ^{18}F -FDG PET/CT and clinicopathological characteristics in NSCLC. **Materials and Methods:** ^{18}F -FDG

PET/CT metabolic parameters including maximum standard uptake (SUVmax), metabolic tumor volume and total lesion glycolysis of primary lesion (MTV-P, TLG-P), and combination of primary lesion and metastases (MTV-C, TLG-C), were compared with PD-L1-positive expression in patients with NSCLC. Moreover, clinicopathological characteristics, including age, gender, smoking history, serum tumor markers, tumor location, size, TNM stage, and genetic mutation were also reviewed. **Results:** All 374 patients (215 men; 159 women; age: 63 ± 9 years) included 283 adenocarcinomas (ACs) and 91 squamous cell carcinomas (SCCs). PD-L1 expression was positive in 27.8% (104/374) cases. SUVmax, TLG-P, and TLG-C of PD-L1-positivity was significantly higher than PD-L1-negativity. Moreover, PD-L1 expression was obviously correlated with man, smoking, and central NSCLC. If ACs and SCCs were separately analyzed, PD-L1 positivity in ACs and SCCs was 21.6% (61/283) and 47.5% (43/91), respectively, and only SUVmax was obviously associated with PD-L1 expression. Furthermore, multivariate analysis revealed that only SUVmax was an independent predictor of PD-L1 positive expression in overall NSCLC, AC, and SCC, respectively. Using a SUVmax cut-off value of 9.8, PD-L1 status of NSCLC was predicted by ^{18}F -FDG PET/CT with sensitivity, specificity, and accuracy of 77.9%, 70.0%, and 72.2%, respectively. **Conclusion:** PD-L1 expression of NSCLC was related with SUVmax, TLG, man, smoking, and central location. However, only SUVmax was an independent predictor of PD-L1 positivity, which could help to select NSCLC candidates for immunotherapy. **References:** None

Aim/Introduction: Increased metabolic tumour volume (MTV) in DLBCL is reported to be inversely related to progression-free (PFS) and/or overall survival (OS). However the characteristics of the relationship are not fully understood, as most studies have analysed continuous MTV data in a categorical fashion which is not recommended for optimizing predictive performance. Our aim was to study the relationship between MTV as a continuous variable with PFS and OS and determine the best statistical model to describe it. **Materials and Methods:** Patient level data from 1091 DLBCL patients enrolled in 4 studies collated by the PETRA consortium (<https://petralymphoma.org>) were used to examine the relationship between baseline MTV and 3-year PFS and OS using Cox regression models. MTV was calculated using a fixed SUV ≥ 4.0 threshold. To decide on the best shape and fit of MTV in these models, different transformations of the MTV variable (natural log transformation, MTV squared and linear spline (LSP) and restricted cubic spline (RCS) functions) were plotted and compared with a linear model where MTV was assumed

to have a linear relationship with PFS and OS. A spline function describes the association for multiple intervals of MTV, without the assumption of linearity. These MTV transformations were added to the univariable Cox models and the models adjusted for international prognostic index (IPI). The fit of the models was tested and compared with likelihood-ratio tests, R squared and c-index values for discrimination. These analyses were repeated in the separate study cohorts and in the merged dataset. **Results:** The RCS models showed highest R-squared values and showed a significantly better ($p < 0.001$) fit for PFS and OS than the MTV squared and LSP model in the merged dataset, which was confirmed by the curved shape of the plot of the relationship between MTV and PFS and OS. The shape of the curve showed an increasing risk of progression, relapse or death with increasing values of MTV. The rise in risk was higher for lower MTV values. Results were consistent for IPI adjusted and unadjusted models in the separate research cohorts and in the merged dataset. Differences in discriminative ability of various transformations of MTV were less clear. **Conclusion:** We recommend that MTV is used as a restricted cubic spline function in future analyses to obtain the optimal predictive performance. **References:** None

Hybrid ICG-^{99m}Tc-nanocolloid, on the road towards becoming the new standard for sentinel node biopsy in penile cancer? Results from 740 inguinal basins assessed at a single institution

H. M. de Vries¹, P. Dell'Oglio², E. Mazzone³, G. H. KleinJan³, H. G. van der Poel¹, S. Horenblas¹, F. W. B. van Leeuwen³, O. R. Brouwer¹;

¹Netherlands Cancer Institute - Antoni van Leeuwenhoek hospital, Amsterdam, NETHERLANDS, ²ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY, ³Leiden University Medical Center, Leiden, NETHERLANDS.

Aim/Introduction: Sentinel node (SN) biopsy in penile cancer (PeCa) is typically performed using ^{99m}Tc-nanocolloid and blue dye. Recent reports suggested that the hybrid radioactive and fluorescent tracer indocyanine green (ICG)-^{99m}Tc-nanocolloid may improve intraoperative optical SN identification. However, further investigation was required before this technique could be adopted at a larger scale. The aims of the current study were to confirm the reliability of ICG-^{99m}Tc-nanocolloid and to assess whether blue dye is still of added value, in the largest series of PeCa SN biopsies with ICG-^{99m}Tc-nanocolloid to date. **Materials and Methods:** 400 $\geq T1G2N0$ PeCa patients were scheduled for SN biopsy and treatment of the primary tumour at a single European centre. After peritumoural injection of ICG-^{99m}Tc-nanocolloid, SNs were preoperatively identified with lymphoscintigraphy and SPECT/CT. Intraoperatively, SNs were pursued via gamma tracing, visual identification (blue

dye) and near-infrared fluorescence imaging. In the overall cohort (n=400), intraoperative SN identification rates using radio- and fluorescence guidance were assessed. In those patients who received ICG-^{99m}Tc-nanocolloid and blue dye (n=266), fluorescence SN identification rates were compared with blue dye using a chi-square test. **Results:** 740 groins were assessed. No tracer-related adverse events were reported. All preoperatively defined SNs (n=1163) were intraoperatively localized. 98% of all excised SNs were detectable with gamma probe and 96% were visible with fluorescence imaging. The 95 SNs that were tumour-positive were all both radioactive and fluorescent. In the fluorescence vs. blue dye analysis (n=266), fluorescence imaging yielded a 39.2% higher SN detection-rate relative to blue dye (95.3 vs. 56.1%). 100% (n=58) of the SNs that were tumour-positive at pathology could be intraoperatively visualized by fluorescence imaging, whereas merely 69% (n=40) were stained blue. **Conclusion:** This study confirms that ICG-^{99m}Tc-nanocolloid is a reliable SN tracer for PeCa that significantly improves optical SN detection over blue dye. **References:** None

Aim/Introduction: We previously identified brain regions

whose metabolic impairment contributes to DLB clinical core features expression and we demonstrated an influence of severity of global cognitive impairment on the hypometabolic DLB pattern and in particular on the expression of the cingulate island sign (CIS) (1). In this study we aim to evaluate the impact of age and education (as a proxy of cognitive reserve, CR) on the DLB-related pattern in probable DLB patients belonging to E-DLB consortium database. **Materials and Methods:** Brain FDG-PET and clinical/demographic information were available in 168 patients recruited in 10 centers belonging to the E-DLB consortium (age 73.4±7.0; 93 males; MMSE-score 22.2±4.7; Education 10.4±4.0 years). Principal component analysis was applied to identify brain regions relevant to the local data variance. A regression analysis to the locally normalized intensities was performed to generate an age-sensitive map as well as a CR-sensitive map (both maps were also adjusted for the other confounding variables, i.e., MMSE score, Gender, Center, and either education or age, respectively). p<0.05 was regarded as significant. **Results:** Age negatively covaried with metabolism in fronto-mesial and fronto-insular cortex, anterior and posterior cingulate while it positively covaried with lateral temporal, occipital and posterior parietal metabolism in the left hemisphere. Education positively covaried with metabolism in insula, medial frontal gyrus, medial temporal lobe and basal ganglia in both hemispheres and negatively covaried with metabolism in left parietal cortex, and bilateral precuneus. **Conclusion:** CR-related mechanisms are at work in DLB. In particular education negatively affects metabolism in bilateral precuneus while not in PCC suggesting that the DLB-typical CIS (2) is more expressed in patients with high CR. By contrast the DLB-typical CIS may be blunted in older DLB patients. In fact, age negatively covaried with metabolism in bilateral posterior cingulate thus reducing the expression of the CIS. The present results suggest that non disease-specific variables such as CR and age may be a further source of heterogeneity in the relationship between clinical symptoms and related metabolic patterns in DLB patients. These findings point out the importance of tailoring the interpretation of biomarkers results considering individual patients' characteristics also in DLB patients. **References:** (1) Morbelli S et al. OP-502

Progression to overt Coronary artery disease in Patients with Diabetes Mellitus at High Coronary Risk: 5 year follow-up of the prospective multicenter BARDOT Trial

F. Caobelli, P. Haaf, G. Haenny, M. Pfisterer, M. Zellweger;

Universitätsspital Basel, Basel, SWITZERLAND.

Aim/Introduction: The Basel Asymptomatic high-Risk Diabetics' Outcome Trial (BARDOT) [1] demonstrated that asymptomatic diabetic patients with an abnormal myocardial perfusion scintigraphy (MPS) were at increased risk of major cardiac events (MACE) at 2-years follow-up. It remains unclear whether this finding holds true even for a longer follow-up. **Materials and Methods:** Four hundred patients with type-2 diabetes and neither history nor symptoms of CAD were evaluated. They underwent clinical evaluation and MPS with either physical or pharmacologic stress test. Patients were followed up for 5 years. MPS-based diagnosis of CAD was defined as summed stress score (SSS) ≥ 4 and/or summed difference score (SDS) ≥ 2 . A fully unremarkable scan was defined as SSS and SDS=0. MACEs were defined as myocardial infarction, cardiac death or late coronary revascularization. Patients with detectable CAD were randomly assigned to medical or invasive treatment. **Results:** At baseline, an abnormal MPS was found in 87 of 400 patients (22%). MACE within 5 years occurred in 14 patients with abnormal MPS (16.1%) and in 22 with normal scan (1.7%, $p=0.009$); 15 deaths were recorded. An abnormal MPS was a predictor of MACEs occurrence: HR- (95% CI) 2.537 (1.238 - 5.199, $p=0.011$). At Kaplan-Meier analysis, patients with normal MPS had lower rates of MACEs than patients with abnormal scans ($p=0.016$). Patients with SSS = 0 ($n=285$) had also lower rate of all-cause death (2.5% vs. 7.1%, $p=0.033$). Patients undergoing revascularization experienced significant lower rate of MACE ($n=2$, 6.7%, $p=0.007$) and mortality ($p=0.002$) compared to those treated with optimal medical therapy **Conclusion:** High-risk asymptomatic patients with DM and normal MPS (78%) have a lower rate of first manifestations of coronary artery disease (CAD) even at 5-years follow-up. A SSS value =0 predicted a very low all-cause mortality rate, similar to that of a normal population. Conversely, patients with abnormal MPS at baseline (22%) have a 7-fold higher rate of progression to overt CAD. Our results confirm that if patients with diabetes are clinically at high risk of CAD as in BARDOT, they should be considered for ischemia testing. A normal scan predicts a good 5-year outcome, while evidence suggests that those with CAD should be treated with a combined invasive and medical approach. **References:** [1] JACC Cardiovasc Imaging. 2014;7:1001-10.

Biodistribution and Dosimetry of ^{177}Lu -satoreotide-tetraxetan: an Interim Analysis of a Multi-Centre, Open-Label Phase I/II Study in Patients with Neuroendocrine Tumours

D. Wild¹, S. Beykan², H. Grønbaek³, J. Bearegard⁴, C. Ansquer⁵, A. Haug⁶, N. Lenzo⁷, S. Navalkisoor⁸, G. Nicolas¹, L. Durand-Gasselino⁹, C. Powell¹⁰, B. Pais¹¹, R. Hicks¹², U. Eberlein², M.

Lassmann²;

¹University Hospital Basel, Basel, SWITZERLAND, ²University of Würzburg, Würzburg, GERMANY, ³Aarhus University Hospital, Aarhus, DENMARK, ⁴CHU de Quebec, Université Laval, Quebec, QC, CANADA, ⁵CHU de Nantes, Nantes, FRANCE, ⁶University Hospital Vienna, Vienna, AUSTRIA, ⁷GenesisCare Theranostics, Ramsay Hollywood Private Hospital, Perth, AUSTRALIA, ⁸Royal Free Hospital, London, UNITED KINGDOM, ⁹Ipsen, Les Ulis, FRANCE, ¹⁰Ipsen, Cambridge, MA, UNITED STATES OF AMERICA, ¹¹Ipsen, Hoofddorp, NETHERLANDS, ¹²Peter McCallum Cancer Centre, Melbourne, AUSTRALIA.

Aim/Introduction: ^{177}Lu -satoreotide-tetraxetan (^{177}Lu -IPN01072, ^{177}Lu -OPS201 or ^{177}Lu -DOTA-JR11), a novel somatostatin receptor 2 antagonist, has shown acceptable toxicity in patients with progressive neuroendocrine tumours (NETs) at approximately 4.5 GBq/cycle¹. We report an interim analysis (IA) of ^{177}Lu -satoreotide-tetraxetan biodistribution and dosimetry from an on-going phase I/II study. **Materials and Methods:** Part A of the phase I study enrolled 15 patients with well-differentiated grade 1/2 NETs who each received 3 cycles of 4.5 GBq with 300 μg peptide mass ^{177}Lu -satoreotide-tetraxetan. Part B, which had enrolled 20 patients at the IA cut-off date, explored separately escalation of activity and peptide mass (up to 6 GBq/cycle, 300-1300 μg peptide/4.5GBq cycle). Cumulative renal, bone marrow (BM), splenic, hepatic and tumour dosimetry was assessed for each subject after each administration. **Results:** After the first 3 patients were enrolled in cohort 1 of part B, the planned administered activity of 6 GBq was reduced to 4.5 GBq due to cumulative BM absorbed dose exceeding the prespecified 1.5 Gy threshold in 2 patients, and thrombocytopenia in one patient. At the IA cut-off, dosimetry data was summarized for 25 patients having no major protocol violation affecting dosimetry variables. Among those, 16 (64%) had received all 3 treatment cycles (including 2 patients who received a fourth cycle) with a cumulative activity of 13.4 ± 1.6 GBq. At cycle 1, ^{177}Lu -satoreotide-tetraxetan delivered radiation primarily to tumour lesions (specific absorbed dose [SAD] ranging from 0.43 to 27 Gy/GBq, median 2.9 Gy/GBq), followed by kidneys and spleen (median SAD 0.82 to 0.94 Gy/GBq and 0.86 Gy/GBq, respectively) and to a lesser extent to liver (median SAD 0.18 Gy/GBq) and BM (median SAD 0.090 Gy/GBq). Part A preliminary analysis showed comparable SAD (median percent change <15%, $N=7-10$) for kidneys, BM and liver between cycle 1 and cycle 3. Similarly, comparable BM SAD was observed when 300 μg or 700 μg were administered (cohort 3, $N=4$) but this finding shall be confirmed when more data is available. In the IA of safety population ($N=35$), haematological toxicity (grade ≥ 3) consisted of lymphopenia (51.4% patients), thrombocytopenia (14.2%), neutropenia (8.6%), and anaemia (2.8%) but were not associated with bleedings or

infections. **Conclusion:** These preliminary results show that ^{177}Lu -satoreotide-tetraxetan efficiently targets tumours in patients with well-differentiated grade 1/2 NETs. Dosimetry supports the ^{177}Lu -satoreotide-tetraxetan acceptable safety profile at median cumulative activity of 13.0 GBq over 3 cycles in patients with NETs. **References:** 1. Wild et al. *J Nucl Med*. 2014; 55(8): 1248-1252

OP-504

Lymph node staging by FDG-PET/CT and MRI in cervical uterine cancer: the impact on FIGO stage migration and prognostic value

J. Holm¹, A. Thomassen¹, O. Gerke¹, M. H. Vilstrup¹, D. Spasojevic², S. E. Sponholtz³, K. M. Jochumsen³, P. T. Jensen⁴, M. G. Hildebrandt¹;

¹Department of Nuclear Medicine, Odense University Hospital, Odense C, DENMARK, ²Department of Radiology, Odense University Hospital, Odense C, DENMARK, ³Department of Gynecology and Obstetrics, Odense University Hospital, Odense C, DENMARK, ⁴Department of Obstetrics and Gynecology, Aarhus University Hospital, Aarhus, Denmark, Odense C, DENMARK.

Aim/Introduction: The new and revised staging for carcinoma of the uterine cervix (CCU) proposed by the FIGO committee in 2018 includes imaging in the staging process. It suggests a stage migration of early-stage FIGO I and II patients with retroperitoneal lymph node metastasis to a new FIGO (2018) stage IIIC. We aimed to investigate the prognostic value of suspected lymph node metastases by FDG-PET/CT and MRI in women with early stages FIGO (2009) I and II. **Materials and Methods:** In this clinical register study, we included 535 women with biopsy verified uterine cervical cancer at Odense University Hospital, Denmark from 2007–2016. Women referred for diagnostic work-up underwent FDG-PET/CT and MRI before gynecological examination. Stratified analyses were performed for patients with CCU FIGO (2009) stage IA, IB1, IB2 and II. We compared disease-specific survival in each stage for patients with and without imaging signs of retroperitoneal lymph node involvement (N+, N0) and performed Kaplan-Meier analysis. Lymph node involvement was assessed by both imaging modalities combined: if either of the imaging modalities were lymph node positive, the result was regarded as positive (N+). If both modalities were lymph node negative, the result was regarded as negative (N0). **Results:** A total of 425 patients were clinically staged FIGO I and II: 36, 195, 30, and 164 women were staged FIGO IA, IB1, IB2, and II, respectively. Overall, 106 women (25%) had suspected lymph node metastases on imaging and stratified by FIGO stage the number was 0 (0%) in stage IA, 22 (11%) in IB1, 14 (47%) in IB2, and 70 (43%) women in II. The 5-year disease specific survival rates for women with FIGO stage IB1, IB2, and II comparing lymph node negative vs. lymph node positive patients were 99% (95% CI: 95–100) vs. 95% (72–99), 100% (NA) vs. 64% (34–83), and 82% (72–88) vs. 62% (49–72), respectively. **Conclusion:** One fourth of the patients in this study had suspected lymph node metastasis on

imaging and would be upstaged to FIGO stage IIIC by the new FIGO classification. The 5-year disease-specific survival was significantly higher in the lymph node negative group compared with the lymph node positive group, based on imaging findings alone. The prognostic value of staging lymph node metastasis by imaging in FIGO stages I and II CCU in this study supports the migration of patients with signs of lymph node disease towards a more advanced stage. **References:** None
